I_Y = Gross moment of inertia, in [cm^4], of the hull transverse section about its horizontal neutral axis, to be calculated according to Cl.2.1.7.

I_Z = Gross moment of inertia, in [cm^4], of the hull transverse section about its vertical neutral axis, to be calculated according to Cl.2.1.7.

x = X coordinate of the calculation point with respect to the reference coordinate system in [m], as defined in Chapter 1, Section 2, 2.5.

z = Z co-ordinate of the calculation point with respect to the reference co-ordinate system in [m], as defined in Chapter 1, Section 2, 2.5.

z_n = Z co-ordinate of horizontal neutral axis of the hull transverse sections with gross scantling defined in 1.4, in [m], with respect to the reference co-ordinate system defined in Chapter 1, Section 2, 2.5.

z_D = Z coordinate of strength deck at ship side, in [m].

Z_B = Gross section modulus, in [cm^3], at bottom, to be calculated according Cl.2.1.6.

Z_D = Gross section modulus, in [cm^3], at deck, to be calculated according Cl.2.1.6.

2.1 Vertical hull girder bending strength

2.1.1 General

• Scantlings of all continuous hull girder longitudinal strength members based on section modulus requirement in Cl.2.1.2 and moment of inertia requirement in Cl.2.1.3 are to

be maintained within 0.4L amidships. However, in special cases, based on consideration of ship type, hull form and loading conditions, the scantlings may be gradually reduced towards the end of the 0.4L amidships, bearing in mind the desire not to inhibit the vessel's loading flexibility.

• The k material factors are defined with respect to the materials used for the bottom and deck members contributing to the hull girder longitudinal strength according to Section 1, 1.4. When higher strength steels are used, the requirements of Cl.2.1.8 apply.

2.1.2 Minimum Hull Girder Section Modulus

The minimum gross hull girder section modulus, Z_{min} in [cm^3] about the transverse neutral axis at midship is not to be less than obtained from the following equation:

$$Z_{min} = k.C.L^2.B(C_b + 0.7)(0.5 + 0.5R_s)$$

where,

$C = C_1$, for new ships

$C = 0.9\ C_1$, for ships in service

$$C_1 = 4 + 0.0412L \text{ for } L < 90[m]$$

$$C_1 = 10.75 - \left(\frac{300 - L}{100}\right)^{\frac{3}{2}} \text{ for } 90 \leq L \leq 300[m]$$

$$C_1 = 10.75 \text{ for } 300 < L < 350[m]$$

$$C_1 = 10.75 - \left(\frac{L - 350}{150}\right)^{\frac{3}{2}} \text{ for } 350 \leq L \leq 500[m]$$

2.1.3 Minimum Hull Girder Moment of Inertia

The gross moment of inertia I_{min} of the hull section about the transverse neutral axis, at midship, is not to be less than:

$$I_{min} = 3.C_1.L^3B(C_b + 0.7)R_S\ [cm^4]$$

2.1.4 Hull Girder Section Modulus with in 0.4L amidships

At any transverse section, the required gross hull section modulus Z_{gr}, in [cm^3] with in 0.4L amidships about the transverse neutral axis for the still water bending moments $[M_{sw}]$ and wave bending moments $[M_{wv}]$ is not to be less than obtained from the following equation:

$$Z_{gr} = \left(\frac{M_{sw} + M_{wv}}{\sigma_L}\right) \times 10^3$$

where,

σ_L = Permissible hull girder bending stress

= 175/k [N/mm^2] within 0.4L amidships

= 125/k [N/mm^2] within 0.1L from A.P. and F.P.

Between the specified regions σ_L is to be obtained by linear interpolation.

In the region outside 0.4L amidships, the scantlings are to be gradually tapered to the local requirements at ends.

2.1.5 Hull Girder Strength Outside of 0.4L Amidships

2.1.5.1 The strength of the hull girder is to be checked at sections outside of 0.4L amidships. The required bending strength outside 0.4L amidships is to be determined as specified in Cl.2.1.4. As a minimum, hull girder bending strength checks are to be carried out specifically at the following locations:

• In way of the forward end of the engine room.

• In way of the forward end of the foremost cargo hold.

• At any locations where there are significant changes in hull cross-section.

• At any locations where there are changes in the framing system.

• At any locations where there is a change of material from Midship.

2.1.5.2 Buckling strength of members contributing to the longitudinal strength and subjected to compressive and shear stresses is to be checked, in particular in regions where changes in the framing system or significant changes in the hull cross-section occur. The buckling evaluation criteria is given in Chapter 9.

2.1.5.3 For ships with large deck openings in the strength deck, such as containerships, sections at or near to the aft and forward quarter length positions are to be checked. For such ships with cargo holds aft of the

superstructure, deckhouse or engine room, strength checks of sections in way of the aft end of the aft-most holds, and the aft end of the deckhouse or engine room are to be performed.

2.1.6 Section Modulus at any point

2.1.6.1 The gross section modulus, Z in [cm^3], at any point of a hull transverse section is obtained, from the following formula:

$$Z = \frac{I_Y}{|z - z_n|} \times 10^{-2}$$

2.1.6.2 At bottom

The gross section modulus at bottom, Z_B in [cm^3], is obtained from the following formulae:

$$Z_B = \frac{I_Y}{z_n} \times 10^{-2}$$

2.1.6.3 At deck

The gross section modulus at deck, Z_D in [cm^3], is obtained from the following formulae:

$$Z_D = \frac{I_Y}{V_D} \times 10^{-2}$$

2.1.6.4 Equivalent deck line

• In case of ships with effective longitudinal members, as specified in Cl.1.4.5 and Cl.1.4.6 are positioned above a line extending from strength deck at side to a position $((z_D - z_n)/0.9)$ from the neutral axis at the centerline, the equivalent deck line is obtained, in [m], from the following formula:

$$V_D = (z_T - z_n)\left(0.9 + 0.2\left(\frac{y_T}{B}\right)\right) \geq (z_D - z_n)$$

• When no effective longitudinal members as specified in Cl.1.4.5 and Cl.1.4.6 are positioned above a line extending from strength deck at side to a position $((z_D - z_n)/0.9)$ from the neutral axis at the centreline, the equivalent deck line is obtained, in [m], from the following formula:

$$V_D = (z_D - z_n)$$

where,

y_T, z_T = Y and Z coordinates of the top of continuous trunk, hatch coaming, longitudinal stiffeners or girders, to be measured for the point which maximizes the value of V_D, in [m].

2.1.7 Moments of inertia

The gross moment of inertia, I_Y and I_Z, in [cm^4], are those, calculated about the horizontal and vertical neutral axes, respectively, of the hull transverse sections defined in 1.4.

2.1.8 Extent of high strength steel

2.1.8.1 Where high strength steels are used in the main hull structure in order to reduce the section modulus requirement, the vertical and longitudinal extent of its use is to be such that adjacent structure made of ordinary hull structural steel is not stressed beyond the stress level permissible for ordinary steel.

2.1.8.2 Vertical Extent

The vertical extent of the high strength steel used in deck zone or bottom zone is to be as shown in the Figure 2.1.8.1, the distance z_0 in [m], is not to be more than:

$$z_0 = \frac{I_y}{Z} \times 10^{-2}$$

where,

Z = Rule midship section modulus required for ordinary steel (k=1.0) as given in Cl.2.1.2 and Cl.2.1.4.

For narrow beam ships the vertical extent of high strength steel may have to be increased after special consideration.

2.1.8.3 Longitudinal Extent

The longitudinal extent of the high strength steel is to be 0.4L amidships and beyond, such that at the junction with ordinary steel the scantlings are equal to those required for an identical ship built of ordinary steel. At the junction, continuity in scantlings is to be maintained. Refer Figure 2.1.8.2.

2.1.9 Permissible vertical still water bending moments for harbour/sheltered water condition

The permissible still water bending moments, M_{sw-har} in [kN-m], for harbour/sheltered operations in hogging and sagging is to comply with the following criteria:

$$|M_{sw-har}| \leq |M_{sw} + 0.5M_{wv}|$$

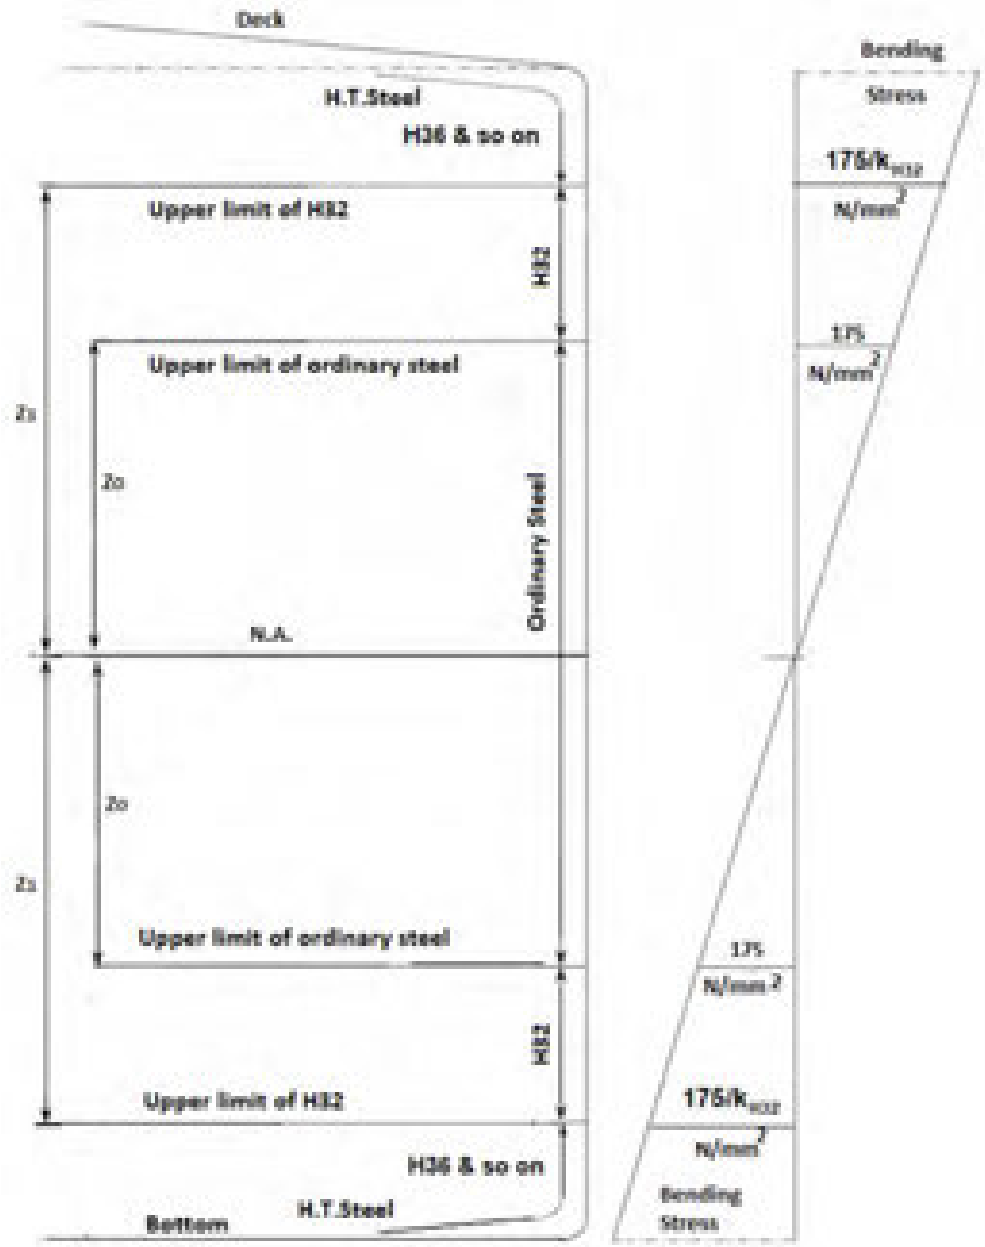

Figure 2.1.8.1: Vertical extent of higher strength steel

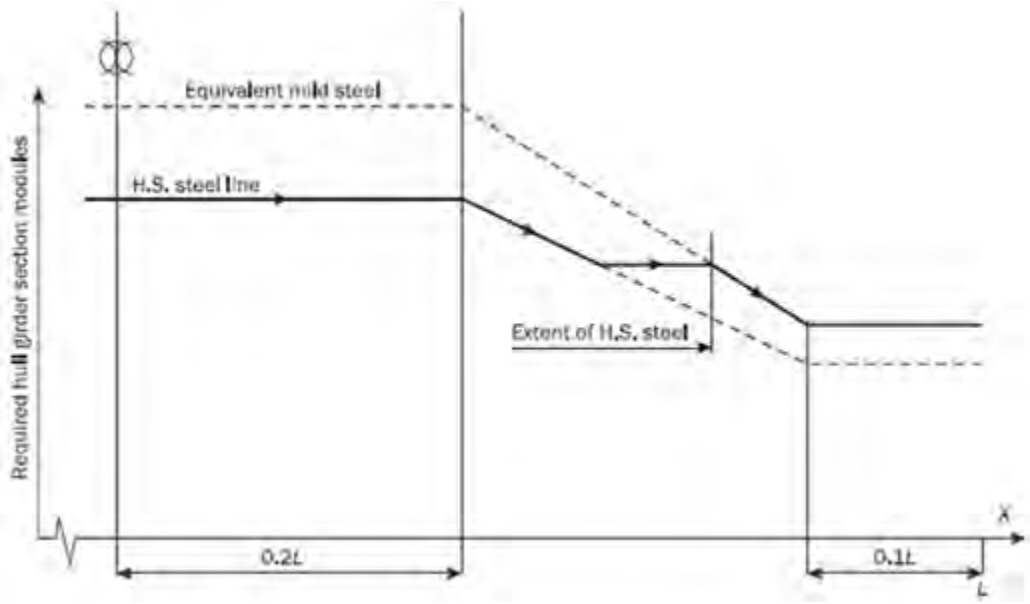

Figure 2.1.8.2: Longitudinal extent of higher strength steel

2.2 Vertical hull girder shear strength

2.2.1 General

2.2.1.1 Hull girder shear strength calculations are to be carried out for ships with length L≥ 65[m].

2.2.1.2 For passenger ships, the assessment of permissible still water shear forces is to take into consideration the effectiveness of the continuous superstructures and the sizes and arrangements of window and door openings.

2.2.1.3 Where longitudinal bulkheads are perforated by cut-outs, the assessment of permissible still water shear forces is to take into consideration the loss of material.

2.2.1.4 For calculating the total shear stress, $[\tau]$, due to still-water and wave-induced loads at a particular section, the maximum algebraic sum of the shear force due to still-water $[Q_{sw}]$ and wave $[Q_{wv}]$ at that particular section to be used.

2.2.1.5 The thickness of the side shell, inner shell and the longitudinal bulkheads, is to be such that the total shear stress $[\tau]$, based on the total shear force is not to exceed 110/k [N/mm^2].

2.2.2 Total hull girder shear capacity

The total vertical hull girder shear capacity, Q_R in [kN], is the minimum of the calculated values for all plates "i" contributing to the hull girder shear of the transverse section considered and is obtained by the following formula:

$$Q_R = \min_i \left(\frac{\tau_{perm} \cdot t_i}{q_{vi_gr}} \right) 10^{-3}$$

where:

τ_{perm} = Permissible shear stress, in [N/mm^2], for plate i, to be taken as:

= 110/k

t_i = Gross thickness, in [mm], for plate i considered.

2.2.3 Permissible still water shear force in sea going conditions

2.2.3.1 The positive and negative permissible vertical still water shear force, in [kN], for seagoing condition is to comply with the following criteria:

$$|Q_{sw}| \leq Q_R - |Q_{wv}|$$

The shear force Q_{wv} used above is to be taken with the same sign as the considered shear force Q_{sw}.

2.2.3.2 The vertical still water shear forces, in [kN], for all loading conditions for seagoing operations is to comply with the following criteria:

$$|Q_{sw-lcd} - \Delta Q_s| \leq |Q_{sw}|$$

The shear force Q_{sw} used above is to be taken with the same sign as the considered shear force Q_{sw_lcd}.

2.2.4 Permissible still water shear force in harbour/sheltered water condition

2.2.4.1 The positive and negative permissible vertical still water shear force, in [kN], for harbour/sheltered water operations is to comply with the following criteria:

$$|Q_{sw-har}| \leq |Q_{sw} + 0.5Q_{wv}|$$

The shear force Q_{wv} used above is to be taken with the same sign as the considered shear force Q_{sw-har}.

2.2.4.2 The vertical still water shear forces, in [kN], for all loading conditions for harbour/sheltered water operations is to comply with the following criteria:

$$|Q_{sw-lcd-har} - \Delta Q_s| \leq |Q_{sw-har}|$$

The shear force $Q_{sw-lcd-har}$ used above is to be taken with the same sign as the considered shear force Q_{sw-har}.

2.2.5 Shear force corrections

For hull configurations where there are no longitudinal bulkheads (excluding the inner shell), shear force correction, which takes into account the portion of loads transmitted by the double bottom longitudinal girders to the transverse bulkheads, is to be considered.

Shear force correction is defined as the difference between shear force on a shear panel determined from shear flow calculation and the actual shear force.

For the considered cargo hold, the shear force correction at the considered transverse section is to be obtained, in [kN], from the following formula:

$$\Delta Q_s = C_d \alpha \left| \frac{M}{B_H \ell_H} - \rho T_1 \right|$$

where:

ΔQ_S = shear correction due to uneven transverse load distribution and shear carrying longitudinal bottom members (girders or stiffeners).

= 0 for nearly uniform loading conditions.

C_d = Distribution coefficient taken as:

= -1 at the aft end of the considered cargo hold except for aftmost cargo hold.

= 1 at the fore end of the considered cargo hold except for foremost cargo hold.

= 0 at mid-length of the cargo hold.

= 0 at the aft bulkhead of the aftmost cargo hold.

= 0 at the fore bulkhead of the foremost cargo hold.

= Linearly distributed at other locations.

α = Coefficient taken as:

$$\alpha = g \frac{\ell_o b_o}{2 + \varphi \frac{\ell_o}{b_o}}$$

$$\varphi = 1.38 + 1.55 \frac{\ell_o}{b_o} \text{ but not graeater than } 3.7.$$

M = Mass, in [t], in the hold in way of the considered transverse section for the considered loading condition. M is to include the mass of ballast water and fuel oil located directly below the flat portion of the inner bottom, if any, excluding the portion under the bulkhead stool.

B_H = Breadth of the cargo hold, in [m], measured at mid-length of the cargo hold and at the mid height between the top of hopper tank and the bottom of topside tank, if fitted as given below in Figure 2.2.5.1.

ℓ_H = Length of the cargo hold, in [m], at the centreline between the transverse bulkheads. This is to be measured to the mid-depth of the corrugated bulkhead(s) if fitted as given below in Figure 2.2.5.1.

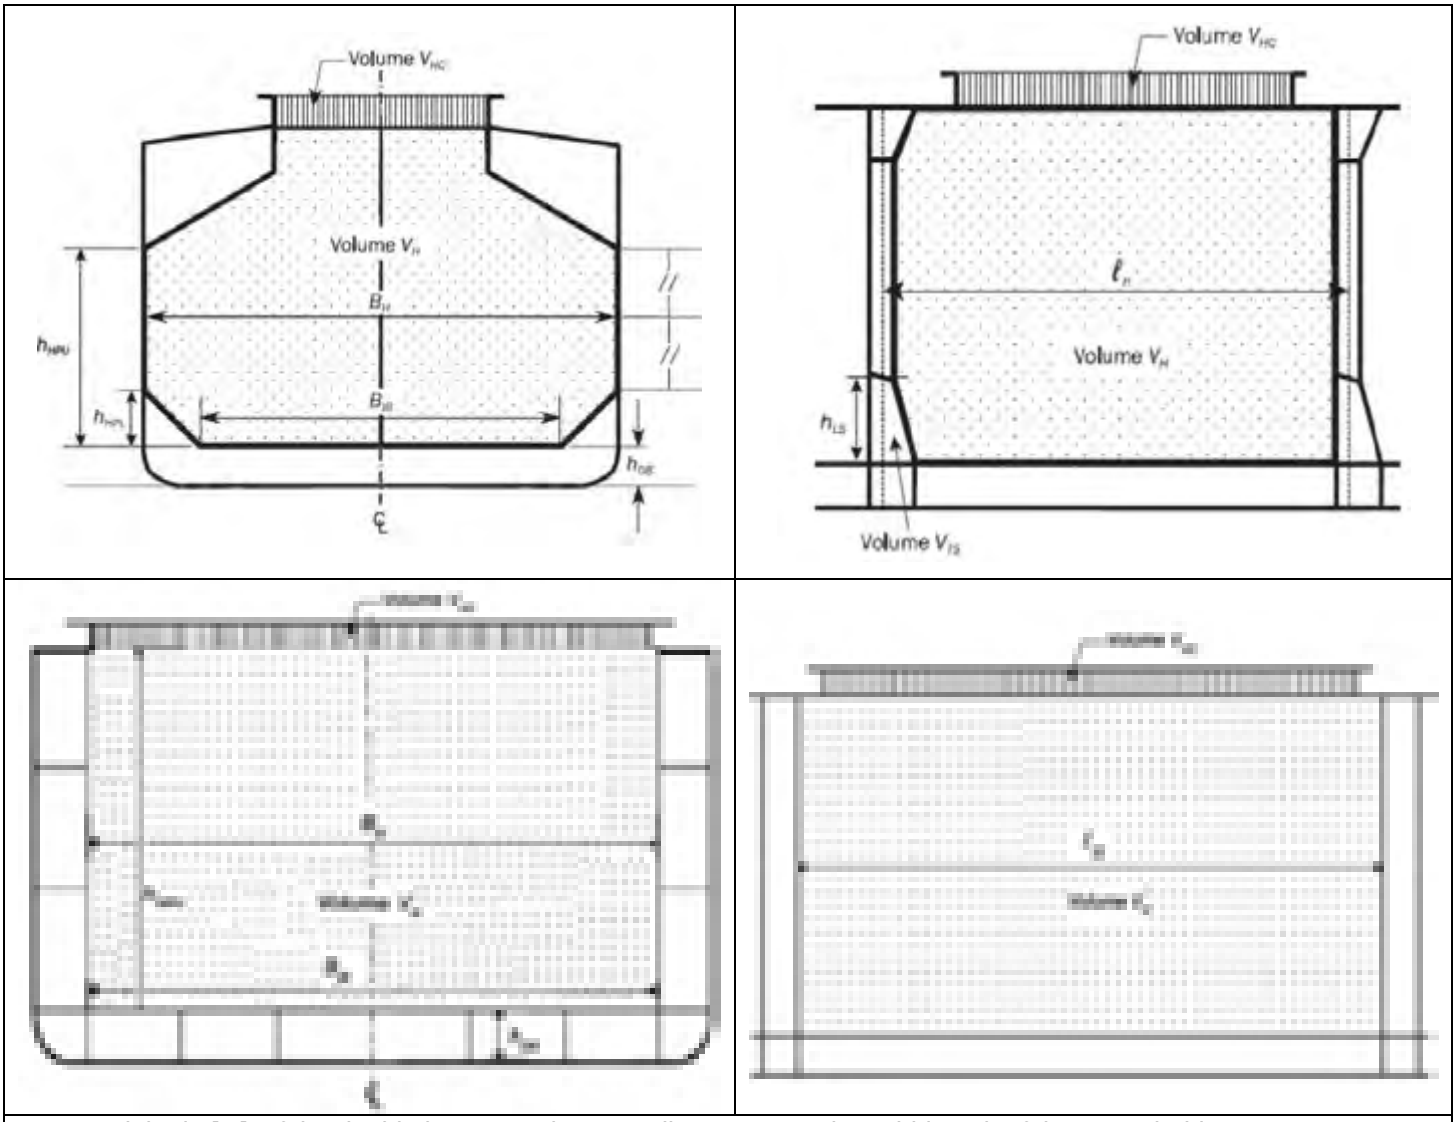
ℓ_o, b_o = Length and breadth, respectively, in [m], of the flat portion of the double bottom in way of the hold considered; b_o is to be measured on the hull transverse section at the middle of the hold.

T_1 = Draught, in [m], measured vertically on the hull transverse section at the middle of the hold

considered, from the moulded baseline to the waterline in the loading condition considered.

ΔQ_{CE} = Shear force correction for the empty hold as given below in Figure 2.2.5.2.

ΔQ_{CF} = Shear force correction for the loaded hold as given below in Figure 2.2.5.2.



h_{DB} = Height, in [m], of the double bottom at the centreline, measured at mid-length of the cargo hold.
h_{HPL} = Vertical distance, in [m], from the inner bottom at centreline to the upper intersection of hopper tank and side shell or inner side for double side bulk carriers, determined at mid length of the considered cargo hold.
h_{HPL} = 0 if there is no hopper tank.
h_{HPU} = Vertical distance, in [m], from the inner bottom at centreline to the lower intersection of topside tank and side shell or inner side for double side bulk carriers, determined at mid length of the cargo hold at midship.
h_{LS} = Mean height, in [m], of the lower stool, measured from the inner bottom.

Figure 2.2.5.1: Definition of cargo hold parameters for bulk carrier

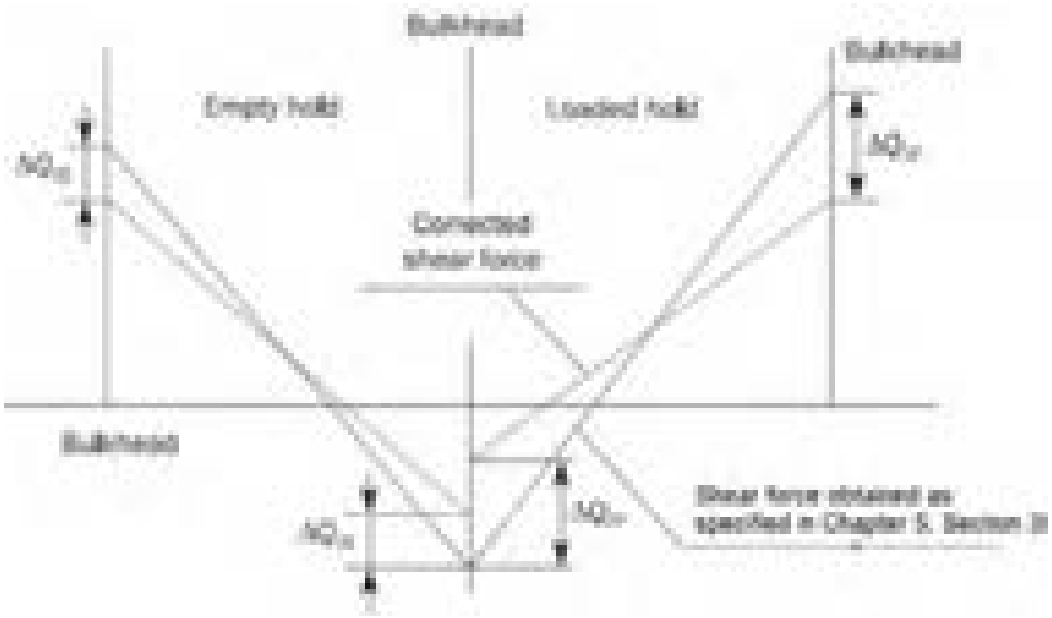


Figure 2.2.5.2: Shear force correction

Section 3

Hull Girder Yield Check

Symbols

For symbols not defined in this section, Refer to Chapter 1, Section 2.

I_{y-n50} = Net moment of inertia, in [m^4], of the hull transverse section about its horizontal neutral axis.

I_{z-n50} = Net moment of inertia, in [m^4], of the hull transverse section about its vertical neutral axis

M_{sw-h}, M_{sw-s} = Permissible vertical still-water bending moment in [kN-m], for hogging and sagging respectively, in seagoing condition at the hull transverse section being considered as defined in Chapter 5, Section 3, Cl.3.4.2.

Q_{sw} = Permissible positive or negative still water shear force for seagoing operation, in [kN], at the hull transverse section considered, as defined in Chapter 5, Section 3, Cl.3.5.1.

M_{wv-_LC} = Vertical wave bending moment in [kN-m], for a dynamic load case, at the hull transverse section being considered as defined in Chapter 5, Section 3, Cl. 3.7.2.

For vessels L<90[m], $M_{wv_LC} = M_{wv}$ as defined in Chapter 5, Section 3, Cl.3.6.1 to be considered.

Q_{wv-_LC} = Positive and negative vertical wave shear force, in [kN], for seagoing Condition for a dynamic load case at the hull transverse section being considered, as defined in Chapter 5, Section 3, Cl.3.7.3.

For vessels L<90[m], $Q_{wv_LC} = Q_{wv_}$ as defined in Chapter 5, Section 3, Cl.3.6.2 to be considered.

M_{wh-LC} = Horizontal wave bending moment, in [kN-m], for a dynamic load case at the hull Transverse section being considered, as defined in Chapter 5, Section 3, Cl.3.7.4.

For vessels L<90[m], $M_{wh-LC} = M_{wh}$ as defined in Chapter 5, Section 3, Cl.3.6.3 to be considered.

q_{vi_n50} = Unit shear flow for hull girder vertical shear force, in [mm^{-1}], for the plate i based on net thickness t_{i_net}, in [mm].

x = X coordinate, in [m], of the calculation point with respect to the reference coordinate system defined in Chapter 1, Section 2, 2.5.

y = Y coordinate, in [m], of the calculation point with respect to the reference coordinate system defined in Chapter 1, Section 2, 2.5.

z = Z coordinate, in [m], of the calculation point with respect to the reference coordinate system defined in Chapter 1, Section 2, 2.5.

z_{n-n50} = Z coordinate, in [m], of horizontal neutral axis of the hull transverse section with net scantlings, with respect to the reference coordinate system defined in Chapter 1, Section 2, 2.5.

3.1 Application

3.1.1 General

This section gives the criteria for calculating the hull girder bending and shear strength with respect to the dynamic load cases as defined in Chapter 5, Section 2, 2.4. The hull girder stresses as defined in 3.2 for ships without large deck openings and in 3.3 for ships with large deck openings obtained are used for following local assessments:

- hull local scantling assessment according to Chapter 7
- buckling assessment according to Chapter 9
- fatigue assessment according to Chapter 10
- special requirements according to Chapter 11.

3.2 Ships without large deck openings

3.2.1 Hull girder longitudinal stresses

For seagoing condition, the hull girder longitudinal stress σ_{hg}, in [N/mm^2] at any

transverse section, about the transverse neutral axis for the still water bending moment $[M_{sw}]$ and wave bending moments (vertical and horizontal bending moments $[M_{wv}]$ and $[M_{wh}]$ respectively) is obtained from the following formula:

$$\sigma_{hg} = \sigma_{hg-sw} + \sigma_{hg-dyn}$$

where:

σ_{hg-sw} = $\begin{cases}\sigma_{sw-h}\\ \sigma_{sw-s}\end{cases}$

σ_{hg-dyn} = $\sigma_{wv-LC} + \sigma_{wh-LC}$

3.2.2 Hull girder shear stresses

For seagoing condition, the hull girder shear stress, τ_{hg} in [N/mm^2], induced by vertical shear forces for a dynamic load case at the transverse section considered is obtained from the following formula:

$$\tau_{hg} = \tau_{hg-sw} + \tau_{hg-dyn}$$

where:

τ_{hg-sw} = $\begin{cases}\tau_{sw-pos}\\ \tau_{sw-neg}\end{cases}$

τ_{hg-dyn} = τ_{wv-LC}

3.3 Ships with large deck openings

3.3.1 Hull girder longitudinal stresses

In case of ships with large deck openings, the additional longitudinal stresses caused by still water and wave torsional moments are also to be considered. Hence, for the seagoing condition, the hull girder longitudinal stress σ_{hg}, in [N/mm^2], for a dynamic load case at the transverse section being considered is obtained from the following formula:

$$\sigma_{hg} = \sigma_{hg-sw} + \sigma_{hg-dyn}$$

where:

σ_{hg-sw} = $\begin{cases}\sigma_{sw-h} + |\sigma_{st}|\\ \sigma_{sw-h} - |\sigma_{st}|\\ \sigma_{sw-s} + |\sigma_{st}|\\ \sigma_{sw-s} - |\sigma_{st}|\end{cases}$

σ_{hg-dyn} = $\sigma_{wv-LC} + C.\sigma_{wh-LC} + \sigma_{wt-LC}$

where:

C = reduction coefficient due to combination with warping stress

= 0.85

σ_{st} = The longitudinal warping stress in [N/mm^2], induced by still water torsional moment in sea going condition. Refer Cl.3.5.1.3.

σ_{wt-LC} = The longitudinal warping stress, in [N/mm^2], induced by wave torsional moment for a dynamic load case, at the transverse section considered in seagoing condition. Refer Cl.3.5.1.3.

3.3.2 Hull girder shear stresses

In case of ships with large deck openings, the additional shear stresses caused by still water and wave torsional moments are also to be considered. Hence, for the seagoing condition, the hull girder shear stress, τ_{hg} in [N/mm^2], for a dynamic load case at the transverse section being considered is obtained from the following formula:

$$\tau_{hg} = \tau_{hg-sw} + \tau_{hg-dyn}$$

where:

τ_{hg-sw} = $\begin{cases}\tau_{sw-pos} + \tau_{st}\\ \tau_{sw-pos} - \tau_{st}\\ \tau_{sw-neg} + \tau_{st}\\ \tau_{sw-neg} - \tau_{st}\end{cases}$

τ_{hg-dyn} = $\tau_{wv-LC} + \tau_{wt-LC}$

τ_{st} = The warping shear stress in [N/mm^2], induced by still water torsional moment in sea going condition. Refer Cl.3.5.2.3.

τ_{wt-LC} = The warping shear stress, in [N/mm^2], induced by wave torsional moment for a dynamic load case, at the transverse section considered in seagoing condition. Refer Cl.3.5.2.3.

3.4 Equivalent stress

3.4.1 The equivalent stress, in [N/mm^2], related to the hull girder longitudinal and shear stresses, σ_{hg} and τ_{hg}, defined in Cl.3.3.1 and Cl.3.3.3 respectively, at any point being considered is obtained from the following formula:

$$\sigma_v = \sqrt{(\sigma_{hg}^2 + 3\tau_{hg}^2)}$$

3.4.2 Design criteria

The equivalent stress, σ_v in [N/mm^2], at any point along the length L of the ship considered, is to comply with the following criteria:

$$\sigma_v \leq \sigma_{v-perm}$$

where:

σ_{v-perm} = Permissible equivalent stress, in [N/mm^2], to be taken as:

$= 220/k$

3.5 Definitions of hull girder stress components

3.5.1 Longitudinal stress

3.5.1.1 Longitudinal stresses induced by still water vertical hull girder bending moment

The longitudinal stresses, in [N/mm^2], induced by vertical still water bending moment (in hogging and sagging cases) in seagoing condition at the transverse section considered, are obtained from the following formula:

$$\sigma_{sw-h} = \frac{M_{sw-h}}{I_{y-n50}}(z - z_{n-n50})10^{-3}$$

$$\sigma_{sw-s} = \frac{M_{sw-s}}{I_{y-n50}}(z - z_{n-n50})10^{-3}$$

3.5.1.2 Longitudinal stresses induced by dynamic hull girder bending moment

The longitudinal stresses, in [N/mm^2], induced by vertical and horizontal wave bending moment for a dynamic load case in seagoing condition at the transverse section considered, are obtained from the following formula:

$$\sigma_{wv-LC} = \frac{M_{wv-LC}}{I_{y-n50}}(z - z_{n-n50})10^{-3}$$

$$\sigma_{wh-LC} = -\frac{M_{wh-LC}}{I_{z-n50}}\, y.10^{-3}$$

3.5.1.3 Longitudinal warping stresses induced by wave and still water hull girder torsion

The longitudinal warping stress, σ_{st} and σ_{wt-LC} in [N/mm^2], induced by still water torsional moment, M_{st} and wave torsional moment for a dynamic load case, M_{wt-LC}, respectively at the transverse section considered in seagoing condition, is to be determined by direct calculations. Refer to the IRS Guideline for "Evaluation of Warping Stresses in Ships with Wide Hatch Openings Due To Torsion Moments" for the calculations.

3.5.2 Shear stresses

3.5.2.1 Shear stresses induced by still water vertical hull girder shear force

The shear stresses, in [N/mm^2], induced by vertical still water shear force in seagoing condition at the transverse section considered, are obtained from the following formulae:

$$\tau_{sw-pos} = \frac{Q_{sw-pos} \cdot q_{vi-n50}}{t_{i-n50}}10^3$$

$$\tau_{sw-neg} = \frac{Q_{sw-neg} \cdot q_{vi-n50}}{t_{i-n50}}10^3$$

3.5.2.2 Shear stresses induced by dynamic vertical hull girder shear force

The shear stresses, in [N/mm^2], induced by dynamic vertical shear force for a dynamic load case at the transverse section considered is obtained from the following formula:

$$\tau_{wv-LC} = \frac{Q_{wv-LC} \cdot q_{vi-n50}}{t_{i-n50}}10^3$$

3.5.2.3 Warping shear stresses induced by wave and still water hull girder torsion

The warping shear stress, τ_{st} and τ_{wt-LC} in [N/mm^2], induced by still water torsional moment, M_{st} and wave torsional moment for a dynamic load case, $M_{\tau-wt-LC}$, respectively at the transverse section considered in seagoing condition, is to be determined by direct calculations. Refer to the IRS Guideline for "Evaluation of Warping Stresses in Ships with Wide Hatch Openings Due To Torsion Moments" for the calculations.

Section 4

Hull girder Ultimate Strength Check

Symbols

For symbols not defined in this section, Refer to Chapter 1, Section 2.

M_{sw-h}, M_{sw-s} = Permissible vertical still water bending moment in seagoing condition, in [kN-m], at the hull transverse section being considered in hogging and sagging, as defined in Chapter 5, Section 3, Cl.3.4.2.

M_{wv} = Vertical wave bending moment in seagoing condition, in [kN-m], at the hull transverse section being considered in hogging and sagging, as defined in Chapter 5, Section 3, Cl.3.6.1.

4.1 Application

4.1.1 General

4.1.1.1 This section applies to all sea going ships with unrestricted service, length, L≥ 150[m] and ships having single deck.

4.1.1.2 The hull girder ultimate strength requirements given in Cl.4.2.1 applies mainly to the cargo space area and to the following locations:

- in way of the forward end of the engine room
- in way of the forward end of the foremost cargo hold
- at any locations where there are significant changes in hull cross-section
- at any locations where there are changes in the framing system
- At any locations where there is a change of material from Midship.

In addition, for ships with large deck openings like container ships following locations are also to be checked:

- sections at or near to 0.25L and 0.75L.
- sections in way of the aft end of the aft-most holds, and the aft end of the deckhouse or engine room, if the cargo holds are at the aft of the superstructure, deckhouse or engine room.

4.1.1.3 The hull girder ultimate bending capacity is to be checked to ensure that it satisfies the criteria given in 4.2.

4.1.1.4 The checking criteria given in 4.2 are applicable to intact ships only.

4.1.1.5 The hull girder ultimate bending capacity, M_U is defined as the maximum bending moment capacity of the hull girder beyond which the hull structure collapses.

4.2 Checking criteria

4.2.1 General

4.2.1.1 The vertical hull girder ultimate bending capacity is to be checked for hogging and sagging conditions for load components as defined in Table 4.2.1.

Table 4.2.1: Load Components

Load components	**Permissible still water bending moment, M_{sw-U}**
Seagoing condition (S+D)	M_{sw-h} or M_{sw-s}

4.2.1.2 The vertical hull girder ultimate bending capacity at any hull transverse section is to satisfy the following criteria:

$$M \leq \frac{M_U}{\gamma_R}$$

where:

M = Vertical bending moment in sea going condition in [kN-m], to be obtained as specified in 4.3.

M_U = Vertical hull girder ultimate bending capacity, in [kN-m], to be obtained as specified in 4.4.

γ_R = partial safety factor for the vertical hull girder ultimate bending capacity to be taken as:

$$\gamma_R = \gamma_M \gamma_{DB}$$

γ_M = Partial safety factor for the vertical hull girder ultimate bending capacity, covering material, geometric and strength prediction uncertainties; in general, to be taken as:

= 1.05 for container ships

= 1.1 for other ship types

γ_{DB} = Partial safety factor for the vertical hull girder ultimate bending capacity, covering the effect of double bottom bending, to be taken as:

For hogging conditions except flooded condition:

= 1.25 for empty cargo holds in alternate condition of bulk carrier having notation "BULK CARRIER Strengthened for heavy cargos, hold(s)… (to be specified) ...may be empty".

= 1.1 for (i) oil tankers (ii) bulk carriers having notation "BULK CARRIER" and "BULK CARRIER Strengthened for heavy cargos", for loaded cargo holds in alternate condition of bulk carrier having notation "BULK CARRIER Strengthened for heavy cargos, hold(s)…(to be specified)..may be empty".

= 1.0 for passenger ships.

= 1.15 for container ships.

For sagging conditions except flooded condition: = 1.0.

For hogging and sagging condition, for flooded condition: = 1.0

4.3 Hull girder ultimate bending loads

4.3.1 The vertical hull girder bending moment in hogging and sagging conditions, in [kN-m], to be considered in the ultimate strength check is to be taken as:

$$M = \gamma_S M_{sw-U} + \gamma_W M_{wv}$$

where:

M_{sw-U} = Permissible still water bending moment, in [kN-m], in hogging and sagging conditions at the hull transverse section considered as defined in Table 4.2.1.

γ_S = Partial safety factor for the still water bending moment, to be taken as:

= 1.0

γ_W = Partial safety factor for the vertical wave bending moment, to be taken as:

= 1.2.

4.4 Hull girder ultimate bending capacity

4.4.1 Curve $M - \chi$

The ultimate bending moment capacities of a hull girder transverse section, in hogging and sagging conditions, are defined as the maximum values of the curve of bending moment capacity [M] versus the curvature [χ] of the transverse section considered (Refer Figure 4.4.1). The curvature [χ] is positive for hogging condition and negative for sagging condition.

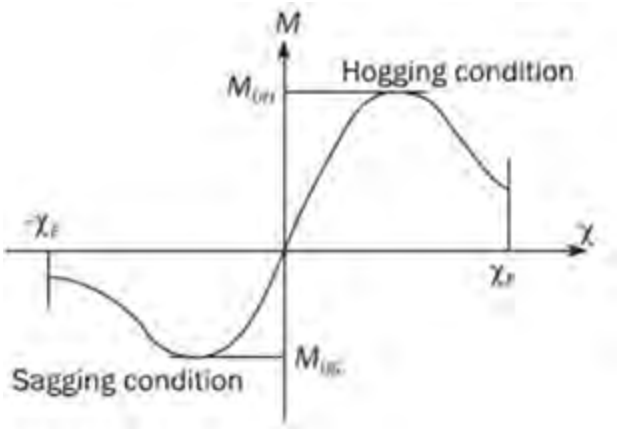

Figure 4.4.1: Bending moment capacity versus curvature [χ]

The hull girder ultimate bending moment capacity M_U, is to be calculated using the incremental-iterative method specified in Part 5, Chapter 5, Section 7.2 or using an alternative method specified in Part 5, Chapter 5, Section 7.3.

4.4.2 Hull girder transverse sections

The hull girder transverse sections are constituted by the elements contributing to the hull girder longitudinal strength, considered with their net scantlings, according to Section 1, Cl.1.4.1.

APPENDIX A

DIRECT CALCULATION OF SHEAR FLOW

A.1 Calculation Formula

A.1.1 General

This appendix describes the procedures of direct calculation of shear flow around a ship's cross section due to hull girder vertical shear force. Shear flow q_v, at each location in the cross section, is calculated by considering the cross section is subjected to a unit vertical shear force, 1[N], in the direction of z coordinate.

The unit shear flow per mm, q_v in [N/mm], is to be taken as:

$$q_v = q_D + q_I$$

where:

q_D = Determinate shear flow, as defined in A.1.2.

q_I = Indeterminate shear flow which circulates around the closed cells, as defined in A.1.3.

In the calculation of the unit shear flow, the longitudinal stiffeners are to be taken into account.

A.1.2 Determinate shear flow

A.1.2.1 The determinate shear flow, q_D in [N/mm], at each location in the cross section can be obtained from the following line integration:

$$q_D(s) = -\frac{1}{10^6\, I_y}\int_0^S (z - z_n)\, t\, ds$$

where:

s = Coordinate value of running coordinate along the cross section, in [m].

I_y = Moment inertia of the cross section, in [m^4].

t = Thickness of plating, in [mm], or equivalent thickness of corrugated plate as defined in Section 1, Cl.1.4.6.

A.1.2.1 It is assumed that the cross section is composed of line segments as shown in Figure A.1.1 (where each line segment has a constant plate net thickness), the determinate shear flow can be calculated by the following equation:

$$q_{Dk} = q_D(\ell) = -\frac{t.\ell}{2x10^6\, I_y}(z_k + z_i - 2z_n) + q_{Di}$$

where:

q_{Dk}, q_{Di} = Determinate shear flow at node k and node i respectively, in [N/mm].

ℓ = Length of line segments, in [m].

z_k, z_i = Z coordinate of the end points k and i of line segment, in [m], as defined in Figure A.1.1.

A.1.2.2 Where the cross section includes closed cells, the closed cell are to be cut with virtual slits, as shown in Figure A.1.2 in order to obtain the determinate shear flow. These virtual slits must not be located in walls which form part of another closed cell.

A.1.2.3 Calculations of the determinate shear flow at bifurcation points can be calculated by water flow calculations as shown in Figure A.1.2.

A.1.3 Indeterminate shear flow

A.1.3.1 The indeterminate shear flow around closed cells of a cross section is considered as a constant value within the same closed cell. The following system of equation for determination of indeterminate shear flows can be developed. In the equations, contour integrations of several parameters around all closed cells are performed.

$$q_{Ik}\oint_k \frac{1}{t}ds - \sum_{i=1}^{N_w}\left(q_{Ii}\oint_{k\&i}\frac{1}{t}ds\right) = -\oint_k \frac{q_D}{t}ds$$

where:

N_w = Number of common walls shared by cell k and all other cells.

$k\&i$ = Common wall shared by cells k and i

q_{Ik}, q_{Ii} = Indeterminate shear flow around the closed cell k and i respectively [N/mm].

A.1.3.2 With assuming assembly of line segments shown in Figure A.1.1, the equations in A.1.3.1 can be expressed as follows:

$$q_{Ik}\sum_{k=1}^{N_k}\left(\frac{\ell}{t}\right)_k - \sum_{i=1}^{N_w}\left\{q_{Ii}\left[\sum_{k=1}^{N_m}\left(\frac{\ell}{t}\right)_k\right]_i\right\} = -\sum_{k=1}^{N_k}\phi_k$$

$$\phi_k = \left[-\frac{\ell^2}{6\times 10^3 I_Y}(z_k + 2z_i - 3z_n) + \frac{\ell}{t}q_{Di}\right]$$

where:

N_k = Number of line segments in cell k.

N_m = Number of line segments on the common wall shared by cells k and I, Refer Figure A.1.3.

q_{Di} = Determinate shear flow, in [N/mm], calculated according to A.1.2.1.

A.1.3.2 The difference in the directions of running coordinates specified in A.1.2 and in this section has to be considered.

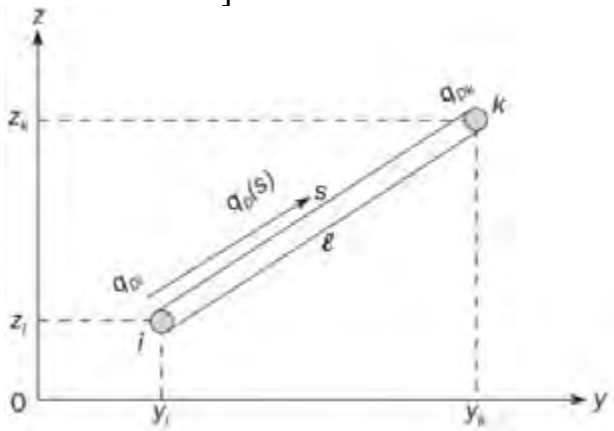

Figure A.1.1: Definition of line segment

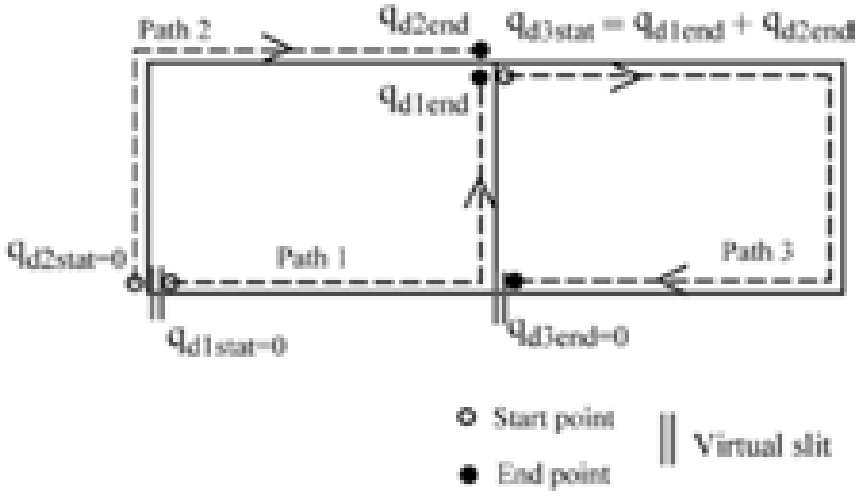

Figure A.1.2: Placement of virtual slits and calculation of determinate shear flow at bifurcation points

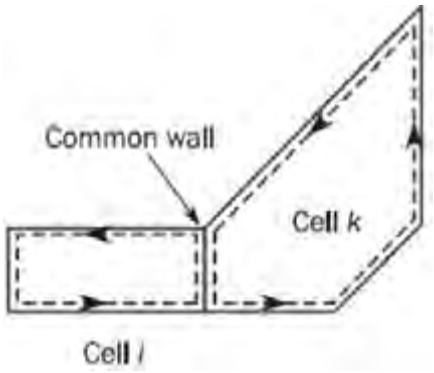

Figure A.1.3: Closed cells and common wall

A.2 Computation of sectional properties

A.2.1 Properties of the cross section are to be obtained by the following formulae where the cross section is assumed as the assembly of line segments:

$$\ell = \sqrt{(y_k - y_i)^2 + (z_k - z_i)^2}$$

$$a = \ell . t . 10^{-3}$$

$$A = \sum a$$

$$s_y = \frac{a}{2}(z_k - z_i)$$

$$S_y = \sum s_y$$

$$i_{y0} = \frac{a}{3}\left(z_k^2 + z_{k.} z_i + z_i^2\right)$$

$$I_{y0} = \sum i_{y0}$$

where:

a, A = Area of the line segment and the cross section respectively, in [m^2].

s_y, S_y = First moment of the line segment and the cross section about the baseline, in [m^3].

i_{y0}, I_{y0} = Moment inertia of the line segment and the cross section about the baseline, in [m^4].

A.2.2 The height of horizontal neutral axis, z_n in [m], can be obtained as follows:

$$z_n = \frac{S_y}{A}$$

A.2.3 Inertia moment about the horizontal neutral axis, in m4, can be calculated as follows:

$$I_y = I_{y0} - {z_n}^2 . A$$

Section 1

General

1.1 Application

1.1.1 This chapter applies to hull structure over the full length of the ship.

1.1.2 This chapter provides requirements for evaluation of plating, stiffeners and Primary Supporting Members (PSM) subject to lateral pressure, local loads and to hull girder loads, as applicable. Requirements are specified for:

- Load application in Section 2.

- Minimum thickness of plates, stiffeners and PSM in Section 3.

- Plating in Section 4

- Stiffeners in Section 5

- PSM and pillars in Section 6

- Intersection of stiffeners and PSM in Section 7

- Superstructure, deckhouse and Companionways in Section 8.

In addition, other requirements not related to defined design load sets, are provided.

1.1.3 Required scantlings

The offered net scantling is to be greater than or equal to the required scantlings based on requirements provided in this chapter.

1.1.4 Additional local strength requirements

- Additional local strength requirements are provided in Chapter 11, considering bow impact loads, bottom slamming loads, sloshing loads, wheel loading and additional local strength requirement for various structural members.

The design values of loads to be considered are given in Chapter 5.

- Scantlings of hull members contributing to the longitudinal strength are also to comply with the requirements of Chapter 6.

- The plating's, stiffeners and PSM's are also to comply with the requirements of buckling strength given in Chapter 9.

1.2 Acceptance criteria

1.2.1 Acceptance criteria set to be selected for scantling requirements are based on design load as follows:

- AC-I for design load S; static loads.

- AC-II for design load S+D; combination of static and dynamic loads.

- AC-IV for Accidental load like flooding.

Section 2

Load Application

Symbols

For symbols not defined in this section, Refer to Chapter 1, Section 2.

2.1 Load combination

2.1.1 Hull girder stress

2.1.1.1 Hull girder longitudinal stress applicable for static loads 'S'

The hull girder longitudinal stress σ_{hg} in [N/mm^2], for static load 'S' to be taken as:

$$\sigma_{hg} = \sigma_{hg-sw}$$

where:

σ_{hg-sw} = Hull girder longitudinal stress, in [N/mm^2], due to vertical still water bending moment as defined in Chapter 6, Section 3, 3.2 for ships without large deck openings and in Chapter 6 section 3, 3.3 for ships with large deck openings.

2.1.1.2 Hull girder longitudinal stress applicable for loads 'S+D'

The hull girder longitudinal stress σ_{hg} in [N/mm^2], for loads 'S+D' to be taken as defined in Chapter 6, Section 3, 3.2 for ships without large deck openings and in Chapter 6 section 3,3.3 for ships with large deck openings.

2.2 Lateral pressures

2.2.1 Lateral pressure in intact conditions

The static and dynamic lateral pressures (defined in Chapter 5) induced by the sea and the various types of cargoes, ballast and other liquids are to be considered. Applied loads will depend on the location of the elements under consideration, and the adjacent type of compartments.

Sloshing pressures are to be applied to tank structures, according to Chapter 11, Section 7.

2.2.2 Lateral pressure in flooded conditions

Following compartments are subjected to lateral pressure in flooded conditions:

- Watertight boundaries of compartments not intended to carry liquids (excluding shell envelope).

- Watertight boundaries of compartments intended to carry liquids which have overflow height below freeboard deck.

- Plating located below the deepest equilibrium waterline (excluding side shell plating) which constitute boundaries intended to stop vertical and horizontal flooding.

2.3 Pressure combination

2.3.1 Elements of the outer shell

If the compartment adjacent to the outer shell is intended to carry liquids, the static and dynamic lateral pressures to be considered are the differences between the internal pressures and

the external sea pressures at the corresponding draught.

If the compartment adjacent to the outer shell is not intended to carry liquids, the internal pressures and the external sea pressures are considered individually.

2.3.2 Elements other than those of the outer shell

Except as specified in Cl.2.3.1, the static and dynamic lateral pressures on an element separating two adjacent compartments are those obtained considering the two compartments individually loaded.

2.4 Design load sets

2.4.1 Application

These requirements apply to:

- Plating and stiffeners along the full length of main hull of the ship.
- Primary supporting members, if scantlings are not determined by global FE analysis or cargo hold analysis
- Plating, stiffeners and primary supporting members in superstructures and deckhouses contributing to hull girder longitudinal strength.

2.4.2 Load components

The static and dynamic load components are to be determined in accordance with Chapter 5, Section 6, Cl.6.2.1.

Radius of gyration, K_r, and metacentric height, GM, are to be in accordance with Chapter 5, Section 2 for the considered loading conditions specified in the design load sets given in Table 2.4.3.

2.4.3 Design load sets for plating, stiffeners and PSM

Design load sets for plating, stiffeners and primary supporting members are given in Table 2.4.3. Impact and sloshing load sets are considered in Chapter 11.

Table 2.4.3 Design load sets

Structural member	Design load set	Design load scenario	Load component[4)]	Draught	Acceptance criteria	Loading condition
External shell and exposed deck	SEA-1	1	$P_S + P_W$, P_D	T_{SC}	AC-II	Full load condition
Superstructure side			max (P_W, P_{SI})			
External shell	SEA-2	2	P_S	T_{SC}	AC-I	Harbour condition
Boundaries of water ballast tanks and ballast holds	WB-1	1	$P_{ls-1} + P_{ld} - (P_S + P_W)$[1)]	T_B	AC-II	Normal ballast condition
	WB-2	2	$\max(P_{ls-2}, P_{ls-ST}) - P_S$[1)]	min (T_B, $0.25T_{SC}$)	AC-I	Harbour and Tank Testing condition
	WB-3	3	$P_{ls-3} + P_{ld} - (P_S + P_W)$[1)]	T_B	AC-II	Water ballast exchange
	WB-4	4	$P_{ls-4} + P_{ld} - (P_S + P_W)$[1)]			
Boundaries of tanks other than	TK-1	1	$P_{ls-1} + P_{ld} - (P_S + P_W)$[1)]	T_B	AC-II	Normal ballast condition

water ballast tanks	TK-2	2	$\max(P_{ls-2}, P_{ls-ST}) - P_S$ [1)]	$0.25T_{SC}$	AC-I	Harbour and Tank Testing condition
Bulk cargo hold	BC-1	1	$P_{bs} + P_{bd}$	T_{SC}	AC-II	Homogeneous loading, fully filled hold
	BC-2	2	P_{bs}		AC-I	
	BC-3	1	$P_{bs} + P_{bd}$	T_{SC}	AC-II	Homogeneous loading, Partially filled hold [5)]
	BC-4	2	P_{bs}		AC-I	
Cargo oil/Liquid cargo tank	LT-1	1	$P_{ls-1} + P_{ld} - (P_S + P_W)$ [1)]	T_{SC}	AC-II	Full Load condition
	LT-3			$0.6T_{SC}$		Partial load condition
	LT-2	2	$\max(P_{ls-2}, P_{ls-ST}) - P_S$ [1)]	T_{SC}	AC-I	Harbour and Tank Testing condition
Internal structures in tanks (e.g., Webs of PSM's)	INT-1		P_{int}	T_{SC}	AC-I	-
Collision bulkhead	FD-1	5	P_{in-f}	T_{DAM}	AC-I	Flooded condition
Watertight boundaries other than collision bulkhead					AC-IV	
Exposed decks and non-exposed decks and platforms with distributed load	UDL-1 [2)]	1	$P_{dl-s} + P_{dl-d}$ $F_{U-s} + F_{U-d}$	T_{SC} [3)]	AC-II	Full load condition
	UDL-2 [2)]	2	P_{dl-s} F_{U-s}	-	AC-I	
Decks and hatch covers/ RO/RO equipment with wheel loading	WL-1 [2)]	1	P_{wl-1}	T_{SC} [3)]	AC-II	Full load condition
	WL-2 [2)]	2	P_{wl-2}	-	AC-I	

1) $(P_S + P_W)$ and P_S is considered for external shell only.
2) Distributed or concentrated loads only. Need not to be combined with simultaneously occurring green sea pressure.
3) For cargo loads, draught, GM and K_r values may be based on actual cargo conditions in the loading manual.
4) Local loads:
P_S = Hydrostatic sea pressure as given in Chapter 5, Section 4, Cl.4.1.2.
P_W = Wave pressure as given in Chapter 5, Section 4, Cl.4.1.3.
P_D = External dynamic design pressure for exposed decks and wheelhouse top due to green sea loading as given in Chapter 5, Section 4, Cl.4.2.2 and Chapter 5, Section 4, Cl.4.3.2, respectively
P_A = Design pressure for end bulkheads of superstructure and deckhouse walls as given in Chapter 5, Section 4, Cl.4.3.4.
P_{SI} = External design pressure for external side of superstructure as given in Chapter 5, Section 4, Cl.4.3.3.
P_{ls-1} = Static tank pressure during normal operations at sea as given in Chapter 5, Section 5, Cl.5.1.2.1(a).

P_{ls-2} = Static tank pressure during normal operations at harbour/sheltered water as given in Chapter 5, Section 5, Cl.5.1.2.1(b).

P_{ls-3} = Static tank pressure during flow through ballast water exchange as given in Chapter 5, Section 5, Cl.5.1.2.1(c).

P_{ls-4} = Static tank pressure due to sequential ballast water exchange as given in Chapter 5, Section 5, Cl.5.1.2.1(d).

P_{ls-ST} = Static tank testing pressure as given in Chapter 5, Section 5, Cl.5.1.2.1(f).

P_{in-f} = Internal pressure in flooded condition as given in Chapter 5, Section 5, Cl.5.1.1.2.

P_{int} = Minimum pressure for internal structures in tanks as given in Chapter 5 Section 5, Cl.5.3.1.

P_{dl} = Pressure due to distributed deck load as given in Chapter 5, Section 4, Cl.4.2.3.1 or Chapter 5, Section 5, Cl.5.2.2.

F_U = Force on exposed and non-exposed decks and platforms due to unit loads as given in Chapter 5, Section 4, Cl.4.2.3.2.

P_{wl-1} = Design pressure for wheel loading during normal operation at sea as given in Chapter 11, Section 5.

P_{wl-2} = Design pressure for wheel loading during normal operation at harbour as given in in Chapter 11, Section 5.

5) Considered for heavy cargo densities.

Section 3

Minimum Thickness

Symbols

For symbols not defined in this section, Refer to Chapter 1, Section 2.

M_{GRAB} = Mass of unladen grab, in [t].

3.1 Plating

3.1.1 The net thickness of plating in [mm], is to comply with the appropriate minimum thickness requirements given in Table 3.1.1 and given by:

$$t_{net} = a + bL\sqrt{k}$$

where:

a = coefficient as defined in Table 3.1.1.

b = coefficient as defined in Table 3.1.1.

L = Rule length, but need not be taken greater than 300[m].

Table 3.1.1: Minimum net thickness for plating in [mm]

Sl. No	Plating	Location	Coefficients	
			a	b
1	Keel plate	-	6.5	0.035
2	Bottom plate	-	4.5	0.035
3	Bilge plate	-	4.5	0.035
4	Side shell and super structure side	From upper end of bilge plating to T_{SC} + 4.6m	4.5	0.035
		From T_{SC} + 4.6 m to T_{SC} + 6.9m		0.025
		From T_{SC} + 6.9 m to T_{SC} + 9.2m		0.015
		Elsewhere		0.01
5	Deck plate	Weather deck, Strength deck[1)]	4.5	0.02
		Boundary for cargo tanks, water ballast tanks and hold intended for cargo in bulk	4.5	0.02
		Tween decks and first tier of erections	4.5	0.015
		Other decks[2),3)]	4.5	0.01
6	Inner bottom	General	5	0.02
		Cargo spaces loaded through cargo hatches except container holds	5.5	0.025
7	Bulkheads	Watertight (Transverse and longitudinal) /Tank bulkheads	4.5	0.015
		Bulkheads for cargo tanks		
		Peak bulkheads		
		Hold intended for bulk cargo		
		Non-tight bulkhead, Wash bulkheads, Bulkheads between dry spaces.	4.5	0.01
		Pillar bulkheads in fore and aft peaks	7.0	
		Pillar bulkheads in holds[5)]	7.0	
		Pillar bulkheads in tween decks[5)]	6.5	
		Walls in accommodation	4.5	

8	Other members	Other plates in general	4.5	0.01

1) Includes Forecastle deck also.
2) For the decks not contributing to hull girder longitudinal strength, b may be taken equal to 0.
3) Where deck coverings in accordance with Chapter 2, Section 3.10 are provided, the deck thickness may be reduced by 10 percent without being less than 4.5[mm].
4) For ships discharged by grabs, the net plating thickness 't' of the inner bottom and exposed parts of sloping bulkheads is not to be less than:

$$t = 0.62\sqrt{s.k}\left(\frac{M_{GRAB}}{20}\right)^{0.25} [mm]$$

Where ceiling is fitted, the above requirement may be reduced by 2[mm].
The slope bulkhead plating of increased thickness is to extend for a minimum distance corresponding to a vertical height of 1.5[m] above the line of the inner bottom.
5) For ships L<90[m], minimum thickness of Pillar bulkheads is to be 5.5[mm].

3.2 Stiffeners and Tripping brackets

3.2.1 Minimum thickness requirements

The net thickness of the web and face plate, if any, of stiffeners and tripping brackets in [mm], is to comply with the minimum net thickness given in Table 3.2.1 and given by,

$$t_{net} = a + bL$$

where,

a = coefficient as defined in Table 3.2.1.

b = coefficient as defined in Table 3.2.1.

L = Rule length, but need not be taken greater than 250[m].

Table 3.2.1: Minimum net thickness for stiffeners and tripping brackets

Sl. No	Element	Location	Coefficients	
			a	b
1	Stiffeners and attached end brackets	Watertight boundaries: Tank boundary, Cargo hold, boundary of dry bulk cargo, strength deck and shell up to freeboard deck	3.5	0.015
		Other structure	3	0.015
		Structures in deckhouse and superstructure and decks for vessels with more than 2 continuous decks above 0.7D from baseline	4	-
2	Tripping brackets		4.5	0.01

3.3 Primary supporting members

3.3.1 Minimum thickness requirements of PSM's

3.3.1.1 The net thickness of web plating and flange of primary supporting members in [mm], is to comply with the appropriate minimum thickness requirements given by:

$$t_{net} = a + bL\sqrt{k}$$

where:

a = coefficient as defined in Table 3.3.1.

b = coefficient as defined in Table 3.3.1.

L = Rule length, but need not be taken greater than 250[m].

Table 3.3.1: Minimum net thickness for PSM's in [mm]					
Sl. No	**Member**	**Location**	**Within 0.4L amidships (Including Machinery space Unless noted otherwise)**		**Remarks**
			Coefficients		
			a	**b**	
1	Double bottom	Center girder	5	0.03	
		Lower strake of centreline wash bulkhead			
		Side girder	5	0.02	
		Floors	5	0.02	
		Girders bounding a duct keel	5	0.025	Refer Notes 2&3
		Margin plate	5	0.02	Refer Notes 1&3
2	Single bottom	Center girder	6	0.04	Refer Note 1
		Side girder	5	0.04	
		Floors	5	0.025	Refer Note 4
	Other PSM's				
3	Peak Spaces	PSM's in Aft and Fore peak	5	0.05	Refer Note 5
4	PSM's not mentioned above	At tank boundaries, boundaries of holds intended for cargo in bulk, single strength deck and shell up to freeboard deck	5	0.015	
		Deckhouses and superstructures and decks for vessels with more than 2 continuous decks above 0.7D from baseline	4.5	0.015	Refer Note 6
		Elsewhere	4	0.015	

Note 1: Towards the fore and after ends, the scantlings of the bottom members may be reduced by 10%.

Note 2: The minimum net thickness is to be taken not less than that required for the centre girder.

Note 3: In the engine room, thickness of girders bounding duct keel and margin plate is to be increased by 1[mm].

Note 4: In the engine room, the thickness of floors webs is to be increased by 1[mm] and the face plate area of floor (as given in Table 3.3.2) is to be increased by 50%.

Note 5: May not be taken greater than 10[mm].

Note 6: May not be taken greater than 6.5[mm].

Table 3.3.2: Transversely framed Single bottom PSM's		
Item	**Depth 'd' in [mm]**	**Face plate area 'a' in [cm^2]**
Floor	40(B+T)	3.5 T. k^$^{0.5}$
Center girder	As for floors	5+0.6L k
Side girders	As for floors	5+0.3L k
1) The thickness of face plates is not to be less than 1/15 of the face width.		
(2) The top of floors, in general, is to be level from side to side. However, in ships having considerable rise of floor, the depth of web at 10 % of the span from ends, is not to be less than 0.5d [mm].		

3.3.2 Where single bottom in the cargo region is stiffened by transverse frames supported by longitudinal girders, the scantlings of the frames and longitudinal girders are to be determined in accordance with Section 6, Cl.6.1.2 for section modulus and Chapter 3, section 7, Cl.7.4.8.1 for girder web area.

3.3.3 The longitudinal girders are to be satisfactorily stiffened against buckling in accordance with the requirements given in Chapter 9. Tripping brackets are to be fitted in accordance with the requirements given in Chapter 3, Section 6.

Section 4

Plating

Symbols

For symbols not defined in this section, Refer to Chapter 1, Section 2.

α_p = correction factor for the panel aspect ratio to be taken as below but not to be greater than 1.0:

$$\alpha_p = 1.2 - \frac{b}{2.1\,a}$$

a = Length of plate panel, in [mm], as defined in Chapter 3 Section 7, Cl.7.5.1.

b = Breadth of plate panel, in [mm], as defined in Chapter 3 Section 7, Cl.7.5.1.

P = Design pressure for the considered design load set, Refer Section 2, 2.4, calculated at the load calculation point defined in Chapter 3 Section 7, Cl.7.5.2, in [kN/m^2].

σ_{hg} = Hull girder longitudinal stress, in [N/mm^2], as defined in Section 2, 2.1, calculated at the load calculation point as defined in Chapter 3, Section 7, Cl.7.5.2.

4.1 Plating subjected to lateral pressure

4.1.1 General

4.1.1.1 The net thickness, in [mm], is not to be taken less than the greatest value for all applicable design load sets, as defined in Section 2, Cl.2.4.3, given by:

$$t_{net} = 0.0158.\alpha_p.b\sqrt{\frac{|P|}{\chi.C_a.R_{eH}}}$$

where:

C_a = Permissible bending stress coefficient for plate taken equal to:

$$C_a = \beta - \alpha\frac{|\sigma_{hg}|}{R_{eH}}$$

not to be taken greater than $C_{a\text{-}max}$

β = Coefficient as defined in Table 4.11.

α = Coefficient as defined in Table 4.11.

C_{a-max} = Maximum permissible bending stress coefficient as defined in Table 4.11.

χ = Coefficient taken equal to:

- In intact condition:

= 0.70 for inner bottom or bilge hopper tank plating in cargo holds of bulk carriers

= 1.0 for other cases.

- In flooded condition:

= 1.00 for collision bulkheads for acceptance criteria set AC-I,

= 1.15 for other watertight boundaries of compartments.

Table 4.1.1: Plating, definition of β, α and $C_{a\text{-}max}$

Acceptance criteria	Structural member		β	α	C_{a-max}
AC-I	Longitudinal Strength members	Longitudinal stiffened plating	0.9	0.5	0.8
		Transverse stiffened plating	0.9	1.0	0.8
	Other members		0.8	0.0	0.8
AC-II/ AC-IV	Longitudinal Strength members	Longitudinal stiffened plating	1.05	0.5	0.95
		Transverse stiffened plating	1.05	1.0	0.95
	Other members		1.0	0.0	1.0

4.1.2 Plating of corrugated bulkheads

4.1.2.1 Cold and hot formed corrugations

The net thicknesses, in [mm], of the web and flange plates of corrugated bulkheads are not to be taken less than the greatest value calculated for all applicable design load sets, as defined in Chapter 7, Section 2, Cl.2.4.3, given by:

$$t_{net} = 0.0158\, b_p \sqrt{\frac{|P|}{C_{CB}.\, R_{eH}}}$$

where:

b_p = Breadth of plane corrugation plating in [mm].

= a for flange plating, in [mm], as defined in Figure 4.1.2.

= c for web plating, in [mm], as defined in Figure 4.1.2.

C_{CB} = Permissible bending stress coefficient for corrugated bulkhead plating taken equal to:

$$C_{CB} = \beta_{CB} - \alpha_{CB} \frac{|\sigma_{hg}|}{R_{eH}},$$

not to be greater than $C_{CB-max.}$

β_{CB} = Coefficient as defined in Table 4.1.2.

α_{CB} = Coefficient as defined in Table 4.1.2.

C_{CB-max}= Maximum permissible bending stress coefficient as defined in Table 4.1.2.

Table 4.1.2: Definition of β_{CB}, α_{CB} and $C_{CB-max.}$

Acceptance criteria set	Structural member	β_{CB}	α_{CB}	C_{CB-max}
AC-I	a) Horizontally corrugated longitudinal bulkheads	0.90	0.50	0.75
	b) Other corrugated bulkheads			
	• Transverse	0.75	0.00	0.75
	• Vertically corrugated longitudinal bulkheads			
AC-II	a) Horizontally corrugated longitudinal bulkheads	1.05	0.50	0.90
	b) Other corrugated bulkheads			
	• Transverse	0.90	0.00	0.90
	• Vertically corrugated longitudinal bulkheads			

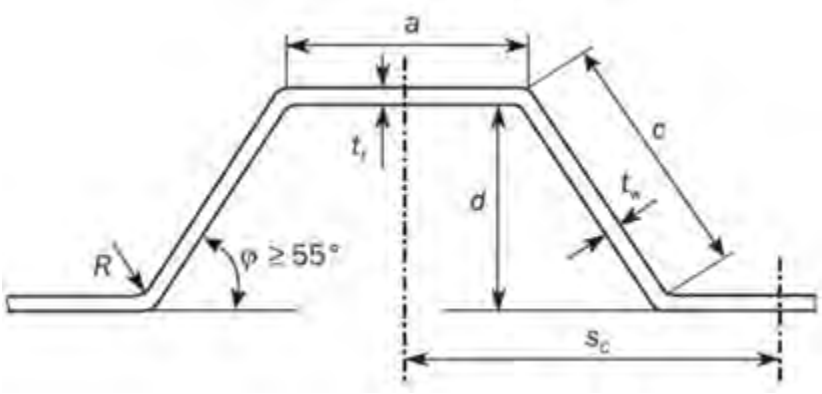

Figure 4.1.2: Dimensions of a corrugated bulkhead

4.1.2.2 Built-up corrugations

For built-up corrugations, with flange and web plate of different thickness, the net thickness, in [mm], is to be taken as the greatest value calculated for all applicable design load sets, as defined in Chapter 7, Section 2, Cl.2.4.3, given by:

$$t_1 = \sqrt{\frac{0.0005\, {b_p}^2.\, |P|}{C_{CB}.\, R_{eH}} - (t_2)^2}$$

where:

t_1 = Net thickness of the thicker plating, in [mm] either flange or web.

t_2 = Net required thickness of the thinner plating, in [mm] either flange or web, not to be less than required by Cl.4.1.2.1.

b_p = Breadth of thicker plate, in [mm] either flange or web.

C_{CB} = Permissible bending stress coefficient as defined in Cl.4.1.2.1.

4.1.3 Bilge plating

4.1.3.1 The thickness of plating in bilge area as defined in Chapter 1, Section 2, Cl.2.6.6 is to be equal or greater than the lesser of Section 3, Cl.3.1.1 and Cl.4.1.3.3, and also to satisfy Cl.4.1.3.2.

4.1.3.2 The net thickness of bilge plating is not to be taken less than the offered net thickness for the adjacent bottom shell or adjacent side shell plating, whichever is greater.

4.1.3.3 The net thickness of rounded bilge plating, in [mm], is not to be taken less than:

$$t_{net} = 6.45 \times 10^{-4}(P_{ex}.s_b)^{0.4}R^{0.6}$$

where:

P_{ex} = Design sea pressure in [kN/m^2] for the design load set SEA-1 calculated at the lower turn of the bilge.

R = Effective bilge radius in [mm].

$$R = R_0 + 0.5(\Delta s_1 + \Delta s_2)$$

R_0 = Radius of curvature, in [mm]. Refer Figure 4.5.8.

Δs_1 = Distance between the lower turn of bilge and the outermost bottom longitudinal, in [mm], Refer Figure 4.1.3. Where the outermost bottom longitudinal is within the curvature, this distance is to be taken as zero.

Δs_2 = Distance between the upper turn of bilge and the lowest side longitudinal, in [mm], Refer Figure 4.1.3. Where the lowest side longitudinal is within the curvature, this distance is to be taken as zero.

s_b = Distance, in [mm] between transverse stiffeners, webs or bilge brackets.

4.1.3.4 Longitudinally stiffened bilge plating is to be assessed as regular stiffened plating. The bilge thickness is not to be less than the lesser of the value obtained by Cl.4.1.1.1 and Cl.4.1.3.3. A bilge keel is not considered as an effective 'longitudinal stiffening' member.

4.1.3.5 Transverse extension of bilge minimum plate thickness

Where a plate seam is located in the straight plate just below the lowest stiffener on the sideshell, any increased thickness required for the bilge plating does not have to be extended to the adjacent plate above the bilge provided the plate seam is not more than $s_2/4$ below the lowest side longitudinal.

Similarly, for the flat part of adjacent bottom plating, any increased thickness for the bilge plating does not have to be extended to the adjacent plate provided that the plate seam is not more than $s_1/4$ beyond the outboard bottom longitudinal. For definition of s_1 and s_2, Refer Figure 4.1.3.

4.1.3.6 Hull envelope framing in bilge area

For transversely stiffened bilge plating, a longitudinal is to be fitted at the bottom and at the side close to the position where the curvature of the bilge plate starts. The scantling of those longitudinals are to be not less than the one of the closer adjacent stiffener. The distance between the lower turn of bilge and the outermost bottom longitudinal, Δs_1, is generally not to be greater than one-third of the spacing between the two outermost bottom longitudinals,s_1.

Similarly, the distance between the upper turn of the bilge and the lowest side longitudinal, Δs_2, is generally not to be greater than one-third of the spacing between the two lowest side longitudinals, s_2. Refer Figure 4.1.3.

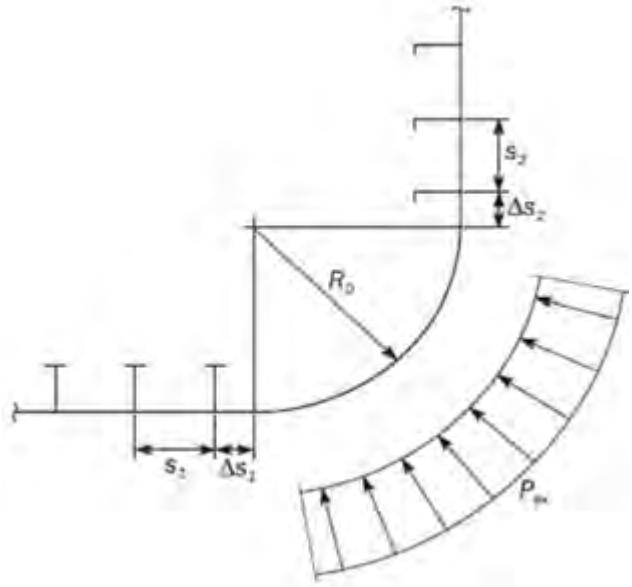

Figure 4.1.3: Transverse stiffened bilge plating

4.1.4 Local strength of plating for ships with L<90 [m]

4.1.4.1 Application

The yield check in Cl.4.1.1 are generally based on values of C_{a-max} and C_{CB-max} when considering envelope loads applied in accordance with Chapter 5, Section 6, Table 6.2.1.2 and provided:

- Scantlings of longitudinal members in midship region is checked and found in compliance with Cl.4.1.1 using stress coefficient calculated with applicable hull girder stress and also found in compliance with the buckling requirements in accordance with Chapter 9.

- Scantlings of longitudinal members are kept constant within 0.4L amidship and tapered toward fore and aft end.

Section 5

Stiffeners

Symbols

For symbols not defined in this section, Refer to Chapter 1, Section 2.

P = Design pressure, in [kN/m^2], for the considered design load set, Refer Section 2, 2.4, calculated at the load calculation point as defined in Chapter 3, Section 7, Cl.7.5.2.

σ_{hg} = Hull girder longitudinal stress, in [N/mm^2], as defined in Section 2, 2.1, calculated at the load calculation point as defined in Chapter 3, Section 7, Cl.7.5.2.

ℓ_{bdg} = Effective bending span, in [m,] as defined in Chapter 3, Section 7, Cl.7.1.1.

ℓ_{shr} = Effective shear span, in [m], as defined in Chapter 3, Section 7, Cl.7.1.3 for stiffeners.

d_{shr} = Effective shear depth, in [mm], as defined in Chapter 3, Section 7, Cl.7.4.3 for stiffeners.

χ = Coefficient taken equal to:

- In intact condition:

= 0.90 for stiffeners attached to inner bottom or bilge hopper tank plating in cargo holds of bulk carriers,

= 1.0 for other cases.

- In flooded condition:

= 1.00 for collision bulkheads for acceptance criteria set AC-I.

= 1.15 for other watertight boundaries of compartments.

5.1 Stiffeners subjected to lateral pressure

5.1.1 Yielding check

5.1.1.1 Web plating

The minimum net web thickness, t_w in [mm], is not to be taken less than the greatest value calculated for all applicable design load sets as defined in Section 2, Cl.2.4.3, given by:

$$t_w = \frac{f_{shr}.|P|.s.\ell_{shr}}{d_{shr}.\chi.C_t.\tau_{eH}}$$

with $\chi.C_t$ not to be taken greater than 1.0.

where:

f_{shr} = Shear force distribution factor taken as:

For continuous stiffeners with fixed ends, f_{shr} is not to be taken less than:

= 0.5 for horizontal stiffeners and upper end of vertical stiffeners.

= 0.7 for lower end of vertical stiffeners.

For non-continuous stiffeners with simply supported ends

= 0.5 for all stiffeners.

For stiffeners with end fixity different from above, variable load or being part of grillage, the requirement in Cl.5.1.2 applies.

C_t = Permissible shear stress coefficient for the design load set being considered, taken as:

= 0.75 for acceptance criteria set AC-I.

= 0.90 for acceptance criteria set AC-II.

5.1.1.2 Section modulus

The minimum net section modulus, Z in [cm^3], is not to be taken less than the greatest value calculated for all applicable design load sets as defined in Section 2, Cl.2.4.3, given by:

$$Z = \frac{|P|.s.\ell_{bdg}^2}{f_{bdg}.\chi.C_s.R_{eH}}$$

with $\chi.C_s$ not to be taken greater than 1.0

where:

f_{bdg} = Bending moment factor taken as:

For all continuous horizontal and vertical stiffeners, f_{bdg} is to be taken from Table 5.1.1.1.

For all non-continuous stiffeners, f_{bdg} is taken as:

= 8 For simply supported ends

= 10 For fixed at both ends

For stiffeners with end fixity different from above, variable load or being part of grillage, the requirement in Cl.5.1.2 applies.

C_s = Permissible bending stress coefficient as defined in Table 5.1.1.1 for the design load set being considered.

β_s = Coefficient as defined in Table 5.1.1.2.

α_s = Coefficient as defined in Table 5.1.1.2.

C_{s-max}= Maximum permissible bending stress coefficient as defined in Table 5.1.1.2.

Table 5.1.1.1: Definition of C_s

Structural member	**Sign of hull girder bending stress, σ_{hg}**	**Lateral pressure acting on**	Stiffener boundary condition (1)	f_{bdg}	**Coefficient C_s**
For continuous stiffeners	Tension (positive)	Stiffener side	F - F	12	$C_s = \beta_s - \alpha_s \frac{\lvert\sigma_{hg}\rvert}{R_{eH}}$ but not to be taken greater than C_{s-max}
			F - S	8	
			S - S	8	$C_s = C_{s-max}$
		Plate side	F - F	24	$C_s = \beta_s - \alpha_s \frac{\lvert\sigma_{hg}\rvert}{R_{eH}}$ but not to be taken greater than C_{s-max}
			F - S	14	
			S - S	8	
	Compression (negative)	Stiffener side	F - F	24	$C_s = \beta_s - \alpha_s \frac{\lvert\sigma_{hg}\rvert}{R_{eH}}$ but not to be taken greater than C_{s-max}
			F - S	14	
			S - S	8	
		Plate side	F - F	12	$C_s = \beta_s - \alpha_s \frac{\lvert\sigma_{hg}\rvert}{R_{eH}}$ but not to be taken greater than C_{s-max}
			F - S	8	
			S - S	8	$C_s = C_{s-max}$
For non-continuous stiffeners	Tension (positive)	Plate side	Refer Cl. 5.1.1.2		$C_s = \beta_s - \alpha_s \frac{\lvert\sigma_{hg}\rvert}{R_{eH}}$ but not to be taken greater than C_{s-max}
	Compression (negative)	Stiffener side			
	Tension (positive)	Stiffener side			$C_s = C_{s-max}$
	Compression (negative)	Plate side			

(1) F - F stands for both ends of the stiffener fixed against rotation
F - S stands for one end of the stiffener fixed and the other not fixed against rotation
S - S stands for both ends of the stiffener not fixed against rotation

Table 5.1.1.2: Definition of $\alpha_s, \beta_s, C_{s-max.}$				
Acceptance criteria set	**Structural member**	β_s	α_s	$C_{s-max.}$
AC-I	Longitudinal strength member	0.85	1.00	0.75
	Transverse or vertical member	0.75	0.00	0.75
AC-II/AC-IV	Longitudinal strength member	1.00	1.00	0.90
	Transverse or vertical member	0.90	0.00	0.90

5.1.1.3 Groups of equal ordinary stiffeners

Scantlings of stiffeners based on requirements in Cl.5.1.1.1 and Cl.5.1.1.2 may be decided based on the concept of grouping designated sequentially placed stiffeners of equal scantlings on a single stiffened panel between primary supporting members. The scantling of the group is to be taken as the greater of the following:

- The average of the required scantling of all stiffeners within a group.

- 90% of the maximum scantling required for any one stiffener within the group.

5.1.1.4 Plate and stiffener of different materials

When the minimum specified yield stress of a stiffener exceeds the minimum specified yield stress of the attached plate by more than 35%, the following criterion is to be satisfied:

$$\sigma_s \leq \left[\sigma_p - \frac{\alpha_s |\sigma_{hg}|}{\beta_s}\right]\frac{Z_p}{Z} + \frac{\alpha_s |\sigma_{hg}|}{\beta_s}$$

where:

σ_s = Minimum specified yield stress, in [N/mm^2], of the material of the stiffener.

σ_p = Minimum specified yield stress, in [N/mm^2], of the material of the attached plate.

σ_{hg} = Hull girder bending stress, in [N/mm^2], as defined in Section 2, Cl.2.1.1 with $|\sigma_{hg}|$ not to be taken less than $0.4\,\sigma_p$.

Z = Net section modulus, in [cm^3], in way of face plate/free edge of the stiffener.

Z_p = Net section modulus, in [cm^3], in way of the attached plate of stiffener.

α_s , β_s = Coefficients defined in Table 5.1.1.2.

5.1.1.5 Struts connecting ordinary stiffeners

The net sectional area,A_{SR} in [cm^2], and the net moment of inertia about the main axis, I_{SR} in [cm^4], of struts connecting stiffeners is not be less than the values obtained from the following formulae:

$$A_{SR} = \frac{P_{SR}.s.\ell}{20000}$$

$$I_{SR} = \frac{0.75.s.\ell(P_{SR1} + P_{SR2})A_{ASR}.\ell_{SR}^2}{47200.A_{ASR} - s.\ell(P_{SR1} + P_{SR2})}$$

where:

P_{SR} = Pressure in [kN/m^2], to be taken as the greater of the following values:

$$P_{SR} = 0.5(P_{SR1} + P_{SR2})$$

$$P_{SR} = P_{SR3}$$

P_{SR1} = External pressure in way of the strut, in [kN/m^2], acting on one side, outside the compartment in which the strut is located.

P_{SR2} = External pressure in way of the strut, in [kN/m^2], acting on the opposite side, outside the compartment in which the strut is located.

P_{SR3} = Internal pressure at mid-span of the strut, in [kN/m^2], in the compartment in which the strut is located.

s = Spacing, in [mm], of stiffeners, measured at mid-span along the chord.

ℓ = Span, in [m], of stiffeners connected by the strut.

ℓ_{SR} = Length of the strut, in [m].

A_{ASR} = Actual net sectional area of the strut, in [cm^2].

5.1.1.6 Net section modulus of corrugations

(a) The net section modulus of a corrugation may be obtained, in [cm^3], from the following formula:

$$Z = \left[d\left(\frac{3.a.t_f + c.t_w}{6}\right)\right] 10^{-3}$$

where:

t_f, t_w = Net thickness of the plating of the corrugation, in [mm], Refer Section 4, Figure 4.1.2.

d, a, c = Dimensions of the corrugation, in [mm], Refer Section 4, Figure 4.1.2.

Where the web continuity is not ensured at ends of the bulkhead, the net section modulus of a corrugation is to be obtained, in [cm^3], from the following formula:

$$Z = 0.5\, a.t_f.d\, 10^{-3}$$

(b) The net section modulus, in [cm^3], of corrugated bulkheads subjected to lateral pressure is not to be less than the value obtained from the following formula:

$$Z = \frac{|p|.S_c.\ell_{bdg}^2}{f_{bdg}.C_s.R_{eH}}$$

S_c = Half pitch length, in [mm], of the corrugation, as defined in Refer Section 4, Figure 4.1.2.

ℓ_{bdg} = Effective bending span, in [m,] as defined in Chapter 3, Section 6, Cl.6.4.3.

C_s = Permissible bending stress coefficient as defined in Table 5.1.1.1 for the design load set being considered.

f_{bdg} = Bending moment factor as defined in Cl.5.1.1.2.

5.1.2 Beam analysis

5.1.2.1 Application

The maximum bending stress, σ_b and shear stress, τ in a stiffener using net properties with reduced end fixity, variable load or being part of grillage are to be determined by direct calculations taking into account the following:

The distribution of static and dynamic pressures and forces, if any.

- The number and position of intermediate supports (e.g., decks, girders, etc.).

- The condition of fixity at the ends of the stiffener and at intermediate supports.

- The geometrical characteristics of the stiffener on the intermediate spans.

- The effective breadth, b_{eff}, for yield check.as given in Chapter 3, Section 7, Cl.7.4.4.

5.1.2.2 Stress criteria

The calculated stress, in [N/mm^2] is to comply with the following criteria where the coefficients C_t and C_s, are defined in Cl.5.1.1.1 and Cl.5.1.1.2.

$$\tau \leq \chi C_t \tau_{eH}$$

$$\sigma_b \leq \chi C_s R_{eH}$$

5.1.3 Yielding strength of stiffeners for ships with L<90 [m]

5.1.3.1 Application

The yield check in Cl.5.1.1 and Cl.5.1.2 are generally based on C_{s-max} when considering envelope loads applied in accordance with Chapter 5, Section 6, Table 6.2.1.2 and provided:

- Scantlings of longitudinal members in midship region is checked and found in compliance with Cl.5.1.1 or Cl.5.1.2 using stress coefficient calculated with applicable hull girder stress and also found in compliance with the buckling requirements in accordance with Chapter 9.

- Scantlings of longitudinal members are kept constant within 0.4L amidship and tapered toward fore and aft end.

Section 6

Primary Supporting Members and Pillars

Symbols

For symbols not defined in this section, Refer to Chapter 1, Section 2.

P = Design pressure, in [kN/m^2], for the considered design load set, Refer Section 2, 2.4, calculated at the load calculation point as defined in Chapter 3 Section 7, Cl.7.5.2.

σ_{hg} = Hull girder longitudinal stress, in [N/mm^2], as defined in Section 2, 2.1, calculated at the load calculation point as defined in Chapter 3, Section 7, Cl.7.5.2.

ℓ_{bdg} = Effective bending span, in [m,] as defined in Chapter 3, Section 7, Cl.7.1.7.

ℓ_{shr} = Effective shear span, in [m], as defined in Chapter 3, Section 7, Cl.7.1.8 for PSM's.

χ = Coefficient taken equal to:

- In intact condition:

= 0.90 for primary supporting members attached to inner bottom or bilge hopper tank plating in cargo holds of bulk carriers,

= 1.0 for other cases.

- In flooded condition:

= 1.00 for collision bulkheads for acceptance criteria set AC-I.

= 1.15 for other watertight boundaries of compartments.

6.1 PSM subjected to lateral pressure

6.1.1 General

The requirements of this section apply to primary supporting members (PSM's) subjected to lateral pressure and concentrated loads and pillars subjected to compressive axial loads. The yielding and buckling check is to be carried out for such members subjected to specific loads. Alternatively, the scantlings of the members are to be verified by means of FE analysis as defined in Chapter 8.

6.1.2 Net section modulus

The section modulus, Z in [cm^3], of primary supporting members subjected to lateral pressure, calculated in accordance with Chapter 3 Section 7, Cl.7.4.7, is not to be taken less than the greatest value for all applicable design load sets defined in Section 2, Cl.2.4.3, given by:

$$Z = \frac{1000\,|P|.S.\ell_{bdg}^2}{\chi.f_{bdg}.C_s.R_{eH}}$$

where:

f_{bdg} = Bending moment distribution factor, as given in Table 6.1.2.2.

C_s = Permissible bending stress coefficient taken equal to

$$C_s = \beta_s - \alpha_s \frac{|\sigma_{hg}|}{R_{eH}}$$

β_s = Coefficient as defined in Table 6.1.2.1.

α_s = Coefficient as defined in Table 6.1.2.1.

C_{s-max}= Maximum permissible bending stress coefficient as defined in Table 6.1.2.1.

The section modulus is to be based on the effective breadth of attached plating, b_{eff}, as defined in Chapter 3 Section 7, Cl.7.3.2.

6.1.3 Net shear area

6.1.3.1 The net shear area, A_{sh} in [cm^2], of primary supporting members subjected to lateral pressure is not to be taken less than the greatest value for all applicable design load sets defined in Section 2, Cl.2.4.3, given by:

$$A_{sh} = \frac{10\,|P|.S.f_{shr}.\ell_{shr}}{\chi.C_t.\tau_{eH}}$$

where:

f_{shr} = Shear force distribution factor, as given in Table 6.1.2.2.

C_t = Permissible shear stress coefficient for the acceptance criteria set being considered, as given in Table 6.1.2.1.

Table 6.1.2.1: Permissible bending and shear stress coefficients for primary supporting members					
Acceptance criteria set	**Structure attached to PSM** (All boundaries, including decks and flats)	β_s	α_s	C_{s-max}	C_t
AC-I	Members subjected to hull girder loads	0.85	1.00	0.7	0.7
	Members not subjected to hull girder loads	0.70	0.00		
AC-II/AC-IV	Members subjected to hull girder loads	0.95	1.00	0.85	0.85
	Members not subjected to hull girder loads	0.85	0.00		

Table 6.1.2.2: Bending moment and shear force factors, f_{bdg} and f_{shr}						
Load and boundary condition			**Bending moment and shear force distribution factors (based on load at mid span, where load varies)**			
Position				1	2	3
Load model	**1 Support**	**2 Field**	**3 Support**	f_{bdg1} f_{shr1}	f_{bdg2}	f_{bdg3} f_{shr3}
A				12.0 0.50	24.0 -	12.0 0.50
B				- 0.38	14.2 -	8.0 0.63
C				- 0.50	8.0 -	- 0.50
D				15.0 0.3	23.3 -	10.0 0.70
E				- 0.20	16.8 -	7.5 0.80
F				- -	- -	2.0 1.0

Note 1 The bending moment distribution factor, f_{bdg} for the support positions is applicable for a distance of $0.2\ell_{bdg}$ from the end of the effective bending span of the primary supporting member.

Note 2 The shear force distribution factor, f_{shr} for the support positions is applicable for a distance of $0.2\ell_{shr}$ from the end of the effective shear span of the primary supporting member.

Note 3 Application of f_{bdg} and f_{shr}
The section modulus requirement within $0.2\ell_{bdg}$ from the end of the effective span is to be determined using the applicable f_{bdg1} and f_{bdg3}, however the f_{bdg} is not to be taken greater than 12.
The section modulus of mid-span area is to be determined using $f_{bdg} = 24$ or f_{bdg2} from the table if lesser.
The shear area requirement for end connections within $0.2\ell_{shr}$ from the end of the effective span is to be determined using $f_{shr} = 0.5$ or the applicable f_{shr1} or f_{shr3}, whichever is greater.
For models A through F, the value of f_{shr} may be gradually reduced outside of $0.2\ell_{shr}$ towards $0.5f_{shr}$ at mid-span, where f_{shr} is the greater value of f_{shr1} and f_{shr3}.

6.2 Advanced calculation methods

6.2.1 Direct strength - beam analysis

Where complex grillage structures are employed or cross ties are fitted inside shell primary supporting members or bulkhead girders, which are a part of a complex girder system in holds for heavy cargo or tanks, the scantlings are to be determined by direct calculation taking into account:

- The distribution of still water and wave pressure and forces, if any.

- The number and position of intermediate supports (e.g., decks, girders, etc.).

- The condition of fixity at the ends of the primary supporting members and at intermediate supports.

- The geometrical characteristics of the primary supporting members on the intermediate spans.

- The effective breadth, b_{eff}, for yield check as given in in Chapter 3, Section 7, Cl.7.3.2

- Hull girder loads, when $|\sigma_{hg}| \geq 0.15R_{eH}$

6.2.2 Analysis criteria

The calculated stress, in [N/mm^2], are to comply with the following criteria where the coefficients C_t and C_s, are defined in Table 6.1.2.1.

$$\tau \leq \chi C_t \tau_{eH}$$

$$\sigma \leq \chi C_s R_{eH}$$

where:

τ = Shear stress in member, in [N/mm^2].

σ = Normal stress in member, in [N/mm^2].

C_s = Permissible bending stress coefficient taken equal to

$$C_s = \beta_s - \alpha_s \frac{|\sigma_{hg}|}{R_{eH}}$$

β_s = Coefficient as defined in Table 6.1.2.1.

α_s = Coefficient as defined in Table 6.1.2.1.

$C_{s-max.}$= Maximum permissible bending stress coefficient as defined in Table 6.1.2.1.

C_t = Permissible shear stress coefficient as defined in Table 6.1.2.1.

6.2.3 Yield and buckling criteria for finite element analysis

When finite element analysis is used for analysis of PSM then all significant stress components is to be considered, to a similar extent as for cargo hold analysis as described in Chapter 8. The strength is to satisfy the yield criteria given in Chapter 8, Section 3 and buckling criteria given in Chapter 9.

6.2.4 Buckling criteria for beam analysis

Buckling assessment may be required for panels with high compressive stresses e.g., bottom/deck in midship area, with acceptance criteria given in Chapter 9, Section 4.

The normal stresses including hull girder longitudinal stress, σ_{hg}, and the shear stresses

taken from the strength assessment to be applied for buckling capacity calculation of plate panels, as given in Chapter 9, Section 4, is to be corrected as given in Chapter 9, Section 5, Cl.5.2.2.7.

6.3 Pillars

6.3.1 Pillars subjected to compressive axial load

The maximum applied compressive axial load on a pillar, F_{cp} , in [kN], is to be taken as the greatest value calculated for all applicable design load sets as defined in Section 2, Cl.2.4.3, and is given by the following formula:

$$F_{cp} = P.b.\ell + F_{a-upr}$$

where:

b = Mean breadth of area supported, in [m].

ℓ = Mean length of area supported, in [m].

F_{a-upr} = Axial load from pillar including axial load from pillars above, in [kN], if any.

The buckling check of the pillar is to be performed according to Chapter 9, Section 4,4.5, with σ_c in [N/mm^2], as

$$\sigma_c = 10\frac{F_{cp}}{A}$$

A = Net cross section area, in [cm^2], of the pillar.

6.3.2 Pillars subject to tensile axial load

Pillars and PSM members subjected to tensile axial load are to satisfy the criteria given in Cl.6.2.2.

$$\tau \leq \chi C_t \tau_{eH}$$

$$\sigma \leq \chi C_s R_{eH}$$

where:

σ = Normal stress in [N/mm^2], for the minimum cross section inclusive end connections

τ = Shear stress in [N/mm^2] the bracket/gusset end connections

C_s = Permissible normal stress coefficient as defined in Table 6.1.2.1.

C_t = Permissible shear stress coefficient as defined in Table 6.1.2.1.

End connections of the pillars are also to be verified for tensile loads as above.

6.3.3 Pillars subjected to combined axial load and bending

With reference to Cl.6.3.1, only compressive axial load is to be considered for the buckling check of pillars. For pillars subjected to combined axial load and bending, buckling utilization is to be checked in accordance with Chapter 9, Section 1.

Section 7

Intersection of Stiffeners and Primary Supporting Member

Symbols

For symbols not defined in this section, Refer to Chapter 1, Section 2.

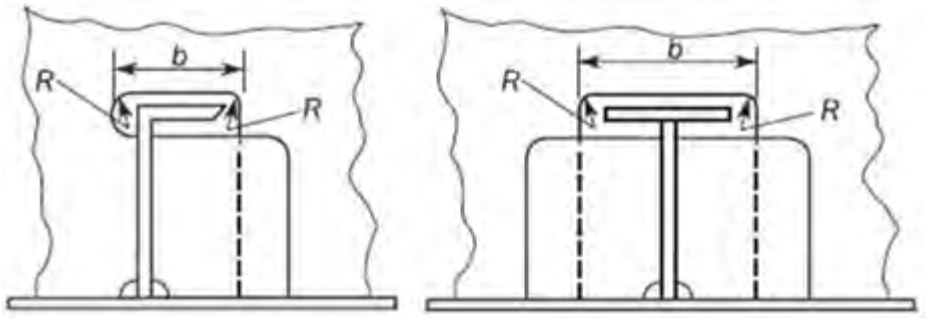
7.1 Cutouts

7.1.1 Cutouts for the passage of stiffeners through the web of primary supporting members, and the related collaring arrangements, are to be designed to minimize stress concentrations around the perimeter of the opening and on the attached web stiffeners.

7.1.2 The total depth of cut-outs without lug or collar plate is to be not greater than 50% of the depth of the primary supporting member. A larger depth of cut-outs may be accepted given that shear strength and buckling capacity are sufficient.

7.1.3 Cut-outs in way of cross tie ends and floors under bulkhead stools or in high stress areas are to be fitted with lug plates welded to the attached plating, Refer Figure 7.1.3.

Where ordinary stiffeners are continuous through primary supporting members, they are to be connected to the web plating so as to ensure proper transmission of loads.



$R \geq 0.2b$ but not less than 25mm.

Figure 7.1.3: Lug plates welded to the attached plating

7.1.4 Lug type collar plates are to be fitted in cut-outs where required for compliance with the requirements of 7.2, and in areas of high stress concentrations, e.g., in way of primary supporting member toes. Refer Figure 7.1.4 for typical lug arrangements.

7.1.5 At connection to shell envelope longitudinals below the scantling draught, T_{sc} and at connection to inner bottom longitudinals, a soft heel is to be provided in way of the heel of the primary supporting member web stiffeners when the calculated direct stress, σ_w, in the primary supporting member web stiffener according to 7.2 exceeds 80% of the permissible values. The soft heel is to have a keyhole, similar to that shown in item (c) in Figure 7.1.5.

A soft heel is not required at the intersection with watertight bulkheads and primary supporting members, where a back bracket is fitted or where the primary supporting member web is welded to the stiffener face plate.

When calculating the direct stress, σ_w, the bottom slamming or bow impact loads using the design pressures defined in Chapter 11, Section 3 and 2 respectively, need not be applied.

7.1.6 Cut-outs are to have rounded corners and the corner radii, R, are to be as large as practicable, with a minimum of 20% of the breadth, b, of the cut-out or 25 [mm], whichever is greater. The corner radii, R, does not need to be greater than 50[mm], Refer Figure 7.1.3. Consideration is to be given to other shapes on the basis of maintaining equivalent strength and minimizing stress concentration.

Consideration is to be given to the provision of adequate drainage and unimpeded flow of air and water when designing the cut-outs and connection details.

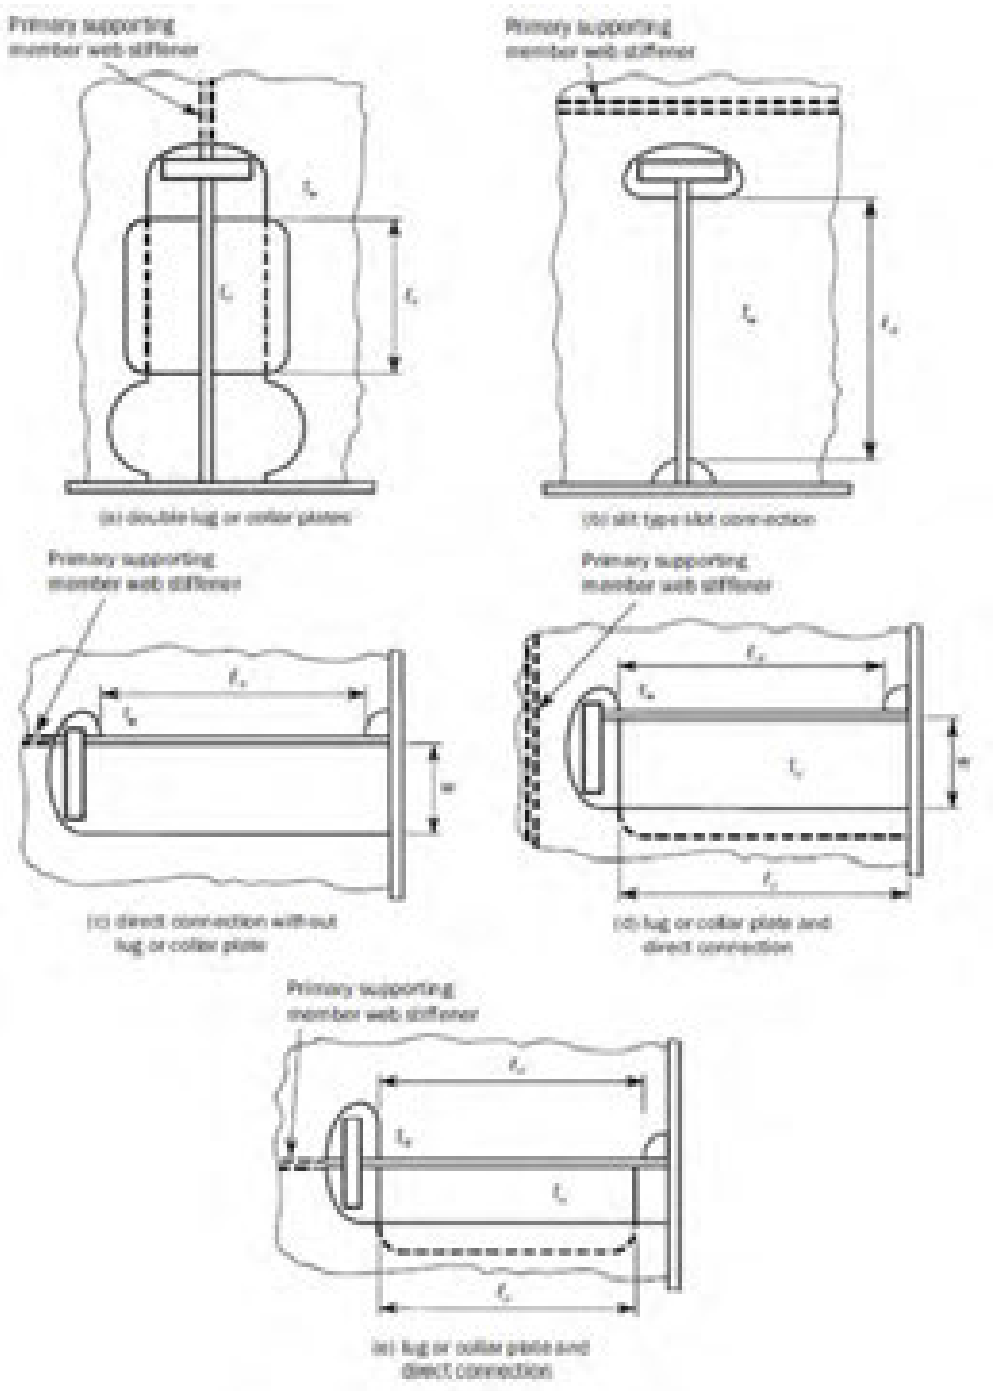


Figure 7.1.4: Symmetric and asymmetric cut-outs

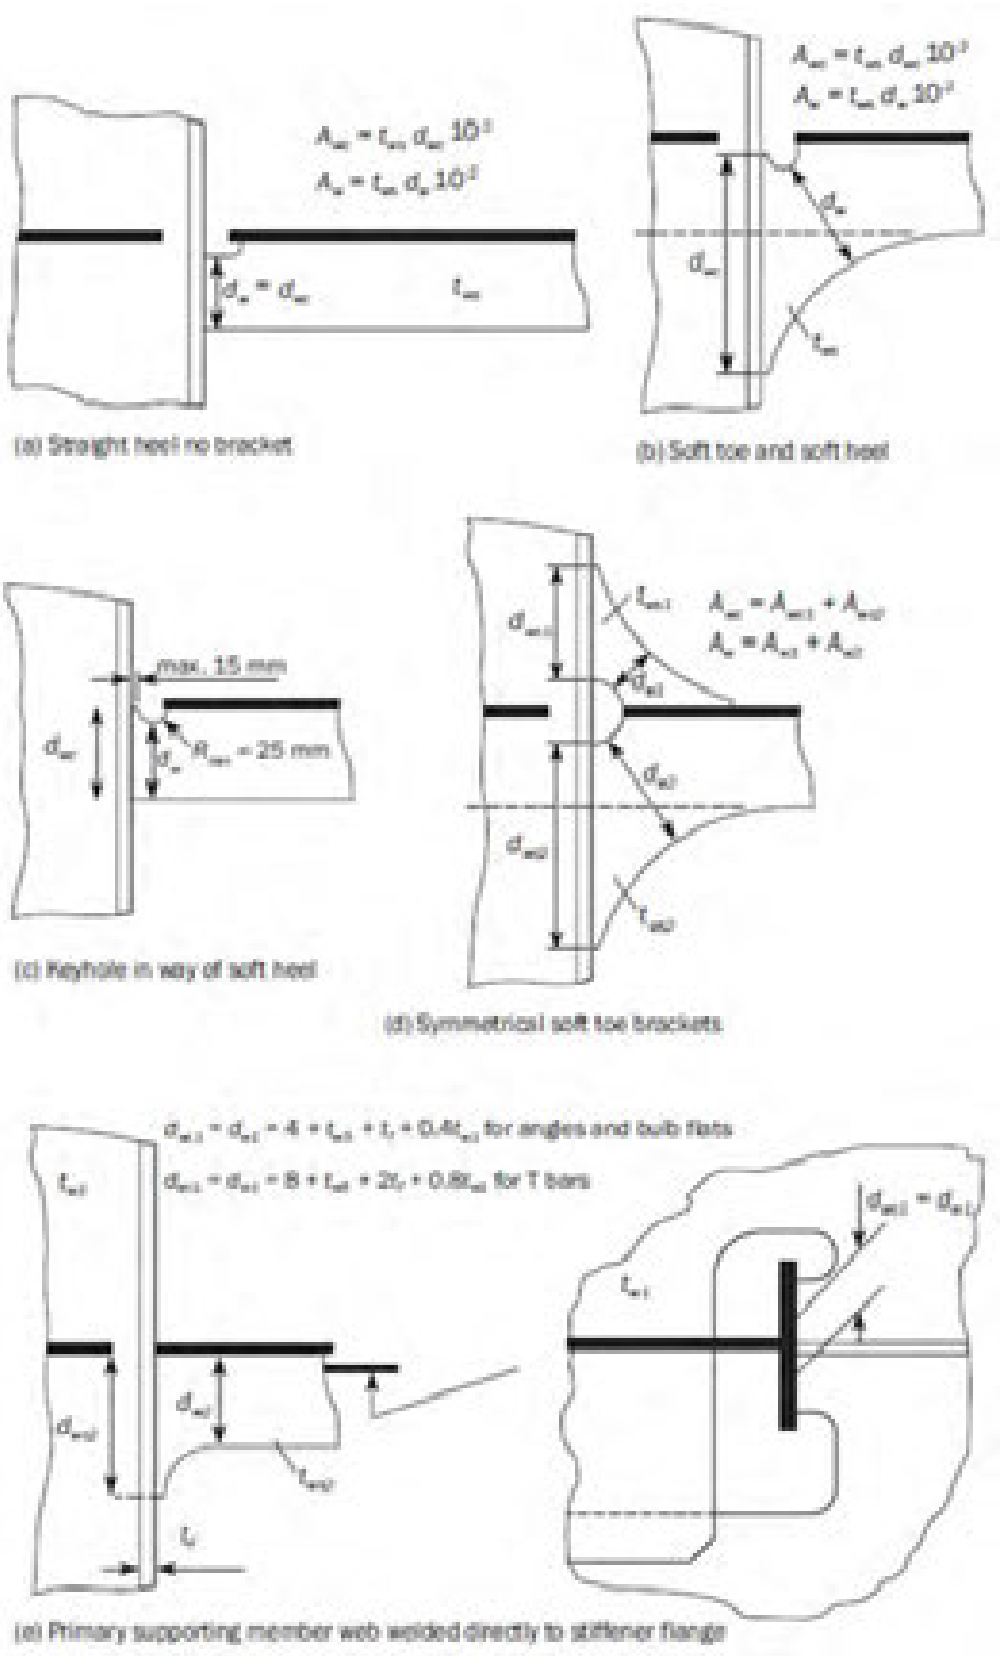

Figure 7.1.5: Primary supporting member web stiffener details

Symbols shown in Figure 7.1.5 is to be taken as:

t_w, t_{ws1}, t_{ws2} = Net thickness, in [mm], of the PSM web stiffener/backing bracket.

d_w, d_{w1}, d_{w2} = Minimum depth, in [mm], of the PSM web stiffener/backing bracket.

d_{wc}, d_{wc1}, d_{wc2} = Length of connection, in [mm], between the PSM web stiffener/backing bracket and the stiffener.

t_f = Net thickness of the flange, in [mm]. For bulb profile, t_f is to be obtained as defined in Chapter 3, Section 7, Cl.7.4.1.

7.2 Connection of stiffeners to PSM

7.2.1 Application

For ships of length L≥90[m] the calculation of connection of stiffeners to PSM, can be performed according to 7.2 and a simplified calculation method for ships of length L<90[m] according to 7.3.

7.2.2 General

For connection of stiffeners to PSM in case of lateral pressure, Cl.7.2.3 and Cl.7.2.4 are to be applied.

The cross-sectional areas of the connections are to be determined from the proportion of load transmitted through each component in association with its appropriate permissible stress.

7.2.3 The load, W_1, in [kN], transmitted through the shear connection is to be taken as follows.

7.2.3.1 If the web stiffener is connected to the intersecting stiffener:

$$W_1 = W\left(\alpha_a + \frac{A_1}{4f_c A_w + A_1}\right)$$

7.2.3.2 If the web stiffener is not connected to the intersecting stiffener:

$$W_1 = W$$

where:

W = Total load, in [kN], transmitted through the stiffener connection to the PSM taken equal to:

$$W = \frac{P_1 s_1\left(S_1 - \frac{s_1}{2000}\right) + P_2 s_2\left(S_2 - \frac{s_2}{2000}\right)}{2\sin(\varphi_{w1})\sin(\varphi_{w2})} 10^{-3}$$

P_1, P_2 = Design pressure applied on the stiffener for the design load set being considered, in [kN/m^2], on each side of the considered connection.

For bow impact loads or bottom slamming, P_1 and P_2 are the design pressure as defined in Chapter 11, Section 2 and Chapter 11, Section 3 respectively.

S_1, S_2 = Spacing between the considered and the adjacent PSM on each side of the considered connection, in [m].

s_1, s_2 = Spacing of the stiffener, in [mm], on each side of the considered connection.

α_a = Panel aspect ratio, not to be taken greater than 0.25.

$$\alpha_a = \frac{s}{1000\,S}$$

$$S = \frac{S_1 + S_2}{2}$$

$$s = \frac{s_1 + s_2}{2}$$

φ_{w1} = Angle, in [deg], between the PSM web and the attached plating, as defined in Chapter 3 Section 7.φ_{w1} is to be taken equal to 90 [deg] if the angle is greater than or equal to 75 [deg].

φ_{w2} = Angle, in [deg], between the stiffener web and the attached plating, as defined in Chapter 3 Section 7.φ_{w2} is to be taken equal to 90 [deg] if the angle is greater than or equal to 75 [deg].

A_1 = Effective net shear area, in [cm^2], of the connection, to be taken equal to:

$$A_1 = A_{1d} + A_{1c}$$

In case of a slit type slot connections area, A_1, is given by:

$$A_1 = 2A_{1d}$$

In case of a typical double lug or collar plate connection area, A_1, is given by:

$$A_1 = 2A_{1c}$$

A_{1d} = Net shear connection area, in [cm^2], excluding lug or collar plate, as given by:

$$A_{1d} = \ell_d t_w 10^{-2}$$

ℓ_d = Length of direct connection, in [mm], between stiffener and PSM web, in [mm].

t_w = Net web thickness, in [mm], of the primary supporting member,

A_{1c} = Net shear connection area, in [cm^2], with lug or collar plate, given by:

$$A_{1c} = f_1 \ell_c t_c 10^{-2}$$

ℓ_c = Length of connection in [mm], between lug or collar plate and PSM.

t_c = Net thickness of lug or collar plate, in [mm], not to be taken greater than the net thickness of the adjacent PSM web.

f_1 = Shear stiffness coefficient, taken as:

= 1.0, for stiffeners of symmetrical cross section.

= 140/w, not to be taken greater than 1.0, for stiffeners of asymmetrical cross section.

w = Width of the cut-out, in [mm], for an asymmetrical stiffener, measured from the cut-out side of the stiffener web, as indicated in Figure 7.1.4.

A_w = Effective net cross sectional area, in [cm^2], of the PSM web stiffener in way of the connection including backing bracket where fitted, as shown in Figure 7.1.5. If the PSM web stiffener incorporates a soft heel ending or soft heel and soft toe ending, A_w is to be measured at the throat of the connection, as shown in Figure 7.1.5.

f_c = Collar load factor taken equal to:

For intersecting stiffeners of symmetrical cross section:

$$f_c = 1.85 \text{ for } A_w \leq 14$$

$$f_c = 1.85 - 0.0441(A_w - 14) \text{ for } 14 < A_w \leq 31$$

$$f_c = 1.1 - 0.013(A_w - 31) \text{ for } 31 < A_w \leq 58$$

$$f_c = 0.75 \text{ for } A_w > 58$$

For intersecting stiffeners of asymmetrical cross section:

$$f_c = 0.68 + 0.0172 \frac{\ell_s}{A_w}$$

ℓ_s = Connection length equal to:

For a single lug or collar plate connection to the PSM:

$$\ell_s = \ell_c$$

For a single sided direct connection to the PSM:

$$\ell_s = \ell_d$$

In the case of a lug or collar plus a direct connection:

$$\ell_s = 0.5(\ell_c + \ell_d)$$

7.2.4 The load, W_2 in kN, transmitted through the PSM web stiffener is to be taken as:

7.2.4.1 if the web stiffener is connected to the intersecting stiffener:

$$W_2 = W\left(1 - \alpha_a - \frac{A_1}{4 f_c A_w + A_1}\right)$$

7.2.4.2 If the web stiffener is not connected to the intersecting stiffener:

$$W_2 = 0$$

where:

W = Load, in [kN], as defined in Cl.7.2.3.

f_c = Collar load factor as defined in Cl.7.2.3.

α_a = Panel aspect ratio, as defined in Cl.7.2.3.

A_1 = Effective net shear area, in [cm^2], as defined in Cl.7.2.3.

A_w = Effective net cross sectional area, in [cm^2], as defined in Cl.7.2.3.

The values of A_w, A_{wc} and A_1 are to be such that the calculated stresses satisfy the following criteria:

• For the connection to the PSM web stiffener not in way of the weld: $\sigma_w \leq \sigma_{perm}$

• For the connection to the PSM web stiffener in way of the weld: $\sigma_{wc} \leq \sigma_{perm}$

• For the shear connection to the PSM web: $\tau_w \leq \tau_{perm}$

σ_w = Direct stress, in [N/mm^2], in the PSM web stiffener at the minimum bracket area away from the weld connection:

$$\sigma_w = 10\frac{W_2}{A_w}$$

σ_{wc} = Direct stress, in [N/mm^2], in the PSM web stiffener in way of the weld connection:

$$\sigma_{wc} = 10\frac{W_2}{A_{wc}}$$

τ_w = Shear stress, in [N/mm^2], in the shear connection to the PSM web:

$$\tau_w = 10\frac{W_1}{A_1}$$

A_{wc} = effective net area, in [cm^2], of the PSM web stiffener in way of the weld as shown in Figure 7.1.5.

σ_{perm} = Permissible direct stress, in [N/mm^2], as given in Table 7.2.3 for AC-I, AC-II, AC-III.

τ_{perm} = Permissible shear stress, in [N/mm^2], as given in Table 7.2.3 for AC-I, AC-II, AC-III.

Table 7.2.3: Permissible stresses for connection between stiffeners and PSMs

Item	Direct stress, σ_{perm}, in [N/mm^2]			Shear stress, τ_{perm}, in [N/mm^2]		
	Acceptance criteria set[1)]			Acceptance criteria set[1)]		
	AC-I	AC-II	AC-III	AC-I	AC-II	AC-III
PSM web stiffener	$0.83R_{eH}$[(3)]	R_{eH}	R_{eH}	-	-	-
PSM web stiffener to intersecting stiffener in way of weld connection: • Double continuous fillet • Partial penetration weld	$0.58\ R_{eH}$[(3)] $0.83R_{eH}$[(2)(3)]	$0.70\sigma_y$[(3)] σ_y[(2)]	$R_{eH}(3)$ $R_{eH}(2)$	-	-	-
PSM stiffener to intersecting stiffener in way of lapped welding	$0.5R_{eH}$	$0.6R_{eH}$	R_{eH}	-	-	-
Shear connection including lugs or collar plates: • Single sided connection • Double sided connection	- -	- -	- -	$0.71\tau_{eH}$ $0.83\tau_{eH}$	$0.85\tau_{eH}$ τ_{eH}	τ_{eH} τ_{eH}

(1) Acceptance criteria for the design load sets are given in Section 2.
(2) The root face is not to be greater than one third of the gross thickness of the PSM stiffener.
(3) Permissible stresses may be increased by 5% where a soft heel is provided in way of the heel of the PSM web stiffener.

7.2.5 Where a backing bracket is fitted in addition to the PSM web stiffener, it is to be aligned with the web stiffener, and on the opposite side. The arm length of the backing bracket is not to be less than the depth of the web stiffener. The net cross sectional area through the throat of the bracket is to be included in the calculation of A_w as shown in Figure 7.1.5.

7.2.6 Lapped connections of PSM web stiffeners or tripping brackets to stiffeners are not permitted within 0.4L for vessels with single deck and with length L≥150 [m].

7.2.7 Where the web stiffener of the PSM is parallel to the web of the intersecting stiffener, but not connected to it, the offset PSM web stiffener is to be located in close proximity to the slot edge. The ends of the offset web stiffeners are to be suitably tapered and softened.

To facilitate access for welding the offset stiffeners are to be located 50[mm] from the slot edge furthest from the web of the secondary member.

Locations where the web stiffener of the PSM are not connected to the intersecting stiffeners as well as the detail arrangements are to be specially considered on the basis of their ability to transmit load with equivalent effectiveness to that of Cl.7.2.2 through Cl.7.2.7. Details of calculations made and/or testing procedures and results are to be submitted.

7.2.8 The size of the fillet welds for connections between stiffeners and PSM is to be calculated according to Chapter 17 based on the weld factors given in Table 7.2.8.

For the welding in way of the shear connection the size is not to be less than that required for the PSM web plate for the location under consideration.

Table 7.2.8: Weld factors, f_{weld}, for connection between stiffeners and PSM's

Item	Acceptance criteria	Weld Factor
Primary supporting member to intersecting stiffener	AC I	$0.6\,\sigma_{wc}/\sigma_{perm}$ not to be less than 0.38
	AC II	
	AC III	
Shear connection inclusive lug or collar plate	AC I	0.38
	AC II	
	AC III	
Shear connection inclusive of lug or collar plate, where the web stiffener of the PSM is not connected to the intersection stiffener	AC I	$0.6\ \tau_w/\tau_{perm}$ not to be less than 0.44
	AC II	
	AC III	

Note 1:
τ_w = Shear stress, in [N/mm^2], as defined in Cl.7.2.4.
σ_{wc} = Stress, in [N/mm^2], as defined in Cl.7.2.4.
τ_{perm} = Permissible shear stress, in [N/mm^2], Refer Table 7.2.3.
σ_{perm} = Permissible direct stress, in [N/mm^2], Refer Table 7.2.3.
W = Load, in kN, as defined in Cl.7.2.3.
A_1 : Effective net shear area, in [cm^2], defined in Cl.7.2.3.
A_w : Effective net cross sectional area, in [cm^2], defined in Cl.7.2.3.

7.3 Simplified calculation of connection of stiffeners to PSM

7.3.1 Application

The simplified calculation method given below can be applied for ships of length L<90[m].

7.3.2 General

For connection of stiffeners to PSM in case of lateral pressure, Cl.7.3.3 is to be applied.

The cross sectional areas of the connections are to be determined from the proportion of load transmitted through each component in association with its appropriate permissible stress.

7.3.3 The total load, in [kN], transmitted through the connection to the PSM is to be taken equal to:

$$W = \frac{P.s}{\sin(\varphi_{w1})\sin(\varphi_{w2})}\left(S - \frac{s}{2000}\right)10^{-3}$$

where:

P = Design pressure applied on the stiffener for the design load set being considered, in [kN/m^2].

For stiffeners subjected to different pressure, P_1 and P_2, at each side of the PSM, the average load for the two sides is to be applied to estimate the reaction force, e.g., vertical stiffeners at transverse bulkhead, taken as:

$$P = 0.5(P_1 + P_2)$$

S = Average spacing of the considered PSM crossed by the stiffener, in [m]. For stiffeners having different spans on each side of PSM (i.e., different PSM spacing, S_1 and S_2), the average span is taken as:

$$S = 0.5(S_1 + S_2)$$

A_1 = Effective net shear area, in [cm^2], of the connection to the PSM web, to be taken equal to the sum of the single or double sided connection:

$$A_1 \geq \frac{10W_1}{\tau_{perm}}$$

A_w = Effective net cross sectional area, in [cm^2], of the PSM web stiffener in way of the connection including backing bracket where fitted, as shown in Figure 7.1.5.

$$A_w \geq \frac{10W_2}{\sigma_{perm}}$$

W_1= The load transmitted through the shear connection, in [kN].

(a) If the web stiffener is connected to the intersecting stiffener:

$W_1 = 0.4W$ for symmetrical cross sections, e.g., T-profile.

$W_1 = 0.5W$ for asymmetrical cross sections, e.g., L-profile.

(b) If the web stiffener is not connected to the intersecting stiffener:

$$W_1 = W$$

W_2 = The load transmitted through the PSM web stiffener, in [kN].

$W_2 = W - W_1 = 0.6W$ for symmetrical cross sections, e.g., T-profile.

$W_2 = W - W_1 = 0.5W$ for asymmetrical cross sections, e.g., L-profile.

Where the web stiffener is not connected to the intersecting stiffener, $W_2 = 0$.

σ_{perm} = Permissible direct stress, in [N/mm^2], as given in Table 7.3.3.

τ_{perm} = Permissible shear stress, in [N/mm^2], as given in Table 7.3.3.

7.3.4 The size of the fillet welds for connections between stiffeners and PSM is to be calculated according to Chapter 16 based on the weld factors given in Table 7.3.4.

Table 7.3.3: Load distribution and permissible stresses						
Load	**Direct stress, σ_{perm}**			**Shear stress, τ_{perm}**		
	AC-I	AC-II	AC-III	AC-I	AC-II	AC-III
W_2	$0.52R_{eH}$	$0.63R_{eH}$	$0.9R_{eH}$			
W_1				$0.64\tau_{eH}$	$0.76\tau_{eH}$	$0.9\tau_{eH}$

Table 7.3.4: Weld factors, f_{weld}, for connection between stiffeners and PSM's

Section 8

Superstructure, Deckhouse and Companionways

Symbols

For symbols not defined in this section, Refer to Chapter 1, Section 2.

8.1 General

8.1.1 Application

8.1.1.1 The requirements of this section are applicable to superstructures, deckhouses and companionways.

8.1.1.2 The minimum scantling requirements of the decks and sides of the superstructures and deckhouses are to be in accordance with Section 3.

8.1.1.3 Applicable rule requirements and design pressures and forces for plate, stiffener and primary supporting members are given in Table 8.1.1 for the different design load sets.

Exposed sides of superstructures, when in line with ship side, inclusive their supporting structure is to comply with the bow impact requirements given in Chapter 11, Section 2, if applicable.

8.1.1.4 With reference to Chapter 2, Section 4, Cl.4.3.1, all scantlings referred in 8.3 are gross, unless otherwise specified.

Table 8.1.1: Design load sets

Structural member	Design load set	Design load scenario	Load component [3]	Applicable rule requirements	Acceptance criteria	Loading condition
Superstructure side	SEA-1	1	$\max(P_W, P_{SI})$	Section 4, Section 5 and Section 6	AC-II	Full load condition
PSM's on - Superstructure front and aft bulkheads - Deckhouse side, front and aft bulkheads				Section 6		
Superstructure front and aft bulkheads [4]	SEA-1	1	P_A	Section 8	-	-
Deckhouse side, front and aft bulkheads [4]						
Exposed decks	SEA-1	1	P_D	Section 4, Section 5 and Section 6	AC-II	Full load condition
Exposed decks and non-exposed decks with distributed load	UDL-1 [1]	1	$P_{dl-s} + P_{dl-d}$ $F_{U-s} + F_{U-d}$			Normal ballast condition [2]
	UDL-2 [1]	2	P_{dl-s} F_{U-s}		AC-I	-

Exposed decks and non-exposed decks with wheel loading	WL-1[1)]	1	P_{wl-1}	Chapter 11	AC-II	Normal ballast condition[2)]
	WL-2[1)]	2	P_{wl-2}		AC-I	-

Notes:
1) Distributed or concentrated loads only. Need not to be combined with simultaneously occurring green sea pressure.
2) For cargo loads, draught, GM and k_r values may be based on actual cargo conditions in the loading manual.
3) Local loads:
P_W = Wave pressure as given in Chapter 5, Section 4, Cl.4.1.3.
P_D = External dynamic design pressure for exposed decks and wheelhouse top due to green sea loading as given in Chapter 5, Section 4, Cl.4.2.2 and Chapter 5, Section 4, Cl.4.3.2, respectively
P_A = Design pressure for end bulkheads of superstructure and deckhouse walls (side, front and aft bulkheads) as given in Chapter 5, Section 4, Cl.4.3.4.
P_{SI} = External design pressure for external side of superstructure as given in Chapter 5, Section 4, Cl.4.3.3.
P_{dl-s} = Static pressure due to distributed deck load as given in Chapter 5, Section 4,4.2.3.1 or Chapter 5, Section 5, 5.2.2.
P_{dl-d} = Dynamic pressure due to distributed deck load as given in Chapter 5, Section 4,4.2.3.1.
F_U = Force on exposed and non-exposed decks and platforms due to unit loads as given in Chapter 5, Section 4, Cl.4.2.3.2.
P_{wl-1} = Design pressure for wheel loading during normal operation at sea as given in Chapter 11, Section 5.
P_{wl-2} = Design pressure for wheel loading during normal operation at harbour as given in in Chapter 11, Section 5.
4) Applicable to plate and stiffeners only.

8.1.2 Definitions

8.1.2.1 For definitions of the terms 'Superstructure' and 'Deckhouse' refer to Chapter 1.

8.1.2.2 Superstructure deck is a deck forming the upper boundary of a superstructure.

Where the summer freeboard is increased such that the resulting draught is not more than that corresponding to the minimum summer freeboard for the same ship from an assumed freeboard deck located at a distance equal to or greater than the standard superstructure height below the actual freeboard deck;

The actual freeboard deck may be treated as the superstructure deck, while considering the requirements given in this chapter.

8.1.2.3 Where the freeboard is increased in accordance with Cl.8.1.2.2 above, the first tier above the uppermost continuous deck may be treated as the second tier. The lowest tier is normally the tier that is directly situated on the deck to which the rule depth 'D' is measured.

8.1.2.4 Long deckhouse is a deckhouse having more than 0.15L of its length within 0.4L amidships.

8.2 Structural Arrangement and Details

8.2.1 Structural continuity

8.2.1.1 Adequate transverse strength is to be provided to the deckhouses and superstructures by means of transverse bulkheads, girders and web frames.

8.2.1.2 The front and the after-end bulkheads of the superstructures and deckhouses should be effectively supported below by a transverse bulkhead or by a combination of partial bulkheads, girders and pillars.

Similarly, the exposed sides and internal bulkheads of various tiers of erections are to be

located, as far as practicable, above bulkheads or above deep girders below, or equivalent.

8.2.1.3 Local reinforcement is to be provided in way of large openings and areas supporting lifesaving appliances or high loads from other equipment, fittings, etc.

8.2.1.4 Arrangements are to be made to minimize the effect of discontinuities in erections. All openings cut on the sides are to be substantially framed and have well rounded corners. Continuous coamings or girders are to be fitted below and above doors and similar openings. Horizontal stiffeners are to be fitted at the upper and lower edge of large openings for windows.

8.2.1.5 At the ends of superstructures, which have no set-in from the ships' side, and at the ends of poop and bridge, the side plating is to extend beyond the ends of the superstructure, and is to be gradually reduced in height down to the sheer strake. The transition should be smooth and without any discontinuity. The extended plating is to be adequately stiffened, particularly at its upper edge.

8.2.1.6 In the case of superstructures exceeding 0.15L in length and ending within 0.4L amidships, the side plating of the superstructures is to be increased by 25% in way of the break.

8.2.1.7 The thickness of sheer strake is to be increased by 30% on each side of a superstructure end bulkhead located within 0.4L amidships if the superstructure deck is a partial strength deck.

8.2.1.8 Deck girders are to be fitted below the sides of long deckhouses and are to extend at least three frame spaces beyond the deckhouse ends. The depth of the girders is to be at least 100 [mm] greater than the depth of the beams and the girders are to be adequately stiffened at the lower edge.

8.2.1.9 The connection area between the corners of long deckhouses and deck plating should be increased locally. Deck beams under the corners of deck houses are not to be scalloped for a distance of 0.5[m] on either side of the corners.

8.2.1.10 Web frames, transverse partial bulkheads or other equivalent strengthening are to be fitted inside deckhouses of at least 0.5B in breadth extending more than 0.15L in length within 0.4L amidships. These transverse strengthening reinforcements are to be spaced approximately 9[m] apart and are to be arranged, where practicable, in line with the transverse bulkheads below.

8.2.2 End attachments

8.2.2.1 Webs of lower tier stiffeners are to be welded to the decks at their ends.

8.2.2.2 Deck stiffeners or transverse beams are to be connected to side frames by brackets according to Chapter 3, Section 6, Cl.6.2.2. Beams crossing longitudinal walls and girders may be attached to the stiffeners of longitudinal walls and the webs of girders respectively by welding without brackets.

8.2.2.3 Face plates of longitudinal and transverse deck girders are to be stiffened by tripping brackets according to Chapter 3, Section 6, Cl.6.3.3.

8.2.2.4 Vertical frames of superstructure are to be welded to the main frames below, or to the deck under provision of a sufficient supporting structure.

8.2.3 Navigation bridge visibility

Attention is drawn to Chapter V, Regulation 22 of SOLAS 1994 Amendments regarding Navigation Bridge Visibility requirements, applicable to ships of loadline length equal to or greater than 55[m].

8.3 Scantlings

For minimum thicknesses in general, Refer Section 3. For members not covered by Section 3, Refer Cl.8.3.1 to Cl.8.3.2.

8.3.1 Thickness of bulkhead and side plating

8.3.1.1 The gross thickness, in [mm], of front and aft bulkheads of superstructure and deck house side and bulkheads is not to be taken less than:

$$t = 0.95\ s\sqrt{k.P_A}$$

but in no case is the thickness to be less than given below:

$t = (5 + 0.01L_1)\sqrt{k}$ for first tier above freeboard deck

$t = (4 + 0.01L_1)\sqrt{k}$ for upper tiers but not less than 5.0[mm]

For ships with $L_1 < 65m$, the minimum thickness of plating should be as follows:

t_{min} = 5mm for the lowest unprotected front
= 4mm for all other cases

where:

P_A = Lateral pressure in [kN/m^2] defined in Chapter 5 Section 4, Cl.4.3.4.1.

L_1 = Length of the ship, but need not be taken greater than 300[m].

s = Spacing of stiffeners, in [m].

8.3.1.2 The net thickness, in [mm], of plating of sides of superstructures is to be taken not less than:

$$t_{net} = 0.0158.\alpha_p.b\sqrt{\frac{|P|}{\chi.C_a.R_{eH}}}$$

where:

P = Lateral pressure in [kN/m^2] to be taken as given in Table 8.1.1.

C_a = Permissible bending stress coefficient for plate as defined in Section 4, Cl.4.1.1.1.

χ = Coefficient as defined in Section 4, Cl.4.1.1.1

8.3.2 Stiffeners

8.3.2.1 The gross section modulus of stiffeners, in [cm^3], on fronts, sides and end bulkheads of all erections other than sides of superstructures is not to be taken less than:

$$Z = 0.35.k.s.\ \ell^2\ .P_A$$

where,

s = Spacing of stiffeners (m), measured along the plating.

ℓ = Unsupported span (m), which is to be taken as the 'tween deck height but in no case less than 2.0[m].

8.3.2.2 Webs of stiffeners on sides and after ends of the lowest tiers of all erections are to be welded to the deck at both ends. Scantlings for other types of end connections are to be specially considered.

8.3.2.3 The section modulus of deck house side stiffeners need not be greater than that of side frames on the deck situated directly below, taking account of spacing and span.

8.3.2.4 For longitudinals on sides of long deck house within 0.4L amidships and at strength deck level is given by:

$$Z = 0.625\ s\ \ell^2 P_A$$

The modulus may be linearly decreased to the general value at the first deck above the strength deck and at 0.1L from the perpendiculars.

8.3.2.5 Stiffeners on fronts are to be connected to deck at both ends with a connection area 'a' not less than

$$a = 0.07 s\ \ell\ P_A\ k$$

8.3.2.6 The net section modulus of stiffeners, in [cm^3], on sides of superstructures is to be taken not less than:

$$Z = \frac{|P|.s.\ell_{bdg}^2}{f_{bdg}.\chi.C_s.R_{eH}}$$

with $\chi.C_s$ not to be taken greater than 1.0

where:

P = Lateral pressure in [kN/m^2] to be taken as given in Table 8.1.1.

f_{bdg} = Bending moment factor as defined in Section 5, Cl.5.1.1.2.

C_s = As defined in Section 5, Cl.5.1.1.2

χ = Coefficient as defined in Section 5, Cl.5.1.1.2.

8.3.3 Thickness of protected casings and internal walls

8.3.3.1 The gross thickness, in [mm], of plate for the protected casing and internal wall is:

$t = (0.0085\ s)\sqrt{k}$ but not less than $6.0\sqrt{k}$ for bulkheads in way of cargo holds

$t = (0.0065\ s)\sqrt{k}$ but not less than $5.0\sqrt{k}$ for bulkheads in way of accommodations

where,

s = Spacing of stiffeners, in [mm] but not to be taken less than 760[mm].

8.3.3.2 The gross section modulus of stiffeners, in [cm^3], of protected machinery casings is not to be less than:

$$Z = 0.003.s.\ell^2.\sqrt{k}$$

where, ℓ is not to be taken less than 2.5[m].

8.3.3.3 Casings supporting one or more decks above are to be adequately strengthened.

8.4 Alternative grillage analysis for girders and transverses

8.4.1 Where arrangements of deck girders and transverses are such it acts as a grillage structure; additional analysis may be carried out with a structural model based on the gross scantling.

The resulting stresses are not to exceed the following permissible bending, shear and equivalent stresses, in [N/mm^2], taken as:

$$\sigma_b = 150/k$$

$$\tau = 100/k$$

$$\sigma_{eqv} = 180/k$$

8.4.2 In direct strength analysis of primary support members, for superstructure or deck house, the design pressure and forces are to be applied consistently with the application for the hull structure. The green sea loads are to be calculated according to Chapter 5 and interpolated in vertical direction.

8.5 Aluminium deckhouse or superstructure

8.5.1 Scantlings

8.5.1.1 Scantlings of plates and stiffeners is to be in accordance with 8.2 and 8.3.

8.5.1.2 For Aluminium deckhouse or superstructure, the material factor to be used is k_a instead of k. Refer Chapter 2, Section 1, 1.3 for the calculation of k_a.

8.6 Companionways

The scantlings of companionways are to be determined in accordance with 8.3.

Section 9

Bulwarks and Guard Rails

Symbols

For symbols not defined in this section, Refer to Chapter 1, Section 2.

9.1 General

9.1.1 Application

Bulwarks or guard rails are to be fitted around all exposed decks.

9.1.2 General requirements

9.1.2.1 The height of the bulwarks or guard rails measured above the sheathing, if any, is not to be less than 1.0[m] and are to be constructed as required in 9.2 and 9.3.

9.1.2.2 Consideration will be given to cases where this height would interfere with the normal operation of the ship.

9.1.2.3 The freeing arrangements in bulwarks are to be in accordance with Cl.9.2.3.

9.2 Bulwark

9.2.1 Bulwark construction

9.2.1.1 Plate bulwarks are to be stiffened at the upper edge by a suitable rail and supported either by stays or plate brackets spaced not more than 2.0[m] apart. The free edge of the stay or the plate bracket is to be stiffened. The spacing of stays forward of 0.07L from F.P. is to be not more than 1.2[m] on Type 'A', Type 'B-60' and Type 'B-100' ships as defined in the ICLL.

9.2.1.2 In the case of ships intended for the carriage of timber deck cargoes, the specific provisions of the freeboard regulations are to be complied with.

9.2.1.3 Where bulwarks are cut in way of a gangway or other openings, stays of increased strength are to be fitted at the ends of the openings.

9.2.1.4 Bulwark stays are to be supported by, or are to be in line with, suitable underdeck stiffening, which is to be connected by double continuous fillet welds in way of the bulwark stay connection.

9.2.1.5 Bulwarks are to be adequately strengthened in way of the eye plates for cargo gear, and in way of the mooring pipes the plating is to be increased in thickness and also adequately stiffened.

9.2.1.6 Bulwarks are generally not to be welded to the top of the sheer strake within 0.6L amidships.

Within 0.6L amidships, bulwarks are to be arranged to ensure that they are free from hull girder stresses.

9.2.1.7 Bulwarks should not be cut in way of the breaks of the superstructures, and are also to be arranged to ensure their freedom from main structural stresses.

9.2.1.8 At the ends of the superstructures where the side plating is extended and tapered to align with the bulwark plating, the transition plating is to be suitably stiffened and supported. Where freeing ports or other openings are essential in this plate, they are to be suitably framed and kept well clear of the free edge

9.2.1.9 Where mooring fittings subject the bulwark to large forces, the stays are to be adequately strengthened.

9.2.2 Bulwark scantlings

9.2.2.1 Plating

The gross thickness of the bulwark plating is not to be less than that required for the superstructure side plating in the same location if the height of the bulwark is equal to or greater than 1.8[m]. Where the height of the bulwark is 1.0[m], the thickness need not exceed 6.0[mm]. For intermediate bulwark heights the thickness may be obtained by interpolation. For ships L ≤ 30[m], the thickness need not exceed 5.5[mm].

9.2.2.2 Stays

(a) The gross section modulus 'Z' in [cm^3] at the bottom of the bulwark stay is not to be less than:

$$Z = (33 + 0.44L)h^2 s$$

Where,

h = Height of the bulwark from the top of the deck plating to the top of the rail, in [m].

s = Spacing of bulwark stays, in [m].

L = Length of ship, in [m], but to be taken not greater than 100[m].

(b) In the calculation of section modulus 'Z', only the material connected to the deck is to be included.

The bulb or flange of the stay may be taken into account were connected to the deck, and where, at the ends of the ship, the bulwark plating is connected to the sheer strake, a width of plating not exceeding 600[mm] may also be included. The free edge of the stay is to be stiffened.

(c) When the bulwark is subjected to loads from any deck cargo, the scantlings will be specially considered.

9.2.3 Freeing Ports

9.2.3.1 Basic area

(a) Where bulwarks on the weather portion on freeboard or superstructure decks form wells, provision is to be made for rapidly freeing the decks of water and for draining them. In general, the minimum freeing area "A" in [m^2], on each side of the ship for each well on the freeboard deck is to be given by the following in cases where the sheer in way of the well is standard or greater than standard.

– Where length of the bulwark (ℓ) in the well is less than or equal to 20[m] - $A_1 = 0.7 + 0.035\ell$

- Where (ℓ) exceeds 20[m] $A_1 = 0.07\ell$

ℓ need not to be taken greater than $0.7L_L$, where L_L is the Load line length of the vessel (Refer Chapter 1)

(b) If the bulwark is more than 1.2[m] in average height, the required area is to be increased by 0.004 [m^2] per meter of length of the well for each 0.1[m] difference in height. If the bulwark is less than 0.9[m] in average height, the required area may be decreased in the same proportion.

(c) The minimum area for each well on superstructure decks is to be one half of the area obtained above. Wells on raised quarter decks should be treated as being on freeboard deck.

9.2.3.2 Vessels with Less than Standard Sheer

In ships with no sheer the area of freeing ports as calculated above is to be increased by 50%. Where the sheer is less than standard, percentage of increase to be obtained by linear interpolation.

9.2.3.3 Multiple wells

On a flush deck ship with a substantial deckhouse amidships, it is considered that the deckhouse provides sufficient break to form two wells and that each could be given the required freeing port area based upon the length of the 'well'. It would not then be allowed to base the area upon $0.7L_L$.

For a 'substantial' deckhouse, the breadth of the deckhouse should be at least 80% of the beam of the vessel and the passageways along the sides of the ship should not exceed 1.5[m] in width.

Where a screen bulkhead is fitted completely across the vessel, at the forward end of a midship deck house, this would effectively divide the exposed deck into wells and no limitation on the breadth of the deckhouse is considered necessary in this case.

9.2.3.4 Freeing port area for continuous trunk or continuous hatchway coaming

The effectiveness of the freeing port area in bulwarks required in 9.2.3.1 above depends on the free flow across the deck of a ship. Where a vessel is fitted with a trunk, and open rails are not fitted on weather parts of the freeboard deck in way of the trunk for at least half their length, or where continuous or substantially continuous hatchway side coamings are fitted between detached superstructures, the minimum area of the freeing-port openings is to be calculated from the following Table 9.2.3.

Table 9.2.3: Minimum area of freeing ports	
Breadth of hatchway or trunk in relation to the breadth of ship	Area of freeing ports in relation to the total area of the bulwarks
40% or less	20%
75% or more	10%

The area of freeing ports at intermediate breadths are to be obtained by linear interpolation.

9.2.3.5 The freeflow area on deck is the net area of gaps between hatchways, and between hatchways and superstructures and deckhouses up to the actual height of the bulwark.

The freeing port area in bulwarks should be assessed in relation to the net flow area as follows:

(i) If the freeflow area is not less than the freeing area calculated from Cl.9.2.3.4 above as if the hatchway coamings were continuous, then the minimum freeing port area calculated from Cl.9.2.3.1 and Cl.9.2.3.2 should be deemed sufficient.

(ii) If the freeflow area is equal to or less than the freeing area calculated from Cl.9.2.3.1 and Cl.9.2.3.2, the minimum freeing area in the bulwarks should be determined from Cl.9.2.3.4.

(iii) If the freeflow area is smaller than calculated from Cl.9.2.3.4 but greater than calculated from 9.2.3.1 and 9.2.3.2, the minimum freeing port area should be determined from the following formula.

$$A_3 = A_1 + A_2 - f_p$$

where,

A_1 = Minimum freeing area [m^2] calculated from Cl.9.2.3.1 and Cl.9.2.3.2.

A_2 = Minimum freeing area [m^2] calculated from Cl.9.2.3.4.

f_p = The total net area of passages and gaps between hatch ends and superstructures or deckhouses up to the actual height of bulwark [m^2].

9.2.3.6 Freeing ports in way of wells in combination with open superstructures

In the case of vessels having open superstructures on the freeboard or superstructure decks, which open to wells formed by bulwarks on the peripheries of the open decks, the minimum freeing port areas on each side of the ship for the open superstructure A_s and for the open well A_w are to be determined as follows:

(a) Area of the freeing port in [m^2], for the open well is not to be less than that obtained from the following formula:

$$A_w = (0.07\ell_w + A_c)S_c\left(\frac{0.5h_s}{h_w}\right) \text{ for } \ell_t \geq 20[\text{m}]$$

$$A_w = (0.7 + 0.035\ell_w + A_c)S_c\left(\frac{0.5h_s}{h_w}\right)$$

$$\text{for } \ell_t \leq 20[\text{m}]$$

where,

A_1 = Freeing port area, in [m^2], required for an open well of length ℓ_w, in accordance with Cl.9.2.3.1

(b) The freeing port area in [m^2], for the open superstructure is to be not less than that obtained from the following formula:

$$A_s = (0.07\ell_t)S_c\frac{b_0}{\ell_t}\left(1 - \left(\frac{\ell_w}{\ell_t}\right)^2\right)\left(\frac{0.5h_s}{h_w}\right)$$

$$\text{for } \ell_t \geq 20[\text{m}]$$

$$A_s = (0.7 + 0.035\ell_t)S_c\frac{b_0}{\ell_t}\left(1 - \left(\frac{\ell_w}{\ell_t}\right)^2\right)\left(\frac{0.5h_s}{h_w}\right)$$

$$\text{for } \ell_t \leq 20[\text{m}]$$

where:

ℓ_t = Total well length, in [m], to be taken equal to:

$$\ell_t = \ell_w + \ell_s$$

ℓ_w = The length of the open deck enclosed by bulwarks in [m]

ℓ_s = The length of the common space within the open superstructure, in [m]

S_c = Sheer correction factor

= 1.5 for no sheer

= 0 for standard sheer

For intermediate values of sheer S_c to be interpolated.

b_0 = Breadth of openings in the end bulkhead of the enclosed superstructure, in [m]

h_w = Height of the well deck above the freeboard deck, in [m]

h_s = Standard superstructure height, in [m] as defined in Chapter 1, Section 2, Cl.2.2.5, Table 2.2.5

h_b = Height of bulwark, in [m], not to be taken as greater than h_s

A_c = Bulwark height correction factor, in [m^2], taken as:

= 0 for bulwarks between 0.9 and 1.2 [m] in height

= 0.04 ℓ_w (h_b − 1.2) for bulwarks of height greater than 1.2 [m]

= 0.04 ℓ_w (h_b − 0.9) for bulwarks of height less than 0.9 [m].

To adjust the freeing port area for the distance of the well deck above the freeboard deck, for decks located more than $0.5h_s$ above the freeboard deck, multiply by the factor $0.5(h_s/h_w)$.

9.2.4 Freeing Port arrangement

9.2.4.1 The lower edges of the freeing ports are to be as near the deck as practicable.

9.2.4.2 Two-thirds of the freeing-port area required is to be provided in the half of the well nearest the lowest point of the sheer curve. With zero or little sheer on the exposed freeboard deck or an exposed superstructure deck, it is considered that the freeing port area should be spread along the length of the well. One third of the freeing port area required is to be evenly spread along the remaining length of the well

9.2.4.3 All freeing port openings in the bulwarks are be protected by rails or bars spaced not more than 230[mm] apart. If shutters are fitted to freeing ports, arrangements are provided to prevent jamming. Hinges are to have pins or bearings of non-corrodible material. If shutters are fitted with securing devices, these appliances are to be of approved construction.

9.2.4.4 Openings in bulwarks are to be arranged so that the protection of the crew is to be at least equivalent to that provided by the horizontal courses in Cl.9.3.2.5. For this purpose, vertical rails or bars spaced 230[mm] apart may be accepted in lieu of rails or bars arranged horizontally.

9.2.5 Special requirements

9.2.5.1 Freeing arrangement for Type ‘A’ and Type ‘B-100’ ships with trunks

(i) Type ‘A’ and Type ‘B-100’ ships with bulwarks/trunks are to have open rails fitted for at least half the length of the exposed parts of the freeboard deck or other effective freeing arrangements are to be provided. It is considered that a freeing port area in the lower part of the bulwarks, of 33% of the total area of the bulwark provides the 'other effective freeing arrangements' and may be considered equivalent to the requirement of 50% open rails.

However, for Type A ships which have superstructures connected by trunks open rails are to be fitted for the whole length of the exposed part of the freeboard deck.

(ii) The upper edge of the sheer strake is to be kept as low as possible.

9.2.5.2 Freeing arrangement for Type 'B-60'

For Type B ships with freeboards reduced by not more than 60% of the difference between the freeboards given in Tables B and A of the International Loadline Convention, 1966; there are to be freeing port area in the lower part of the bulwarks equal to at least 25% of the total area of the bulwarks. The upper edge of the sheer strake is to be kept as low as possible.

9.3 Guard rails

9.3.1 General

Guard rails fitted according to Cl.9.1.1 and Cl.9.1.2, should meet the following requirements given in Cl.9.3.2.

Guard rails fitted on superstructure and freeboard decks are to have at least 3 courses. The opening below the lowest course of guard rails is not to exceed 230[mm]. The other courses are to be spaced not more than 380[mm] apart. Where rounded gunwales are fitted the guard rail supports are to be placed on the flat of the deck, as close as possible to the beginning of the curvature of the gunwale. In other locations, guard rails with at least two courses are to be fitted.

In the case of ships with welded sheer strake, the stanchions are not to be attached to the sheer strake, upstand or a continuous gutter bar.

9.3.2 Guard rail construction

The guard rails fitted should meet the following requirements:

9.3.2.1 Fixed, removable or hinged stanchions are to be fitted about 1.5[m] apart. Removable or hinged stanchions are to be capable of being locked in the upright position.

9.3.2.2 At least every third stanchion is to be supported by a bracket or stay.

In lieu of at least every third stanchion supported by stay, alternatively any of the following options may be provided: (Refer Figure 9.3.2):

(i) At least every third stanchion of increased breadth: $k.\,b_s = 2.9\,b_s$

(ii) At least every second stanchion of increased breadth: $k.\,b_s = 2.4\,b_s$

(iii) Every stanchion of increased breadth: $k.\,b_s = 1.9\,b_s$

where,

b_s = Breadth of normal stanchion according to the design standard.

In any arrangement of (i), (ii) or (iii) above, the following detail is to be complied with:

Flat steel stanchions of increased breadth are to be aligned with member below deck which is to be minimum100 x 12 flat bar welded to deck by double continuous fillet welds with leg size of minimum 7[mm] or as specified by the design standard. The stanchions with increased breadth need not be aligned with under deck structure for deck plating exceeding 20[mm].

9.3.2.3 Wire ropes may only be accepted in lieu of guardrails in special circumstances and then only in limited lengths.

9.3.2.4 Lengths of chain may be accepted in lieu of guard rails if they are fitted between two fixed stanchions and/or bulwarks.

9.3.2.5 The clear opening below the lowest course of the guard rails is not to exceed 230[mm]. Where this course is not measured from the deck, but from the sheer strake or a waterway bar, which is not in the same vertical plane as the rails, the length of opening is the diagonal distance between the lowest of the rails and the top of the sheer strake or waterway bar. The other courses are not to be more than 380[mm] apart.

9.3.2.6 Wires are to be made taut by means of turnbuckles.

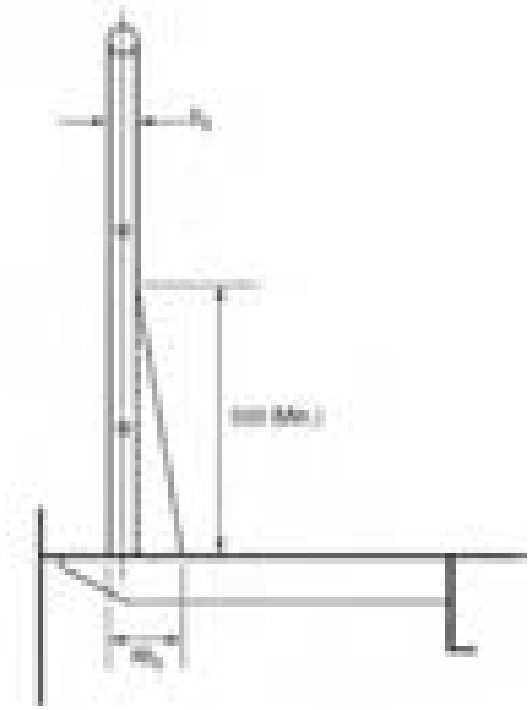

Figure 9.3.2: Guardrail Stanchion

9.4 Gangways, walkways and passageways

9.4.1 Satisfactory means (in the form of guard rails, life lines, gangways or under deck passages etc.) are to be provided for the protection of the crew in getting to and from their quarters, the machinery space and all other parts used in the necessary work of the ship in accordance with Table 9.4.1.

Protection for the crew in the form of guard rails or life lines are to be provided above the deck cargo if there is no convenient passage on or below the deck of the ship.

9.4.2 Protection of crew requirements for specific types

Note: Some Administrations may have more stringent requirements for protection of crew than those given below.

Protection of crew are to be provided by at least one of the means denoted in Table 9.4.1. Acceptable arrangements referred to in the table are defined as follows:

(a) A well-lighted and ventilated under-deck passageway (clear opening 0.8[m] wide, 2.0[m] high) as close as practicable to the freeboard deck, connecting and providing access to the locations in question.

(b) On or near the centreline of a ship a permanent and efficiently constructed gangway fitted at or above the level of the superstructure deck, providing a continuous platform at least 0.6[m] in width and a nonslip surface, with guard rails extending on each side throughout its length. Guard rails are to be at least 1[m] high with courses as required in Cl.9.3.1 and Cl.9.3.2.5 above and supported by stanchions spaced not more than1.5 [m]; a foot stop are to be provided.

(c) A permanent walkway at least 0.6[m] in width fitted at freeboard deck level consisting of two rows of guard rails with stanchions spaced not more than 3[m]. The number of courses of rails and their spacing are to be as required by Cl.9.3.1 and Cl.9.3.2.5. On type B ships, hatchway coamings not less than 0.6[m] in height may be regarded as forming one side of the walkway, provided that between the hatchways two rows of guardrails are fitted.

(d) A 10[mm] minimum diameter wire rope lifeline supported by stanchions about 10[m] apart, or A single handrail or wire rope attached to hatch coamings, continued and adequately supported between hatchways.

(e) A permanent and efficiently constructed gangway fitted at or above the level of the superstructure deck on or as near as practicable to the centre line of the ship:

– located so as not to hinder easy access across the working areas of the deck;

– providing a continuous platform at least 1.0[m] in width

– constructed of fire resistant and non-slip material;

Note: FRP gratings used in lieu of steel gratings for safe access to tanker bows are to possess:

- low flame spread characteristics and are not to generate excessive quantities of smoke and toxic products, as per the FTP Code; and

- adequate structural fire integrity as per national / international standards (for example, the standard specification for Fibre Reinforced Polymer (FRP) gratings used in marine construction and shipbuilding (ASTM F 3059, latest version)).

– fitted with guard rails extending on each side throughout its length; guard rails are to be at least 1.0[m] high with courses as required by Cl.9.3.2.5 and supported by stanchions spaced not more than 1.5[m].

– provided with a foot stop on each side;

– having openings, with ladders where appropriate, to and from the deck. Openings should not be more than 40[m] apart;

– having shelters of substantial construction set in way of the gangway at intervals not exceeding 45[m] if the length of the exposed deck to be traversed exceeds 70[m]. Every such shelter should be capable of accommodating at least one person and be so constructed as to afford weather protection on the forward, port and starboard sides.

(f) A permanent and efficiently constructed walkway fitted at freeboard deck level on or as near as practicable to the centre line of the ship having the same specifications as those for a permanent gangway listed in (e) except for foot-stops. On type B ships (certified for the carriage of liquids in bulk), with a combined height of hatch coaming and fitted hatch cover of together not less than 1[m] in height the hatchway coamings may be regarded as forming one side of the walkway, provided that between the hatchways two rows of guard rails are fitted.

Alternative transverse locations to (c), (d) and (f) above: (indicated as (1) to (5) in Table 9.4.1.)

(1) at or near centre line of ship; or fitted on hatchways at or near centre line of ship

(2) fitted on each side of the ship

(3) fitted on one side of the ship, provision being made for fitting on either side

(4) fitted on one side only

(5) fitted on each side of the hatchways as near to the centre line as practicable.

Additional requirements are also to be met:

– In all cases where wire ropes are fitted, adequate devices are to be provided to ensure their tautness.

– Wire ropes may only be accepted in lieu of guardrails in special circumstances and then only in limited lengths.

- Lengths of chain may only be accepted in lieu of guardrails if fitted between two fixed stanchions.

– Where stanchions are fitted, every 3rd stanchion to be supported by a bracket or stay.

– Removable or hinged stanchions to be capable of being locked in the upright position.

– A means of passage over obstructions, if any, such as pipes or other fittings of a permanent nature, should be provided.

– Generally, the width of the gangway or deck-level walkway should not exceed 1.5[m].

– For tankers less than 100[m] in length, the minimum width of the gangway platform or deck level walkway fitted in accordance with arrangement (e) or (f), respectively, may be reduced to 0.6[m].

9.4.3 A fore and aft permanent gangway, constructed in accordance with the provisions of regulation Cl.9.4.2(e), to be fitted on type 'A' ships at the level of the superstructure deck between the poop and the midship bridge or deckhouse where fitted. The arrangement contained in regulation Cl.9.4.2(a) is considered an equivalent means of access to carry out the purpose of the gangway.

9.4.4 Safe access from the gangway level are to be available between separate crew accommodations and also between crew accommodations and the machinery space.

	2.1.1	Between poop and bow or	$\leq (\mathrm{A_f} + \mathrm{H_s})^*$	a e f (1) f (5)			
	2.1.2	Between a deckhouse containing living accommodation or navigating equipment, or both, and bow, or					
	2.1.3	In the case of a flush deck vessel, between crew accommodation and the	$> (\mathrm{A_f} + \mathrm{H_s})^*$	a e f (1)			

		forward end of ship		f (2)
	2.2 2.2.1	**Access to After End** In the case of a flush deck vessel, between crew accommodation and the after end of ship***		As required in 1.2.4 for other types of ships

* A_f = the minimum summer freeboard calculated as type A ship regardless of the type of freeboard actually assigned.
H_s = the standard height of superstructure as defined in ICLL Regulation 33, in [mm].

** Oil tankers, chemical tankers and gas carriers as defined in SOLAS Ch. II-1/2.12, VII/8.2 and VII/11.2, respectively, as amended.

*** Access to after end of ships is not applicable when crew accommodation is located aft.

Note: Deviations from some or all of these requirements or alternative arrangements for such cases as ships with very high gangways (i.e., certain gas carriers) may be allowed subject to agreement case-by-case with the relevant flag Administration.

Section 10

Means of Embarkation and Disembarkation

10.1 General

10.1.1 Ships constructed on or after 1 Jan 2010 are to be provided with means of embarkation and disembarkation such as gangways and accommodation ladders, for use in port and in port related operations in accordance with the requirements of this section. However, compliance with particular provisions may be waived by the Administration, if it is deemed to be unreasonable or impractical.

10.1.2 Where means of embarkation and disembarkation other than those specifically covered in the section are fitted, an equivalent level of safety is to be provided.

10.1.3 For all ships (i.e., constructed before, on or after 1 Jan 2010), means of embarkation and disembarkation are to be inspected and maintained in suitable condition for the intended purpose. Requirements for surveys of such means are given in Part 1, Chapter 2 of the rules.

10.2 Construction

10.2.1 Accommodation ladders and gangways for means of embarkation and disembarkation which are provided on board ships constructed on or after 1 Jan 2010 are to meet applicable international standards such as ISO 5488:1979, “Shipbuilding – accommodation ladders”, ISO 7061:1993, “Shipbuilding – aluminium shore gangways for seagoing vessels” and/or national standards and/or other requirements recognized by the Administration. Such accommodation ladders and gangways fitted on ships constructed before 1 Jan 2010, which are replaced after that date, should, in so far as is reasonable and practicable, comply with the requirements of this section.

10.2.2 The structure of the accommodation ladders and gangways and their fittings and attachments should be such as to allow regular inspection, maintenance of all parts and, if necessary, lubrication of their pivot pin. Special care should be taken to ensure that the welding work is carried out satisfactorily.

10.2.3 The construction and test of accommodation ladder winches are to be in accordance with applicable international standards such as ISO 7364:1983 “Shipbuilding and marine structures – deck machinery – accommodation ladder winches”.

10.3 Installation

10.3.1 Location

As far as practicable, the means of embarkation and disembarkation are to be sited clear of the working area and are not to be placed where cargo or other suspended loads may pass overhead.

10.3.2 Lighting

Adequate lighting is to be provided to illuminate the means of embarkation and disembarkation, the position on deck where persons embark or disembark and the controls of the arrangement.

10.3.3 Lifebuoy

A lifebuoy equipped with a self-igniting light and a buoyant lifeline is to be available for immediate use in the vicinity of the embarkation and disembarkation arrangement when in use.

10.3.4 Arrangement

10.3.4.1 Each accommodation ladder is to be of such a length to ensure that, at a maximum design operating angle of inclination, the lowest platform will be not more than 600[mm] above the waterline in the “lightest seagoing condition”, as defined in the following:

“Lightest seagoing condition” is the loading condition with the ship on even keel, without cargo, with 10% stores and fuel remaining and in the case of a passenger ship with the full number of passengers and crew and their luggage.

10.3.4.2 The arrangement at the head of the accommodation ladder is to provide direct access between the ladder and the ship’s deck by a platform securely guarded by handrails and adequate handholds. The ladder should be securely attached to the ship to prevent overturning.

10.3.4.3 For ships on which the height of the embarkation / disembarkation deck exceeds 20[m] above the waterline specified in Cl.10.3.4.1 and on other ships where compliance with the provisions of Cl.10.3.4.1 is considered impractical, an alternative means of providing safe access to the ship or supplementary means of safe access to the bottom platform of the accommodation ladder may be accepted.

10.3.5 Marking

Each accommodation ladder or gangway is to be clearly marked at each end with a plate showing the restrictions on the safe operation and loading, including the maximum and minimum permitted design angles of inclination, design load, maximum load on bottom end plate, etc. Where the maximum operational load is less than the design load, it should also be shown on the marking plate.

10.3.6 Test

10.3.6.1 After installation, the winch and the accommodation ladder are to be operationally tested to confirm proper operation and condition of the winch and the ladder after the test.

10.3.6.2 The winch is to be tested as a part of the complete accommodation ladder unit through a minimum of two times hoisting and lowering of the accommodation ladder in accordance with the onboard test requirement specified in applicable international standards such as ISO 7364:1983.

10.3.6.3 Every new accommodation ladder is to be subjected to a static load test of the specified maximum working load upon installation.

10.3.7 Positioning

10.3.7.1 Gangways are not to be used at an angle of inclination greater than 30[deg] from the horizontal and accommodation ladders are not to be used at an angle greater than 55[deg] from the horizontal, unless designed and constructed for use at angles greater than these and marked as such, as required by Cl.10.3.5.

10.3.7.2 Gangways are not to be secured to ship's guardrails unless they have been designed for that purpose. If positioned through an open section of bulwark or railings, any remaining gaps are to be adequately fenced.

10.3.7.3 Adequate lighting for means of embarkation and disembarkation and for the immediate approaches are to be ensured from the ship and/or the shore in hours of darkness.

10.3.8 Safety net

A safety net is to be mounted in way of the accommodation ladders and gangways where it is possible that a person may fall from them or between the ship and quayside.

10.3.9 Verification

Upon installation the entire arrangement of the means of embarkation and disembarkation will be verified for compliance with the requirements of this section.

10.4 Inspection and maintenance

10.4.1 The maintenance and inspection requirements for means of embarkation and disembarkation are to be addressed by the ship's safety management system.

10.4.2 The wires used to support the means of embarkation and disembarkation are to be renewed when necessary due to deterioration or at intervals of not more than 5 years, whichever is earlier.

10.4.3 Arrangements should also be made to examine the underside of gangways and accommodation ladders at regular intervals.

10.4.4 All inspections, maintenance work and repairs of accommodation ladders and gangways should be recorded in order to provide an accurate history for each appliance. The information to be recorded appropriately on board should include the date of the most recent inspection, the name of the person or body who carried out that inspection, the due date for the next inspection and the dates of renewal of wires used to support the embarkation and disembarkation arrangement.

Chapter 8

Finite Element Analysis

Contents

Section

1 *General*
2 *Full Ship Strength Analysis*
3 *Cargo Hold Analysis*
4 *Local Structural Strength Analysis*

Section 1

General

1.1 Scope

1.1.1 This chapter provides requirements applicable to ships for assessing the structural strength and scantling of hull structures using finite element (FE) analysis. Aspects such as modeling techniques, loads and loading conditions, acceptance criteria and documentation required for FE analysis are also discussed.

1.2 Types of FE analysis

1.2.1 Rule covers the following types of FE analyses:

1.2.1.1 Full ship strength analysis for assessing the hull girder strength and scantlings and to provide the correct boundary conditions to partial ship structural models or to local FE models, wherever applicable.

1.2.1.2 Cargo hold analysis for assessing the strength of longitudinal hull girder structural members, primary supporting structural members and bulkheads.

1.2.1.3 Local structural strength analysis or fine mesh analysis for assessing highly stressed areas in local structural details.

1.2.1.4 Very fine mesh analysis is to assess the fatigue capacity of the structural details according to Chapter 10.

1.3 Loads and Loading conditions

1.3.1 FE calculations are to be based on the most severe, realistic loading conditions, as applicable, for the ship and are taken as specified in Section 2.3.

1.3.2 General design loads are specified in Section 2, Cl.2.3.1 and Section 3, Cl.3.3.6.

1.3.3 For specific type of ships, Part 5 is to be referred for design loads and FE design load combinations.

1.4 Net scantling approach

1.4.1 FE models for full ship strength analysis, cargo hold analysis, local fine mesh analysis and very fine mesh analysis, are to be based on the net scantling approach, as defined in Chapter 2, Section 4, Table 4.6.2.

1.4.2 Buckling capacity assessment is to be based on corrosion addition, as defined in Chapter 2, Section 4, Table 4.6.2.

1.5 Material properties

1.5.1 Steel and aluminum are the preferred materials as load carrying members. If special materials are used, e.g. composites, wood etc. such material may be included as anisotropic material in FE model. Such properties are to be defined on a case to case basis. Additionally,

Refer Part 3, Chapter 2, Section 1.2 and Section 1.3.

1.6 Type of Finite Elements used in analysis

1.6.1 The structural assessment is to be based on linear finite element analysis of three-dimensional structural models. The general types of finite elements to be used in the finite element analysis are given in IRS Guidelines on Structural Assessment of Ships based on Finite Element Method, Section 1, Cl.1.3.3 for finite element-based assessment.

1.6.2 In general, two-noded line elements and four-noded isotropic shell elements are considered to be sufficient to represent hull structures.

1.7 Submission of analysis report

1.7.1 A detailed report of the structural analysis is to be submitted to IRS in order to demonstrate the compliance with specified structural design criteria.

1.7.2 The major information to be included in the report are the following:

1.7.2.1 List of plans (drawings, loading manual etc.) used including their drawing numbers, names, revisions and dates.

1.7.2.2 Detailed description of structural modeling including all modeling assumptions, model compliance with actual structure and any deviations in geometry and arrangement of structure compared with plans.

1.7.2.3 Documentation related to the computer program used to transfer the hydrodynamic load to the 3D FE structural model.

1.7.2.4 Plots clearly demonstrating correct structural modeling and property assignment.

1.7.2.5 List of units used in the analysis.

1.7.2.6 Details of material properties, plate thickness and beam properties used in the model.

1.7.2.7 Details of the boundary condition.

1.7.2.8 Details of all loading conditions reviewed with calculated hull girder shear force, bending moment and torsional moment distributions.

1.7.2.9 All data relating to load application and its verification.

1.7.2.10 Plots/results showing the expected behavior of the structural model under the applied loads.

1.7.2.11 Summaries and plots of global and local deflections and reaction forces are to be shown to verify the load cases.

1.7.2.12 Summaries and plots of stress distribution to demonstrate that the design criteria are not exceeded in any member. Wherever otherwise, plots should clearly point out such members/locations.

1.7.2.13 Details and results of panel buckling analysis (unstiffened and stiffened).

1.7.2.14 Details and results of pillar buckling analysis, wherever applicable.

1.7.2.15 Proposed modifications and amendments to structure, including the revised estimation of stresses, deflections, buckling and fatigue showing compliance to design criteria.

1.7.2.16 Structural analysis results related to specific type of ships as detailed in Part 5

1.7.2.17 Reference of the Finite Element program including its version and date.

1.7.2.18 Any other necessary data or information pertaining to the analysis.

1.8 Computer program used for the analysis

1.8.1 Any finite element computation program recognized by IRS may be utilized for structural assessment to determine the stress and deflection of the hull structure, provided that the combined effects of bending, shear, axial and torsional deformations are considered.

1.8.2 Any computer program that has demonstrated to provide reliable results to the satisfaction of IRS is regarded as a recognized program. It is recommended that the designer consults IRS on the suitability of a computer program intended to be used prior to the commencement of work.

Section 2

Full Ship Strength Analysis

2.1 Scope

2.1.1 The purpose of the full ship strength analysis is to evaluate the overall hull girder stiffness and to assess the global stresses and deformations of primary hull members.

2.1.2 Full ship strength analysis covers the whole ship and is performed when the structural response of the hull girder cannot otherwise be sufficiently determined by prescriptive calculations for:

2.1.2.1 Ships with novel designs (e.g.: ships with huge openings in the side shell, where structural responses cannot be calculated solely based on beam theory).

2.1.2.2 Ships with large deck openings (e.g.: Container ships with large deck openings subjected to high torsional deformation and stresses.)

2.1.2.3 Ships with or without limited transverse bulkheads over the length of the ship (e.g., Ro-Ro ship or car carrier)

2.1.2.4 Large passenger ships (L>150[m]) with partly effective superstructure and/or partly effective upper part of hull girder, and

2.1.2.5 For specific class notation **FST** (Full Ship Strength Analysis)

2.1.3 According to the hull shape and ship type notation, the full ship strength analysis is to be performed to assess and verify compliance with the criteria as specified in Section 2.4. Additional requirements for specific ship types are given in Part 5.

2.2 Structural model

2.2.1 The full ship FE model represents the actual geometry of the ship and must cover the entire length, breadth and width of the vessel.

2.2.2 All members that contribute to the overall structural integrity of the hull girder such as primary supporting members, transverse members (watertight/non-watertight bulkheads, deck and cross deck structure etc.), double side structures (shell plating, inner hull, stringers and web frames) and double bottom structures (bottom plate, inner bottom plate, girders, floors etc.) are to be included in the FE model in order to simulate the stiffness of hull girder.

2.2.3 Mesh size, model idealization and boundary conditions are described in IRS Guidelines on Structural Assessment of Ships based on Finite Element Method. Additional requirements for specific type of ships are given in Part 5.

2.3 Loading conditions

2.3.1 Loads for full ship strength analysis are to be determined by sea-keeping analysis/ direct hydrodynamic calculations.

2.3.2 The loading conditions are to be taken as per ship type. For specific ship types, refer to Part 5.

2.3.3 Load application is to be performed as described in IRS Guidelines on *Application of Direct Seakeeping Loads in Structural Analysis of Ships*.

2.4 Analysis criteria

2.4.1 General

The analysis criteria that apply for full ship FE model are described in this section. Structural adequacy of hull girder structural members and primary structural and secondary structural members are to be checked. FE analysis results for failure mode of material yielding, buckling and fatigue are to be checked. Wherever, the full ship FE model is partially or entirely refined to a mesh arrangement as used for partial ship analysis, the analysis criteria for partial ship analysis apply, as given in Section 3.4.

2.4.2 Yield strength

2.4.2.1 For all plates of the structural members, the von Mises stress, σ_{vm} [N/mm^2] is to be calculated based on the membrane normal and shear stresses of the shell element. The stresses are to be evaluated at the element centroid of the mid-plane (layer), as follows:

$$\sigma_{vm} = \sqrt{{\sigma_x}^2 - \sigma_x\sigma_y + {\sigma_y}^2 + 3{\tau_{xy}}^2}$$

where,

σ_x, σ_y = Element normal membrane stresses, in [N/mm^2].

τ_{xy} = Element shear stress, in [N/mm^2].

2.4.2.2 Nominal axial (normal), shear and von Mises stresses derived from a full ship analysis are to be checked according to the acceptance criteria given in Part 5 for specific ship type.

2.4.3 Deflection criteria for primary supporting members

2.4.3.1 The maximum relative deflection of primary supporting members such as girders is not to exceed the following criteria:

$$\delta_{max} = \frac{l_i}{325}$$

where,

δ_{max} = Maximum relative deflection, in [mm].

l_i = Span of primary girder, in [mm].

2.4.4 Buckling strength

2.4.4.1 All major structural elements need to be individually assessed against buckling requirements as per Chapter 9, Section 3.

2.4.5 Fatigue strength

2.4.5.1 Fatigue strength analysis of relevant structural details is to be performed as per IRS Guidelines on Fatigue Design Assessment of Ship Structures.

2.4.5.2 General assumptions, methodology and acceptance criteria for the fatigue strength assessment are given in IRS Guidelines on Fatigue Design Assessment of Ship Structures.

Section 3

Cargo Hold Analysis

3.1 General

3.1.1 Definitions

3.1.1.1 Cargo hold analysis: For ships with cargo hold or tank arrangement, the analysis performed to assess the strength of longitudinal hull girder structural members, primary supporting structural members and bulkheads.

3.1.1.2 Evaluation area: The evaluation area is an area in the part ship model, where the verification of results against the acceptance criteria are to be carried out. For a cargo hold structural analysis, evaluation area is defined in Cl.3.4.1.

3.1.2 The FE model extent for a cargo hold analysis is defined in Cl.3.3.2.

3.1.3 For ships without cargo hold arrangement or for evaluation areas outside cargo area, the analysis procedures given in this chapter can be used with special consideration.

3.1.4 The length of FE model is to be selected in such a way that boundary condition at the ends of the model are sufficiently away from the evaluation area so that it does not interfere with the results.

3.2 Application

3.2.1 This section gives the application of the cargo hold analysis which is mandatory for:

- Ships having rule length L >150[m]
- Ships with novel design
- Specific ship types as given in Part 5
- or whenever required by IRS.

3.2.2 Cargo hold strength analysis of mid-ship is mandatory to applicable ships given in Cl.3.2.1.

3.2.3 FE based strength assessment is to be performed outside mid-ship region if structural loads are substantially different from that of mid-ship region. This analysis is mandatory for specific ship types as given in Part 5.

3.2.4 Scantlings of primary supporting members outside the evaluation area should be

assessed for equivalency to those evaluated by FEA.

3.2.5 Primary supporting members outside cargo hold region not analyzed using FEM are to be assessed using the procedure given in Chapter 7, Section 6.

3.2.6 FE model extent, boundary conditions, applicable loading cases and acceptance criteria are to be as given in the following sections. For specific ship types, additional analysis requirements are given in Part 5.

3.3 Structural model

3.3.1 Model idealization

3.3.1.1 All main longitudinal and transverse structural elements are to be modelled.

3.3.1.2 All plates and stiffeners on the structure, including web stiffeners, are to be modelled. Brackets which contribute to primary supporting member strength and the size of which is not less than the typical mesh size (s × s), Refer Cl.3.3.4, are to be modelled.

3.3.1.3 Openings are to be modelled in accordance with IRS Guidelines on Structural Assessment of Ships based on Finite Element Method.

3.3.2 Model extent

3.3.2.1 For the purpose of the FE analysis, the mid-hold is defined as the middle hold(s) of the three cargo hold length FE model. In case of foremost and aft-most cargo hold assessment, the mid-hold represents the foremost and aft-most cargo hold including the slop tank if any, respectively. Additional details regarding modelling and extent of foremost and aft-most cargo hold are given in IRS Guidelines on Structural Assessment of Ships based on Finite Element Method.

3.3.2.2 The longitudinal extent of the cargo hold FE model is to cover three cargo hold lengths. The transverse bulkheads and the web frames at the ends of the model are to be modelled.

3.3.2.3 Transverse extent: Both port and starboard sides of the ship are to be modelled.

3.3.2.4 Vertical extent: The full depth of the ship is to be modelled including all primary and secondary members above the upper deck, trunks, forecastle and/or cargo hatch coaming, if any. The superstructure or deck house in way of machinery space and the bulwark are not required to be included in the model.

3.3.2.5 Additional details related to specific ship types are to be taken as per Part 5.

3.3.3 Finite element types

3.3.3.1 Plates are to be modelled using shell element and stiffeners are to be modelled as beam elements having axial, torsional, bi-directional shear and bending stiffness. The eccentricity of the neutral axis is to be modelled.

3.3.3.2 Sniped stiffeners, face plates of primary supporting members and brackets are to be modelled using rod or beam elements.

3.3.4 Mesh

3.3.4.1 The shell element mesh is to follow the stiffening system as far as practicable, hence representing the actual plate panels between stiffeners i.e. (s × s), where ‘s’ is the stiffener spacing.

3.3.4.2 Detailed guidelines on mesh configuration are given in IRS Guidelines on Structural Assessment of Ships based on Finite Element Method.

3.3.5 Boundary conditions

3.3.5.1 The boundary conditions given applicable to cargo hold analyses in cargo hold region are given in IRS Guidelines on Structural Assessment of Ships based on Finite Element Method.

3.3.6 Loads and Loading conditions

3.3.6.1 FE load combination definition

FE load combination is defined as a loading pattern, a draught, a value of still water bending and shear force, associated with a given dynamic load case.

3.3.6.2 Design load combination

(a) For cargo hold structural strength analysis, the design load combinations specified in Chapter 5, Section 6 are to be used for considered ship type and considered cargo hold regions.

(b) Each design load combination consists of a loading pattern and dynamic load cases as

given in Chapter 5, Section 2. Each load combination requires the application of the structural weight, internal and external pressures and hull girder loads.

(c) For seagoing condition with extreme sea loads, both static and dynamic load components (S+D) are applied.

(d) For harbour and tank testing condition, only static load components (S) are applied.

(e) Design load combinations for specific type of ship are to be taken as per Part 5.

3.3.6.3 Design loads

(a) Design loads are to be applied as given in Chapter 5. Loads for specific ship types are to be taken as given in Part 5. Design loads are to be combined with FE load combination as discussed in Cl.3.3.6.2.

(b) Where the loading conditions specified by the designer are not covered by the load combinations given in IRS rules, these additional loading conditions are to be examined according to the procedure in IRS Guidelines on Structural Assessment of Ships based on Finite Element Method.

3.3.6.4 Load application

(a) All simultaneously acting global and local loads are to be applied on the FE model. Application of loads are to be performed as described in IRS Guidelines on Application of Direct Seakeeping Loads in Structural Analysis of Ships.

. Particular types of load for specific ships are to be applied as per the relevant class guideline. Load application includes the following loads:

- Structural weight
- External and Internal loads
- Hull girder loads
- Quasi-static and Inertial loads
– Target values for hull girder loads

(b) Effect of the weight of hull structure is to be included in cargo hold analysis. Density of steel may be taken as 7850[kg/m^3].

(c) External pressure is to be calculated in accordance with Chapter 5, Section 4. External pressures include static sea pressure, wave pressure and green sea pressure.

(d) Internal pressure is to be calculated for each load case in accordance with Chapter 5, Section 5 for design load scenarios as given in Chapter 5, Section 6. Internal pressure application is to be performed as per ship type described in IRS Guidelines on Application of Direct Seakeeping Loads in Structural Analysis of Ships.

(e) Hull girder loads in terms of shear force, bending moment and torsional moment are to be applied on the FE model corresponding to each loading condition.

(f) The hull girder loads are the combinations of still water hull girder loads and wave induced hull girder loads as specified in Chapter 5, Section 3. For each required FE load combination, the wave induced hull girder loads are to be calculated with the Load Combination Factors (LCFs), specified in Chapter 5, Section 2. When the FE load combinations are not specified in Part 5 for a considered ship type, the required component of hull girder loads will be decided by IRS on a case-to-case basis.

(g) The required target hull girder load values are to be achieved at given locations for each load combination. The target locations for hull girder shear force, bending moment and torsional moments is to be taken as given in IRS Guidelines on Structural Assessment of Ships based on Finite Element Method. For specific ship types, Part 5 and IRS Guidelines on Structural Assessment of Ships based on Finite Element Method are to be referred.

(h) Load application is to be carried out as per IRS Guidelines on Application of Direct Seakeeping Loads in Structural Analysis of Ships.

3.4 Analysis criteria

3.4.1 Evaluation areas

3.4.1.1 Mid-hold cargo analysis

Verification of results against the acceptance criteria is to be carried out within the longitudinal extent of the mid-hold for the following structural members:

- All hull girder longitudinal structural members
- All primary supporting structural members
- Bulkheads, including forward and aft transverse bulkheads of the mid-hold.

3.4.1.2 Fore- and aftmost cargo hold analyses

For the fore- and aftmost cargo hold analysis, the evaluation areas extend to the following structural elements, in addition to elements listed in Cl.3.4.1.1:

- Foremost Cargo hold: All structural members being part of the collision bulkhead, and extending to one web frame spacing forward of the collision bulkhead.

– Aftmost Cargo hold: All structural members being part of the transverse bulkhead of the aftmost cargo hold and all hull girder longitudinal structural members aft of this transverse bulkhead with the extent of 15% of the aftmost cargo hold length.

3.4.2 Yield Strength Assessment

3.4.2.1 Von Mises Stress

For all plates of the structural members within the evaluation area, the von Mises stress, σ_{vm} [N/mm^2] is to be calculated based on the membrane normal and shear stresses of the shell element. The stresses are to be evaluated at the element centroid of the mid- plane (layer), as follows:

$$\sigma_{vm} = \sqrt{{\sigma_x}^2 - \sigma_x\sigma_y + {\sigma_y}^2 + 3{\tau_{xy}}^2}$$

where,

σ_x, σ_y = Element normal membrane stresses, in [N/mm^2].

τ_{xy} = Element shear stress, in [N/mm^2].

3.4.2.2 Axial stress in beams and rod elements

For beams and rod elements, the axial stress, σ_{axial} [N/mm^2] is to be calculated based on axial force alone. The axial stress is to be evaluated at the middle of element length.

3.4.2.3 Yield criteria

(a) The structural elements given in Cl.3.4.1 are to comply with the following criteria:

$$\lambda_y \leq \lambda_{yperm}$$

where:

λ_y = Yield utilization factor

In general,

$\lambda_y = \frac{\sigma_{vm}}{R_Y}$ for shell elements

$\lambda_y = \frac{|\sigma_{axial}|}{R_Y}$ for rod or beam elements

$\lambda_y = \frac{|\sigma_{axial}|}{R_{eH}}$ for rod or beam elements representing curved flanges.

σ_{vm} = von Mises stress, in [N/mm^2].

σ_{axial} = Axial stress rod and beam element, in [N/mm^2].

λ_{yperm}= Coarse mesh permissible yield utilization factors defined in Table 3.4.2.3.

R_y = Nominal yield stress, taken equal to 235/k

(b) The yield check criteria are to be based on axial stress for the following members:

- The flange of primary supporting members
- The intersections between the flange and web of the corrugations, according to Cl.3.4.2.4.

(c) Where the von Mises stress of the elements in the cargo hold FE model in way of the area under investigation by fine mesh exceeds the yield criteria, average von Mises stress, obtained from the fine mesh analysis, calculated over an area equivalent to the mesh size of the cargo hold finite element model is to satisfy the yield criteria above.

(d) In way of cut-outs, yield utilization factor is to be obtained with shear stress correction, as given in Cl.3.4.2.5.

3.4.2.4 Coarse mesh permissible yield utilization factors

The coarse mesh permissible yield utilization factors, λ_{yperm}, given in Table 3.4.2.3 are based on the mesh sizes and element types described in Cl.3.3.3 to Cl.3.3.4.

The yield utilization factor resulting from element stresses of each structural component are not to exceed the permissible values as given in Table 3.4.2.3.

Table 3.4.2.3: Coarse mesh permissible yield utilization factor			
Structural Members	**Load Components**	**Acceptance criteria (1)**	λ_{yperm}
Plating of all longitudinal hull girder structural members, primary supporting structural members and bulkheads. Dummy rod of corrugated bulkhead. Face plate of primary supporting members modelled using shell or rod elements.	Load combination: S Load combination: S+D	AC-I AC-II	0.80 1.0
Corrugation of corrugated bulkheads under lateral pressure from liquid loads, for shell elements only. For corrugation angle between 45° and 55° the reduction in, λ_{yperm} as given in Chapter 3, Section 6, Cl.6.4.1.2 applies.	Load combination: S Load combination: S+D	AC-I AC-II	0.72 0.90
(1) Refer Chapter 1, Section 1, Cl.1.10 for acceptance criteria definition			

3.4.2.5 Corrugation of corrugated bulkhead

The stress in corrugation of corrugated bulkheads is to be evaluated based on:

- The von Mises stress, σ_{vm}, in shell elements on the flange and web of the corrugation.

- The axial stress, σ_{axial}, in dummy rod elements, modelled with unit cross sectional properties at the intersection between the flange and web of the corrugation.

3.4.2.6 Shear stress correction for cut-outs

Except as indicated in Cl.3.4.2.7, the element shear stress in way of cut-outs in webs is to be corrected for loss in shear area in accordance with the following formula. The corrected element shear stress is to be used to calculate the von Mises stress of the element for verification against the yield criteria.

$$\tau_{cor} = \frac{h\, t_{mod}}{A_{shr-n50}} \tau_{elem}$$

where:

τ_{cor} = Corrected element shear stress, in [N/mm^2].

t_{mod} = Modelled web thickness, in [mm], in way of opening.

h = Height of web of girder, in [mm], in way of opening, Refer Table 3.4.2.5. Where the geometry of the opening is modelled, h is to be taken as the height of web of the girder deducting the height of the modelled opening.

τ_{elem} = Element shear stress, in [N/mm^2] before correction.

$A_{shr-n50}$ = Effective net shear area of web [mm^2] taken as the web area deducting the area lost of all openings, including slots for stiffeners, calculated in accordance with Chapter 3, Section 7, Cl.7.4.8.

3.4.2.7 Exceptions for shear stress correction for openings

Correction of element shear stress due to presence of cut-outs is not required for cases given in Table 3.4.2.6 provided yield criteria given in Cl.3.4.2.3 is satisfied based on the following yield utilization factor:

$$\lambda_y = \frac{\lambda_{y,FE}}{C_r}$$

where:

$\lambda_{y,FE}$ = yield utilization factor from FE assessment with openings not reflected in the model.

C_r = reduction factor for yield criteria as given in Table 3.4.2.6.

If the above criterion is not satisfied then the criteria as given in Cl.3.4.2.6 needs to be applied.

3.4.3 Buckling strength assessment

All structural elements in FE analysis carried out in accordance with this section are to be assessed individually against the buckling requirements as defined in Chapter 9, Section 4.

Table 3.4.2.5: Representation of openings in primary supporting webs

Criteria	Modeling Requirement
$h_0/h < 0.5$ and $g_0 < 2.0$	Opening need not be modeled
$h_0/h \geq 0.5$ and $g_0 \geq 2.0$	Opening geometry needs to be represented in the model

$$g_o = \left(1 + \frac{{l_o}^2}{2.6\,(h - h_o)^2}\right)$$

l_o **=** Length of opening parallel to primary supporting member web direction, in [m], Refer Figure 3.4.2.5(a). For sequential openings where the distance, d_o between openings is less than 0.25h, the length l_o is to be taken as the length across openings as shown in Figure 3.4.2.5(b).

h_o = Height of opening parallel to depth of web, in m, Refer Figure 3.4.2.5(a) and Figure 3.4.2.5(b).

h = Height of web of primary supporting member in way of opening, in m, Refer Figure 3.4.2.5(a) and Figure 3.4.2.5(b).

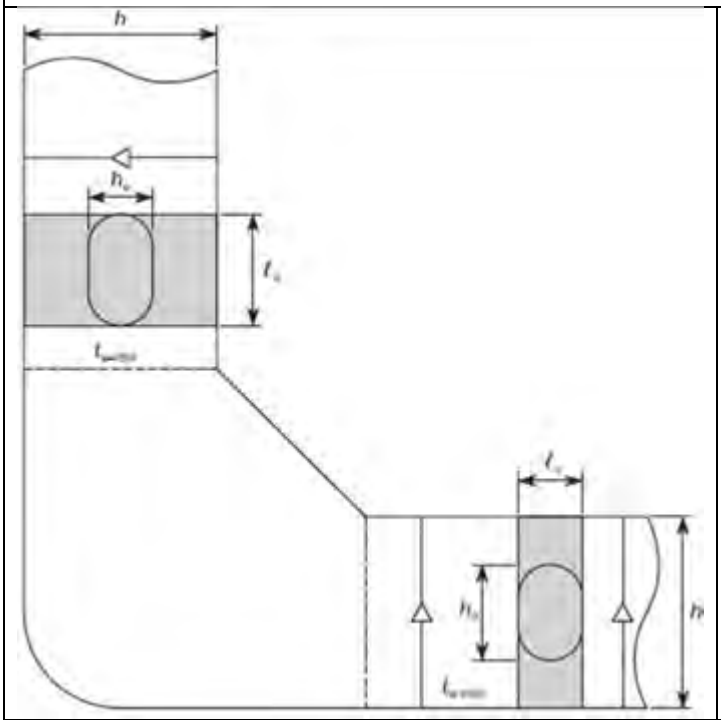

Figure 3.4.2.5(a): Openings in Primary Supporting member

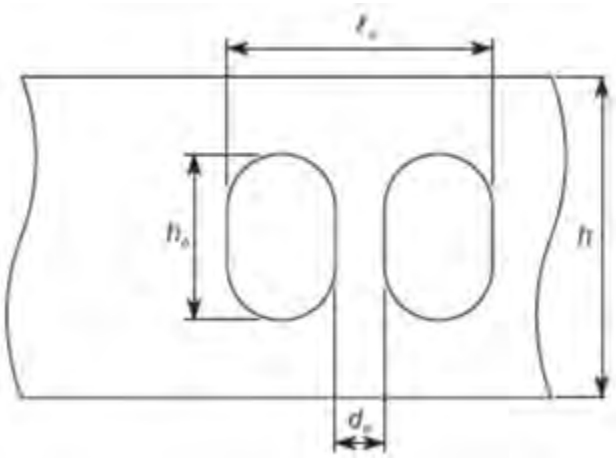

Figure 3.4.2.5(b): Length for Sequential openings with d_0 < 0.25h

Table 3.4.2.6: Exceptions for shear stress correction			
Identification	**Figure**	**Difference between modeled shear area and the net effective shear area in % of the modeled shear area** $\frac{\mathbf{A_{FEM} - A_{shr}}}{\mathbf{A_{FEM}}}.\mathbf{100}\%$	**Reduction factor for yield criteria,** C_r
Upper and lower slots for local support stiffeners fitted with lugs or collar plates		< 15 %	0.85

Section 4

Local Structural Strength Analysis

4.1 Scope

4.1.1 All structural details which are considered critical are analyzed using local structural strength analysis. Additionally, local strength analysis is carried out on structural details which are required by specific ship types as given in Part 5.

4.1.2 The structural details are assessed by fine mesh FE analysis according to the requirements given in this section. Detailed procedures are given in IRS *Guidelines on Structural Assessment of Ships based on Finite Element Method*.

4.1.3 The selection of critical locations on the structural members and general procedure for screening of critical locations for fine mesh analysis is to be in accordance with the requirements given in IRS *Guidelines on Structural Assessment of Ships based on Finite Element Method,* in general.

4.1.4 The details to be assessed by fine mesh analysis are to be modelled according to the requirements given in IRS *Guidelines on Structural Assessment of Ships based on Finite Element Method*, under the FE load combinations defined in 4.3 and to comply with the acceptance criteria given in 4.4.

4.2 Structural model

4.2.1 General

Evaluation of detailed stresses requires the use of refined finite element mesh in way of areas of high stress. This fine mesh analysis can be performed using a separate local finite element model with fine mesh zones in conjunction with the boundary conditions obtained from the partial or global FE model. Alternately, fine mesh zones can be directly integrated into the partial ship model or global FE model, as applicable.

4.2.2 Model Extent

If a separate local fine mesh model is used, its extent is to be such that the calculated stresses at the evaluation area are not significantly affected by the imposed boundary conditions. The boundary of the fine mesh model is to coincide with primary supporting members, such as web frames, girders, stringers, floors etc.

4.2.3 Mesh size

4.2.3.1 The mesh size in the fine mesh zones is not to be greater than 50[mm] x 50[mm].

4.2.3.2 The extent of the fine mesh zone is not to be less than 10 elements in all directions from the area under investigation. A smooth transition of mesh density from fine mesh zone to the boundary of the fine mesh model is to be maintained.

4.3 FE Load combinations

4.3.1 General

4.3.1.1 The fine mesh analysis is to be carried out for all FE load combinations applied to the corresponding partial ship or full ship FE analysis.

4.3.2 Application of loads and boundary conditions

4.3.2.1 Where a separate local model is used for the fine mesh detailed stress analysis the displacements or forces from the cargo tank model (or full ship model) are to be applied to the corresponding boundary contour on the local model. All loads, including local loads and loads applied for hull girder bending moment and/or shear force adjustments, in way of the structure represented by the separate local finite element model are to be applied to the model.

4.4 Analysis criteria

4.4.1 Reference stress:

4.4.1.1 Reference stress, σ_{vm} in [N/mm^2] is based on the membrane direct axial and shear stresses of the plate element evaluated at the element centroid. Where shell elements are used, the stresses are to be evaluated at the mid plane of the element.

4.4.2 Permissible stress:

4.4.2.1 The maximum permissible stresses are based on the mesh size of 50[mm] × 50[mm].

4.4.2.2 Where a smaller mesh size is used, an area weighted von Mises stress calculated over an area equal to the specified mesh size may be used to compare with the permissible stresses and is calculated as follows:

$$\sigma_{vm-av} = \frac{\sum_1^n A_i \sigma_{vm-i}}{\sum_1^n A_i}$$

where,

σ_{vm-av} = Average von Mises stress in [N/mm^2].

A_i = Area of the mesh size, in [mm^2]

4.4.2.3 The averaging is to be based only on elements with their entire boundary located within the desired area. The average stress is to be calculated based on stresses at element centroid; stress values obtained by interpolation and/or extrapolation are not to be used. Stress averaging is not to be carried across structural discontinuities and abutting structure.

4.4.3 Acceptance criteria

4.4.3.1 Verification of stress results against the acceptance criteria is to be carried out in accordance with Cl.4.4.3.2.

4.4.3.2 The structural assessment is to demonstrate that the von Mises stresses obtained from the fine mesh analysis do not exceed the maximum permissible stress, as follows:

$$\lambda_f \leq \lambda_{fperm}$$

where,

λ_f = Fine mesh yield utilization factor.

In general,

$\lambda_y = \frac{\sigma_{vm}}{R_Y}$ for shell elements

$\lambda_y = \frac{|\sigma_{axial}|}{R_Y}$ for rod or beam elements

σ_{vm} = von Mises Stress, in [N/mm^2].

σ_{axial} = Axial Stress in rod element, in [N/mm^2].

λ_{fperm} = Permissible fine mesh utilization factor, as given in the Table 4.4.3.

R_y = Nominal yield stress, taken equal to 235/k

Table 4.4.3: Permissible fine mesh yield utilization factor, λ_{fperm}

Structural Member	Acceptance criteria	Load components	λ_{fperm}
Elements not adjacent to weld	AC-I	S	1.36 f_f
	AC-II	S+D	1.7 f_f
Elements adjacent to weld	AC-I	S	1.2 f_f
	AC-II	S+D	1.5 f_f

where,
f_f = fatigue factor taken as:
= 1.0 in general
= 1.2 for details where fatigue strength is verified by hot spot stresses based on very fine mesh finite element analysis, Refer IRS *Guidelines on Fatigue Design Assessment of Ship Structures*.

Appendix A - Stress-based reference stresses

Section 1

General

Symbols

For symbols not defined in this section, Refer to Chapter 1, Section 2.

1.1 Assumption

1.1.1 This chapter contains the strength criteria for buckling and ultimate strength of local supporting members, primary supporting members, and other structures such as pillars, corrugated bulkheads, and brackets. These criteria are to be applied as specified in Chapter 7 (Hull Local Structures) and Chapter 8 (Finite Element Analysis).

1.1.2 For each structural member, the characteristic buckling strength is to be taken as the most unfavourable/critical buckling failure mode.

1.1.3 Unless otherwise specified, the buckling strength of structural members in this chapter is based on net scantling obtained by deducting t_c, from the gross offered thickness, where t_c is defined in Chapter 2, Section 5.

1.1.4 In this chapter, compressive and shear stresses are taken as positive whereas the tensile stresses are taken as negative.

1.2 Application

1.2.1 Scope

The buckling checks are to be carried out according to:

- Section 2 for the slenderness requirements of plates, longitudinal and transverse stiffeners, primary supporting members, brackets, and other structures such as pillars.

- Section 3 for the hull girder buckling requirements of plates, longitudinal and transverse stiffeners, primary supporting members, and other structures.

- Section 4 for the buckling requirements of the FE analysis for the plates, stiffened panels, and other structures. Buckling analysis according to Section 4 is also applicable for beam analysis of structure elements subject to compressive and shear stresses.

- Section 5, for the buckling capacity of prescriptive and FE buckling requirements.

1.2.2 Stiffeners:

The buckling check of the stiffeners referred to in this Chapter is applicable to the stiffener fitted along the long edge of the buckling panel.

1.2.3 Enlarged stiffeners:

Enlarged stiffeners, with or without web stiffening, used in platforms for Permanent Means of Access (PMA) are to be considered as primary supporting members (PSM) and are to comply with the following requirements:

1.2.3.1 Slenderness requirements for primary supporting members are as follows:

- For enlarged stiffener webs, Refer to Section 2, Cl. 2.4.1.1 (i).

- For enlarged stiffener flange, Refer to Section 2, Cl.2.4.1.1 (ii) and Section 2, Cl.2.5.1.

- For web stiffeners fitted on enlarged stiffeners, Refer to Section 2, Cl.2.3.1.1 and Section 2, Cl.2.3.1.3.

1.2.3.2 Buckling strength for prescriptive requirements is as follows:

- For enlarged stiffener webs, Refer to Section 3, Cl.3.2.

- For web stiffeners fitted on enlarged stiffeners, Refer to Section 3, Cl.3.1 and Section 3, Cl.3.3.

1.2.3.3 All structural elements used for PMA are to be comply with the buckling requirements of the FE analysis in Section 4, when applicable.

1.2.3.4 Buckling strength of longitudinal PMA platforms without stiffeners fitted on enlarged stiffener web is to be checked using the criteria for local supporting members in Section 3, Cl. 3.1 and Section 3, Cl. 3.3.

1.3 Definitions

1.3.1 Assessment methods

The buckling assessment is carried out according to one of the two methods by considering the type of boundary conditions on the plate panel, as follows:

1.3.1.1 Method A

All the edges of the elementary plate panel are forced to remain straight (but free to move in the in-plane directions) due to the surrounding structure/neighbouring plates.

1.3.1.2 Method B

The edges of the elementary plate panel are not forced to remain straight due to low in-plane stiffness at the edges and/or no surrounding structure/neighbouring plates.

1.3.2 Buckling utilization factor:

1.3.2.1 General

The utilisation factor, η is defined as the ratio between the applied loads and the corresponding ultimate capacity or buckling strength.

1.3.2.2 Combined load case

- For combined loads, the utilisation factor, η_{act} is defined as the ratio of the applied equivalent stress and the corresponding buckling capacity, as shown in Figure 1.3.2, and is taken as:

$$\eta_{act} = \frac{W_{act}}{W_u} = \frac{1}{\gamma_c}$$

where:

W_{act} = Equivalent applied stress, in [N/mm^2], due to the combined membrane stress, the actual applied stress are given in Section 3 and Section 4 for buckling assessment by prescriptive and finite element analysis respectively.

W_u = Equivalent buckling capacity, in [N/mm^2], for plates and stiffeners, their respective buckling or ultimate capacities are given in Section 5.

γ_c = Stress multiplier factor at failure.

For each typical failure mode, the corresponding capacity of the panel is calculated by applying the actual stress combination and then increasing or decreasing the stresses proportionally until collapse.

Figure 1.3.2 illustrates the buckling capacity and the buckling utilization factor of a structural member subject to σ_x and σ_y stresses.

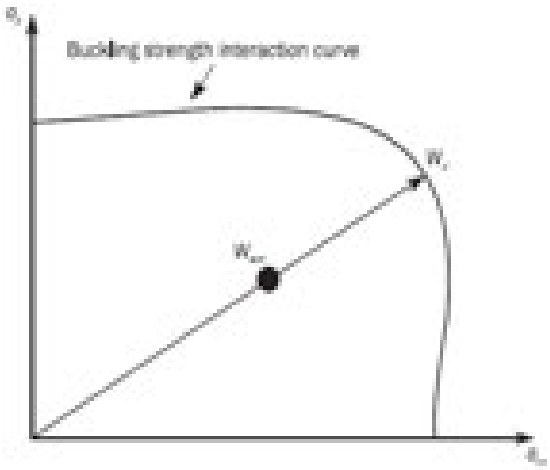

Figure 1.3.2: Example of buckling capacity and buckling utilisation factor

1.3.3 Allowable buckling utilisation factor

The allowable buckling utilisation factor is defined as per Table 1.3.3 (applicable for vessels L≥90[m]). For L< 90[m], Refer to Section 3, Cl 3.4.

1.3.4 Buckling acceptance criteria

1.3.4.1 A structural member is considered to have an acceptable buckling strength if it satisfies the following criterion

$$\eta_{act} \leq \eta_{all}$$

where,

η_{act} = Buckling utilisation factor based on the applied stress as per Cl.1.3.2.

η_{all} = Allowable buckling utilisation factor as per Cl.1.3.3.

Table 1.3.3: Allowable buckling utilisation factor (η_{all})

Structural member	Acceptance criteria	Design Load Scenario	η_{all}
Plates and stiffeners/ stiffened panels	AC-I	S	0.80
	AC-II, AC-III	S + D	1.00
	AC-IV[1)]	S	1.00
Struts, pillars, and crossties	AC-I	S	0.65
	AC-II, AC-III	S + D	0.75
	AC-IV[1)]	S	0.75
Corrugations of corrugated bulkheads under lateral pressure from liquid loads. For corrugation angles between 45[deg] and 55[deg] the reduction in η_{all} as given in Chapter 3, Section 6, Cl.6.4.1.2 applies.	AC-I	S	0.72
	AC-II, AC-III	S + D	0.90
	AC-IV[1)]	S	0.90
1) For members of the collision bulkhead, AC-I is to be used.			

Section 2

Slenderness Requirements

Symbols

For symbols not defined in this section, Refer to Chapter 1, Section 2.

b_{f-out} = Maximum distance, in [mm], from the mid-thickness of the web to the flange edge, as shown in Figure 2.3.1.

h_w = Depth of stiffener web, in [mm], as shown in Figure 2.3.1.

l_b = Effective length of the edge of the bracket, in [mm], as defined in Table 2.5.1.

s_{eff} = Effective width of the attached plate of the stiffener, in [mm], taken equal to = 0.8s

t_f = Net flange thickness, in [mm].

t_p = Net thickness of plate, in [mm].

t_w= Net web thickness, in [mm].

2.1 Structural Elements

2.1.1 General

All structural elements are to comply with the applicable slenderness and proportion requirements given in Section 2.2 to Section 2.4. A lower specified minimum yield stress value than the actual value can be used for assessing the following slenderness criteria, provided that the requirements specified in Section 3 and Section 4 are satisfied with the same lower specified minimum yield stress value.

2.2 Plates

2.2.1 Application

Based on requirements in accordance with Section 3 and Section 4, slenderness requirements according to Section 2, Cl 2.2.2 may be specially considered. The plate slenderness requirement does not apply to transversely stiffened bilge plates and gunwales with radius.

2.2.2 Net thickness of plate panels

$$t_p \geq \frac{b}{C}\sqrt{\frac{R_{eH}}{235}}$$

where,

b = Distance, in [mm], between stiffeners at mid-length of plate field, as shown in Chapter 3, Section 7 (Figure 7.2.1).

R_{eH} = Specified minimum yield stress of the plate material, in [N/mm^2].

A lower specified minimum yield stress may be used in this slenderness criterion provided the requirements specified in Section 3 and Section 4 are satisfied for the strake assumed in the same lower specified minimum yield stress value.

C = Slenderness coefficient taken as:

= 100 for the outer shell including the strength deck except in superstructures, for vessels with length L≥ 90[m].

= 125 for the outer shell including the strength deck except in superstructures, for vessels with length L< 90[m].

= 175 for internal structural members, except tank boundaries, in vessels with more than three continuous decks and for members in deck house/superstructure

= 125 for other structures not mentioned above.

2.3 Stiffeners

2.3.1 Proportions of stiffeners (except for U-type stiffeners)

2.3.1.1 Net thickness of stiffeners

The net thickness of stiffeners is to satisfy the following criteria:

(i) Stiffener web plate

$$t_w \geq \frac{h_w}{C_w}\sqrt{\frac{R_{eH}}{235}}$$

(ii) Flange

$$t_f \geq \frac{b_{f-out}}{C_f}\sqrt{\frac{R_{eH}}{235}}$$

where,

C_w, C_f = Slenderness coefficients given in Table 2.3.1.

If requirement [2.3.1.1(ii)] is not fulfilled, the effective free flange out-stand, in [mm], used in strength assessment including the calculation of actual net section modulus is not be taken greater than:

$$b_{f-out-max} = C_f . t_f \sqrt{\frac{235}{R_{eH}}}$$

For built-up profile where the relevant yielding strength defined in Chapter 7 and Chapter 8 for the web of built-up profile without the edge stiffener is acceptable, as an alternative the web can be assessed according to the web requirements of Angle and L2 in Table 2.3.1 and the edge stiffener can be assessed as a flat bar stiffener according to Cl.2.3.1.1. The requirement to flange is to be taken as per Cl.2.3.1.2.

Table 2.3.1: Slenderness coefficients

Type of profile	C_w	C_f
Angle bars and L2	75	12[1)]
T-bars	75	12[1)]
Bulb bars	45	-
Flat bars	22	-
1) C_f = 22, non-continuous straight flanges with end		

2.3.1.2 Net dimensions of angle and T-bars

The total flange breadth, in [mm], for angle and T-bars needs to satisfy the following criterion:

$$b_f \geq 0.20\, h_w$$

2.3.1.3 Bending stiffness of stiffeners

The net moment of inertia, in [cm^4], of the stiffener with the effective width of the attached plate, s_{eff}, about the neutral axis parallel to the attached plating, is not to be less than the minimum value given by:

$$I_{st} \geq Cl^2 A_{eff} \frac{R_{eH}}{235}$$

where,

A_{eff} = Net sectional area of stiffener including the effective attached plate, s_{eff}, in [cm^2].

R_{eH} = Specified minimum yield stress of the material of the attached plate, in [N/mm^2].

C = Slenderness coefficient taken as:

= 1.43 for longitudinal stiffeners including sniped stiffeners.

= 0.72 for other stiffeners.

2.4 Primary Supporting Members

2.4.1 Proportions and stiffness

2.4.1.1 Proportions of web plate and flange

The net thicknesses of the web plates and flanges of primary supporting members are to satisfy the following criteria:

(i) Web Plate

$$t_w \geq \frac{s_w}{C_w}\sqrt{\frac{R_{eH}}{235}}$$

(ii) Flange

$$t_f \geq \frac{b_{f-out}}{C_f}\sqrt{\frac{R_{eH}}{235}}$$

where,

s_w = Plate breadth, in [mm], taken as the spacing of the web stiffeners. (See web-plate idealisation also)

C_w = Slenderness coefficient for the web plate taken as:

= 125 for double-skin construction

= 100 elsewhere

C_f = Slenderness coefficient for the flange taken as 12

If requirement [Cl.2.4.1.1 (ii)] is not fulfilled, the effective free flange out-stand, in [mm], used in strength assessment including the calculation of actual net section modulus, is not be taken greater than:

$$b_{f-out-max} = C_f . t_f \sqrt{\frac{235}{R_{eH}}}$$

2.4.1.2 Deck transverse primary supporting members

The net moment of inertia for deck transverse primary supporting members, in [cm^4], supporting deck longitudinals subject to axial compressive hull girder stress, within its central half of the bending span, is to comply with the following criterion:

$$I_{PSM-n50} \geq 300 \frac{\ell_{bdg}^4}{s\, S^3} I_{st}$$

where,

$I_{PSM-n50}$= Net moment of inertia, in [cm^4], of deck transverse primary supporting member, with an effective width of attached plate equal to 0.8S

l_{bdg} = Unsupported bending span of deck transverse primary supporting member in [m], as defined in Chapter 3, Section 7.

ℓ = Length between zero-points of bending moment curve of deck transverse primary supporting member with uniformly distributed load, in m:

$\ell = l_{bdg}$

for deck transverse primary supporting member arranged above the deck without strong rotational support at ends

$\ell = 0.7\ l_{bdg}$

for deck transverse primary supporting member arranged under the deck and connected to the side tank,

S = Spacing of deck transverse primary supporting members, in [m], as defined in Chapter 3, Section 7.

I_{st} = Moment of inertia in [cm^4] of deck stiffeners within the central half of the bending span as given in Cl.2.3.1.3.

2.4.2 Web stiffeners of primary supporting members

2.4.2.1 Proportion of web stiffeners

The net thickness of the web and flange of web stiffeners fitted on primary supporting members is to satisfy the requirements specified in Cl.2.3.1.1 and Cl.2.3.1.2.

2.4.2.2 Bending stiffness of web stiffeners

The net moment of inertia, in [cm^4], of web stiffener, I_{st}, fitted on primary supporting members, with the effective attached plate, s_{eff}, should not be less than the minimum moment of inertia as defined in Table 2.4.2.

Table 2.4.2: Stiffness criteria for web stiffeners		
Stiffener arrangement		Minimum moment of inertia of web stiffeners, in [cm^4]
A		$I_{st} \geq C\, l^2 A_{eff} \frac{R_{eH}}{235}$
B		$I_{st} \geq 1.14\, l\, s^2 t_w \left(2.5\, \frac{1000\, l}{s} - 2\, \frac{s}{1000 l}\right) \frac{R_{eH}}{235} 10^{-5}$

where:
C = Slenderness coefficient to be taken as:
C = 1.43 for longitudinal stiffeners including sniped stiffeners.
C = 0.72 for other stiffeners.

l = Length of web stiffener, in [m].
For web stiffeners welded to local supporting members, the length is to be measured between the flanges of the local support members.

For sniped web stiffeners, the length is to be measured between the lateral supports, e.g., the total distance between the flanges of the primary supporting member as shown for stiffener arrangement B.

A_{eff} = Net section area of web stiffener including effective attached plate, S_{eff}, in [cm^2].

t_w = Net web thickness of the primary supporting member, in [mm].

R_{eH} = Specified minimum yield stress of the material of the web plate of the primary supporting member, in [N/mm^2].

2.5 Brackets

2.5.1 Tripping Brackets

2.5.1.1 Unsupported flange length

Dimensions of tripping brackets are to be in accordance with Chapter 3, Section 6, Cl. 6.3.3. The unsupported length of the flange of the primary supporting member, in [m], i.e., the distance between tripping brackets, is not to be greater than:

$$S_b = b_f C \sqrt{\frac{A_{f-n50}}{\left(A_{f-n50} + \frac{A_{w-n50}}{3}\right)} \left(\frac{235}{\sigma_y}\right)}$$

; but need not be less than S_{b-min}

where,

b_f = Flange breadth of primary supporting members, in [mm].

C = Slenderness coefficient taken as:

C = 0.022 for symmetrical flanges.

C = 0.033 for asymmetrical flanges.

A_{f-n50}= Net cross-sectional area of the flange, in [cm^2]

A_{w-n50}= Net cross-sectional area of the web plate, in [cm^2]

R_{eH} = Specified minimum yield stress of the PSM material, in [N/mm^2]

S_{b-min} = Minimum unsupported flange length is taken as:

S_{b-min} = 3.0 m for tank/hold boundaries, or hull envelope including external decks.

S_{b-min}= 4.0 m for other areas.

2.5.1.2 Edge Stiffening

Tripping brackets on primary supporting members are to be stiffened by a flange or edge stiffener if the effective length of the edge, l_b, as defined in Table 2.5.1, in [mm], is greater than:

$$l_b = 75t_b$$

where,

t_b = Bracket net web thickness, in [mm].

2.5.2 End Bracket:

2.5.2.1 Proportions

The net web thickness of end brackets, in [mm], subject to compressive stresses should not be less than:

$$t_b = \frac{d_b}{C}\sqrt{\frac{R_{eH}}{235}}$$

where,

d_b = Depth of brackets, in [mm], as defined in Table 2.5.1.

C = Slenderness coefficient as defined in Table 2.5.1.

R_{eH} = Specified minimum yield stress of the end bracket material, in [N/mm^2]. R_{eH} is not to be taken less than the value of the non-continuous member it is supporting but need not be taken greater than that value.

2.5.3 Edge reinforcement

2.5.3.1 Edge reinforcement of bracket edges

The depth of the stiffener web, in [mm], of edge stiffeners in way of bracket edges should not be less than:

$h_w = Cl_b/1000\sqrt{\frac{R_{eH}}{235}}$ or 50[mm] (whichever is greater)

where,

C = Slenderness coefficient taken as:

C = 75 for end brackets.

C = 50 for tripping brackets.

R_{eH} = Specified minimum yield stress of the stiffener material, in [N/mm^2], not to be taken less than the value of the bracket.

2.5.3.2 Proportions of edge stiffeners

The net thickness of the web plate and flange of the edge stiffener should satisfy the requirements specified in Cl.2.3.1.1 and Cl.2.3.1.2.

2.6 Pillars

2.6.1 Proportions of I-section pillars

For I-sections, the thickness of the web plate and the thickness of the flange are to comply with the requirements specified in Cl. 2.3.1.1 and Cl. 2.3.1.2.

2.6.2 Proportions of box section pillars

The thickness of thin-walled box sections is to comply with the requirements specified in Cl. 2.3.1.1 (i).

2.6.3 Proportions of circular section pillars

The net thickness, t , of circular section pillars, in [mm], is to comply with the following criterion:

$$t \geq \frac{r}{50}$$

where,

r = Mid-thickness radius of the circular section, in [mm].

2.7 Edge Reinforcement in way of openings

2.7.1 Depth of edge stiffener

When fitted as shown in Figure 2.7.1, the depth of the web, h_w, in [mm], of edge stiffeners in way of openings is not to be less than:

$h_w = Cl\sqrt{\frac{R_{eH}}{235}}$ or 50 [mm] (whichever is greater).

where,

C = Slenderness coefficient taken as 50

R_{eH} = Specified minimum yield stress of the edge stiffener material, in [N/mm^2].

l = Length of edge stiffener in way of opening, in [m], as defined in Figure 2.7.1

2.7.2 Proportions of edge stiffeners

The net thickness of the web plate and flange of the edge stiffener needs to satisfy the requirements specified in Cl. 2.3.1.1 and Cl. 2.3.1.2

The net thickness of the web plate and flange of the edge stiffener needs to satisfy the requirements specified in Cl. 2.3.1.1 and Cl. 2.

Table 2.5.1: Buckling coefficient, C, for proportions of brackets

Mode	C
Brackets without edge stiffener 	$C = 20\left(\frac{d_b}{l_b}\right) + 16$ Where: $0.25 \leq \frac{d_b}{l_b} \leq 1.00$
Brackets with edge stiffener 	$C = 70$

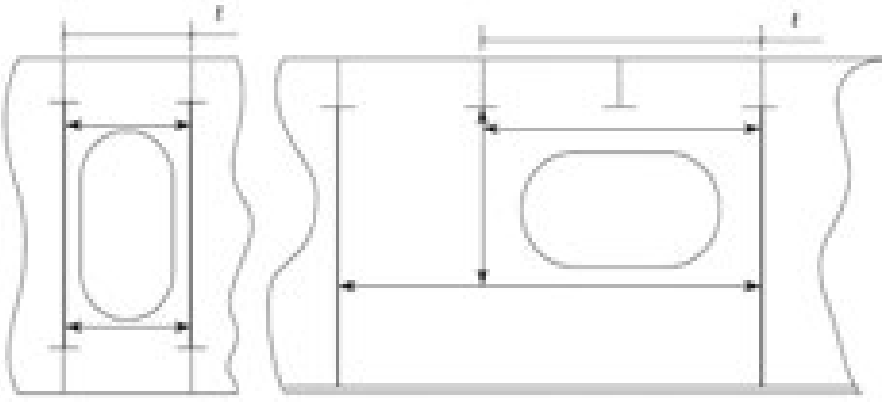

Figure 2.7.1: Typical edge reinforcements

Section 3

Buckling Requirements for Prescriptive Analysis

Symbols

For symbols not defined in this section, Refer to Chapter 1, Section 2.

η_{all} = Allowable buckling utilisation factor, as defined in Section 1, Cl. 1.3.3.

EPP = Elementary Plate Panel as defined in Chapter 3, Section 7, Cl.7.5.1.

LCP = Load calculation point as defined in Chapter 3, Section 7, Cl.7.5.2.

3.1 General

3.1.1 Scope

3.1.1.1 This section applies to plate panels including curved plate panels and stiffeners subject to hull girder compression and shear stresses. Additionally, the following structural members are also to be checked:

- Corrugations of longitudinal corrugated bulkhead
- Strut
- Pillar
- Cross tie

3.1.1.2 The hull girder buckling strength requirements apply along the full length of the ship.

3.1.1.3 Design load sets

The buckling checks are to be performed for all design load sets defined in Chapter 7, Section 2, Cl. 2.4. For each design load set, for all dynamic load cases, the lateral pressure is to be determined according to Chapter 5 at the load calculation point (LCP) defined in Chapter 3, Section 7 and is to be applied together with the hull girder stress combinations given in Section 3, Cl. 3.2.2.

3.1.2 Equivalent Plate Panel

3.1.2.1 In longitudinal stiffening arrangement, when the plate thickness varies over the width *b*, of a plate panel, the buckling check is to be performed for an equivalent plate panel width, combined with the smaller plate thickness, t_1. The width of this equivalent plate panel, b_{eq}, in [mm], is defined by the following formula:

$$b_{eq} = l_1 + l_2 \left(\frac{t_1}{t_2}\right)^{1.5}$$

where,

l_1 = Width of the part of the plate panel with the smaller net plate thickness, t_1, in [mm], as defined in Figure 3.1.1.

l_2 = Width of the part of the plate panel with the greater net plate thickness, t_2, in [mm], as defined in Figure 3.1.1.

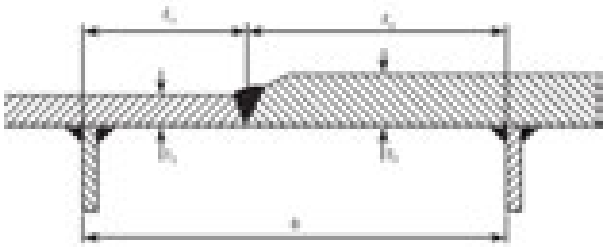

Figure 3.1.1: Plate thickness change over the width

3.1.2.2 In transverse stiffening arrangement, when an EPP is made with different thicknesses, the buckling check of the plate and stiffeners are to be made for each thickness considered constant on the EPP, the stresses, and pressures being estimated for the EPP at the LCP.

3.1.2.3 Materials

When the plate panel is made of different materials, the minimum yield strength is to be used for the buckling assessment.

3.2 Hull girder stress

3.2.1 General

3.2.1.1 Hull girder stress applicable for load components 'S'

The hull girder bending stresses, σ_{hg} in [N/mm^2] for load component S, is taken as:

$$\sigma_{hg} = \sigma_{hg-sw}$$

where,

σ_{hg-sw} = Hull girder bending stress, in [N/mm^2], due to vertical still water bending moment as defined in Chapter 6, Section 3 Cl. 3.2 for ships without large deck openings and in Chapter 6, Section 3, Cl. 3.3 for ships with large deck openings.

3.2.1.2 Hull girder stress applicable for load components 'S+D'

The hull girder bending stresses, σ_{hg} in [N/mm^2] for load component, 'S+D' is to be taken as defined in Chapter 6, Section 3, Cl. 3.2 for ships without large deck openings and in Chapter 6, Section 3, Cl.3.3 for ships with large deck openings.

3.2.1.3 The hull girder shear stresses, τ_{hg} in [N/mm^2], are determined according to Chapter 6, Section 3, Cl.3.2 and Cl.3.3.

3.2.2 Stress combinations

Each elementary plate panel and stiffeners are to satisfy the criteria defined in Section 3.3 with the following stress combinations:

3.2.2.1 Longitudinal stiffening arrangement:

(1) Stress combination 1 with:

$\sigma_x = \sigma_{hg}$
$\sigma_y = 0$
$\tau = 0.7\,\tau_{hg}$

(2) Stress combination 2 with:

$\sigma_x = 0.7\,\sigma_{hg}$
$\sigma_y = 0$
$\tau = \tau_{hg}$

3.2.2.2 Transverse stiffening arrangement

(1) Stress combination 1 with:

$\sigma_x = 0$
$\sigma_y = \sigma_{hg}$
$\tau = 0.7\,\tau_{hg}$

(2) Stress combination 2 with:

$\sigma_x = 0$
$\sigma_y = 0.7\,\sigma_{hg}$
$\tau = \tau_{hg}$

where,

σ_{hg} = Hull girder bending stress in the elementary plate panel or stiffener, as defined in Cl. 3.2.1.1 and Cl. 3.2.1.2, in [N/mm^2].

τ_{hg} = Hull girder shear stress, in [N/mm^2], in the elementary plate panel or stiffener attached plate as defined in Cl.3.2.1.3.

3.3 Buckling criteria

3.3.1 Overall stiffened panel

The buckling strength of overall stiffened panels is to satisfy the following criterion:

$$\eta_{overall} \leq \eta_{all}$$

where,

$\eta_{overall}$ = Maximum utilization factor as defined in Section 5, Cl.5.2.1.

3.3.2 Plates

The buckling strength of elementary plate panels is to satisfy the following criterion:

$$\eta_{plate} \leq \eta_{all}$$

where,

η_{plate} = Maximum plate utilization factor calculated according to SP-A, as defined in Section 5, Cl. 5.2.2.

For the determination of η_{plate} for vertically stiffened plating, Cases 12 and 16 of Section 5, Table 5.2.2.3 corresponding to the shorter edge of the plate panel clamped, may be considered together with a mean σ_y stress and ψ_y = 1, provided that the shorter edges are supported by longitudinal plating/decks and are located within $0.7\,z_1$ from the horizontal neutral axis.

where,

$'z_1'$ is the distance from the horizontal neutral axis to the equivalent deck line or baseline respectively as defined in Chapter 6, Section 2, Cl.2.1.8.

3.3.3 Stiffeners

The buckling strength of stiffeners is to satisfy the following criterion:

$$\eta_{\text{stiffener}} \leq \eta_{\text{all}}$$

where,

$\eta_{\text{stiffener}}$ = Maximum stiffener utilisation factor, as defined in Section 5, Cl.5.2.3.

Note 1: This capacity check can only be fulfilled when the overall stiffened panel capacity, as defined in Cl.3.1.1, is satisfied.

3.3.4 Vertically corrugated longitudinal bulkheads

The shear buckling strength of vertically corrugated longitudinal bulkheads is to satisfy the following criterion:

$$\eta_{\text{shear}} \leq \eta_{\text{all}}$$

where,

η_{shear} = Maximum shear utilisation factor corrugated bulkhead.

$$\eta_{\text{shear}} = \frac{\tau_{\text{bhd}}}{\tau_c}$$

τ_{bhd} = Hull girder shear stress, in [N/mm^2], in the longitudinal bulkheads taken as defined in Cl.3.2.1.3.

τ_c = Shear critical stress, in [N/mm^2], as defined in Section 5, Cl.5.2.2.

3.3.5 Horizontally corrugated longitudinal bulkheads

Each corrugation, within the extension of half flange, web, and half flange, is to satisfy the following criterion:

$$\eta \leq \eta_{\text{all}}$$

where,

η = Overall column utilisation factor, as defined in Section 5, Cl.5.3.1.

End constraints factor corresponding to pinned ends is to be applied except for fixed end support to be used in way of stool with the width exceeding two times the depth of the corrugation.

3.3.6 Struts, pillars, and cross ties

The compressive buckling strength of struts, pillars, and cross ties is to satisfy the following criterion:

$$\eta \leq \eta_{\text{all}}$$

where,

η = Maximum buckling utilisation factor of struts, pillars, or cross ties, defined in Section 5, Cl.5.4.1.

3.4 Application to vessels with L<90[m]

3.4.1 For ships with L< 90[m] the buckling requirement is to be obtained from Sections 3.4 to 3.8, in lieu of the requirements described in Sections 3.1 to 3.3. These requirements apply to plate panels and longitudinals subject to hull girder bending and shear stresses.

3.4.2 Buckling strength of members contributing to the longitudinal strength and subjected to compressive and shear stresses are to be checked, especially in regions where changes in the framing system or significant changes in the hull cross-section occur.

3.4.3 The hull girder buckling strength requirements apply along the full length of the ship.

3.5 Elastic buckling stresses

3.5.1 Elastic Buckling of Plates

3.5.1.1 Compression:

The ideal elastic buckling stress 'σ_E' for plating in [N/mm^2] may be taken as:

$$\sigma_E = 0.9\,K\,E\left[\frac{(t - t_c)}{s}\right]^2$$

where,

For plating with longitudinal stiffeners in the direction parallel to the compressive stress:

$$K = \frac{8.4}{\psi + 1.1}$$

For $0 \leq \psi \leq 1$

For plating with transverse stiffeners in the direction perpendicular to compressive stress:

$$K = C\left[1 + \left(\frac{s}{1000l}\right)^2\right]^2 \frac{2.1}{\psi + 1.1}$$

For $0 \leq \psi \leq 1$

ψ = Stress ratio of the smallest to the largest compressive stress assuming a linear variation (Refer Figure 3.5.1).

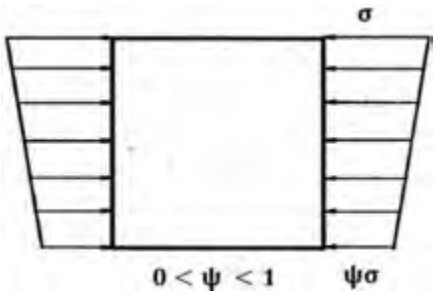

Figure 3.5.1: Schematic for stress ratio

E = Modulus of Elasticity, 2.06×10^5 [N/mm^2], for steel.

s = Shorter side of the plate panel in [mm].

l = Longer side of the plate panel in [m].

C = Coefficient for various structural members, Refer Table 3.5.1.

Table 3.5.1: Coefficient 'C' for various structural members

Structural Member	C
Plating stiffened by primary supporting members (floors or deep girders)	1.30
Stiffeners are angles or T-sections	1.21
Stiffeners are bulb flats	1.10
Stiffeners are flat bars	1.05

3.5.1.2 Shear:

The ideal elastic buckling stress for plate panels in shear in [N/mm^2] may be taken as:

$$\tau_E = 0.9\, K_S\, E \left[\frac{(t - t_c)}{s}\right]^2$$

where,

$$K_S = 5.34 + 4\left(\frac{s}{1000l}\right)^2$$

3.5.2 Elastic Buckling of Longitudinals

3.5.2.1 Column Buckling without rotation of the cross-section

Ideal elastic buckling stress $'\sigma_E'$ for the lateral column buckling mode of longitudinals (perpendicular to the plane of plating), in [N/mm^2], is given by:

$$\sigma_E = \frac{0.001\, E\, I_a}{A\, l^2}$$

where:

I_a = Net moment of inertia [cm^4], of the longitudinal including plate flange, about the neutral axis parallel to the plating and calculated with net thickness.

A = Net Cross-sectional area [cm^2], of the longitudinal including plate flange.

l = Span [m], of the longitudinal.

In the calculation of I_a and A, the attached plating area corresponding to the longitudinal spacing and net thickness is to be included.

3.5.2.2 Torsional Buckling Mode

The ideal elastic buckling stress value $'\sigma_E'$ for the torsional buckling mode of longitudinals, in [N/mm^2], may be taken as:

$$\sigma_E = \frac{\pi^2\, E\, I_w}{10^4\, I_p\, l^2}\left(m^2 + \frac{K}{m^2}\right) + 0.385\, E\, \frac{I_t}{I_p}$$

where,

m = Number of deformation half waves depending on K, as per Table 3.5.2.

I_t = Net St. Venant's moment of inertia, in [cm^4], of profile (without plate flange).

$= \frac{h_w\, t_w^3\, 10^{-4}}{3}$ For flat bars (slabs)

$= \frac{1}{3}\left[h_w\, t_w^3 + b_f\, t_f^3\, \left(1 - 0.63\, \frac{t_f}{b_f}\right)\right] 10^{-4}$ For flanged profiles

I_p = Net Polar moment of inertia, in [cm^4], of profile about the connection of stiffener to the plate.

$= \frac{t_w\, h_w^3\, 10^{-4}}{3}$ For flat bars (slabs)

$= \left[\frac{t_w\, h_w^3}{3} + b_f\, h_w^2\, t_f\right] 10^{-4}$ For flanged profiles

I_w= Net Sectorial moment of inertia of profile in [cm^6], about the connection of stiffener to the plate.

$= \frac{t_w{}^3\, h_w^3\, 10^{-6}}{36}$ For flat bars (slabs)

$= \frac{t_f\, b_f^3\, h_w^2\, 10^{-6}}{12}$ For T- profiles

$= \frac{b_f^3\, h_w^2 \left[t_f\left(b_f^2 + 2\, b_f\, h_w + 4\, h_w^2\right) + (3\, t_w\, b_f\, h_w)\right] 10^{-6}}{12\,(b_f + h_w)^2}$

For Angles and bulb sections

h_w = Web height, in [mm].

t_w = Net Web thickness, [in mm].

b_f = Flange width, in [mm].

t_f = Net Flange thickness, in [mm]. For bulb profiles, the mean thickness of the bulb may be used.

$K = \frac{C\, l^4\, 10^6}{\pi^4\, E\, I_w}$

C = Spring stiffness exerted by supporting plate panel.

$$C = \frac{k_p\, E\, t_p^3\, t_w^3}{3\, s\, t_w^3 + 4\, k_p\, h_w\, t_p^3}$$

l = Span of the profile, in [m].

s = Spacing of profiles, in [mm]

$k_p = (1 - \eta_p)$, not to be taken less than zero; for flanged profiles need not be taken less than 0.1.

t_p= Net plate thickness [mm]

η = Utilization factor

$$\eta = \frac{\sigma_c}{\sigma_{Ep}}$$

σ_c = Calculated compressive stress for longitudinals as per Cl.3.7.1.

σ_{Ep}= Elastic buckling stress of supporting plate calculated as per Cl.3.5.1.

Table 3.5.2: Number of deformation half waves depending on K

K	$0 < K < 4$	$4 < K < 36$	$36 < K < 144$	$144 < K < 400$	$(m-1)^2 m^2 \le K \le (m+1)^2 m^2$
m	1	2	3	4	m

3.5.2.3 Web and Flange Buckling

For web plates of longitudinals, the ideal buckling stress $'\sigma_E'$ value for the web buckling mode, in [N/mm^2], may be taken as:

$$\sigma_E = 3.8\, E\, \left(\frac{t_w}{h_w}\right)^2$$

Buckling of flanges on angles and T-sections of longitudinals is taken care of if the as-built flange thickness is not less than 1/15 of the flange width on one side of the web.

3.5.3 Critical column buckling stress of axially loaded members:

The critical column buckling stress of axially loaded members $'\sigma_E'$, in [N/mm^2], may be taken as:

$$\sigma_E = 0.001\, C\, E\, \left[\frac{i}{l_m}\right]^2$$

C = Coefficient to be obtained as per Table 3.5.4.

Table 3.5.4: Coefficient 'C' for various boundary conditions	
Boundary conditions of the member	**C**
Both ends fixed	4
One end is fixed; one end pinned 	2
Both ends pinned 	1

I = Net moment of inertia of the member, [cm^4], about the axis perpendicular to the direction of buckling being considered.

a = Cross-sectional area of the member, [cm^2].

i = Radius of gyration of the member, [cm].

$$i = \sqrt{\frac{I}{a}}$$

l_m = length of the member, in [m].

Where end connections of a member are different for the two principal axes, σ_E is to be found out for both cases using appropriate values of 'C' and 'I'.

3.6 Critical Buckling Stresses

3.6.1 Compression

The critical compressive buckling stress 'σ_{cr}' may be determined as follows:

$\sigma_{cr} = \sigma_E$ when $\sigma_E \leq 0.5\ R_{eH}$

$\sigma_{cr} = R_{eH}\left(1 - \frac{R_{eH}}{4\sigma_E}\right)$ when $\sigma_E > 0.5\ R_{eH}$

where,

σ_E = Ideal elastic buckling stress, in [N/mm^2], as per Cl.3.5.1.1.

R_{eH} = Yield stress of the material, in [N/mm^2].

3.6.2 Shear

The critical shear buckling stress 'τ_{cr}' may be determined as follows:

$\tau_{cr} = \tau_E$ when $\tau_E \leq 0.5\ \tau_y$

$\tau_{cr} = \tau_y\left(1 - \frac{\tau_y}{4\tau_E}\right)$ when $\tau_E > 0.5\ \tau_y$

where,

τ_E = Ideal elastic buckling stress in shear, in [N/mm^2], as perCl.3.5.1.2.

τ_y = Yield stress in shear of the material, in [N/mm^2].

$$= \frac{R_{eH}}{\sqrt{3}}$$

3.7 Working Stress

3.7.1 Longitudinal compressive stresses

3.7.1.1 The compressive stress value 'σ_c', in [N/mm^2], for plate panels and stiffeners taking part in the longitudinal strength is to be taken as:

$$\sigma_c = (M_s + M_w)\frac{z_{n-n50}}{I_{y-n50}}$$

but not to be taken less than 30/k [N/mm^2].

where,

M_s = Still water bending moment [kN-m] as per Chapter 5, Section 3, Cl.3.4.1.

M_w = Wave bending moment [kN-m] as per Chapter 5, Section 3, Cl.3.6.1.

Values of sagging moments (M_s and M_w) are to be considered for members above the neutral axis and the hogging values for members below the neutral axis.

I_{y-n50} = Net moment of inertia of the hull girder (considering deduction of 0.5t_c from the gross offered thickness of structural members) about the neutral axis, [cm^4].

z_{n-n50} = Vertical distance [m], from the neutral axis of the hull girder to the member under consideration.

3.7.1.2 For ships with high speed and large flares in the forebody, σ_c as obtained from above is to be increased by σ_{ca} in the region forward of 0.3L abaft of F.P. The value of σ_{ca} in [N/mm^2] is to be taken as:

$\sigma_{ca} = 0$ For $C_{af} < 0.4$

$$\sigma_{ca} = \frac{50}{k}\left(1 - \frac{x}{0.3L}\right) \text{ For } C_{af} > 0.5$$

where,

x = Distance [m], from F.P., however, need not be taken as smaller than 0.1L.

C_{af} = Factor as defined in Chapter 5, Section 3, Cl.3.6.1.2.

Intermediate values of C_{af}, σ_{ca} are to be obtained by interpolation.

3.7.2 Shear Stresses

3.7.2.1 Hull girder shear stresses in plate panels of side shell and longitudinal bulkheads are obtained according to Chapter 6, Section 3, Cl.3.2 for ships without large deck openings, and Chapter 6, Section 3, Cl.3.3 for ships with large deck openings, respectively.

3.7.3 Axial compressive stresses

The compressive stress value 'σ_c', in [N/mm^2], for axially loaded members is to be taken as:

$$\sigma_c = \frac{10\,F}{a}$$

where,

a = Cross-sectional area of the member, in [cm^2].

F = Nominal axial force in the member, in [kN].
$= A_L\, p\, 10^3$

p = Design pressure [N/mm^2] as per Chapter 7, Table 2.4.3.

A_L= Load area, in [m^2], being supported by the member.

In the calculation of axial force 'F', for deck pillars, contributions, if any, from the decks above are also to be considered.

In the calculation of axial force 'F', for cross ties or panting beams, the larger of the design pressure 'p' at either end of the member is to be considered.

3.8 Scantling Criteria

3.8.1 Compression

The critical buckling stress 'σ_{cr}' of plate panels and stiffeners and other members (struts, pillars, and cross ties) to compressive loads is to be such that:

$$\sigma_{cr} \geq \frac{\sigma_c}{\eta}$$

where,

σ_c = Compressive stress to be considered as per Section 3, Cl.3.5.1.

η = Allowable buckling utilization factor as defined in Table 3.8.1.

Table 3.8.1: Utilization factors for various structural members	
Structural Member	**η**
Deck plating, longitudinally stiffened side shell plating, and single bottom plating	1.00
Bottom plating, inner bottom plating in the double bottom, and transversely stiffened side shell plating	0.90
Local plate panels where an extreme load level is applied. (E.g., impact pressure)	1.00
Local plate panels where a normal load level is applied	0.80
Lateral buckling mode of longitudinals	0.85
Torsional and web buckling mode of longitudinals	0.90
Axially loaded members such as pillars, crossties, panting beams, etc. (in general) **(Note 1)**	$= \frac{0.7}{1 + \left(\frac{l_m}{i}\right)}$ (Need not be taken lesser than 0.3)
Note 1: Where the loads are primarily dynamic in nature, to be reduced by 15%.	

3.8.2 Shear

The critical shear stress of plate panels, stiffeners, and other members is to be such that:

$$\tau_{cr} \geq \frac{\tau_c}{\eta}$$

where,

τ_c = Actual shear stress calculated for the plate panels.

Hull girder shear stresses in plate panels of side shell and longitudinal bulkheads are obtained according to Chapter 6, Section 3, Cl.3.2 for ships without large deck openings and Chapter 6, Section 3, Cl.3.3 for ships with large deck openings, respectively.

η = Allowable buckling utilization factor as defined in Table 3.8.2.

Table 3.8.2: Utilization factors for various structural members	
Structural Member	**η**
Ship's side and longitudinal bulkhead subject to hull girder shear forces	0.90
Local panels in girder webs when nominal shear stresses are calculated (τ_c= Q/A)	0.85
Local panels in girder webs where shear stresses are determined by finite element calculation.	0.90

Section 4

Buckling Requirements for Finite Element Analysis

Symbols

For symbols not defined in this section, Refer to Chapter 1, Section 2.

η_{all} = Allowable buckling utilisation factor, as defined in Section 1, Cl.1.3.2.

4.1 General

4.1.1 The requirements given in this section apply to the buckling assessment using finite element analysis for structural elements subjected to compressive stress, shear stress, and lateral pressure.

4.1.2 All structural elements in the FE analysis carried out according to Chapter 8, need to be assessed individually for buckling. The checks are to be performed for the following structural elements:

- stiffened and unstiffened panels, including curved panels
- web plate in way of openings
- corrugated bulkheads
- struts, pillars and cross ties

4.1.4 Verification of buckling strength as per the requirements in this section is also applicable for the structure analysed by beam elements when structural elements are subjected to compressive and shear stresses.

4.2 Stiffened and unstiffened panels

4.2.1 General

4.2.1.1 Boundary condition A and boundary condition B as defined in Section 1, Cl.1.3.1.3 is to be used according to Table 4.2.1.

Table 4.2.1: Structural members

Structural elements	Assessment method	Normal panel definition
Longitudinal structures, Refer example Figure 4.2.1.1		
Longitudinally stiffened panels Shell envelope Deck Inner hull Hopper tank side Longitudinal bulkheads	SP-A	Length: between web frames Width: between primary supporting members
Double bottom longitudinal girders in line with longitudinal bulkhead or connected to the hopper tank side	SP-A	Length: between web frames Width: full web depth
Web of double bottom longitudinal girders not in line with longitudinal bulkhead or not connected to the hopper tank side	SP-B (3)	Length: between web frames Width: full web depth
Web of horizontal girders in double side space connected to hopper tank side	SP-A (3)	Length: between web frames Width: full web depth
Web of horizontal girders in double side space not connected to the hopper tank side	SP-B (3)	Length: between web frames Width: full web depth
Web of single-skin longitudinal girders or stringers	UP-B (3)	Plate between local stiffeners/ face plate/ PSM
Transverse structures, Refer Figure 4.2.1.2		

Web of transverse deck frames including brackets	UP-B (3)	Plate between local stiffeners/face plate/PSM
Vertical web in double-side space	SP-B (3)	Length: full web depth Width: between primary supporting members
Irregularly stiffened panels, e.g., web panels in way of the hopper tank and bilge	UP-B (3)	Plate between local stiffeners/face plate/PSM
Double bottom floors	SP-B (4)	Length: full web depth Width: between primary supporting members
Vertical web frame including brackets	UP-B (3)	Plate between vertical web stiffeners/face plate/ PSM
Cross-tie web plate	UP-B (3)	Plate between vertical web stiffeners/face plate/ PSM
Transverse bulkheads, Refer example Figure 4.2.1.3		
Regularly stiffened bulkhead panels inclusive of the secondary buckling stiffeners perpendicular to the regular stiffener (such as carlings)	SP-A	Length: between primary supporting members Width: between primary supporting members
Irregularly stiffened bulkhead panels, e.g. web panels in way of the hopper tank and bilge	UP-B	Plate between local stiffeners/ face plate
Web plate of bulkhead stringers including brackets	UP-B (3)	Plate between web stiffeners or face plate
Cross deck and transverse corrugated bulkheads, [Refer: Figures 4.2.1.4 and Figure 4.2.1.5]		
Upper/lower stool including stiffeners	SP-A	Length: between internal web diaphragms Width: length of stool side
Stool internal web diaphragm	UP-B (3)	Plate between local stiffeners/ face plate/ PSM
Cross deck	SP-A	Plate between local stiffeners/ PSM

Note 1: SP and UP stand for stiffened and unstiffened panels respectively.

Note 2: A and B stand for Method A and Method B respectively.

Note 3: For PSM web panels with one of the long edges along the face plate or along the attached plating without "inline support", i.e., the edge is free to pull in, boundary condition B (SP-B or UP-B) is to be applied. In other cases, boundary condition A (SP-A or UP-A) is applicable.

Note 4: Typically, the short plate edge is attached to the plate flanges and boundary condition A (SP-A or UP-A) is applicable. However, in case one of the long edges is without "in-line support" and is free to pull in, boundary condition B (SP-B or UP-B) is to be applied.

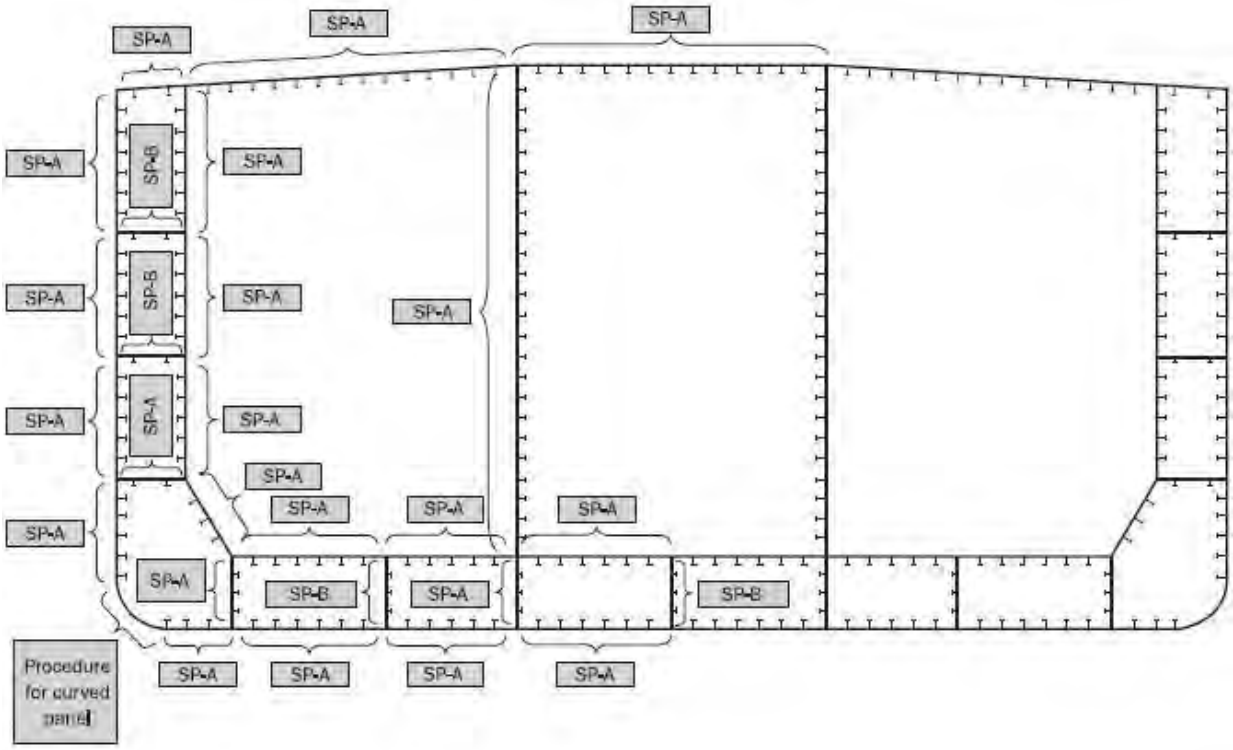

Figure 4.2.1.1: Longitudinal plates for oil tankers

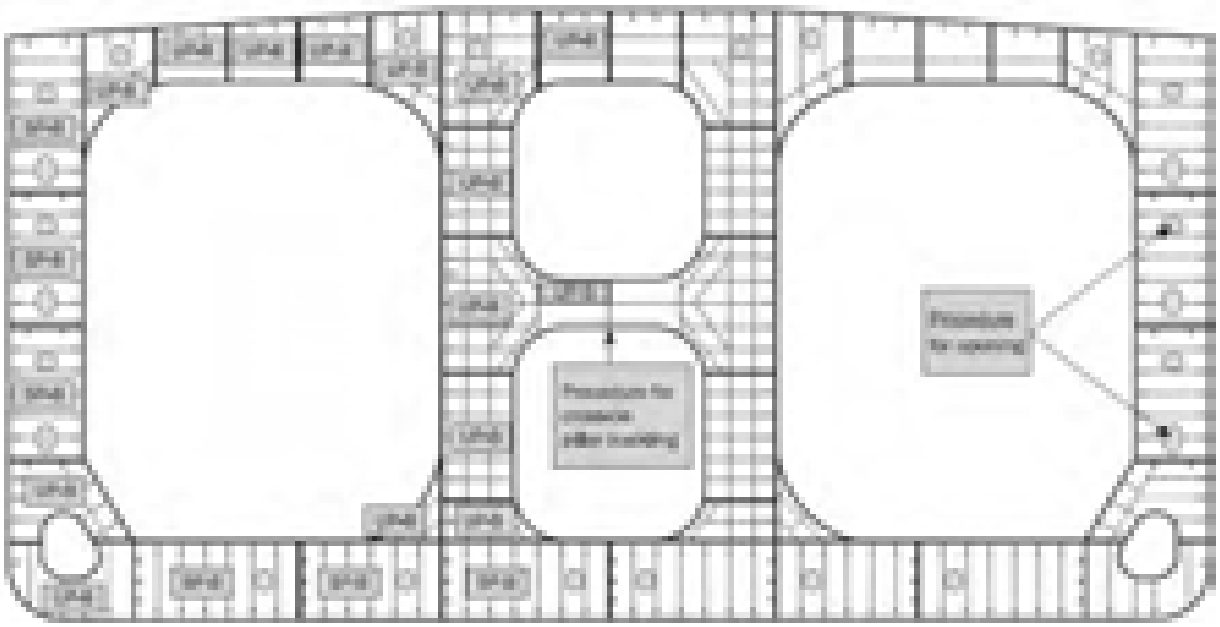

Figure 4.2.1.2: Transverse web frames for oil tankers

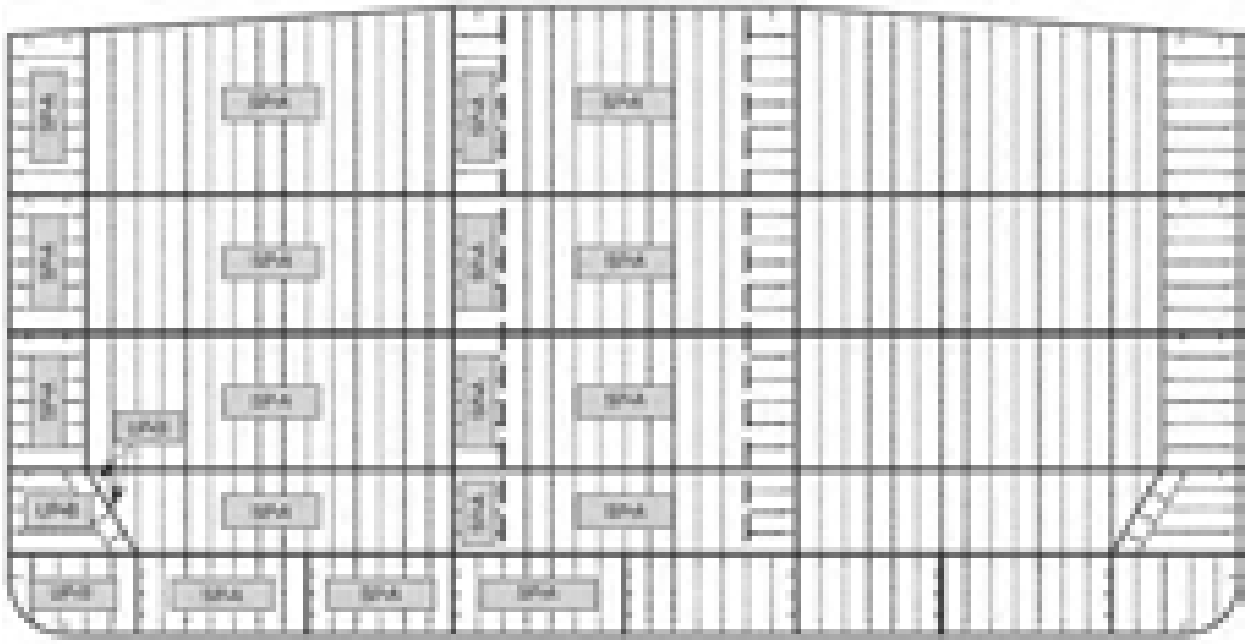

Figure 4.2.1.3: Transverse bulkhead for oil tankers

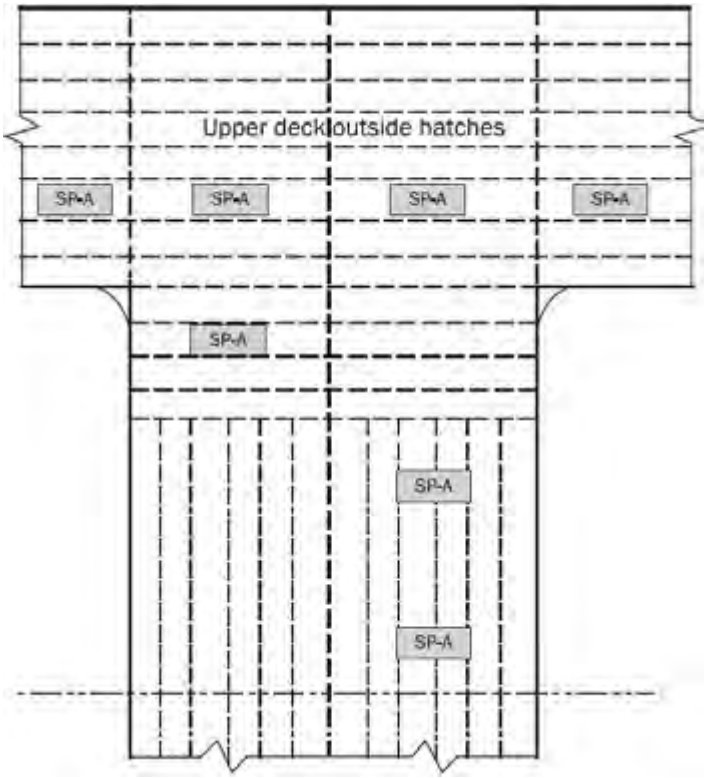

Figure 4.2.1.4: Cross-deck structure

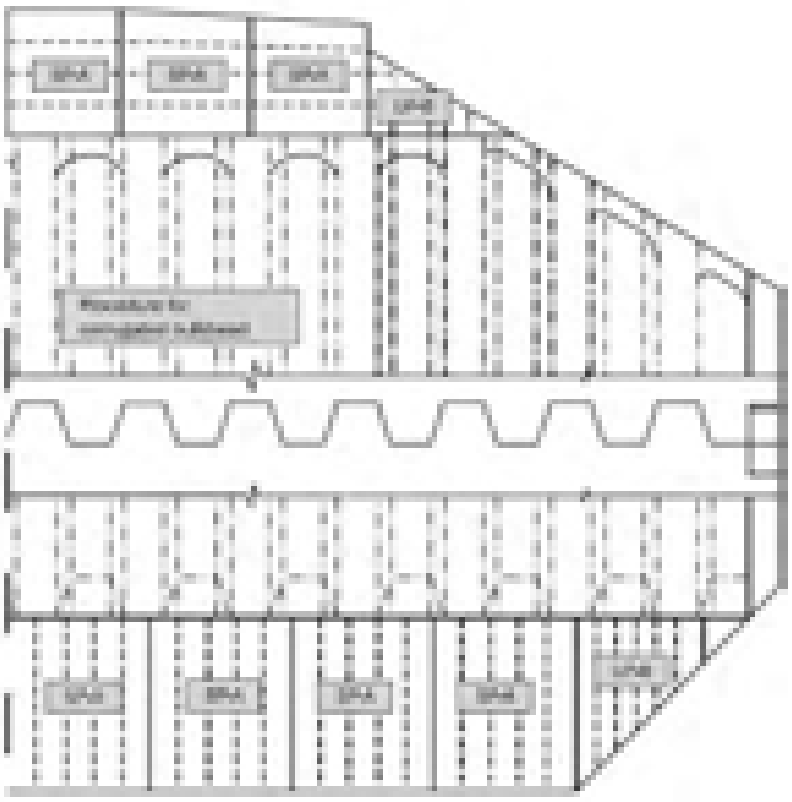

Figure 4.2.1.5: Corrugated bulkhead for bulk carriers

4.2.1.2 Yield stress of the plate panel and stiffener

The panel yield stress $'R_{eH-p}'$ is taken as the minimum value of the specified yield stresses of the elements within the plate panel.

The stiffener yield stress $'R_{eH-s}'$ is taken as the minimum value of the specified yield stresses of the elements within the stiffener.

4.2.1.3 Average thickness of plate panel

Where the plate thickness along a plate panel is not constant, the panel used for the buckling assessment is to be modeled according to Chapter 8 with a weighted average thickness taken as:

$$t_{avr} = \frac{\sum_1^n A_i t_i}{\sum_1^n A_i}$$

where,

A_i = Area of the i-th plate element.

t_i = Net thickness of the i-th plate element.

n = Number of finite elements in the buckling panel.

4.2.2 Stiffened panels

4.2.2.1 To represent the overall buckling behavior, each stiffener with the attached plate is to be modeled as a stiffened panel of the extent defined in Table 4.2.1.

4.2.2.2 If the stiffener properties or stiffener spacing varies within the stiffened panel, the calculations are to be performed separately for all configurations of the panels, i.e., for each stiffener and plate between the stiffeners. Plate thickness, stiffener properties, and stiffener spacing at the considered location need to be assumed for the whole panel.

4.2.2.3 The buckling check of the stiffeners of stiffened panels is only applicable to the stiffeners fitted along the longer side edges of the buckling panel.

4.2.3 Unstiffened panels

4.2.3.1 Irregular plate panel

In way of web frames, stringers, and brackets, the geometry of the panel (i.e., plate bounded by web stiffeners/face plate) may not have a rectangular shape. In this case, for FE analysis, an equivalent rectangular panel is to be defined according to the provisions given in Cl.4.2.3.2 for irregular geometry and Cl.4.2.3.3 for triangular geometry and is to comply with the buckling assessment.

4.2.3.2 Modelling of an unstiffened panel with irregular geometry

Unstiffened panels with irregular geometry are to be idealized into equivalent panels for plate buckling assessment according to the following procedure:

(i) The four corners closest to a right angle, 90 [deg], in the bounding polygon for the plate are identified.

(ii) The distances along the plate-bounding polygon between the corners are calculated, i.e., the sum of all the straight-line segments between the endpoints.

(iii) The pair of opposite edges with the smallest total length is identified, i.e., minimum of $d_1 + d_3$ and $d_2 + d_4$.

(iv) A line joins the middle points of the chosen opposite edges (i.e., a mid-point is defined as the point at half the distance from one end). This line defines the longitudinal direction for the capacity model. The length of the line defines the length of the capacity model 'a' measured from one endpoint.

(v) The length of the shorter side, 'b' in [mm], is to be taken as:

$$b = A/a$$

where,

A = Area of the plate, in [mm^2].

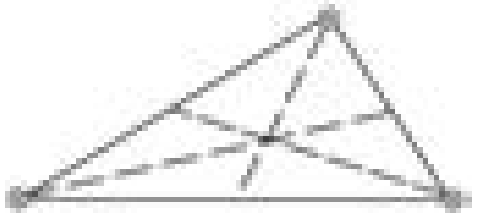
a = Length defined in (iv), in [mm].

(vi) The stresses from the finite element analysis are to be transformed into the local coordinate system of the equivalent rectangular panel. These stresses are to be used for the buckling assessment.

4.2.3.3 Modelling of an unstiffened plate panel with triangular geometry

Unstiffened panels with triangular geometry are to be idealised to equivalent panels for plate buckling assessment according to the following procedure:

(i) Medians are constructed as shown below.



(ii) The longest median is identified. This median the length of which is l_1 in [mm], defines the longitudinal direction for the capacity model.

(iii) The width of the model, l_2, in [mm], is to be taken as:

$$l_2 = A/l_1$$

where,

A = Area of the plate, in [mm^2].

(iv) The lengths of the shorter side, 'b', and of the longer side, 'a', in [mm], of the equivalent rectangular plate panel are to be taken as:

$$b = \frac{l_2}{C_{tr}}$$

$$a = l_1 . C_{tr}$$

where,

$$C_{tr} = 0.4 \frac{l_2}{l_1} + 0.6$$

(v) The stresses from the finite element analysis are to be transformed into the local coordinate system of the equivalent rectangular panel and are to be used for the buckling assessment of the equivalent rectangular panel.

4.2.4 Reference stress

4.2.4.1 The stress distribution is to be taken from the finite element analysis and applied to the buckling model.

4.2.4.2 Stress-based methods for the calculation of reference stresses are defined in Appendix A.

4.2.5 Lateral pressure

4.2.5.1 The lateral pressure applied to the finite element analysis needs to be applied for the buckling assessment.

4.2.5.2 Where the lateral pressure is not constant over a buckling panel defined by a number of finite plate elements, an average lateral pressure, [N/mm^2], is calculated using the following formula:

$$P_{av} = \frac{\sum_{i=1}^{n} A_i \, P_i}{\sum_{i=1}^{n} A_i}$$

where,

A_i = Area of the *i*-th plate element, in [mm^2].

P_i = Lateral pressure of the *i*-th plate element, in [N/mm^2].

n = Number of finite elements in the buckling panel.

4.2.6 Buckling criteria

4.2.6.1 The compressive buckling strength needs to satisfy the following criterion:

$$\eta \leq \eta_{all}$$

where η is the maximum of the relevant utilization factors:

η_{UP-A} = Maximum plate utilisation factor for boundary condition A, Section 5, Cl.5.2.2.

η_{UP-B}= Maximum plate utilisation factor for boundary condition B, Section 5, Cl.5.2.2.

η_{SP-A}= Maximum stiffened panel utilisation factor taken as the maximum of:

- Overall stiffened panel capacity, (See Section 5, Cl.5.2.1).
- Plate capacity calculated as per boundary condition A (See Section 5, Cl. 5.2.2).
- Stiffener buckling strength, (See Section 5, Cl.5.2.3) considering separately the properties (thickness, dimensions), the pressures defined in 4.2.5.2, and the reference stresses of each EPP at both sides of the stiffener.

Note 1: The stiffener buckling capacity check can only be fulfilled when the overall stiffened panel capacity, as defined in Section 5, Cl.5.2.1. is satisfied.

η_{SP-B} = Maximum stiffened panel utilisation factor taken as the maximum of:

- Overall stiffened panel capacity, see Section 5, Cl.5.2.1.
- Plate capacity calculated as per boundary condition B, see Section 5, Cl.5.2.2.
- Stiffener buckling strength, see Section 5, Cl.5.2.3, considering separately the properties (thickness, dimensions), the pressures defined in Cl.4.2.5.2, and reference stresses of each EPP at both sides of the stiffener.

Note 1: The stiffener buckling capacity check can only be fulfilled when the overall stiffened panel capacity, as defined in Section 5, Cl.5.2.1 is satisfied.

4.2.6.2 The web plate of primary supporting members with openings is to satisfy the following criterion:

$$\eta_{\text{opening}} \leq \eta_{\text{all}}$$

where,

η_{opening} = Maximum web plate utilisation factor in way of openings, as defined in Section 5, Cl.5.2.4.

4.3 Corrugated bulkheads

4.3.1 General

Three buckling failure modes are to be assessed on corrugated bulkheads, namely;

- Corrugation overall column buckling.
- Corrugation flange panel buckling.
- Corrugation web panel buckling.

4.3.2 Reference stress

4.3.2.1 Each corrugation flange and web panel are to be assessed.

4.3.2.2 The membrane stresses at the element centroid are to be used.

4.3.2.3 The maximum normal stress parallel to the corrugation, σ_x , is the maximum of the 2 following stresses:

- The normal stress parallel to the corrugation taken at b/2 from the corrugation ends,
- The normal stress parallel to the corrugation within the mid-span of the corrugation.

4.3.2.4 The maximum shear stress is the shear stress which is maximum at the corrugation flange or web at the point b/2 from ends as defined above for the normal stress parallel to the corrugation.

4.3.2.5 In-plane stresses, σ_x and σ_y, and shear stress, τ, are to be taken as element stresses averaged over the width of the considered member (flange or web) at the considered location.

4.3.2.6 When the stress value at b/2 from ends cannot be obtained directly from the finite element, the stress at this location is to be obtained by interpolation on elements in this area. This interpolation needs to be made on elements extending to a distance equal to 3b from the end of the corrugation. The normal stress parallel to the corrugation is to be interpolated as per Chapter 9, Appendix A, i.e., using the 2nd-order polynomial curve. The shear stress at b/2 is obtained by linear interpolation between the elements most close to b/2.

where,

b = width of the considered member of the corrugation, i.e., flange or web.

4.3.2.7 Where more than one plate thickness are used for a flange or web panel, the maximum stress needs to be obtained for each thickness range and is to be checked with the buckling criteria for each thickness.

4.3.3 Overall column buckling

4.3.3.1 The overall buckling failure mode of corrugated bulkheads subjected to axial compression is to be checked for column buckling (e.g., horizontally corrugated bulkheads and vertically corrugated bulkheads subjected to local vertical forces), Refer Table 4.3.3.

Table 4.3.3: Application of overall column buckling for corrugated bulkhead

Bulkhead orientation	Corrugation Orientation	
	Horizontal	Vertical
Longitudinal bulkhead	Required	Required, when subjected to local vertical forces (e.g., crane loads)
Transverse bulkhead	Required	

4.3.3.2 Each corrugation unit within the extension of half flange, web, and half flange, (i.e., single corrugation as shown in grey in Figure 4.3.3), is to satisfy the following criteria:

$$\eta_{overall} \leq \eta_{all}$$

where,

$\eta_{overall}$ = Maximum overall column utilisation factor, as defined in Section 5, Cl. 5.3.1 and Section 5, Cl.5.3.2, considered as a pillar with an unsupported length taken as the length of the corrugation except for vertically corrugated bulkheads where the length, ℓ_{bdg}, is to be applied as per Chapter 3, Section 6, Cl.6.4.

Figure 4.3.3: Single Corrugation

4.3.3.3 End constraint factor, $'f_{end}'$ corresponding to pinned ends is to be applied except for fixed end support to be used in way of stool with the width exceeding two times the depth of the corrugation.

4.3.4 Local buckling

4.3.4.1 The compressive buckling strength of a unit flange and a unit web of corrugation bulkheads is to satisfy the following criterion:

$$\eta_{corr} \leq \eta_{all}$$

where,

η_{corr} = Maximum unit flange or unit web utilisation factor, as defined in Section 5, Cl.5.3.1.

Two stress combinations are to be considered for the application of the above criterion:

- The maximum normal stress parallel to the corrugation, ' σ_x ', combined with the stress perpendicular to the corrugation, ' σ_y ', and with the shear stress, ' τ ', at the location where the maximum normal stress parallel to the corrugation occurs.

- The maximum shear stress, ' τ ', combined with the normal stress parallel to the corrugation, ' σ_x ', and with the stress perpendicular to the corrugation, ' σ_y ', at the location where the maximum shear stress occurs.

The buckling assessment is to be performed for an aspect ratio 'α' equal to 2, and for the thicknesses of the member where the maximum compressive/shear stress occurs (Refer Cl.4.3.2.7).

4.4 Vertically stiffened longitudinal plating in way of the horizontal neutral axis

4.4.1 Buckling criteria

4.4.1.1 Plating

The compressive buckling strength for vertically stiffened longitudinal plating with the shorter edges supported by longitudinal plating/decks and located within $0.7\,z_1$ from the horizontal neutral axis, where 'z_1' is the distance from the horizontal neutral axis to the equivalent deck line or baseline respectively as defined in Chapter 6, Section 2, Cl.2.1.8, may be verified based on the following criterion:

$$\eta_{VSS} \leq \eta_{all}$$

where,

η_{VSS} = Maximum plating utilisation factor calculated according to boundary condition A as defined in Section 5, Cl.5.2.2.1 and considering the following boundary conditions and stress combinations:

(1) The 4 edges are simply supported (Cases 1, 2, and 15 of Section 5, Table 5.2.2.3:

(i) Pure vertical stress:

- The maximum vertical stress of stress elements is used with

$$\alpha = 1 \text{ and } \psi_x = 1.$$

(ii) Maximum vertical stress combined with longitudinal and shear stress:

- The maximum vertical stress in the buckling panel plus the shear and longitudinal stresses at the location where the maximum vertical stress occurs is used with

$$\alpha = 2 \text{ and } \psi_x = \psi_y = 1.$$

- The plate thickness to be considered in the buckling strength check is the one where the maximum vertical stress occurs.

(iii) Maximum shear stress combined with longitudinal and vertical stress:

- The maximum shear stress in the buckling panel plus the longitudinal and vertical stresses at the location where maximum shear stress occurs is used with

$$\alpha = 2 \text{ and } \psi_x = \psi_y = 1.$$

- The plate thickness to be considered in the buckling strength check is the one where the maximum shear stress occurs.

(2) The 2 shorter edges of the plate panel clamped (Cases 11, 12, and 16 of Chapter 9, Section 5, Table 5.2.2.3:

(i) Distributed longitudinal stress associated with vertical and shear stress:

- The actual size of the buckling panel is used to define α.

- The average values for longitudinal, vertical, and shear stresses are to be used.

$$\psi_x = \psi_y = 1.$$

- The plate thickness to be considered in the buckling strength check is the minimum thickness of the buckling panel.

4.4.1.2 Vertical stiffeners

The buckling strength for vertical stiffeners attached to longitudinal plating within $0.7\,z_1$ from the horizontal neutral axis, where $'z_1'$ is the distance from the horizontal neutral axis to the equivalent deck line or baseline respectively as defined in Chapter 6, Section 2, Cl.2.1.8, is to comply with:

$$\eta_{\text{stiffener}} \leq \eta_{\text{all}}$$

where,

$\eta_{\text{stiffener}}$ = Maximum stiffener utilisation factor, as defined in Section 5, Cl.5.2.3.

4.5 Struts, pillars, and cross ties

4.5.1 Buckling criteria

The compressive buckling strength of struts, pillars, and cross ties is to satisfy the following criterion:

$$\eta_{\text{pillar}} \leq \eta_{\text{all}}$$

where,

η_{pillar} = Maximum utilisation factor of struts, pillars, or cross ties, as per Section 5, Cl.5.3.1.

The buckling strength of elementary plate panels of cross ties is to satisfy the following criterion:

$$\eta_{\text{plate}} \leq \eta_{\text{all}}$$

where,

η_{pillar} = Maximum utilisation factor of struts, pillars and cross ties as defined in Section 5, Cl.5.4.

η_{plate} = Maximum plate utilisation factor calculated according to UP-B, as defined in Section 5, Cl.5.2.2.1.

Section 5

Buckling Capacity

Symbols

For symbols not defined in this section, Refer to Chapter 1, Section 2.

A_p = Net sectional area of the stiffener attached plating, in [mm^2], taken as:

$$A_p = s\, t_p$$

A_s = Net sectional area of the stiffener without attached plating, in [mm^2].

a = Length of the longer side of the plate panel, in [mm].

b = Length of the shorter side of the plate panel, in [mm].

b_{eff} = Effective width of the attached plating of a stiffener, in [mm], Refer Cl.5.2.3.5.

b_{eff1} = Effective width of the attached plating of a stiffener, in [mm], without the shear lag effect taken as:

- For $\sigma_x > 0$

— For prescriptive assessment:

$$b_{eff1} = \frac{C_{x1} b_1 + C_{x2} b_2}{2}$$

— For FE analysis,

$$b_{eff} = C_x b$$

- For $\sigma_x \leq 0$

$$b_{eff1} = b$$

b_f = Breadth of the stiffener flange, in [mm].

b_1 , b_2 = Width of plate panel on each side of the considered stiffener, in [mm].

C_{x1}, C_{x2} = Reduction factor defined in Table 5.2.2.3 calculated for the EPP1 and EPP2 on each side of the considered stiffener according to Case 1.

d = Length of the side parallel to the axis of the cylinder corresponding to the curved plate panel as shown in Table 5.2.2.4, in [mm].

d_f = Distance for the extension of flange for L2 profiles, in [mm], as defined in Chapter 2, Section 4, Figure 4.6.2.

e_f = Distance from attached plating to the centre of the flange, in [mm], as shown in Figure 1 to be taken as:

$e_f = h_w$ for flat bar profile.

$e_f = h_w - 0.5t_f$ for bulb profile.

$e_f = h_w + 0.5t_f$ for angle, L2, and Tee profiles.

F_{long} = Coefficient defined in Cl.5.2.2.4.

F_{tran} = Coefficient defined in Cl.5.2.2.5.

h_w = Depth of stiffener web, in [mm], as shown in Figure 5.1.1.

l = Span, in [mm], of stiffener equal to the spacing between primary supporting members or span of side frame equal to the distance between the hopper tank and top wing tank ‘h’ as defined in IRS Part 5, Chapter 1, Section 2, Figure 2.5.7.

R = Radius of curved plate panel, in [mm].

S = Partial safety factor and is to be taken as:

= 1.1 for structures that are exposed to local concentrated loads (e.g., container loads on hatch covers, foundations, etc.).

= 1.15 for stiffeners of bulk carriers with L≥ 150[m] and carrying solid bulk cargoes having a density of 1.0[t/m^3] and above, located on:

- hatchway coamings,
- sloping plate of topside and hopper tanks,
- inner bottom,
- inner side,
- top and bottom stools of transverse bulkheads and
- side shell of single side skin construction.

= 1.0 for all other cases.

R_{eH_p} = Specified minimum yield stress of the plate in [N/mm^2].

R_{eH_s} = Specified minimum yield stress of the stiffener in [N/mm^2].

t_p = Net thickness of plate panel, in [mm].

t_w = Net stiffener web thickness, in [mm].

t_f = Net flange thickness, in [mm].

$x-axis$ = Local axis of a rectangular buckling panel parallel to its long edge.

$y-axis$ = Local axis of a rectangular buckling panel perpendicular to its long edge.

α = Aspect ratio of the plate panel, defined in Table 5.2.2.3 to be taken as:

$$\alpha = \frac{a}{b}$$

β = Coefficient taken as:

$$\beta = \frac{1-\psi}{\alpha}$$

ω = Coefficient taken as:

$$\omega = \min(3;\alpha)$$

σ_x = Stress applied on the edge along the x-axis of the buckling panel, in [N/mm^2].

σ_y = Stress applied on the edge along the y-axis of the buckling panel, in [N/mm^2].

σ_1= Maximum stress, in [N/mm^2].

σ_2 = Minimum stress, in [N/mm^2].

τ_c = Buckling strength in shear, in [N/mm^2]. as defined in Section 5, Cl.5.2.2.3:

τ = Applied shear stress, in [N/mm^2].

σ_E = Elastic buckling reference stress, in [N/mm^2], to be taken as:

- For the application of plate limit state according to Section 5, Cl.5.2.2.1:

$$\sigma_E = \frac{\pi^2 E}{12\,(1-\nu^2)}\left(\frac{t_p}{b}\right)^2$$

- For the application of curved plate panels according to Section 5, Cl.5.2.2.6:

$$\sigma_E = \frac{\pi^2 E}{12\,(1-\nu^2)}\left(\frac{t_p}{d}\right)^2$$

Ψ = Edge stress ratio to be taken as:

$$\Psi = \frac{\sigma_1}{\sigma_2}$$

γ = Stress multiplier factor acting on loads. When the factor is such that the loads reach the interaction formulae, $\gamma = \gamma_c$.

γ_c = Stress multiplier factor at failure.

γ_{GEB} = Stress multiplier factor at global elastic buckling capacity.

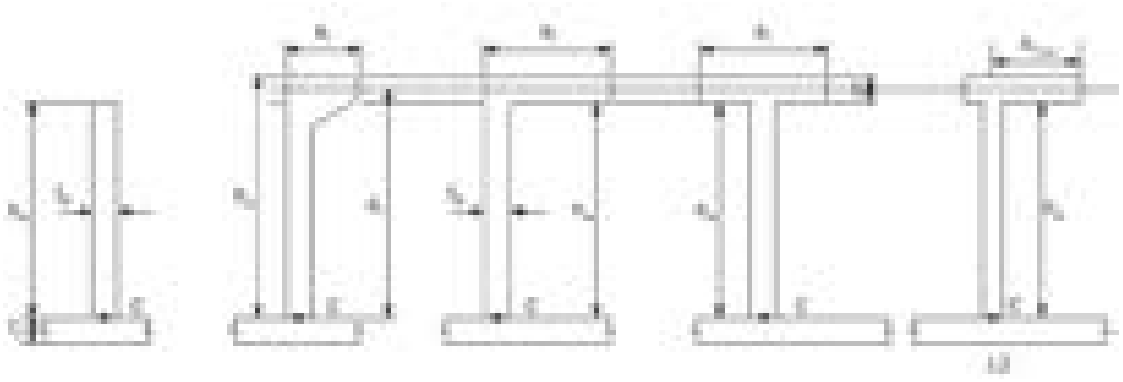


Figure 5.1.1: Stiffener cross-sections

5.1 General

5.1.1 Scope

This section contains the methods for determination of the buckling capacity of plate panels, stiffeners, primary supporting members, struts, pillars, cross ties, and corrugated bulkheads.

5.1.2 For the application of this section, the stresses σ_x, σ_y and τ applied on the structural members are defined in:

- Section 3 for prescriptive requirements.
- Section 4 for FE analysis requirements.

5.1.3 Ultimate buckling capacity

The ultimate buckling capacity is calculated by applying the actual stress combination and then increasing or decreasing the stresses proportionally until the interaction formulae defined in Section 5, Cl.5.2.1, Cl. 5.2.2.1, and Cl.5.2.3.4 are equal to 1.0.

5.1.4 Buckling utilization factor

The buckling utilisation factor of the structural member is equal to the highest utilisation factor obtained for the different buckling modes.

5.1.5 Lateral pressure

The lateral pressure is to be considered a constant in the buckling strength assessment.

5.2 Buckling capacity of plates and stiffeners

5.2.1 Overall stiffened panel capacity

5.2.1.1 The elastic stiffened panel limit state is based on the following interaction formula, which sets a precondition for the buckling check of stiffeners as per Cl.5.2.3.4:

$$\frac{\gamma_c}{\gamma_{GEB}} = 1$$

with the corresponding buckling utilization factor defined as:

$$\eta_{overall} = \frac{1}{\gamma_c}$$

where the stress multiplier factor corresponding to the global elastic buckling capacity, γ_{GEB}, is to be calculated based on the following formulae:

$\gamma_{GEB} = \gamma_{GEB,bi+\tau}$ for $\tau \neq 0$ and ($\sigma_x > 0$ or $\sigma_y > 0$)

$\gamma_{GEB} = \gamma_{GEB,bi}$ for $\tau = 0$ and ($\sigma_x > 0$ or $\sigma_y > 0$)

$\gamma_{GEB} = \gamma_{GEB,\tau}$ for $\tau \neq 0$ and ($\sigma_x \leq 0$ or $\sigma_y \leq 0$)

where $\gamma_{GEB,bi+\tau}$, $\gamma_{GEB,bi}$ and $\gamma_{GEB,\tau}$ are the stress multiplier factors for different load combinations as defined in Section 5, Cl.5.2.1.2, Cl.5.2.1.3, and Cl.5.2.1.4, respectively. For the calculation of $\gamma_{GEB,bi+\tau}$, $\gamma_{GEB,bi}$ and $\gamma_{GEB,\tau}$, neither σ_x nor σ_y is to be taken less than 0.

σ_x, σ_y = Applied normal stresses to the plate panel, in [N/mm^2], to be taken as defined in Cl.5.2.2.7.

τ = Applied shear stress, in [N/mm^2], to be taken as defined in Cl.5.2.2.7.

5.2.1.2 The stress multiplier factor $\gamma_{GEB,bi}$ for the stiffened panel subjected to biaxial loads is taken as:

$$\gamma_{GEB,bi} = \frac{\pi^2}{L_{B1}^2 L_{B2}^2} \frac{[D_{11}L_{B2}^4 + 2(D_{12} + D_{33})n^2 L_{B1}^2 L_{B2}^2 + n^4 D_{22} L_{B1}^4]}{L_{B2}^2 N_x + n^2 L_{B1}^2 N_y}$$

where

N_x = Load per unit length applied on the edge along the x-axis of the stiffened panel, in [N/mm], taken as:

$$N_x = \sigma_{x,av} \frac{(t_p s + t_w h_w + t_f b_f)}{s}$$

For stiffened panels fitted with U-type stiffeners, stiffener spacing 's' is taken as:

$$s = b_1 + b_2$$

where b_1 and b_2 are as defined in Figure 5.2.2.5.

N_y = Load per unit length applied on the edge along the y-axis of the stiffened panel, in [N/mm], taken as:

$$N_y = c\,\sigma_y t_p$$

L_{B1} = Stiffener span, in [mm], equal to the spacing between primary supporting members, i.e., $L_{B1} = l$

For vertically stiffened longitudinal plating with shorter edges supported by longitudinal plating/decks and located within $0.7\,z_1$ from the horizontal neutral axis, where 'z_1' is the distance from the horizontal neutral axis to the

equivalent deck line or baseline respectively as defined in Chapter 6, Section 2, Cl.2.1.8,

$L_{B1} = 0.8\,l$

L_{B2} = Width of the stiffened panel, in [mm], taken as 6 times the stiffener spacing, i.e., $L_{B2} = 6s$.

n = Number of half-waves along the direction perpendicular to the stiffener axis. The factor $\gamma_{GEB,bi}$ is to be minimized with respect to the wave parameter n, i.e., to be taken as the smallest value larger than zero.

c = Factor taking into account the stresses in the attached plating acting perpendicular to the stiffener axis:

$c = 0.5(1 + \psi)$ for $0 \le \psi \le 1$

$c = \frac{1}{2(1-\psi)}$ for $\psi < 0$

ψ = Edge stress ratio for Case 2 according to Table 5.2.2.3

$\sigma_{x,av}$ = Average stress, in [N/mm^2], for both plate and stiffener with Poisson correction, taken as:

$\sigma_{x,av} = \sigma_x - \upsilon\, c\, \sigma_y A_s/(A_p + A_s) \ge 0$ [for $\sigma_x > 0$ and $\sigma_y > 0$]

$\sigma_{x,av} = \sigma_x$ [for $\sigma_x \le 0$ and $\sigma_y \le 0$]

D_{11}, D_{12}, D_{22}, D_{33} = Bending stiffness coefficients, in [N-mm], of the stiffened panel, defined in general as:

$$D_{11} = \frac{E\, I_{eff}\, 10^4}{s}$$

$$D_{12} = \frac{E\, t_p{}^3 \nu}{12\,(1-\nu^2)}$$

$$D_{22} = \frac{E\, t_p{}^3}{12\,(1-\nu^2)}$$

$$D_{33} = \frac{E\, t_p{}^3}{12\,(1+\upsilon)}$$

For stiffened panels fitted with U-type stiffeners, D_{12} and D_{22} are defined as:

$$D_{22} = \frac{E\, t_p{}^3}{12\,(1-\nu^2)} \times \left[1.2 + 4.8 \times Min\left(1.0, \frac{b_1^2}{h_w(b_1+b_2)}\right) \times Min\left(1.0, \left(\frac{t_w}{t_p}\right)^3\right)\right]$$

$$D_{12} = \nu\, D_{22}$$

where

h_w = Breadth of U-type stiffener web as defined in Figure 5.2.2.5.

I_{eff} = Moment of inertia, in [cm^4], of the stiffener including the effective width of attached plating, the same as 'I' defined in Cl.5.2.3.4.

5.2.1.3 The stress multiplier factor $\gamma_{GEB,\tau}$ for the stiffened panel subjected to pure shear load is taken as:

$$\gamma_{GEB,\tau} = \frac{\sqrt[4]{D_{11}^3 D_{22}}}{(L_{B1}/2)^2 N_{xy}}\left[8.125 + 5.64\sqrt{\frac{(D_{12}+D_{33})^2}{D_{11}D_{22}}} - 0.6\frac{(D_{12}+D_{33})^2}{D_{11}D_{22}}\right] \text{ for } D_{11}D_{22} \ge (D_{12}+D_{33})^2$$

$$\gamma_{GEB,\tau} = \frac{\sqrt{2D_{11}(D_{12}+D_{33})}}{(L_{B1}/2)^2 N_{xy}}\left[8.3 + 1.525\frac{D_{11}D_{22}}{(D_{12}+D_{33})^2} - 0.493\frac{D_{11}^2 D_{22}^2}{(D_{12}+D_{33})^4}\right] \text{ for } D_{11}D_{22} < (D_{12}+D_{33})^2$$

where

$N_{xy} = \tau t_p$

5.2.1.4 The stress multiplier factor $\gamma_{GEB,bi+\tau}$ for the stiffened panel subjected to combined loads is taken as:

$$\gamma_{GEB,bi+\tau} = \frac{1}{2}\gamma_{GEB,\tau}^2\left[-\frac{1}{\gamma_{GEB,bi}} + \sqrt{\frac{1}{\gamma_{GEB,bi}^2} + 4\frac{1}{\gamma_{GEB,\tau}^2}}\right]$$

where $\gamma_{GEB,bi}$ and $\gamma_{GEB,\tau}$ are as defined in Cl. 5.2.1.2 and Cl.5.2.1.3, respectively.

5.2.2 Plate Capacity

5.2.2.1 Plate limit state

The plate limit state is based on the following interaction formulae:

$$\left(\frac{\gamma_{c1}\sigma_x S}{\sigma'_{cx}}\right)^{e_o} - B\left(\frac{\gamma_{c1}\sigma_x S}{\sigma'_{cx}}\right)^{e_o/2}\left(\frac{\gamma_{c1}\sigma_y S}{\sigma'_{cy}}\right)^{e_o/2} + \left(\frac{\gamma_{c1}\sigma_y S}{\sigma'_{cy}}\right)^{e_o} + \left(\frac{\gamma_{c1}|\tau|S}{\tau'_c}\right)^{e_o} = 1$$

$$\left(\frac{\gamma_{c2}\sigma_x S}{\sigma'_{cx}}\right)^{2/\beta_p^{0.25}} + \left(\frac{\gamma_{c2}|\tau|S}{\tau'_c}\right)^{2/\beta_p^{0.25}} = 1 \text{ [For } \sigma_x \geq 0]$$

$$\left(\frac{\gamma_{c3}\sigma_y S}{\sigma'_{cy}}\right)^{2/\beta_p^{0.25}} + \left(\frac{\gamma_{c3}|\tau|S}{\tau'_c}\right)^{2/\beta_p^{0.25}} = 1 \text{ [For } \sigma_y \geq 0]$$

$$\frac{\gamma_{c4}|\tau|S}{\tau'_c} = 1$$

with

$$\gamma_c = \min(\gamma_{c1}, \gamma_{c2}, \gamma_{c3}, \gamma_{c4})$$

where,

σ_x, σ_y = Applied normal stress to the plate panel, in [N/mm^2], to be taken as defined in Cl.5.2.2.7.

τ = Applied shear stress to the plate panel, in [N/mm^2].

σ_{cx}' = Ultimate buckling stress, in [N/mm^2], in the direction parallel to the longer edge of the buckling panel as defined in Cl.5.2.2.3.

σ_{cy}' = Ultimate buckling stress, in [N/mm^2], in the direction parallel to the shorter edge of the buckling panel as defined in Cl.5.2.2.3.

$\gamma_{c1}, \gamma_{c2}, \gamma_{c3}, \gamma_{c4}$ = Stress multiplier factors at failure for each of the above different limit states. γ_{c2} and γ_{c3} are only to be considered when $\sigma_x \geq 0$ and $\sigma_y \geq 0$ respectively.

B = Coefficient as given in Table 5.2.2.1.

e_o = Coefficient as given in Table 5.2.2.1

β_p = Plate slenderness parameter to be taken as:

$$\beta_p = \frac{b}{t_p}\sqrt{\frac{R_{eH_P}}{E}}$$

Table 5.2.2.1: Definition of coefficients B and e_o

Applied Stress	B	e_o
$\sigma_x \geq 0$ and $\sigma_y \geq 0$	$0.7 - 0.3\beta_p/\alpha^2$	$2/\beta_p^{0.25}$
$\sigma_x < 0$ or $\sigma_y < 0$	1.0	2.0

5.2.2.2 Reference degree of slenderness

The reference degree of slenderness is to be taken as:

$$\lambda = \sqrt{\frac{R_{eH_p}}{K\,\sigma_E}}$$

where,

K = Buckling factor, as defined in Table 5.2.2.3.and Table 5.2.2.4.

5.2.2.3 Ultimate buckling stresses

The ultimate buckling stresses of plate panels, in [N/mm^2], are to be taken as:

$$\sigma'_{cx} = C_x\, R_{eH_p}$$

$$\sigma'_{cy} = C_y\, R_{eH_p}$$

The ultimate buckling stress of plate panels subject to shear, in [N/mm^2], is to be taken as:

$$\tau'_c = C_\tau \frac{R_{eH_p}}{\sqrt{3}}$$

where,

C_x, C_y, C_τ = Reduction factors, as defined in Table 5.2.2.3.

- For the 1st Equation of Cl.5.2.2.1, when $\sigma_x < 0$ or $\sigma_y < 0$, the reduction factors are to be taken as:

$$C_x = C_y = C_\tau = 1$$

- For the other cases:

— For SP-A and UP-A, C_y is calculated according to Table 5.2.2 (c) by using:

$$c_1 = \left(1 - \frac{1}{\alpha}\right) \geq 0$$

— For SP-B and UP-B, C_y is calculated according to Table 5.2.2.3 by using:

$$c_1 = 1$$

— For vertically stiffened longitudinal plating with shorter edges supported by longitudinal plating/decks and located within $0.7\ z_1$, from the horizontal neutral axis, where $'z_1'$ is the distance from the horizontal neutral axis to the equivalent deck line or baseline respectively as defined in Chapter 6, Section 2, Cl.2.1.8: C_y is calculated according to Table 5.2.2.3 by using:

$$c_1 = \left(1 - \frac{1}{\alpha}\right) \geq 0$$

— For corrugation of corrugated bulkheads, C_y is calculated according to Table 5.2.2.3 by using:

$$c_1 = \left(1 - \frac{1}{\alpha}\right) \geq 0$$

The boundary conditions for plates are to be considered as simply supported, see Cases 1, 2, and 15 of Table 5.2.2.3. If the boundary conditions differ significantly from simple support, a more appropriate boundary condition can be applied according to the different cases of Table 5.2.2.3 subject to the agreement of IRS.

5.2.2.4 Correction factor (F_{long})

The correction factor $'F_{long}'$ depending on the edge stiffener types on the longer side of the buckling panel are defined in Table 5.2.2.2. An average value of F_{long} is to be used for plate panels having different edge stiffeners. For stiffener types other than those mentioned in Table 5.2.2.2, the value of 'c' is to be agreed upon by IRS. In such a case, the value of 'c' higher than those mentioned in Table 5.2.2.2 can be used, provided it is verified by buckling strength check of the panel using non-linear FE analysis and deemed appropriate by IRS.

5.2.2.5 Correction factor (F_{tran})

The correction factor F_{tran} is to be taken as:

• For transversely framed EPP of single side skin bulk carrier, between the hopper and top wing tank with the shorter edges supported by longitudinal plating/decks and located within $0.7z_1$, from the horizontal neutral axis, where z_1, is the distance from the horizontal neutral axis to equivalent deck line or baseline respectively as defined in Chapter 6, Section 2, Cl.2.1.8.

- F_{tran}= 1.25 when the two adjacent frames are supported by one tripping bracket fitted in way of the adjacent plate panels.
- F_{tran} = 1.33 when the two adjacent frames are supported by two tripping brackets each fitted in way of the adjacent plate panels.
- F_{tran} = 1.15 elsewhere.
- For the attached plate of a U-type stiffener fitted on a hatch cover:

$$F_{tran} = \text{Max}(3 - 0.008(F_{tran0} - 6)^2, 1.0) \leq 2.25$$

where

- For EPP b_2

$$F_{tran0} = \text{Min}\left(\frac{b_2}{b_1} + \frac{6b_2^2}{\pi^2 h_w (b_1 + b_2)}\left(\frac{t_w}{t_p}\right)^3, 6.0\right)$$

- For EPP b_1

$$F_{tran0} = \text{Min}\left(\frac{b_1}{b_2} + \frac{6b_1^2}{\pi^2 h_w (b_2 + b_1)}\left(\frac{t_w}{t_p}\right)^3, 6.0\right)$$

with b_1, b_2 and h_w as defined in Figure 5.2.2.5.

Coefficient '*F*', defined in Case 2 of Table 5.2.2.3 is to be replaced by the following formula:

$$F = \left[1 - \left(\frac{K_y}{0.91F_{tran}} - 1\right)/\lambda_p^2\right] c_1 \geq 0$$

• For other cases: F_{tran} = 1

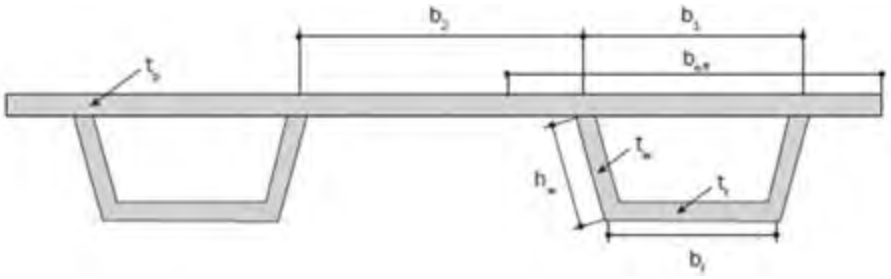

Figure 5.2.2.5: Example of hatch cover fitted with U-type stiffener

5.2.2.6 Curved plate panels

This requirement for the curved plate limit state is applicable when $R/t_p \le 2500$. Otherwise, the requirement for plate limit state given in Section 5, Cl.5.2.2.1 is applicable.

The curved plate limit state is based on the following interaction formula:

$$\left(\frac{\gamma_c\sigma_{ax}S}{C_{ax}R_{eH_P}}\right)^{1.25} - 0.5\left(\frac{\gamma_c\sigma_{ax}S}{C_{ax}R_{eH_P}}\right)\left(\frac{\gamma_c\sigma_{tg}S}{C_{tg}R_{eH_P}}\right) + \left(\frac{\gamma_c\sigma_{tg}S}{C_{tg}R_{eH_P}}\right)^{1.25} + \left(\frac{\gamma_c\tau\sqrt{3}S}{C_\tau R_{eH_P}}\right)^2 = 1$$

where,

σ_{ax} = Applied axial stress to the cylinder corresponding to the curved plate panel, in [N/mm^2]. In the case of tensile axial stresses, σ_{ax}= 0.

σ_{tg} = Applied tangential stress to the cylinder corresponding to the curved plate panel, in [N/mm^2]. In the case of tensile tangential stresses, σ_{tg}= 0.

C_{ax}, C_{tg}, C_{τ} = Buckling reduction factor of the curved plate panel, as defined in Table 5.2.2.4.

The stress multiplier factor, γ_c, of the curved plate panel need not be taken less than the stress multiplier factor, γ_c, for the expanded plate panel according to Section 5, Cl.5.2.2.1.

Edge boundary conditions: – – – – – – – – – Plate edge free Plate edge simply supported Plate edge clamped			

5.2.2.7 Applied normal and shear stresses to plate panels

The normal stresses, σ_x and σ_y, in [N/mm^2], to be applied for the overall stiffened panel capacity and plate panel capacity calculation as given in Section 5, Cl.5.2.1.1 and Cl.5.2.2.1 respectively, are to be taken as follows:

- For FE analysis, the reference stresses as defined in Section 4, Cl.2.4.

- For prescriptive assessment of the overall stiffened panel capacity and the plate panel capacity, the axial or transverse compressive stresses calculated according to Section 3, Cl.3.2.2, at load calculation points of the considered stiffener or the considered elementary plate panel, as defined in Chapter 3, Section 7, Cl.7.6. and Cl.7.5, respectively. However, in case of transverse stiffening arrangement, the transverse compressive stress used for the assessment of the overall stiffened panel capacity is to be taken as the compressive stress calculated at load calculation points of the stiffener attached plating, as defined in Chapter 3, Section 7, Cl.7.5.

- For grillage analysis where the stresses are obtained based on beam theory, the stresses taken as:

$$\sigma_x = \frac{\sigma_{xb} + \nu\sigma_{yb}}{1 - \nu^2}$$

$$\sigma_y = \frac{\sigma_{yb} + \nu\sigma_{xb}}{1 - \nu^2}$$

where,

σ_{xb} , σ_{yb} = Stress, in [N/mm^2], from grillage beam analysis respectively along x or y-axis of the plate attached to the PSM web.

The shear stress τ, in [N/mm^2], to be applied for the overall stiffened panel capacity and plate panel capacity calculation as given in Cl.5.2.1.1 and Cl.5.2.2.1 respectively, are to be taken as follows:

- For FE analysis, the reference shear stresses as defined in Section 4, Cl.2.4.

- For prescriptive assessment of the plate panel capacity, the shear stresses calculated according to Section 3, Cl.3.2.2, at load calculation points of the considered elementary plate panel, as defined in Chapter 3, Section 7, Cl.7.5.

- For prescriptive assessment of the overall stiffened panel capacity, the shear stresses are calculated according to Section 3, Cl.3.2.2, at the following load calculation point:

—At the middle of the full span, 'l', of the considered stiffener.

—At the intersection point between the stiffener and its attached plating

• For grillage beam analysis, $\tau = 0$ in the plate attached to the PSM web.

5.2.3 Stiffeners

5.2.3.1 Buckling modes

The following buckling modes are to be checked:

• Stiffener-induced failure (SI).

• Associated plate-induced failure (PI).

5.2.3.2 Web thickness of the flat bar

To account for the decrease of the stiffness due to local lateral deformation, the effective web thickness of flat bar stiffener, in [mm], are to be used in Section 5, Cl.5.2.1.1 and Cl.5.2.3.4 for the calculation of the net sectional area, As, the net section modulus, Z, and the moment of inertia, I, of the stiffener and is taken as:

$$t_{w-red} = t_w \left(1 - \frac{2\pi^2}{3}\left(\frac{h_w}{s}\right)^2 \left(1 - \frac{b_{eff}}{s}\right)\right)$$

5.2.3.3 Idealization of bulb profile

Bulb profiles are to be considered as equivalent angle profiles, as defined in Chapter 3, Section 7, Cl.7.4.

5.2.3.4 Ultimate buckling capacity

When $\sigma_a + \sigma_b + \sigma_w > 0$, the ultimate buckling capacity for stiffeners is to be checked according to the following interaction formula:

$$\frac{\gamma_c \sigma_a + \sigma_b + \sigma_w}{R_{eH}} S = 1$$

where,

σ_a = Effective axial stress, in [N/mm^2], at mid-span of the stiffener, acting on the stiffener with its attached plating.

$$\sigma_a = \left(\frac{s\, t_p + A_s}{b_{eff1}\, t_p + A_s}\right)\sigma_x$$

σ_x = Nominal axial stress, in [N/mm^2], acting on the stiffener with its attached plating.

• For FE analysis, σ_x is the FE-corrected stress as defined in Section 5, Cl.5.2.3.6 in the attached plating in the direction of the stiffener axis.

• For prescriptive assessment, σ_x is the axial stress calculated according to Section 3, Cl.3.2.2 at the load calculation point of the stiffener, as defined in Chapter 3, Section 7, Cl.7.6.

• For grillage beam analysis, σ_x is the stress acting along the x-axis of the attached buckling panel.

R_{eH} = Specified minimum yield stress of the material, in [N/mm^2].

$R_{eH} = R_{eH-s}$ for stiffener-induced failure (SI).

$R_{eH} = R_{eH-p}$ for plate-induced failure (PI).

σ_b = Bending stress in the stiffener, in [N/mm^2].

$$\sigma_b = \frac{M_0 + M_1 + M_2}{1000\, Z}$$

Z = Net section modulus of the stiffener, in [cm^3], including effective width of plating according to Section 5, Cl.5.2.3.5, to be taken as:

• The section modulus calculated at the top of the stiffener flange for stiffener-induced failure (SI).

• The section modulus calculated at the attached plating for plate-induced failure (PI).

C_{PI} = Plate-induced failure pressure coefficient:

C_{PI} = 1 if the lateral pressure is applied on the side opposite to the stiffener.

C_{PI} = -1 if the lateral pressure is applied on the same side as the stiffener.

C_{SI} = Stiffener-induced failure pressure coefficient:

C_{SI} = 1 if the lateral pressure is applied on the side opposite to the stiffener.

C_{SI} = -1 if the lateral pressure is applied on the same side as the stiffener.

M_1 = Bending moment, in [N-mm], due to the lateral load P:

$M_1 = C_i \frac{|P|\, s\, l^2}{24 \times 10^3}$ for continuous stiffener

$M_1 = C_i \frac{|P|\, s\, l^2}{8 \times 10^3}$ for sniped stiffener

$M_1 = C_i \frac{|P|\, s\, l^2}{14.2 \times 10^3}$ for stiffener sniped at one end and continuous at the other end

P = Lateral load, in [kN/m^2].

• For FE analysis, P is the average pressure as defined in Chapter 9, Section 4, Cl.4.2.5.2 in the attached plating.

• For prescriptive assessment, P is the pressure calculated at the load calculation point of the stiffener, as defined in Chapter 3, Section 7, Cl.7.6.

C_i = Pressure coefficient:

$C_i = C_{SI}$ for stiffener-induced failure (SI).

$C_i = C_{PI}$ for plate-induced failure (PI).

M_2 = Bending moment, in [N-mm], due to eccentricity of sniped stiffeners, to be taken as:

$M_2 = 0$ for continuous stiffeners

$M_2 = C_{snip} w_{na} \gamma \sigma_x (A_p + A_s)$ for stiffeners sniped at one or both ends.

C_{snip} = Coefficient to account for the end effect of the stiffener sniped at one or both ends, to be taken as:

$C_{snip} = -1.2$ for stiffener induced failure (SI)

$C_{snip} = 1.2$ for plate induced failure (PI)

M_o = Bending moment, in [N-mm], due to the lateral deformation w of stiffener:

$M_O = F_E C_{sl} \left(\frac{\gamma}{\gamma_{GEB} - \gamma}\right) w_o$ with precondition $(\gamma_{GEB} - \gamma) > 0$

where γ_{GEB} is the stress multiplier factor of global elastic buckling capacity as defined in Section 5, Cl.5.2.1.

F_E = Ideal elastic buckling force of the stiffener, in [N].

$$F_E = \left(\frac{\pi}{l}\right)^2 EI \,.\, 10^4$$

C_{sl} = Deformation reduction factor to account for global slenderness, to be taken as:

$C_{sl} = 1 - \frac{1}{12}\lambda_G^4$ for $\lambda_G \leq 1.56$

$C_{sl} = 3/\lambda_G^4$ for $\lambda_G > 1.56$

λ_G = The reference degree of global slenderness of the stiffened panel, to be taken as:

$$\lambda_G = \sqrt{\frac{\gamma_{ReH}}{\gamma_{GEB}}}$$

where

$$\gamma_{ReH} = \frac{\min(R_{eH_p},\, R_{eH_s})}{\sqrt{\sigma_{x,av}^2 + \sigma_y^2 - \sigma_{x,av}\sigma_y + 3\tau_{xy}^2}}$$

I = Moment of inertia, in [cm^4], of the stiffener including effective width of attached plating according to Section 5, Cl.5.2.3.5 'I' has to comply with the following requirement:

$$I \geq \frac{s\, t_p^3}{12 \times 10^4}$$

t_p = Net thickness of plate, in [mm], to be taken as:

• For prescriptive requirements: the mean thickness of the two attached plating panels,

• For FE analysis: the thickness of the considered EPP on one side of the stiffener.

w_0 = Assumed imperfection, in [mm], to be taken as:

$$w_0 = l/1000$$

w_{na} = Distance in [mm], from the mid-point of attached plating to the neutral axis of the stiffener calculated with the effective width of the attached plating according to Section 5, Cl.5.2.3.5.

σ_W = Stress due to torsional deformation, in [N/mm^2], to be taken as:

- For stiffener induced failure (SI)
  - o For $\sigma_a > 0$

$$\sigma_W = E y_w e_f \Phi_o \left(\frac{m_{tor}\pi}{l_{tor}}\right)^2 \left[\frac{1}{1-\frac{\gamma\sigma_a}{\sigma_{ET}}} - 1\right]$$

with the precondition that $\sigma_{ET} - \gamma\sigma_a > 0$

  - o For $\sigma_a \leq 0$

$$\sigma_W = 0$$

- For plate induced failure (PI)

$$\sigma_W = 0$$

l_{tor} = Stiffener span in [mm], distance equal to the spacing between primary supporting members, i.e., $l_{tor} = l$. When the stiffener is supported by tripping brackets, l_{tor} should be taken as the maximum spacing between the adjacent primary supporting members and fitted tripping brackets.

y_w = Distance, in [mm], from the centroid of the stiffener cross-section to the free edge of the stiffener flange, to be taken as:

$y_w = \frac{t_w}{2}$ For flat bar

$y_w = b_f - \frac{h_w t_w^2 + t_f b_f^2}{2A_s}$ For angle and bulb profile

$y_w = b_{f-out} + 0.5t_w - \frac{h_w t_w^2 + t_f(b_f^2 - 2b_f d_f)}{2A_s}$ For L2 profile

$y_w = \frac{b_f}{2}$ For T-profile

Φ_o = Coefficient to be taken as:

$$\Phi_o = \frac{l_{tor}}{m_{tor} h_w} 10^{-4}$$

σ_{ET} = Reference stress for torsional buckling, in [N/mm^2]:

$$\sigma_{ET} = \frac{E}{I_p}\left[\left(\left(\frac{m_{tor}\pi}{l_{tor}}\right)^2 I_p \cdot 10^2 + \frac{1}{2(1+\nu)} I_T + \left(\frac{l_{tor}}{m_{tor}\pi}\right)^2 \epsilon \cdot 10^{-4}\right)\right]$$

I_p = Net polar moment of inertia of the stiffener, in [cm^4], about point C as shown in Figure 5.1.1, as defined in Table 5.2.3.2.

Table 5.2.3.2: Moments of inertia

Parameter	Flat bars (1)	Bulb, angle, L2, and T profiles
I_p	$\frac{h_w^3 t_w}{3\times 10^4}$	$\left(\frac{A_w(e_f - 0.5t_f)^2}{3} + A_f e_f^2\right) 10^{-4}$
I_t	$\frac{t_w^3 h_w}{3\times 10^4}\left(1 - 0.63\frac{t_w}{h_w}\right)$	$\frac{(e_f - 0.5t_f)t_w^3}{3\times 10^4}\left(1 - 0.63\frac{t_w}{e_f - 0.5t_f}\right) + \frac{b_f t_f^3}{3\times 10^4}\left(1 - 0.63\frac{t_f}{b_f}\right)$
I_w	$\frac{h_w^3\, t_w^3}{36\times 10^6}$	for the bulb, angle and L2 profiles (2) $\frac{A_f^3 + A_w^3}{36\times 10^6} + \frac{e_f^2}{10^6}\left(\frac{A_f b_f^2 + A_w t_w^2}{3} - \frac{(A_f(b_f - 2d_f) + A_w t_w)^2}{4(A_f + A_w)} - A_f d_f(b_f - d_f)\right)$ for T profiles $\frac{b_f^3\, t_f e_f^2}{12\times 10^6}$

(1) t_w is the net web thickness, in [mm]. t_{w-red} as defined in Section 5, Cl.5.2.3.2 is not to be used in this Table.
(2) d_f is to be taken as 0 for bulb and angle profiles.

I_t = Net St. Venant's moment of inertia of the stiffener, in [cm^4], as defined in Table 5.2.3.2.

I_ω = Net sectorial moment of inertia of the stiffener, in [cm^6], about point C as shown in Figure 5.1.1, as defined in Table 5.2.3.2.

m_{tor} = Number of half waves within l_{tor} , taken as a positive integer in order to give the smallest reference stress for torsional buckling.

ε = Degree of fixation in [mm^2], to be taken as:

$$\varepsilon = \left(\frac{3b}{{t_p}^3} + \frac{2h_w}{{t_w}^3}\right)^{-1}$$

For angle, bulb, L2, and T profile.

$$\varepsilon = \frac{{t_p}^3}{3b}$$

For flat bars

A_w = Net web area, in [mm^2].

A_f = Net flange area, in [mm^2].

5.2.3.5 Effective width of attached plating

The effective width of attached plating of stiffeners, b_{eff}, in [mm], is to be taken as:

• For $\sigma_x > 0$:

- For FE analysis,

$$b_{eff} = \min(C_x b, \chi_s s)$$

- For prescriptive assessment,

$$b_{eff} = \min\left(\frac{C_{x1} b_1 + C_{x2} b_2}{2}, \chi_s s\right)$$

• For $\sigma_x \leq 0$:

$$b_{eff} = \chi_s s$$

where,

χ_s = Effective width coefficient to be taken as:

$$\chi_s = min\left[\frac{1.12}{1+\frac{1.75}{\left(\frac{l_{eff}}{s}\right)^{1.6}}}; 1.0\right] \text{ For } \frac{l_{eff}}{s} \geq 1$$

$$\chi_s = 0.407\frac{l_{eff}}{s} \qquad \text{For } \frac{l_{eff}}{s} < 1$$

l_{eff} = Effective length of the stiffener, in [mm], taken as:

$l_{eff} = \frac{l}{\sqrt{3}}$ for stiffener fixed at both ends.

$l_{eff} = 0.75\, l$ for stiffener simply supported at one end and fixed at the other.

$l_{eff} = l$ for stiffener simply supported at both ends.

5.2.3.6 FE corrected stresses for stiffener capacity

When the reference stresses σ_x and σ_y obtained by FE analysis according to Section 4, Cl.2.4 are both compressive, they are to be corrected according to the following formulae:

• If $\sigma_x < \upsilon\sigma_y$:

$$\sigma_{xcor} = 0$$

• If $\sigma_x \geq \upsilon\sigma_y$:

$$\sigma_{xcor} = \sigma_x - \upsilon\sigma_y$$

5.2.4 Primary supporting members

5.2.4.1 Web plate in way of openings

The web plate of primary supporting members with openings is to be assessed for buckling based on the combined axial compressive and shear stresses.

The web plate adjacent to the opening on both sides is to be considered as individual unstiffened plate panels as shown in Table 5.2.4.

The interaction formulae of Section 5, Cl.5.2.2.1 are to be used with:

$\sigma_x = \sigma_{av}$

$\sigma_y = 0$

$\tau = \tau_{av}$

where,

σ_{av} = Weighted average compressive stress, in [N/mm^2], in the area of the web plate being considered, i.e., P1, P2, or P3 as shown in Table 5.2.4.

For the application of Table 5.2.4, the weighted average shear stress is to be taken as:

- Opening modeled in primary supporting members:

τ_{av} = Weighted average shear stress, in [N/mm^2], in the area of the web plate being considered, i.e., P1, P2, or P3 as shown in Table 5.2.4.

- Opening not modeled in primary supporting members:

τ_{av} = Weighted average shear stress, in [N/mm^2], given in Table 5.2.4.

5.2.4.2 Reduction factors of web plate in way of openings

The reduction factors, C_x or C_y in combination with, C_τ of the plate panel(s) of the web adjacent to the opening is to be taken as shown in Table 5.2.4.

5.2.4.3 The equivalent plate panel of the web plate of primary supporting members crossed by perpendicular stiffeners is idealized as shown in Figure 5.2.4.

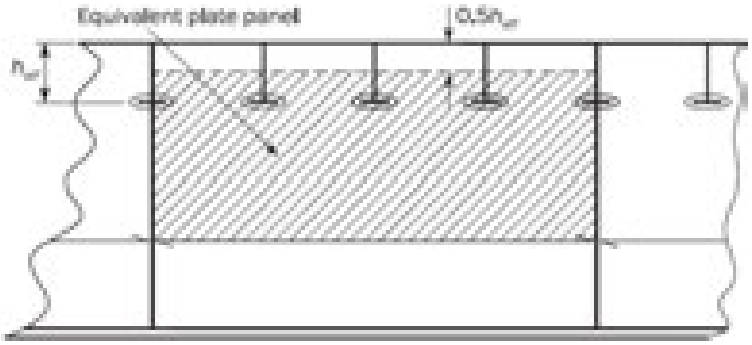

Figure 5.2.4: Web plate idealization

The correction of panel breadth is applicable also for other slot configurations provided that the web or collar plate is attached to at least one side of the passing stiffener

Table 5.2.4: Reduction factors

Configuration	C_x , C_y	C_τ	
		Opening modeled in PSM	**Opening not modeled in PSM**
(a) Without edge reinforcements: 	Separate reduction factors are to be applied to areas P1 and P2 using Case 3 or Case 6 in Table 5.2.2.3, with edge stress ratio: $\Psi = 1.0$	Separate reduction factors are to be applied to areas P1 and P2 using Case 18 or Case 19 in Table 5.2.2.3.	When Case 17 of Table 5.2.2.3 is applicable: A common reduction factor is to be applied to areas P1 and P2 using Case 17 in Table 5.2.2.3 with: $\tau_{av} = \tau_{av(web)}$ When Case 17 of Table 5.2.2.3 is not applicable: Separate reduction factors are to be applied to areas P1 and P2 using Case 18 or Case 19 in Table 5.2.2.3 with: $\tau_{av} = \tau_{av(web)} \frac{h}{h - h_o}$
(b) With edge reinforcements: 	Separate reduction factors are to be applied for areas P1 and P2 using C_x for Case 1 or C_y for Case 2 Table 5.2.2.3 with stress ratio: $\Psi = 1.0$	Separate reduction factors are to be applied for areas P1 and P2 using Case 15 in Table 5.2.2.3.	Separate reduction factors are to be applied to areas P1 and P2 using Case 15 in Table 5.2.2.3 with: $\tau_{av} = \tau_{av(web)} \frac{h}{h - h_o}$
(c) Example of a hole in the web: 		Panels P1 and P2 are to be evaluated as per (a). Panel P3 is to be evaluated as per (b).	

where:
h = Height, in [m], of the web of the primary supporting member in way of the opening.
h_o = Height, in [m], of the opening measured in the depth of the web.
$\tau_{av(web)}$ = Weighted average shear stress, in [N/mm^2] over the web height h of the primary supporting member.
Note 1: Web panels to be considered for buckling in way of openings are shown shaded and numbered P1, P2, etc.

5.3 Corrugated bulkhead

5.3.1 The buckling utilization factor of flange and web of corrugation of corrugated bulkheads is based on the combination of in-plane stresses and shear stress.

The buckling stresses to be used in the interaction formulation in Section 5, Cl.5.2.2.1 are to be determined based on Case 1, 2, and 15, together with the following coefficients:

- $\alpha = 2$
- $\Psi_x = \Psi_y = 1$

5.4 Struts, pillars, and cross ties

5.4.1 Buckling utilization factor

The buckling utilization factor, η, for axially compressed struts, pillars, and cross ties is to be taken as:

$$\eta = \frac{\sigma_{av}}{\sigma_{cr}}$$

where,

σ_{av} = Average axial compressive stress in the member, in [N/mm^2].

σ_{cr} = Minimum critical buckling stress, in [N/mm^2], taken as:

$$\sigma_{cr} = \sigma_E$$

when $\sigma_E \leq 0.5\,\sigma_y$

$$\sigma_{cr} = R_{eH-s}\left(1 - \frac{R_{eH-s}}{4\sigma_E}\right)$$

when $\sigma_E > 0.5\,\sigma_y$

where,

σ_E = Ideal elastic buckling stress, in [N/mm^2], as per Section 5, Cl.5.4.2, Cl.5.4.3 and Cl.5.4.4.

σ_{y-s}= Specified minimum yield stress of the considered member, in [N/mm^2], For built-up members, the lowest specified minimum yield stress is to be used.

5.4.2 Elastic column buckling stress:

The elastic compressive column buckling stress, $'\sigma_{EC}'$, in [N/mm^2], of members subject to axial compression, is to be taken as:

$$\sigma_{EC} = \pi^2 E f_{end} \frac{I}{Al_{pill}{}^2}\, 10^{-4}$$

where:

I = Net moment of inertia about the weakest axis of the cross-section, in [cm^4].

A = Net cross-sectional area of the member, in [cm^2].

l_{pill} = Length of the member, in [m], taken as:

- For pillar and strut: Unsupported length of the member
- For cross tie

- In center tank: distance between the flanges of longitudinal stiffeners on the starboard and port longitudinal bulkheads to which the cross tie's horizontal stringer is attached.

- In wing tank: distance between the flanges of longitudinal stiffeners on the longitudinal bulkhead to which the cross tie's horizontal stringer is attached, and the inner hull plating.

f_{end} = End constraint factor, taken as:

- For pillar and strut

$f_{end} = 1.0$ where both ends are simply supported.

$f_{end} = 2.0$ where one end is simply supported, and the other end is fixed.

$f_{end} = 4.0$ where both ends are fixed.

• For cross tie

$f_{end} = 2.0$

A pillar end may be considered fixed when brackets of adequate size are fitted. Such brackets are to be supported by structural members with greater bending stiffness than the pillar.

5.4.3 Elastic torsional buckling stress:

The elastic torsional column buckling stress, $'\sigma_{ET}'$, in [N/mm^2], with respect to axial compression of members, is to be taken as:

$$\sigma_{ET} = \frac{G\, I_{SV}}{I_{pol}} + \frac{\pi^2\, E\, f_{end}\, c_{warp}}{I_{pol}\, l_{pill}^{\ 2}} 10^{-4}$$

where,

l_{SV}= Net St. Venant's moment of inertia, in [cm^4], Refer Table 5.4.3 for examples of cross sections.

l_{pol}= Net polar moment of inertia about the shear center of cross-section, in [cm^4].

$$l_{pol} = l_y + l_z + A(y_0^2 + z_0^2)$$

c_{warp}= Warping constant, in [cm^6], Refer Table 5.4.3 for examples of cross sections.

l_{pill} = Length of the member, in [m].

y_0 = Transverse position of shear center relative to the cross-sectional centroid, in [cm], Refer Table 5.4.3 for examples of cross sections.

z_0 = Vertical position of shear center relative to the cross-sectional centroid, in [cm], Refer Table 5.4.3 for examples of cross sections.

A = Net cross-sectional area, in [cm^2], as defined in [5.4.2]

I_y= Net moment of inertia about the y-axis, in [cm^4].

I_z= Net moment of inertia about the z-axis, in [cm^4].

5.4.4 Elastic torsional/column buckling stress:

For cross sections where the centroid and the shear center do not coincide, the interaction between the torsional and column buckling mode is to be examined. The elastic torsional/column buckling stress, $'\sigma_{ETF}'$, with respect to axial compression, is to be taken as:

$$\sigma_{ETF} = \frac{1}{2\zeta}\left[(\sigma_{EC} + \sigma_{ET}) - \sqrt{(\sigma_{EC} + \sigma_{ET})^2 - 4\zeta\sigma_{EC}\sigma_{ET}}\right]$$

where,

ζ = Coefficient taken as:

$$\zeta = 1 - \frac{(y_0^2 + z_0^2)A}{I_{pol}}$$

y_0 = Transverse position of shear center relative to the cross-sectional centroid, in [cm], as defined in Cl.5.4.3.

z_0= Vertical position of shear center relative to the cross-sectional centroid, in [cm], as defined in Cl.5.4.3.

A= Net cross-sectional area, in [cm^2], as defined in Cl.5.4.2.

I_{pol}= Net polar moment of inertia about the shear center of cross-section, in [cm^4], as defined in Cl.5.4.3.

σ_{EC}= Elastic column compressive buckling stress, as defined in Cl.5.4.2.

σ_{ET}= Elastic torsional buckling stress, as defined in Cl.5.4.3.

5.5 Stiffened Panels with U-type Stiffeners

5.5.1 Local plate buckling

For stiffened panels with U-type stiffeners, local plate buckling is to be checked for each of the plate panels EPP b_1, b_2, b_f and h_w (Refer Section 5, Figure 5.2.2.5) separately as follows:

- The attached plate panels EPP b_1 and b_2 are to be assessed using SP-A model, where in the calculation of buckling factors K_X as defined in Case 1 of Table 5.2.2.3, the correction factor F_{long} for U-type stiffeners as defined in Table 5.2.2.2 is to be used; and in the calculation of K_y as defined in Case 2 of Table 5.2.2.3, the F_{tran} for U-type stiffeners as defined in Cl.5.2.2.5] is to be used.

- The face plate and web plate panels b_f and h_w are to be assessed using UP-B model with $F_{long} = 1$ and $F_{tran} = 1$.

5.5.2 Overall stiffened panel buckling and stiffener buckling

For a stiffened panel with U-type stiffeners, the overall buckling capacity and ultimate capacity of the stiffeners are to be checked with warping stress $\sigma_W = 0$, and with bending moment of inertia including effective width of attached plating being calculated based on the following assumptions:

- The two web panels of a U-type stiffener are to be taken as perpendicular to the attached plate with thickness equal to t_w and height equal to the distance between the attached plate and the face plate of the stiffener.

- Effective width of the attached plating, b_{eff}, taken as the sum of the b_{eff} calculated for the EPP b_1 and b_2 respectively according to SP-A model.

- Effective width of the attached plating of a stiffener without shear lag effect, b_{eff1}, taken as the sum of the b_{eff1} calculated for the EPP b_1 and b_2 respectively.

Table 5.4.3: Cross-sectional properties

	$I_{SV} = \frac{1}{3}(2b_f t_f^3 + d_{wt}\, t_w^3).10^{-4}$	[cm⁴]
	$c_{warp} = \frac{{d_{wt}}^2\, b_f^3\, t_f}{24}\, 10^{-6}$	[cm⁶]
	$I_{SV} = \frac{1}{3}(b_f t_f^3 + d_{wt}\, t_w^3).10^{-4}$	[cm⁴]
	$y_0 = 0$	[cm]
	$z_0 = -\frac{0.5\, {d_{wt}}^2 t_w}{d_{wt} t_w + b_f t_f} 10^{-1}$	[cm]
	$c_{warp} = \frac{b_f^3\, {t_f}^3 + 4\, d_{wt}^3\, {t_w}^3}{144}\, 10^{-6}$	[cm⁶]
	$I_{SV} = \frac{1}{3}(b_{fu}\, t_f^3 + 2\, d_{wt}\, t_w^3).10^{-4}$	[cm⁴]
	$y_0 = 0$	[cm]
	$z_0 = -\frac{{d_{wt}}^2 t_w\, 10^{-1}}{2\, d_{wt} t_w + b_{fu} t_f} - \frac{0.5\, {d_{wt}}^2 t_w 10^{-1}}{d_{wt} t_w + b_{fu}\, t_f/6}$	[cm]
	$c_{warp} = \frac{b_{fu}^2 d_{wt}^3\, t_w (3 d_{wt} t_w + 2 b_{fu} t_f)}{12(6 d_{wt} t_w + b_{fu} t_f)}\, 10^{-6}$	[cm⁶]
	$I_{SV} = \frac{1}{3}(b_{f1}\, t_{f1}^3 + 2\, b_{f2}\, t_{f2}^3 + b_{f3}\, t_{f3}^3 + d_{wt}\, t_w^3).10^{-4}$	[cm⁴]
	$y_0 = 0$	[cm]
	$z_0 = z_s - \frac{(\, b_{f3}\, d_{wt} t_{f3} + 0.5\, {d_{wt}}^2 t_w)}{d_{wt} t_w + b_{f1}\, t_{f1} + 2 b_{f2}\, t_{f2} + b_{f3}\, t_{f3}} 10^{-1}$	[cm]
	$c_{warp} = \left(I_{f1} {z_s}^2 + \frac{I_{f2} {b_{f1}}^2}{200} + I_{f3} \left(\frac{d_{wt}}{10} - z_s \right)^2 \right)$	[cm⁶]
	$I_{f1} = \left(\frac{(b_{f1} - t_{f2})^3\, t_{f1}}{12} + \frac{b_{f2}\, t_{f2} {b_{f1}}^2}{2} \right) 10^{-4}$	[cm⁴]
	$I_{f2} = \frac{t_{f2}\, {b_{f2}}^3}{12}\, 10^{-4}$	[cm⁴]

	$I_{f3} = \frac{t_{f3}\, b_{f3}{}^{3}}{12} 10^{-4}$	[cm^4]
	$z_s = \frac{I_{f3} d_{wt}}{I_{f1}+I_{f3}} 10^{-1}$	[cm]
Note 1: All dimensions are in [mm]. Note 2: Cross-sectional properties are given for typical cross-sections. Properties for other cross-sections are to be determined by direct calculation.		

Appendix A

Stress-based reference stresses

Symbols

For symbols not defined in this section, Refer to Chapter 1, Section 2.

A_i = Area, in [mm^2], of the i-th plate element of the buckling panel.

n = Number of plate elements in the buckling panel.

σ_{xi} = Actual stress, in [N/mm^2], at the centroid of the i-th plate element in x direction, applied along the shorter edge of the buckling panel.

σ_{yi} = Actual stress, in [N/mm^2], at the centroid of the i-th plate element in the y-direction, applied along the longer edge of the buckling panel.

τ_i = Actual membrane shear stress, in [N/mm^2], at the centroid of the i-th plate element of the buckling panel.

Ψ = Edge stress ratio as defined in Section 5.

A.1 Stress-based method

A.1.1 Introduction

A.1.1.1 General

This section provides a method to determine stress distribution along edges of the considered buckling panel by 2nd order polynomial curve, by linear distribution using the least square method, or by weighted average approach. This method is called the Stress-based Method.

The reference stress is the stress components at the centre of the plate element transferred into the local system of the considered buckling panel.

A.1.1.2 Definition

A regular panel is a plate panel of rectangular shape. An irregular panel is a plate panel that is not regular, as detailed in Section 4, Cl.4.2.3.

A.1.2 Stress application

A.1.2.1 Regular panel

The reference stresses are to be taken as defined in A.2 for a regular panel when the following conditions are satisfied:

- At least, one plate element center is located in each third part of the long edge ‘a’ of a regular panel and

- This element center is located at a distance in the panel local x-direction not less than ‘a/4’ to at least one of the element centers in the adjacent third part of the panel.

Otherwise, the reference stresses are to be taken as defined in A.2.2 for an irregular panel.

A.1.2.2 Irregular panel and curved panel

The reference stresses of an irregular panel or a curved panel are to be taken as defined in A.2.2.

A.2 Reference stresses

A.2.1 Regular Panel

A.2.1.1 Longitudinal stress

The longitudinal stress σ_x applied on the shorter edge of the buckling panel is to be calculated as follows:

For plate buckling assessment, the distribution of $\sigma_x(x)$ is assumed as 2nd order polynomial curve as:

$$\sigma_x(x) = C.x^2 + D.x + E$$

The best-fitting curve $\sigma_x(x)$ is to be obtained by minimizing the square error Π considering the area of each element as a weighting factor.

$$\Pi = \sum_{i=1}^{n} A_i[\sigma_{ix} - (Cx_i^2 + Dx_i + E)]^2$$

The unknown coefficients C, D, and E must yield zero first derivatives, ∂Π with respect to C, D, and E respectively.

$$\frac{\partial \Pi}{\partial C} = 2\sum_{i=1}^{n} A_i x_i^2[\sigma_{ix} - (Cx_i^2 + Dx_i + E)] = 0$$

$$\frac{\partial \Pi}{\partial D} = 2\sum_{i=1}^{n} A_i x_i[\sigma_{ix} - (Cx_i^2 + Dx_i + E)] = 0$$

$$\frac{\partial \Pi}{\partial E} = 2\sum_{i=1}^{n} A_i[\sigma_{ix} - (Cx_i^2 + Dx_i + E)] = 0$$

The unknown coefficients C, D, and E can be obtained by solving the 3 above equations.

$$\sigma_{x1} = \frac{1}{b}\int_0^b \sigma_x(x)\,dx = \frac{b^2}{3}C + \frac{b}{2}D + E$$

$$\sigma_{x2} = \frac{1}{b}\int_{a-b}^{b} \sigma_x(x)\,dx = \left(a^2 - ab + \frac{b^2}{3}\right)C + \left(a - \frac{b}{2}\right)D + E$$

If -D/2C < b/2 or -D/2C > $\left(a - \frac{b}{2}\right)$, σ_{x3} is to be ignored. Otherwise, σ_{x3} is taken as:

$$\sigma_{x3} = \frac{1}{b}\int_{xmin}^{xmax} \sigma_x(x)\,dx = \frac{b^2}{12}C - \frac{D^2}{4C} + E$$

where,

$$xmin = -\frac{b}{2} - \frac{D}{2C}$$

$$xmax = \frac{b}{2} - \frac{D}{2C}$$

The longitudinal stress is to be taken as:

$$\sigma_x = \max(\sigma_{x1}; \sigma_{x2}; \sigma_{x3})$$

The edge stress ratio is to be taken as:

$$\Psi = 1.0$$

• For overall stiffened panel buckling and stiffener buckling assessments, $\sigma_x(x)$ applied on the shorter edge of the attached plate is to be taken as:

$$\sigma_x = \frac{\sum_1^n A_i \sigma_{xi}}{\sum_1^n A_i}$$

The edge stress ratio Ψ_x for the stress σ_x is equal to 1.0.

A.2.1.2 Transverse stress

The transverse stress σ_y applied along the longer edges of the buckling panel is to be calculated by extrapolation of the transverse stresses of all elements up to the shorter edges of the considered buckling panel.

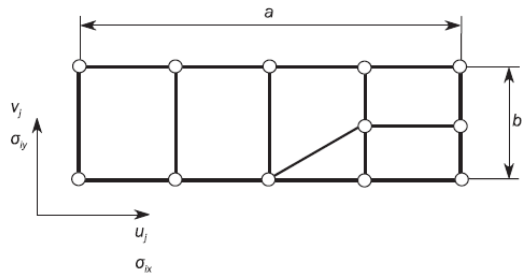

Figure 6.2.1: Buckling panel

The distribution of $\sigma_y(x)$ is assumed as a straight line. Therefore:

$$\sigma_y(x) = A + B.x$$

The best-fitting curve $\sigma_y(x)$ is to be obtained by the least square method minimizing the square error Π considering the area of each element as a weighting factor.

$$\Pi = \sum_{i=1}^{n} A_i\left[\sigma_{iy} - (A + B.x_i)\right]^2$$

The unknown coefficients A and B must yield zero first partial derivatives, ∂Π with respect to A and B, respectively.

$$\frac{\partial \Pi}{\partial A} = 2\sum_{i=1}^{n} A_i\left[\sigma_{iy} - (A + B.x_i)\right] = 0$$

$$\frac{\partial \Pi}{\partial B} = 2\sum_{i=1}^{n} A_i x_i\left[\sigma_{iy} - (A + B.x_i)\right] = 0$$

The unknown coefficients A and B are obtained by solving the 2 above equations and are given as follows:

$$A = \frac{(\sum_{i=1}^n A_i\sigma_{iy})(\sum_{i=1}^n A_i {x_i}^2) - (\sum_{i=1}^n A_i x_i)(\sum_{i=1}^n A_i x_i\,\sigma_{iy})}{(\sum_{i=1}^n A_i)(\sum_{i=1}^n A_i {x_i}^2) - (\sum_{i=1}^n A_i x_i)^2}$$

$$B = \frac{(\sum_{i=1}^n A_i)(\sum_{i=1}^n A_i x_i\,\sigma_{iy}) - (\sum_{i=1}^n A_i x_i)(\sum_{i=1}^n A_i\sigma_{iy})}{(\sum_{i=1}^n A_i)(\sum_{i=1}^n A_i {x_i}^2) - (\sum_{i=1}^n A_i x_i)^2}$$

$$\sigma_y = \max(A, A + Ba)$$

$$\Psi_y = \frac{\min(A, A + Ba)}{\max(A, A + Ba)} \text{ for } \sigma_y \geq 0$$

$$\Psi_y = 1 \text{ for } \sigma_y < 0$$

A.2.1.3 Shear stress

The shear stress τ is to be calculated using a weighted average approach, and is to be taken as:

$$\tau = \frac{\sum_{i=1}^{n} A_i \tau_i}{\sum_{i=1}^{n} A_i}$$

A.2.2 Irregular panel and curved panel

A.2.2.2 Reference stresses

The longitudinal, transverse, and shear stresses are to be calculated using a weighted average approach. They are to be taken as:

$$\sigma_x = \frac{\sum_{i=1}^{n} A_i \sigma_{xi}}{\sum_{i=1}^{n} A_i}$$

$$\sigma_y = \frac{\sum_{i=1}^{n} A_i \sigma_{yi}}{\sum_{i=1}^{n} A_i}$$

$$\tau = \frac{\sum_{i=1}^{n} A_i \tau_i}{\sum_{i=1}^{n} A_i}$$

The edge stress ratios are to be taken as:

$\Psi_x = 1.0$

$\Psi_y = 1.0$

Section 1

General Principles

Symbols

For symbols not defined in this section, Refer to Chapter 1, Section 2.

T_{DF} = Design fatigue life, in year, specified by the designer, but not to be taken less than 25 years**.**

1.1 Application

1.1.1 The requirements of this chapter apply to steel ships with L≥150[m] with unrestricted service and are to be used in conjunction with IRS Guidelines on Structural Assessment of Ships based on Finite Element Method.

1.1.2 The additional class notation **FDA** (**F**atigue **D**esign **A**ssessment) will be assigned to vessels where a fatigue design assessment has been carried out in accordance with the relevant requirements of this chapter. The **FDA** notation is optional for vessels of length L≥ 90[m] and mandatory for vessels of length L≥ 150[m]. If fatigue assessment is carried out for vessels for a greater number of years (>25) and/ or restricted service, then the class notation **FDA (N, specific area of operation)**, would be assigned; where 'N' denotes the number of years.

1.1.3 This chapter provides a simplified fatigue analysis procedure. The reference stress for fatigue may be evaluated using Prescriptive (Simplified beam theory) method or using the Finite Element (FE) method.

1.1.4 Fatigue assessment of ships with non-conventional shapes or with restricted service notation will be specially considered.

1.1.5 Fatigue assessment is performed for ship's structural details to prevent the following types of fatigue failure:

• Fatigue cracks initiating from the toe of the weld and propagating into the plate.

• Fatigue cracks initiating from free edge of non-welded details.

1.1.6 The structural details to be checked for fatigue assessment by simplified stress analysis are given in Section 3 and by finite element stress analysis are given in Section 4. Additional specific details may be requested to be checked on a case-by-case basis by IRS.

1.1.7 The fatigue strength assessment indicated in the chapter is applicable for steel material with specified minimum yield stress less than or equal to 390[N/mm^2]. For steel with specified minimum yield stress value higher than 390[N/mm^2] and for steels with improved fatigue performance, the S-N curves are to be specially considered on case to case basis.

1.2 Definitions

1.2.1 Fatigue damage ratio: Ratio of the number of applied stress cycles and the corresponding number of stress cycles to failure at constant stress range.

1.2.2 Fatigue life: Total time corresponding to the number of stress cycles required to cause fatigue failure of the component. The fatigue life is generally expressed in terms of number of years.

1.2.3 Fatigue stress: Fatigue stress is the stress including corrections, for e.g. mean stress, thickness effect, surface finishing and material factor, relevant for fatigue assessment purpose, i.e.:

- Hot spot stress for welded details

- Local stress at free plate edge

1.2.4 Hot spots: Hot spots are locations in the structure where fatigue cracks may initiate due to the combined effect of nominal structural stress fluctuation and stress concentration effects due to the weld geometry.
Hot spots may be located at:

- Weld toe.

- Weld root of partial penetration or fillet weld.

1.2.5 Hot spot stress: Hot spot stress is a local stress at the weld toe taking into account the stress concentration due to structural discontinuities and presence of welded attachments but disregarding the non-linear stress peak caused by the notch at the weld toe. It is the value of stress on the surface at the hot spot also known as geometric stress or structural stress.

- The hot spot stresses to be considered correspond to the two principal stresses on the surface plating at the weld toe. The first principal stress acts within ±45[deg], perpendicular to the weld and the second principal stress acts outside ±45[deg].Refer Figure 1.2.1.

- The hot spot stress is to be obtained by multiplying the nominal stress by a Stress Concentration Factor (SCF), according to Section 3 or directly by a very fine mesh FE analysis, according to Section 4.

1.2.6 Local stress at free edge: Local stress at free edge is the stress at the plate free edge derived using finite element analysis according to Section 4, Cl.4.2.4.

1.2.7 Load case: Load case is the state of the ship subjected to a combination of loads.

1.2.8 Local notch: A local notch is a localized geometric feature, such as the weld toe, which causes stress concentration. The local notch does not modify the structural stress but generates a non-linear stress peak.

1.2.9 Macro-geometric discontinuity: A global discontinuity, the effect of which is usually not taken into account in structural details, such as large openings, a curved part in a beam, a bend in a flange, and eccentricity in lap joints etc.

1.2.10 Macro-geometric effect: A stress raising effect due to macro-geometry in the vicinity of the welded joint, but not due to the welded joint itself.

1.2.11 Membrane stress: Average normal stress across the thickness of a plate or shell.

1.2.12 Nominal stress: Nominal stress is a general stress in a structural component taking into account macro-geometric effect including effective breadth of flanges but disregarding the stress concentration due to structural discontinuities and the presence of welds. Nominal stress is to be obtained either using coarse or fine mesh FE analysis, as required in Section 4 or using analytical calculation based on beam theory with effective breadth of flanges included, as required in Section 3. Refer Figure 1.2.1.

1.2.13 Notch stress: Notch stress is a peak stress in a notch such as the root of a weld or the edge of a cut-out. This peak stress takes into account the stress concentrations due to the presence of structural geometry and notches. Refer Figure 1.2.1.

1.2.14 Palmgren-Miner rule: Method for estimating fatigue life under variable amplitude loading from the constant amplitude S-N curve. Often referred to as Miner's rule. Fatigue failure is expected when the Miner sum reaches unity.

1.2.15 S-N curve: Graphical presentation of the dependence of fatigue life (N) on fatigue strength (S).

1.2.16 Stress cycle: A part of a stress history containing a stress maximum and a stress minimum.

1.2.17 Stress range: The difference between stress maximum and stress minimum in a stress cycle.

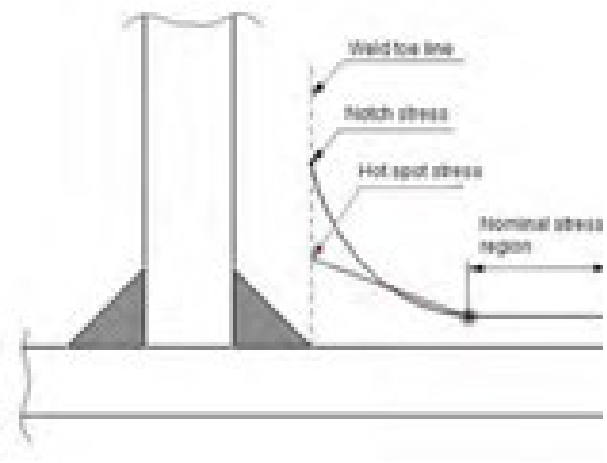

Figure 1.2.1: Stress Definitions

1.3 Assumptions

1.3.1 The following assumptions are made in the fatigue assessment:

- A linear cumulative damage model, i.e. Palmgren-Miner's Rule is used in connection with the design S-N curves with 97.7% probability of survival.

- Design fatigue life, T_{DF}, is taken not less than 25 years.

- Rule quasi-static wave induced loads are based on North Atlantic wave environment. They are determined at 10^{-2} probability level of exceedance.

- Net thickness is used based on net scantling approach according to Chapter 2, Section 4.

- Type of stress used for crack initiating at the weld toe is the hot spot stress. Type of stress used for crack initiating at free edge of non-welded details is local stress at free edge.

- Long term distribution of stress range of a structural detail is assumed to follow a two-parameter Weibull distribution. Weibull shape parameter ξ is equal to 1 and the fatigue stress range $\Delta\sigma_{FS}$ is given at the reference probability level of exceedance equal to 10^{-2}.

- The acceptance criteria for fatigue checking are the total fatigue damage D to be less than or equal to 1 for the design fatigue life.

1.4 Types of environment

1.4.1 Two types of environment are considered for the fatigue detail conditions:

- in air environment

- in corrosive environment without protection

1.5 Corrosion model

1.5.1 The effects of corrosive environment on fatigue life are taken into account by means of:

1.5.1.1 Net scantling approach

The fatigue assessment should be performed based on net scantling approach according to Chapter 2, Section 4.

1.5.1.2 S-N curves.

The basic design S-N curves for corrosive environment are considered to represent the fatigue capacity of material. (Refer Section 2).

1.5.2 Stress correction factor, f_c

1.5.2.1 The global stress is less affected by the corrosion than the local stress due to the probabilistic nature of corrosion, which gives less average corrosion on a global level compared to at a local level. The corrosion allowances are typically higher for local stress calculation than for global stress calculation.

1.5.2.2 For simplified beam model based on net scantlings $t_{n50,}$ the correction factor f_c only applies to the global stresses. When using a global FE model based on net scantlings, the same correction factor applies to both the global and local stresses, i.e. directly on the stress.

The correction factor should be taken as:

- Prescriptive fatigue strength assessment
f_c = 1.0 for local plate and stiffener bending based on t_{n50}

= 0.95 for hull girder stresses based on t_{n50}

- FE based fatigue strength assessment
f_c = 0.95 for stresses based on t_{n50}

1.6 Fatigue failure modes

1.6.1 The following fatigue crack failure modes are generally observed in the ship structure for welded or cut edge details:

- Fatigue cracks initiating from the weld toe into the base material - weld toe failure

- Fatigue cracks initiating from the weld root and propagating into the plate section under the weld - weld root failure

- Fatigue cracks initiating from the weld root and propagating through the weld throat.

- Fatigue cracks initiating from surface irregularity or notch at the free edge into the base material - cut edge failure

1.7 Methodology

1.7.1 Simplified stress analysis

Procedure based on simplified stress analysis, Refer Section 3, is used to determine the hot spot stress at weld toe of longitudinal stiffener end connections. Nominal stresses are calculated by using analytical method based on beam theory according to Section 3, 3.4,3.5 and 3.6. Hot spot stresses are obtained by multiplying nominal stresses by stress concentration factors (SCF) of the considered detail according to Section 3, 3.7.

1.7.2 Finite element stress analysis

Procedure based on finite element stress analysis, Refer Section 4, is used to determine hot spot stress at weld toe of specified structural details, from very fine mesh models. The hot spot stress is generally highly dependent on the finite element model used for representing the structure.

General procedure for the calculation of hot spot stress at weld toe for any welded details except for web stiffened cruciform joints is given in Section 4, 4.5. Procedure for the calculation of hot spot stress at the flange connections for web stiffened cruciform joints is given in Section 4, 4.6. Calculation of local stress for non-welded area is provided in Section 4, Cl.4.5.4.

1.7.3 A simple flowchart of fatigue strength assessment approaches used is shown in Figure 1.7.1. The finite element based fatigue analysis procedure is elaborated in a flowchart given in Figure 1.7.2. Figure 1.7.3 indicates fatigue analysis procedure based on the beam theory approach.

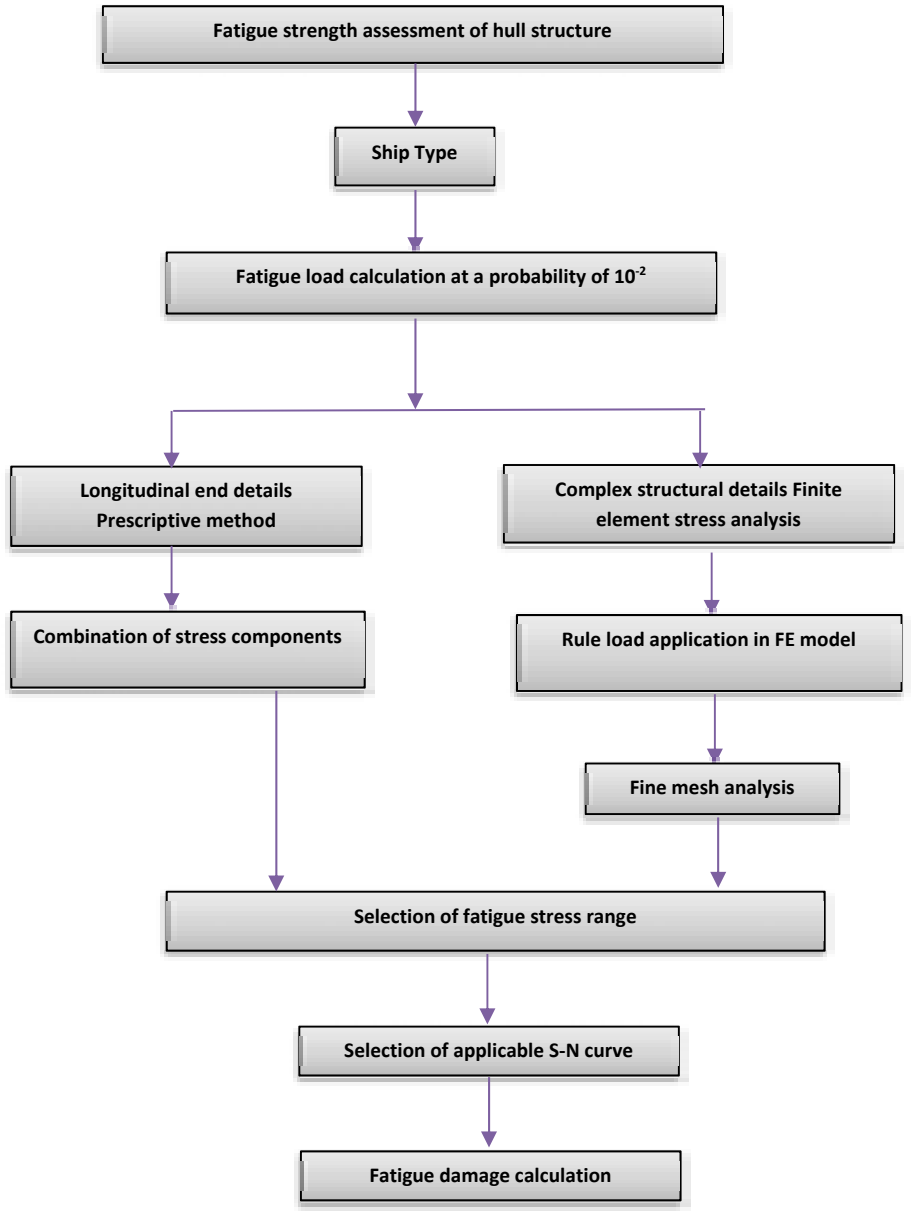

Figure 1.7.1: Flow chart for fatigue strength assessment of hull structure

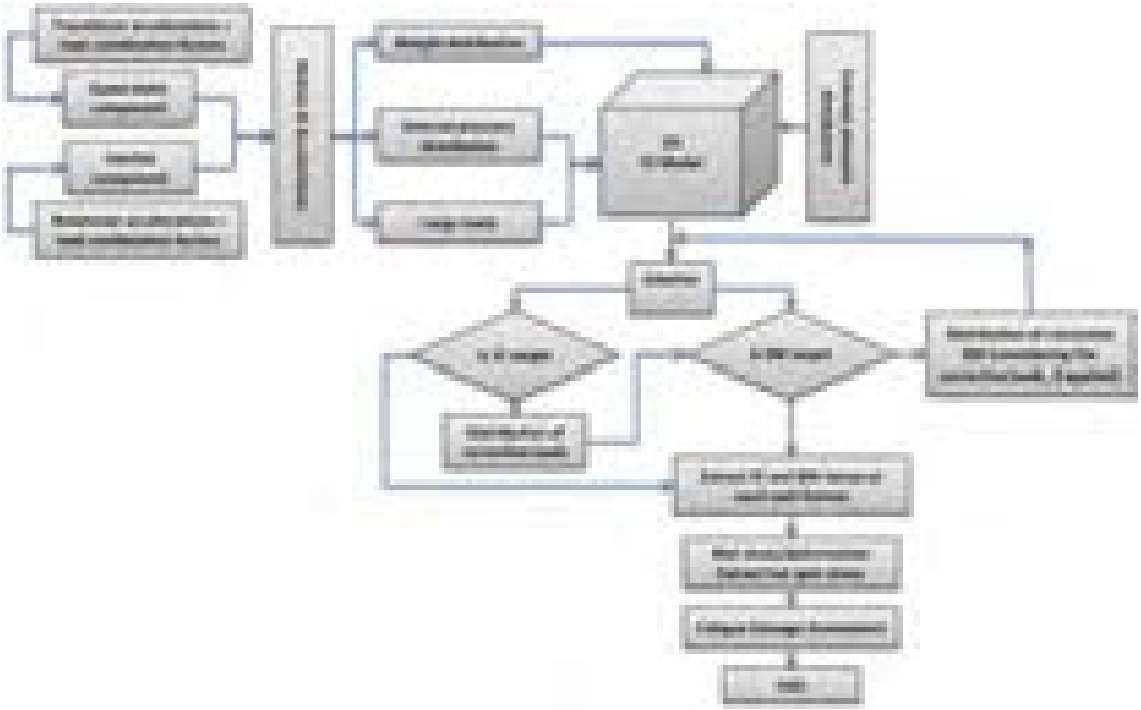

Figure 1.7.2: Procedure for simplified fatigue using FEM

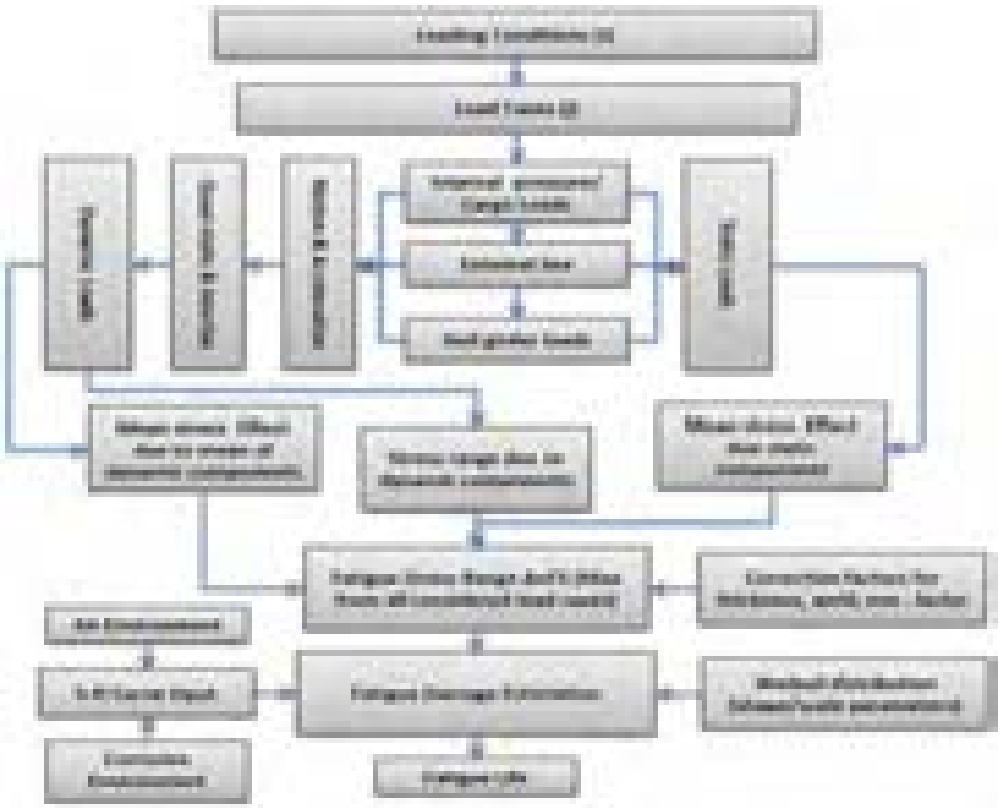

Figure 1.7.3: Procedure for simplified fatigue using beam theory

1.8 Loads

1.8.1 The loads induced in static and dynamic condition are to be considered for fatigue analysis of ship structures which are given below:

- Hull girder loads (bending moments, torsion moment)

- Local loads (wave pressure, inertia and quasi-static loads)

1.8.2 The load cases to be considered for fatigue assessment are given in Chapter 5, Section 2, 2.5. The design load scenario for fatigue assessment is defined in Chapter 5, Section 6, 6.3.

1.8.3 The following loads are not considered for fatigue analysis in these rules:

- dynamic loads resulting from main engine or propeller induced vibratory forces

- dynamic loads due to natural hull girder vibration (springing response)

- dynamic loads due to wave induced hull girder vibrations

- transient loads such as thermal stresses.

- low cycle loads such as cargo variations (cargo loading and unloading) or impact loads such as slamming, sloshing in partially filled tanks

1.9 Loading Conditions

1.9.1 Fatigue analyses are to be carried out for representative loading conditions according to the ship's intended operations.

1.9.2 For novel ship types for which standard loading conditions are generally not defined, the selection of loading conditions is to be performed in consultation with IRS.

1.9.3 Parameters related to a particular loading condition are denoted with a (j) subscript in the rules.

1.9.4 The loading conditions to be considered for some specific ship types and corresponding fraction of time for each loading condition, α(j), are defined in Table 1.9.1. These values are to be used if designers have not specified any values, for corresponding loading conditions.

Table 1.9.1: Standard values for fraction of time in each loading conditions to be used for the fatigue analysis

Vessel type	Full load condition	Normal/partial ballast condition
Tanker	0.5	0.5
Bulk carrier and dry Cargo ship[2)]	0.5	0.5
MPV/ general dry cargo ship[4)]	0.6[3)]	0.4[3)]
Liquefied gas carriers	0.5	0.5
Container ships	0.75[1)]	0.25
Ore Carrier[2)]	0.5	0.5
Passenger Ship[5)]	0.75	0.25
RO-RO[5)]	0.75	0.25
Others [6)]	--	--

1) Two loading conditions, a minimum and maximum hogging condition, is to be checked separately. The lowest fatigue life from the two loading conditions is representative of the calculated fatigue life. For each loading condition, the ballast tank is to be considered as full (to the tank top) 70% and empty 30% of the time, and the fatigue damage is to be calculated as the sum of these two contributions.

2) Applicable for ore carrier, bulk carrier and dry cargo ships except MPV/general dry cargo ships having a long centre cargo hold.

3) For each loading condition, the ballast tank shall be considered as full (to the tank top) 30% and empty 70% of the time, and the fatigue damage shall be calculated as the sum of these two contributions for each loading condition. In the partial condition with empty ballast tanks, bulk cargo pressures should be considered for the hold filled with 70% of the maximum cargo mass and a density of $\rho_c = 1.0$.
4) Applicable for Multi Purpose Vessels (MPV)/general dry cargo ships having a long centre cargo hold.
5) Values used when global FE analysis is required. Prescriptive assessment of longitudinal end connections is not required for passenger vessels.
6) Other ships will be specifically considered.

1.10 Reference Co-ordinate System

1.10.1 The ship geometry, motion, accelerations and loads are defined with respect to right-handed coordinate system are, as shown in Figure 1.10.1.

1.10.2 The sign conventions (Refer Figure 1.10.2) for hull girder loads are as follows:

- The vertical bending moments M_{sw} and M_{wv} are positive when they induce tensile stresses in the strength deck (hogging bending moment) and negative when they induce tensile stresses in the bottom (sagging bending moment).

- The vertical shear forces Q_{sw}, Q_{wv} are positive in the case of downward resulting forces acting aft of the transverse section and upward resulting forces acting forward of the transverse section under consideration.

- The horizontal bending moment M_{wh} is positive when it induces tensile stresses in the starboard side and negative when it induces tensile stresses in the port side.

- The torsional moment M_{wt} is positive in the case of resulting moment acting aft of the transverse section following negative rotation around the X-axis, and of resulting moment acting forward of the transverse section following positive rotation around the X-axis.

Section 2

Fatigue Evaluation

Symbols

For symbols not defined in this section, Refer to Chapter 1 Section 2.

(i) = Suffix which denotes dynamic load case HSM, FSM, BSR-P, BSR-S, BSP-P, BSP-S, OST-P or OST-S specified in Chapter 5.

'i_1' denotes dynamic load case HSM-1, FSM-1, BSR-1P, BSR-1S, BSP-1P, BSP-1S, OST-1P or OST-1S

'i_2' denotes dynamic load case HSM-2, FSM-2, BSR-2P, BSR-2S, BSP-2P, BSP-2S, OST-2P or OST-2S.

(j) = Suffix which denotes loading condition.

T_C = Time in corrosive environment, in years, according to Table 2.5.1.

T_D = Design life, in years, to be taken as 25 years.

T_{DF} = Design fatigue life, in year, specified by the designer, but not to be taken less than 25 years.

T_F = Fatigue life, in year, calculated according to 2.5.

m = Inverse slope of the design S-N curve, as given in Table 2.4.1.1 for in-air environment and in Table 2.4.1.2 for corrosive environment. The inverse slope for S-N curves in-air environment changes from m to m+2 at N = 10^7 cycles.

n_{LC} = Number of applicable loading conditions, as defined in Section 1, Cl.1.9.

f_c = Correction factor as defined in Section 1, Cl.1.5.2.

f_{thick} = Correction factor for plate thickness effect given in Cl.2.3.5.

$f_{mean,i(j)}$ = Correction factor for mean stress effect given in Cl.2.3.4.

2.1 Fatigue analysis methodology

2.1.1 General

In general, assessment of the fatigue strength of structural members includes the following steps:

a) Calculation of stress ranges, according to 2.3.

b) Selection of the design S-N curve, according to 2.4.

c) Calculation of the cumulative damage and the fatigue life calculation, according to 2.5

d) Check the acceptance criteria as per 2.2

2.1.2 Cumulative damage

The fatigue assessment of the structure is based on the application of the Palmgren-Miner rule by estimating the linear cumulative fatigue damage D taken as:

$$D = \sum_{i=1}^{n_{tot}} \frac{n_i}{N_i}$$

where:

n_i = Number of cycles at stress range $\Delta\sigma_i$.

N_i = Number of cycles to failure at stress range $\Delta\sigma_i$.

n_{tot} = Total number of stress range blocks.

i = Stress range block index.

As the long-term stress range distribution of a structural detail in a ship can be described by a two-parameter Weibull distribution, fatigue damage can be obtained by means of a closed form equation, as given in 2.5.

2.2 Acceptance criteria

The design fatigue life, T_{DF}, is to be 25 years, unless a higher value is specified by the designer.

The calculated fatigue life, T_F, is to comply with the following formula:

$$T_F \geq T_{DF}$$

T_{DF} = Design fatigue life, in year, specified by the designer, but not to be taken less than 25 years.

T_F = Fatigue life, in year, calculated according to Cl.2.5.5.

2.3 Reference stresses for fatigue assessment

2.3.1 Fatigue stress

The fatigue stress for each load case of each loading condition is defined in Cl.2.3.2 for welded joints and in Cl.2.3.3 for base material free edge.

The stress range of each loading condition (j) to be considered is the stress range obtained from the predominant load case.

$$\Delta\sigma_{FS,(j)} = \max_i\left(\Delta\sigma_{FS,i(j)}\right)$$

where:

$\Delta\sigma_{FS,i(j)}$ = Fatigue stress range, in [N/mm²], for load case (i) of loading condition (j), as defined in Cl.2.3.2 for welded joints and in Cl.2.3.3 for base material free edge.

2.3.2 Welded joints

For welded joints, the fatigue stress $\Delta\sigma_{FS,i(j)}$, in [N/mm²], corrected for mean stress effect, thickness effect and warping effect, is taken as:

- For simplified stress analysis:

$$\Delta\sigma_{FS,i(j)} = f_{mean,i(j)}.f_{thick}.f_{warp}.\Delta\sigma_{HS,i(j)}$$

- For FE analysis:

2.3.2.1 For web-stiffened cruciform joints:

$$\Delta\sigma_{FS,i(j)} = f_w.f_s.\max\left(\Delta\sigma_{FS1,i(j)}, \Delta\sigma_{FS2,i(j)}\right)$$

2.3.2.2 For other joints:

$$\Delta\sigma_{FS,i(j)} = \max(\text{SideL}, \text{SideR})\left[\max\left(\Delta\sigma_{FS1,i(j)}, \Delta\sigma_{FS2,i(j)}\right)\right]$$

where:

f_w = Correction factor for the effect of stress gradient along weld line = 0.96

f_s = Correction factor for the effect of supporting member = 0.95

$\Delta\sigma_{HS,i(j)}$ = Hot spot stress range, in [N/mm²], due to dynamic loads in load case (i) of loading condition (j) given in Section 3, Cl.3.9.1.

$\Delta\sigma_{FS1,i(j)}$= Fatigue stress range, in [N/mm²], due to the principal hot spot stress range $\Delta\sigma_{HS1,i(j)}$

$$\Delta\sigma_{FS1,i(j)} = f_{mean1,i(j)}.f_{thick}.f_c.\Delta\sigma_{HS1,i(j)}$$

$\Delta\sigma_{FS2,i(j)}$= Fatigue stress range, in [N/mm²], due to the principal hot spot stress range $\Delta\sigma_{HS2,i(j)}$

$$\Delta\sigma_{FS1,i(j)} = 0.9.f_{mean2,i(j)}.f_{thick}.f_c.\Delta\sigma_{HS2,i(j)}$$

SideL, SideR = Left and right side respectively of the line A-A as shown in Section 4, Cl.4.5, Figure 4.5.1 and Figure 4.5.2.

$f_{mean1,i(j)}$ = Correction factor for mean stress effect given in Cl.2.3.4.

$f_{mean2,i(j)}$ = Correction factor for mean stress effect given in Cl.2.3.4.

f_{warp} = Correction factor due to warping effect, taken as:

= 1.07 for the deck longitudinal stiffener of bulk carrier, the closest to the longitudinal hatch coaming in way of the hatch corner as shown in Figure 2.3.1 except f_{warp} = 1.0 when OST is not the dominant load case for all loading conditions.

= 1.04 for following deck longitudinal stiffeners of bulk carrier, except $f_{warp} = 1.0$ when OST is not the dominant load case for all loading conditions.

- The closest stiffener to the longitudinal hatch coaming at one web frame away from the hatch corner, in way of the hatch opening as shown in Figure 2.3.1,

- The second closest stiffener away from the longitudinal hatch coaming in way of the hatch corner as shown in Figure 2.3.1,

= 1.0 for the other cases.

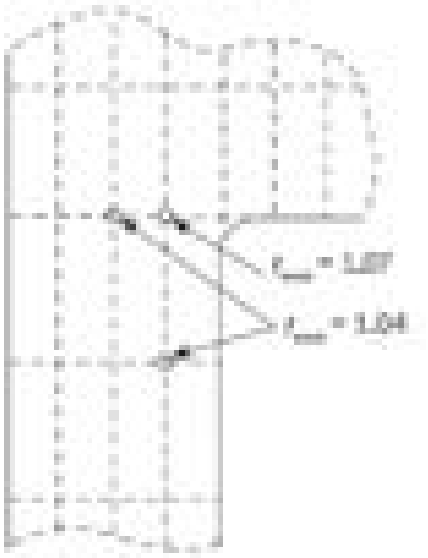

Figure 2.3.1: Warping effect on deck longitudinal stiffeners of bulk carrier

$\Delta\sigma_{HS1,i(j)}$ = Principal hot spot stress ranges, in [N/mm^2], due to dynamic loads for loading condition (j) which acts within ±45° of the perpendicular to the weld toe, determined in Section 4, Cl.4.5.4 and Section 4, Cl. 4.6.2.4 for the two types of shell elements (4-node or 8-node).

$\Delta\sigma_{HS2,i(j)}$ = Principal hot spot stress ranges, in [N/mm^2], due to dynamic loads for loading condition (j) which acts outside ±45° of the perpendicular to the weld toe, determined in Section 4, Cl.4.5.4 and Section 4, Cl.4.6.2.4 for the two types of shell elements (4-node or 8-node).

2.3.3 Base material free edge

For base material free edge, the fatigue stress range, $\Delta\sigma_{FS,(j)}$ in [N/mm^2], is taken as the local stress range at free edge, $\Delta\sigma_{BS,(j)}$, as defined in Section 1, Cl.1.2.6 with correction factors:

$$\Delta\sigma_{FS1,i(j)} = K_{sf}.f_{material}.f_{mean1,i(j)}.f_{thick}.f_c.\Delta\sigma_{BS1,i(j)}$$

where:

K_{sf} = Surface finishing factor for base material given in Cl.2.4.2.2.

$f_{material}$ = Correction factor for material strength, given in Cl.2.3.6.

$\Delta\sigma_{BS,i(j)}$ = Local stress range, in [N/mm^2], due to dynamic loads in load case (i) of loading condition (j) taken as:

$$\Delta\sigma_{BS,i(j)} = \left|\sigma_{BS,i1(j)} - \sigma_{BS,i2(j)}\right|$$

$\sigma_{BS,i1(j)}, \sigma_{BS,i2(j)}$ = Local stress, in [N/mm^2], in load case 'i_1' and 'i_2' of loading condition (j), obtained by very fine mesh FE analysis specified in Section 4.

2.3.4 Mean stress effect

2.3.4.1 Correction factor for mean stress effect

The mean stress correction factor to be considered for each principal hot spot stress range of welded joint, $\Delta\sigma_{HS1,i(j)}$, or for local stress range at free edge, $\sigma_{BS,i1(j)}$, is taken as:

(a) For welded joint:

$$f_{mean,i(j)} = \begin{Bmatrix} \min\left[1.0, 0.9 + 0.2\frac{\sigma_{mcor,i(j)}}{2\Delta\sigma_{HS,i(j)}}\right] \text{ for } \sigma_{m,cor,i(j)} \geq 0 \\ \max\left[0.3, 0.9 + 0.8\frac{\sigma_{mcor,i(j)}}{2\Delta\sigma_{HS,i(j)}}\right] \text{ for } \sigma_{m,cor,i(j)} < 0 \end{Bmatrix}$$

(b) For material:

$$f_{mean,i(j)} = \begin{Bmatrix} \min\left[1.0, 0.8 + 0.4\frac{\sigma_{mcor,i(j)}}{2\Delta\sigma_{BS,i(j)}}\right] \text{ for } \sigma_{m,cor,i(j)} \geq 0 \\ \max\left[0.3, 0.8 + \frac{\sigma_{mcor,i(j)}}{2\Delta\sigma_{BS,i(j)}}\right] \text{ for } \sigma_{m,cor,i(j)} < 0 \end{Bmatrix}$$

where,

$$\sigma_{mcor,i(j)} = \begin{Bmatrix} \sigma_{mean,i(j)} \text{ for } \sigma_{max} \leq R_{eEq} \\ R_{eEq} - \sigma_{max} + \sigma_{mean,i(j)} \text{ for } \sigma_{max} > R_{eEq} \end{Bmatrix}$$

$$\sigma_{max} = \begin{Bmatrix} \text{maxi, (j)}\left(\Delta\sigma_{HS,i(j)} + \sigma_{mean,i(j)}\right) \text{ for welded joint} \\ \text{maxi, (j)}\left(\Delta\sigma_{BS,i(j)} + \sigma_{mean,i(j)}\right) \text{ for base material} \end{Bmatrix}$$

R_{eEq} = max (315,R_{eH})

$\sigma_{mean,i(j)}$ = Fatigue mean stress, in [N/mm^2], for base material calculated according to Cl.2.3.4.2 or for welded joint calculated according to Cl.2.3.4.3 or 2.3.4.4, as applicable.

2.3.4.2 Mean stress for base material free edge
The fatigue mean stress for base material free edge, , $\sigma_{mean,i(j)}$, in [N/mm^2], due to static and dynamic load cases 'i$_1$' and 'i$_2$' of loading condition (j) is calculated by the following formula based on local stress:

$$\sigma_{meani,(j)} = \frac{\sigma_{BS,i1(j)} + \sigma_{BS,i2(j)}}{2}$$

2.3.4.3 Mean stress for simplified stress analysis

The fatigue mean stress to be considered for welded joint assessed by the simplified stress analysis is to be obtained from Section 3, Cl.3.3.5.

The fatigue mean stresses for welded joint due to static and dynamic loads, $\sigma_{meani,(j),pX}$ and $\sigma_{meani,(j),pY}$, in [N/mm^2], for load cases 'i$_1$' and 'i$_2$' of loading condition (j), belonging to the two principal hot spot stress range directions, pX and pY, is calculated by the following formula based on hot spot stress components as defined in Section 4, Cl.4.5.3, 4.6.2.4 and 4.5.5:

θ = Angle between the direction x of the element coordinate system and the principal direction pX of the principal hot spot stress range coordinate system (Section 4, Cl.4.5.3, 4.6.2.4 and 4.5.5). The direction x of the element coordinate system is defined as the normal to the weld toe.

2.3.4.4 Mean stress for FE analysis

$$\sigma_{meani,(j),pX} = \frac{\left(\sigma_{HS,i1(j)}\right)_{xx} + \left(\sigma_{HS,i2(j)}\right)_{xx} + \left(\sigma_{HS,i1(j)}\right)_{yy} + \left(\sigma_{HS,i2(j)}\right)_{yy}}{4} + \frac{\left(\sigma_{HS,i1(j)}\right)_{xx} + \left(\sigma_{HS,i2(j)}\right)_{xx} - \left(\sigma_{HS,i1(j)}\right)_{yy} - \left(\sigma_{HS,i2(j)}\right)_{yy}}{4}.\cos 2\theta + \frac{\left(\sigma_{HS,i1(j)}\right)_{xy} + \left(\sigma_{HS,i2(j)}\right)_{xy}}{2}.\sin 2\theta$$

$$\sigma_{meani,(j),pY} = \frac{\left(\sigma_{HS,i1(j)}\right)_{xx} + \left(\sigma_{HS,i2(j)}\right)_{xx} + \left(\sigma_{HS,i1(j)}\right)_{yy} + \left(\sigma_{HS,i2(j)}\right)_{yy}}{4} - \frac{\left(\sigma_{HS,i1(j)}\right)_{xx} + \left(\sigma_{HS,i2(j)}\right)_{xx} - \left(\sigma_{HS,i1(j)}\right)_{yy} - \left(\sigma_{HS,i2(j)}\right)_{yy}}{4}.\cos 2\theta - \frac{\left(\sigma_{HS,i1(j)}\right)_{xy} + \left(\sigma_{HS,i2(j)}\right)_{xy}}{2}.\sin 2\theta$$

The one of the two mean stresses $\sigma_{meani,(j),pX}$ and $\sigma_{meani,(j),pY}$ which has a principal stress direction with an absolute value less than 45[deg] is defined as $\sigma_{mean1,i(j)}$, belonging to $\sigma_{HS1,i(j)}$. The other mean stress is defined as $\sigma_{mean2,i(j)}$ belonging to $\sigma_{HS2,i(j)}$.

2.3.5 Thickness effect

2.3.5.1 General

Plate thickness primarily influences the fatigue strength of welded joints through the effect of geometry of the weld, and through-thickness stress distribution. The correction factor, f_{thick}, for plate thickness effect is taken as:

$$f_{thick} = 1 \qquad \text{for } t_{eff} \le 22[\text{mm}]$$

$$f_{thick} = \left(\frac{t_{eff}}{22}\right)^{n} \quad \text{for } t_{eff} > 22[\text{mm}]$$

where

n = Thickness exponent given in Table 2.3.5 and Table 2.4.2.2 respectively for welded and non-welded joints. n is to be selected according to the considered stress direction. For this selection, $\Delta\sigma_{HS1}$ and $\Delta\sigma_{HS2}$ are considered perpendicular and parallel to the weld respectively.

t_{eff} = Effective thickness of welds. If values not specified t_{n50} to be used.

t_{n50} = Net thickness, in [mm] of the considered member in way of the hot spot for welded joints or base material free edge.

2.3.5.2 For simplified stress analysis, the net thickness to be considered for stiffeners is as follows:

- Flat bar and Bulb profile: no thickness factor correction,

- Angle bar and T-bar: flange net thickness

2.3.5.3 For FE analysis, the effective thickness to be considered is the thickness of the member where the crack is likely to initiate and propagate.

- For 90[deg] attachments, i.e. cruciform welded joints, transverse T-joints and plates with transverse attachment, the net thickness to be considered is to be taken as:

$$t_{eff} = \min\left(\frac{d}{2}, t_{1n50}\right)$$

where

d = Toe distance in [mm], as shown in Figure 2.3.5, taken as:

$$d = t_{2n50} + 2\ell_{leg}$$

t_{1n50} = Net thickness, in [mm], of the continuous plate as shown in Figure 2.3.5.

t_{2n50} = Net thickness, in [mm], of the transverse attach plate where the hot spot is assessed, as shown in Figure 2.3.5.

ℓ_{leg} = Fillet weld leg length in [mm].

When post-weld treatment methods are applied to improve the fatigue life of considered welded joint, the thickness exponent is provided in 2.6.

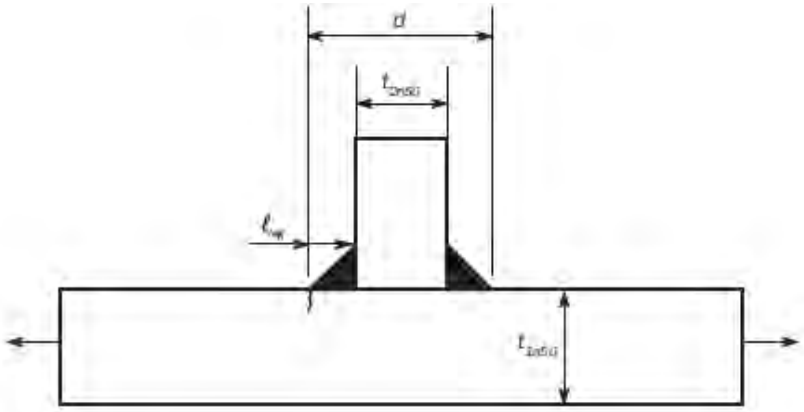

Figure 2.3.5: Toe distance for cruciform welded joints, transverse T-joints and plates with transverse attachment

Table 2.3.5: Welded joints: thickness exponents

Sl. No	Joint category description	Geometry	Condition	n
1	Cruciform joints, transverse T-joints, plates with transverse attachments		As-welded	0.25
			Weld toe treated by post-weld improvement method	0.2

2	Transverse butt welds		As-welded	0.2
			Ground flush or weld toe treated by post-weld improvement method	0.1
3	Longitudinal welds or attachments to plate edges		Any	0.1
			Weld toe treated by post-weld improvement method	0.1
4	Longitudinal attachments on the flat bar or bulb profile		Any	0.0
			Weld toe treated by post-weld improvement method (1)	0.0
5	Longitudinal attachments and doubling plates		As welded	0.2
			Weld toe treated by post-weld improvement method	0.1

6	Longitudinal attachments and doubling plates supported longitudinally		As-welded $t_2 \geq 0.33\ t_1$ else	0.1 0.0
			Weld toe treated by post-weld improvement method (1)	0
(1) No benefit applicable for post-weld treatment of longitudinal end connections				

2.3.5.4 For base material

The thickness effect is not considered for base material and free plate edges assuming good workmanship practice (S-N curve B and C) and when adequate protective measures are taken against wear, tear and corrosion, e.g. from friction from cargo or cargo handling appliances.

2.3.6 Material factor

2.3.6.1 Welded joints

For welded joints, the fatigue strength is independent on the steel yield strength. So, the correction factor for material strength, $f_{material}$, is taken as 1.

2.3.6.2 Non welded details

For non-welded details such as cut plate edges, the fatigue strength increases together with the yield stress of the base material. The fatigue stress range, $\Delta\sigma_{FS,i(j)}$, needs to be corrected for material strength, $f_{material}$, taken as:

$$f_{material} = \frac{1200}{965 + \sigma_y}$$

2.3.7 Environmental factor

The environmental factor is a correction factor representing the ratio of the stress range based on the vertical wave bending moment from a specific trade and the North Atlantic wave environment. For prescriptive loads, the following environmental factors are used

$f_e = 0.8$ for worldwide wave environment

$f_e = 1.0$ for North Atlantic wave environment.

Note:

If hydrodynamic analysis is carried out using a scatter diagram, the environmental factor to be taken as 1.0.

2.4 S-N Curves

2.4.1 Design S-N curves

2.4.1.1 Unless supported by direct measurements, the U.K. HSE (previously DEn) Basic S-N Curves are to be used for determining the fatigue life.

2.4.1.2 The fatigue assessment for welded joints and base material is based on use of S-N curves which are obtained from fatigue tests. The design S-N curves are established at two standard deviations below the mean S-N curves corresponding to 50% of probability of survival for relevant experimental data. Design S-N curves given in Table 2.4.1.1 and Table 2.4.1.2 correspond to a probability of survival of 97.7%.

2.4.1.3 S-N curve scope of application

These S-N curves are applicable to steels with minimum yield strength less than 400[N/mm^2]. For steels with higher yield strength, data obtained from an approved test program are to be used.

2.4.1.4 In-air environment

The basic design curves in-air environment shown in Figure 2.4.1.1 are represented by linear relationships between log (Δσ) and log (N) as follows:

$$\log N = \log(K_2) - m.\log(\Delta\sigma)$$

where

$$\log(K_2) = \log(K_1) - 2.\log(\delta)$$

K_1 = Constant related to mean S-N curve, as given in Table 2.4.1.1.

K_2 = Constant related to design S-N curve, as given in Table 2.4.1.1.

δ = Standard deviation of log (N), as given in Table 2.4.1.1.

$\Delta\sigma_q$ = Stress range at N = 10^7 cycles related to design S-N curve, in [N/mm^2], as given in Table 2.4.1.1.

Table 2.4.1.1: Basic S-N curve data, in-air environment

Class	K_1		m	Standard deviation δ	K_2	Design stress range at 10^7 cycles	Design stress range at $2x10^6$ cycles
	K_1	$\log_{10} K_1$		$\log_{10} \delta$		$\Delta\sigma_q$[N/mm^2]	[N/mm^2]
B	2.343E15	15.3697	4.0	0.1821	1.01E15	100.2	149.9

G	0.566E12	11.7525	3.0	0.1793	0.25E12	29.2	50.0
W	0.368E12	11.5662	3.0	0.1846	0.16E12	25.1	43.1

2.4.1.5 Corrosive environment

The basic design curves for corrosive environment shown in Fig. 2.4.1.2 are represented by linear relationships between log (Δσ) and log (N) as follows:

$$\log N = \log(K_2) - m.\log(\Delta\sigma)$$

N = Predicted number of cycles to failure under stress range Δσ.

K_2 = Constant related to design S-N curve, as given in Table 2.4.1.2.

Table 2.4.1.2: Basic S-N curve data, corrosive environment			
Class	**m**	**K_2**	**Design stress range at $2x10^6$ Cycles [N/mm²]**

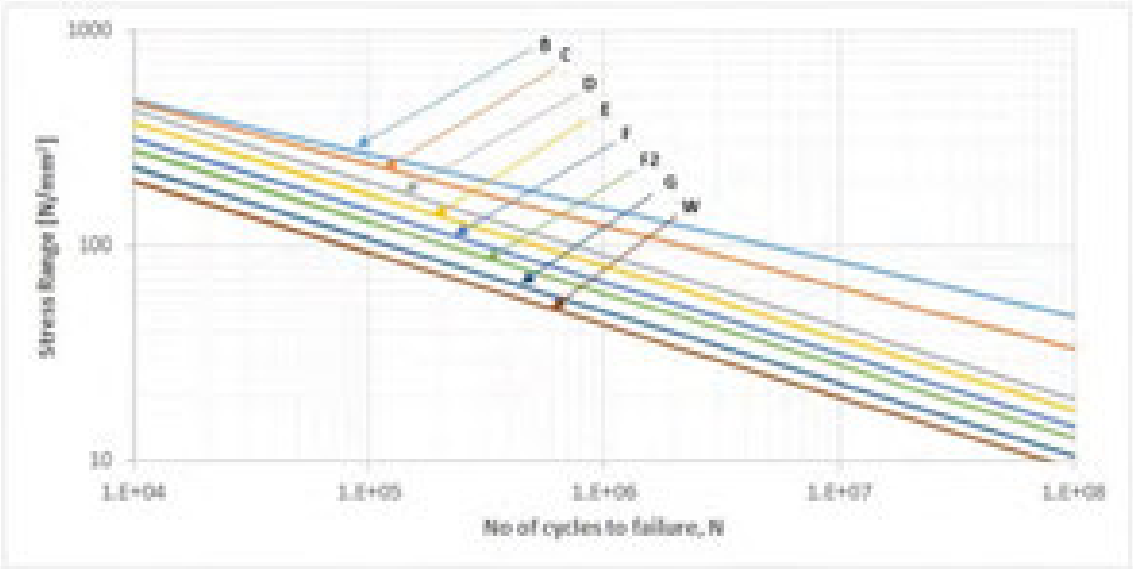

Figure 2.4.1.2: Basic design S-N curves, corrosive environment

2.4.2 Selection of S-N curves

2.4.2.1 General

The HSE S-N Curves for non-tubular joints consist of eight curves, as shown in Table 2.4.1.1 identified by B, C, D, E, F, F2, G and W categories. These curves give the relationship between the nominal stress range and the number of constant amplitude load cycles to failure. Each curve represents a class of welded details depending upon:

- The geometrical arrangement of the detail,

- The direction of the fluctuating stress relative to the detail

- The method of fabrication and inspection of the detail.

The Table 2.4.2.1 provide the summary of details based on above factors. More information can be referred from the UK HSE (1984).

Table 2.4.2.1: Welded Joint Classification for SN curve

SN curve category for Joint Classification	**Description [1]**
Category B	1) Parent metal in the as-rolled condition with no flame-cut edges or with flame-cut edges ground or machined 2) Full penetration butt welds with the weld cap ground flush with the surface and with the weld proved to be free from defects by NDT.
Category C	1) Parent material in the as-rolled condition with automatic flame-cut edges and ensured to be free from cracks. 2) Butt or fillet welds made by an automatic submerged or open arc process and with no stop-start positions within their length. 3) With the weld cap ground flush with the surface and with the weld proved to be free from significant defects by NDT.
Category D	1) As C(2) but with stop-start positions within the length 2) With the welds made either manually or by an automatic process other than submerged arc and in flat position
Category E	1) Intermittent fillet welds
Category F	1) Welds made on a permanent backing strip between plates of equal width and thickness or tapered with a maximum slope of 1/4. 2) Parent material (of the stressed member) or ends of butt or fillet welded attachments (parallel to the direction of applied stresses) on stressed members: - attachment length l ≤ 150[mm] - edge distance d ≥ 10[mm] 3) Parent metal of cruciform or T Joints made with full penetration welds and with any undercut at the corners of the member ground out 4) Parent metal at the toe of weld connection of web stiffeners to girder flanges: edge distance d ≥ 10[mm]. 5) As E(1) but adjacent to cut-outs.
Category F2	1) Parent material (of the stressed member) or ends of butt or fillet welded attachments (parallel to the direction of applied stresses) on stressed members: - attachment length l > 150[mm] - edge distance d ≥ 10[mm] 2) As F(3) with partial penetration or fillet welds with any undercut at the corners of the member ground out. Parent metal of load-carrying fillet welds transverse to the direction of stresses (member X): edge distance d ≥ 10[mm]

Category G	1) Parent material (of the stressed member) at toes or ends of butt or fillet welded attachments on or within 10[mm] of edges or corners. 2) Parent metal of load-carrying fillet welds transverse to the direction of stresses (member X): edge distance d < 10[mm] 3) Parent metal of load-carrying fillet welds parallel to the direction of stresses, with the weld end on plate edge (member Y). 4) Parent metal at the toe of weld connection of web stiffeners to girder flanges: edge distance d < 10[mm]

2.4.2.2 Surface finishing factor

The S-N curve C is applicable to most of non-welded locations taking into account the likelihood of some notching from corrosion, wear and tear in service with surface finishing factor as given in Table 2.4.2.2. Higher surface finishing quality may be applied in using S-N curve B as given in Table 2.4.2.2, provided adequate protective measures are taken against wear, tear and corrosion and finite element analysis according to Section 4.3 and 4.4 is carried out.

Table 2.4.2.2: Non-welded joints: thickness exponent and surface finishing factor

Joint configuration, fatigue crack location and stress direction	Edge cutting process	Edge treatment	Surface finishing	n	K_{sf}	S-N Curve
Base material, Rolled or extruded plates and sections as well as seamless pipes. No surface or rolling defects 	N/A	N/A	No surface nor roll defect (1) (2)	0	0.94	B
Cut edges						
	Machine cutting e.g. by a thermal process or sheared edge cutting	Cutting edges chamfered or rounded by means of smooth grinding, groove direction parallel to the loading direction	Smooth surface free of cracks and notches (1) (2)	0.1	1.00	B
		Cutting edges	Smooth	0.1	1.07	B

		broken or rounded	surface free of cracks and notches (1) (2)			
		No edge treatment	Surface free of cracks and severe notches (inspection procedure) (1) (2)	0.1	1.00	C
	Manually thermally cut e.g. by flame cutting	No edge treatment	Surface free of cracks and severe notches (inspection procedure) (1) (2)	0.1	1.24	C
(1) Stress increases due to geometry of cut-outs to be considered. (2) Fine mesh FE analysis according to Section 4.3 and 4.4.						

2.5 Fatigue damage calculation

2.5.1 General

2.5.1.1 The design fatigue life is divided into a number of time periods due to different loading conditions and due to limitation of the corrosion protection.

2.5.1.2 It is assumed that the corrosion protection (i.e. coating system) is only effective for a limited number of years during which the structural details are protected, i.e. in-air environment. During the remaining part of the design life as specified in Table 2.5.1, the structural details are unprotected i.e. exposed to corrosive environment.

The elementary fatigue damage, given in Cl.2.5.2, is the damage accumulated during a specific loading condition (j) associated with a specific environmental condition either protected condition, i.e. in-air environment, or unprotected condition, i.e. corrosive environment.

The combined fatigue damage, given in Cl.2.5.3, is the combination of damage accumulated for a specific loading condition (j) for the in-air and corrosive environment time.

Total fatigue damage, given in Cl.2.5.4, is the sum of the combined fatigue damages obtained for all loading conditions.

2.5.2 Elementary fatigue damage

The elementary fatigue damage for each fatigue loading condition (j) is to be calculated independently for both protected in-air environment and unprotected corrosive environment, based on the fatigue stress range obtained for the predominant load case and calculated based on a closed form formulation as follows:

$$D_{E(j)} = \frac{\alpha_{(j)}.N_D}{K_2} \frac{\Delta\sigma_{FS,(j)}^m}{(\ln N_R)^{m/\xi}} .\mu_{(j)}.\Gamma\left(1+\frac{m}{\xi}\right)$$

where:

N_D = Total number of wave cycles experienced by ship during the design fatigue life, taken as:

$$N_D = \frac{31.557x10^6(f_0 T_D)}{4\log L}$$

f_0 = Factor taking into account time in seagoing operations excluding time in loading and unloading, repairs, etc. taken as 0.85.

$\alpha_{(j)}$ = Fraction of time in each loading condition given in in Section 1.

$\Delta\sigma_{FS,(j)}$ = Fatigue stress range at the reference probability level of exceedance of 10^{-2}, in [N/mm^2].

N_R = Number of cycles corresponding to the reference probability of exceedance of 10^{-2} = 100.

ξ = Weibull shape parameter, = 1.

$\Gamma(x)$ = Complete Gamma function.

K_2 = Constant of the design S-N curve, as given in 2.4 for in-air environment and for corrosive environment.

$\mu_{(j)}$ = Coefficient taking into account the change of inverse slope of the S-N curve, m.

2.5.2.1 For in-air environment:

$$\mu_{(j)} = 1 - \frac{\left\{\gamma\left(1+\frac{m}{\xi},\upsilon_{(j)}\right) - \upsilon_{(j)}^{-\Delta m/\xi}.\gamma\left(1+\left(\frac{m+\Delta m}{\xi}\right),\upsilon_{(j)}\right)\right\}}{\Gamma\left(1+\frac{m}{\xi}\right)}$$

$$\upsilon_{(j)} = \left(\frac{\Delta\sigma_q}{\Delta\sigma_{FS,(j)}}\right)^{\xi} \ln N_R$$

2.5.2.2 For corrosive environment:

$$\mu_{(j)} = 1.0$$

$\gamma(a,x)$ = Incomplete Gamma function.

$\Delta\sigma_q$ = Stress range, in [N/mm^2], corresponding to the intersection of the two segments of design S-N curve at N = 10^7 cycles, as given in 2.4.

Δm = Change in inverse slope of S-N curve at N=10^7 cycles, = 2

2.5.3 Combined fatigue damage

The combined fatigue damage in protected in-air environment and unprotected corrosive environment for each loading condition (j) is to be calculated as follows:

$$D_{(j)} = D_{E,air(j)}.\frac{T_D - T_C}{T_D} + D_{E,corr(j)}.\frac{T_C}{T_D}$$

where:

$D_{E,air(j)}$ = The elementary fatigue damage for in-air environment for loading condition (j) given in Cl.2.5.2.

$D_{E,corr(j)}$ = The elementary fatigue damage for corrosive environment for loading condition (j) as calculated in Cl.2.5.2.

T_C = Time in corrosive environment, in years, according to Table 2.5.1.

T_D = Design life, in years, to be taken as 25 years.

Table 2.5.1: Time in corrosive environment, T_C

Location of weld joint or structural detail	Time in corrosive environment T_C, in years
Water ballast tank	10
Oil cargo tank	
Lower part1) of cargo hold for dry bulk cargo	
Cargo hold for dry bulk cargo except lower part [1)]	5
Void spaces	5
Fuel oil tanks	5
Cofferdam	
Dry cargo holds	
Hull external surfaces	
Other areas	5

1) Lower part including inner bottom and other structure with a height of 1.5[m] above the inner bottom.

2.5.4 Total fatigue damage

The total fatigue damage for all applicable loading conditions is calculated as follows:

$$D = \sum_{j=1}^{n_{LC}} D_{(j)}$$

where:

$D_{(j)}$ = Combined fatigue damage for each applicable loading condition, as given in Cl.2.5.3.

2.5.5 Fatigue life calculation

The fatigue life, T_F, is taken as:

$$T_F = \frac{T_D}{D_{air}} \text{ if } \frac{T_D}{D_{air}} \leq (T_D - T_C)$$

$$T_F = T_D - T_C + \left(\frac{T_D}{D_{air}} - T_D + T_C\right)\frac{D_{air}}{D_{corr}} \text{ otherwise}$$

where:

D_{air} = Total fatigue damage for all loading conditions in-air environment taken as:

$$D_{air} = \sum_{j=1}^{n_{LC}} D_{E,air(j)}$$

D_{corr} = Total fatigue damage for all loading conditions in corrosive environment taken as:

$$D_{corr} = \sum_{j=1}^{n_{LC}} D_{E,corr(j)}$$

2.6 Weld improvement methods

2.6.1 General

Post-weld fatigue strength improvement methods are to be considered as a supplementary means of achieving the required fatigue life, and subjected to quality control procedures. The benefit from post-weld treatment can only be applied for corrosion free condition and may only be considered provided that a protective coating is applied after the post-weld treatment and maintained during the design life time.

2.6.2 Limitation of the benefit of post-weld treatment

For structural details where the benefit of post-weld treatment is applicable, the calculated fatigue life at the design stage for the considered structural detail excluding the post-weld treatment effects, is not to be less than $T_{DF}/1.47$.

2.6.3 The calculated fatigue life at design stage excluding post-weld treatment effects is not to be less than 25 years.

2.6.4 Post-weld treatment at fabrication stage

There is one basic post-weld treatment method considered in these guideline to improve fatigue strength at the fabrication stage, i.e. weld geometry control and defect removal method by burr grinding.

2.6.5 Weld toe

The post-weld improvement method is applied to the weld toe to increase its fatigue life. The possibility of failure initiation at other locations is always to be considered. If the failure is shifted from the weld toe to the root by applying post-weld treatment, there may be no significant improvement in the overall fatigue performance of the joint. Improvements of the weld root cannot be expected from treatment applied to weld toe. A brief description of the method and the degree of improvement which can be achieved is given in Cl.2.6.6.

2.6.6 Weld toe burr grinding

2.6.6.1 The weld may be machined using a burr grinding tool to produce a favorable shape to reduce stress concentrations and remove defects at the weld toe, Refer Fig. 2.6.6.1. In order to eliminate defects, such as intrusions, undercuts and cold laps, the material in way of the weld toe is to be removed. The depth of grinding is to be at least 0.5[mm] below the bottom of any visible undercut. The total depth of the burr grinding is not to be greater than the lesser of 2[mm] and of 7% the local gross thickness of the machined plate. Any undercut not complying with this requirement is to be repaired by an approved method.

2.6.6.2 To avoid introducing a detrimental notch effect due to small radius grooves, the burr diameter is to be scaled to the plate thickness at the weld toe being ground. The diameter is

to be in the 10 to 25[mm] range for application to welded joints with plate thickness from 10 to 50 [mm]. The resulting root radius of the groove is to be no less than $0.25t_{as-built}$. The weld throat thickness and leg length after burr grinding must comply with the rule requirements or any increased weld sizes as indicated on the approved drawings.

The inspection procedure is to include a check of the weld toe radius, the depth of burr grinding, and confirmation that the weld toe undercut has been removed completely.

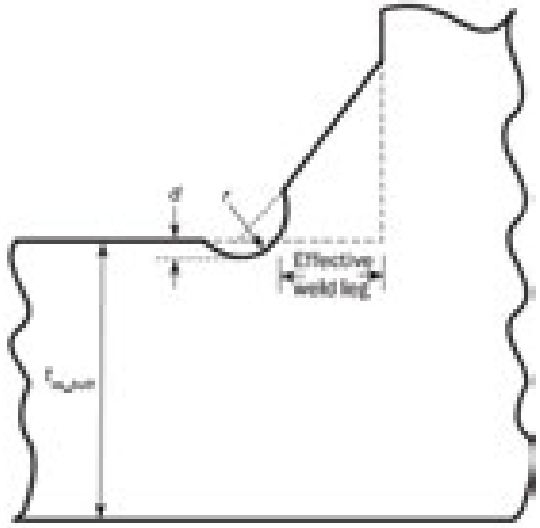

Figure 2.6.6.1: Details of ground weld toe geometry

2.6.7 Fatigue improvement factor

The benefit of burr grinding corresponds to an increase in fatigue strength by a factor of 1.3 (i.e. a reduction of the effective stress range by 1.3), reducing the damage in air to

$$\frac{D_{air}}{2.2}$$

where

D_{air} is the Fatigue damage in air as given in Cl.2.5.5.

2.6.8 Applicability

The application of post-weld improvement and fatigue improvement factor provided is subject to the following:

- The weld type complies with Cl.2.6.9.

- The weld improvement is effective or valid in improving the fatigue strength of structural details under high cycle fatigue conditions and do not apply to low-cycle fatigue conditions, i.e. when $N \leq 5\times10^4$, where N is the number of life cycles to failure.

- Unless otherwise specifically stated, the fatigue improvement factor is to be used for welds, joining steel plates which are between 6 and 50[mm] thick.

- This improvement can only be achieved in a corrosion free condition and may only be considered provided that a suitable protective coating is applied after the post-weld treatment and maintained during the design life time. Hot spots are to be protected from corrosive environment.

- Fatigue improvement factor is to be applied to as-welded transverse butt welds, as-welded T-joint and cruciform welds and as-welded longitudinal attachment welds excluding longitudinal end connections.

- In way of areas prone to mechanical damage, fatigue improvement may occur only if these are adequately protected.

- Treatment of inter-bead toes is required for large multi-pass welds as shown in Figure 2.6.8.

- The yard is to provide the list of details and their locations on the ship for which the post-weld treatment has been applied.

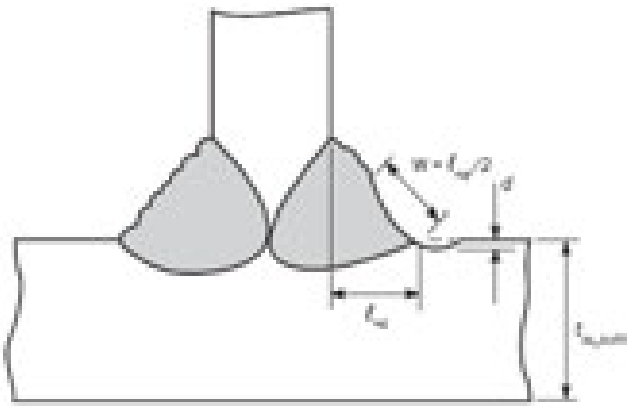

Figure 2.6.8: Extent of weld toe burr grinding to remove inter-bead toes on weld face

(ℓ_{reg}: Weld leg length, W: Width of groove, d: Depth of grinding to be between 0.5 and 1[mm])

2.6.9 Weld type for post-weld treatment

When weld improvements are planned, full or partial penetration welds with a minimum root face according to Chapter 16 are to be used to mitigate or to eliminate the possibility of cracking at the weld root.

Section 3

Simplified Stress Analysis

Symbols

For symbols not defined in this section, Refer to Chapter 1 Section 2.

ℓ_{bdg} = Effective bending span of stiffener, in m, as defined in Chapter 3, Section 7.

I_{y-n50} = Net vertical hull girder moment of inertia in [m^4], at the longitudinal position being considered.

I_{z-n50} = Net horizontal hull girder moment of inertia in [m^4], at the longitudinal position being considered.

Y = Transverse coordinate in [m], of the load calculation point under consideration.

z = Vertical coordinate in [m], of the load calculation point under consideration.

z_n = Distance in [m], from the baseline to the horizontal neutral axis.

K_a = Geometrical stress concentration factor for stress due to axial load given in Cl.3.7.2.

K_b = Geometrical stress concentration factor for stress due to lateral pressure given in Cl.3.7.2.

K_n = Stress concentration factor due to unsymmetrical stiffener geometry, as defined in Cl.3.7.1.

3.1 General

3.1.1 This section provides the procedure for fatigue strength of the longitudinal stiffener end connections. The type of stresses considered in the analysis are explained in 3.3 to 3.6.

3.2 Fatigue approach for longitudinal end connections

3.2.1 The determination of the longitudinal stiffener end connections hot spot stress is based on:

- Nominal stresses from beam theory.

- Stress concentration factors for the different longitudinal end connections as given in 3.7

- Loading conditions specified in Section 1.

3.2.2 The longitudinal stiffener end connection types are described in Cl.3.7.2.

3.3 Axial and bending stress

3.3.1 General

3.3.1.1 This sub-section deals with the assessment of fatigue induced by the axial and bending modes (Figure 3.3.1) in way of longitudinal stiffener connections to primary members.

3.3.1.2 The simplified stress analysis aims at evaluating the hot spot stress at the flange of longitudinal stiffener connections with primary supporting members. The longitudinal stiffener is considered as a beam subjected to:

- axial loads induced by hull girder bending, and

- local bending induced by lateral pressure.

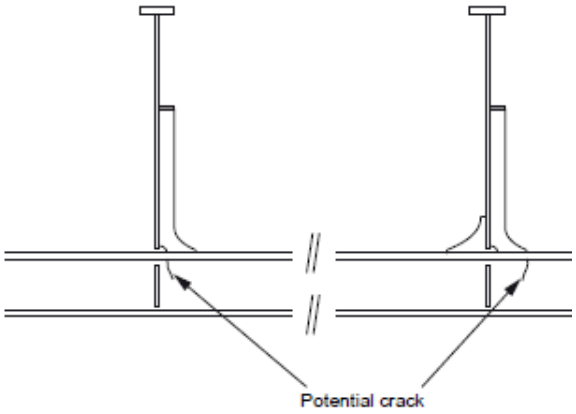

Figure 3.3.1: Areas of potential cracks in longitudinal stiffener web due to bending mode

3.3.2 Effect of primary structure distortion

The hot spot stress ranges and hot spot mean stresses in way of each end connection of longitudinal stiffener, as shown in Figure 3.5.1 are to be evaluated at the flange at following locations:

3.3.2.1 Transverse webs or floors other than those located at transverse bulkhead including swash bulkhead of cargo hold or in way of stool, such that additional hot spot stress due to the relative displacement is not to be considered.

3.3.2.2 Transverse webs or floors located at transverse bulkhead including swash bulkhead of cargo hold or in way of stool, such that additional hot spot stress due to the relative displacement are to be considered.

3.3.3 Stress concentration factors

Stress concentration factors due to unsymmetrical stiffener geometry according to Cl.3.7.1 and due to the stiffener end connection geometry at two potential hot spots (point 'A' and 'B') according to Cl.3.7.2 are to be applied.

For each hot spot of each connection, two geometric stress concentration factors (K_a and K_b) are defined, for both the axial stress and the bending stress respectively. The end connections given in Cl.3.7.2 are based on typical joint geometry under axial and lateral loadings. When a structural detail is different from those shown in Table 3.7.2, a finite element analysis is to be used to demonstrate the adequacy of the detail in terms of fatigue strength, according to Cl.3.7.3.

3.3.4 Hot spot stress range

The hot spot stress range, in [N/mm^2], due to dynamic loads for load case (i) of loading condition (j) is obtained from the following formula:

$$\Delta\sigma_{HS.i(j)} = \left|\left(\sigma_{GD,i1(j)} + \sigma_{LD,i1(j)} + \sigma_{dD,i1(j)}\right) - \left(\sigma_{GD,i2(j)} + \sigma_{LD,i2(j)} + \sigma_{dD,i2(j)}\right)\right|$$

where:

$\sigma_{GD,i1(j)}, \sigma_{GD,i2(j)}$ = Stresses due to global hull girder wave bending moments, in [N/mm^2], as defined in Cl.3.4.1.1.

$\sigma_{LD,i1(j)}, \sigma_{LD,i2(j)}$ = Stresses due to local dynamic pressure, in [N/mm^2], as defined in Cl.3.5.1.1.

$\sigma_{dD,i1(j)}, \sigma_{dD,i2(j)}$ = Stresses due to relative displacement in wave, in [N/mm^2], as defined in Cl.3.5.5.

3.3.5 Hot spot mean stress

The hot spot mean stress, in [N/mm^2], due to static and dynamic loads for load case (i) of loading condition (j) is obtained from the following formula:

$$\sigma_{mean,i(j)} = \sigma_{GS,(j)} + \sigma_{LS,(j)} + \sigma_{dS,(j)} + \sigma_{mLD,i(j)} + \sigma_{mGD,i(j)} + \sigma_{mdD,i(j)}$$

where for the load case (i) of loading condition (j):

$\sigma_{GS,(j)}$ = Stress due to still water hull girder bending moment, in [N/mm^2], as defined in Cl.3.4.1.2.

$\sigma_{LS,(j)}$ = Stress due to local static pressure, in [N/mm^2], as defined in Cl.3.5.1.2.

$\sigma_{dS,(j)}$ = Stress due to relative displacement in still water, in [N/mm^2], as defined in Cl.3.5.6.

$\sigma_{mLD,(j)}$ = Mean stress due to local dynamic pressure, in [N/mm^2], defined as:

$$\sigma_{mLD,i(j)} = \frac{\sigma_{LD,i1(j)} + \sigma_{LD,i2(j)}}{2}$$

$\sigma_{mGD,i(j)}$ = Mean stress due to global wave bending moment, in [N/mm^2], defined as:

$$\sigma_{mGD,i(j)} = \frac{\sigma_{GD,i1(j)} + \sigma_{GD,i2(j)}}{2}$$

$\sigma_{mdD,i(j)}$ = Mean stress due to relative displacement in wave, in [N/mm²], defined as:

$$\sigma_{mdD,i(j)} = \frac{\sigma_{dD,i1(j)} + \sigma_{dD,i2(j)}}{2}$$

3.4 Global Axial Stress

3.4.1 Hull girder bending stress

3.4.1.1 Stress due to hull girder wave bending moments

The hull girder hot spot stress, in [N/mm²], for load cases i_1 and i_2 of considered loading condition (j) is obtained from the following formula:

$$\sigma_{GD,ik(j)} = f_c . K_a . \left(\frac{M_{wv-LC,ik}}{I_{y-n50}} (z - z_n) - \frac{M_{wh-LC,ik}}{I_{z-n50}} . y \right) 10^{-3}$$

where:

$M_{wv-LC,ik}$ = Vertical wave bending moment, in [kN-m], of the considered dynamic load case, at the hull girder load calculation point of the considered longitudinal position for the loading condition (j) for i_k being equal to i_1 and i_2.

$M_{wh-LC,ik}$ = Horizontal wave bending moment, in [kN-m], of the considered dynamic load case, at the hull girder load calculation point of the considered longitudinal position for the loading condition (j) for i_k being equal to i_1 and i_2.

3.4.1.2 Stress due to still water hull girder bending moment

The hull girder hot spot stress due to still water bending moment [N/mm²], in loading condition (j) is obtained from the following formula:

$$\sigma_{GS,(j)} = \frac{f_c . K_a . \beta_{(j)} . M_{sw} . (z - z_n)}{I_{y-n50}} 10^{-3}$$

where:

M_{sw} = Permissible still water vertical bending moment [kN-m], at the hull girder load calculation point of the considered longitudinal position.

$\beta_{(j)}$ = Fraction of permissible still water vertical bending moment, for loading condition (j) as given below in Table 3.4.1.

Table 3.4.1: Fraction of permissible still water vertical bending moments, $\beta_{(j)}$

Vessel type	Full load condition	Normal/partial ballast condition
Tanker	0.6 in sagging condition	0.8 in hogging condition
Bulk carrier and dry Cargo ship[1)]	0.4 in sagging condition	0.8 in hogging condition [2)]
MPV/ general dry cargo ship[3)]	1.0 in sagging condition	1.0 in hogging condition
Liquefied gas carriers	0.7 in sagging condition	0.8 in hogging condition
Container ships	0.90 in hogging condition	0.8 in hogging condition
Ore Carrier[1)]	1.0 in sagging condition	1.0 in hogging condition
Passenger Ship[4)]	--	1.0 in hogging condition
RO-RO[4)]	--	1.0 in hogging condition
Others [5)]	--	

1) Applicable for ore carrier, bulk carrier and dry cargo ships except MPV/general dry cargo ships having a long centre cargo hold.

2) In alternate condition it is taken as 0.75.

3) Applicable for MPV/general dry cargo ships having a long centre cargo hold.

4) Values used when global FE analysis is required. Prescriptive assessment of longitudinal end connections is not required for passenger vessels.

5) Other ships shall be specifically considered.

3.5 Local bending stress

3.5.1 Stress due to stiffener bending

3.5.1.1 Stress due to dynamic pressure

The hot spot stress, in [N/mm^2], due to local dynamic pressure in load case i_1 and i_2 for loading condition (j) is obtained from the following formula:

$$\sigma_{LD,ik(j)} = \frac{K_b . K_n . s . \ell_{bdg}{}^2 . \left(\eta_W . f_{NL} . P_{W,ik(j)} + \eta_{ld} . P_{ld,ik(j)} + \eta_{bd} . P_{bd,ik(j)}\right)\left(1 - \frac{6X_e}{\ell_{bdg}} + \frac{6X_e^2}{\ell_{bdg}{}^2}\right)}{12Z_{eff-n50}}$$

where:

$P_{W,ik(j)}$ = Dynamic wave pressure, at the mid span, in [kN/m^2], in load case i_1 and i_2 for loading condition (j) as given in Chapter 5.

$P_{ld,ik(j)}$ = Dynamic liquid tank pressure, at the mid span, in [kN/m^2]], in load case i_1 and i_2 for loading condition (j) as given in Chapter 5.

Pressure acting on both sides of the stiffener, i.e. applied on the attached plate on stiffener side or on opposite side to the stiffener, could be simultaneously considered if relevant in the loading condition.

For the deck longitudinal stiffeners of bulk carriers, no internal pressure from the topside tank is considered.

$P_{bd,(j)}$ = Dynamic dry bulk cargo pressure at the mid span [kN/m^2], in load case i_1 and i_2 for loading condition (j) as given in Chapter 5.

$\eta_W, \eta_{ld}, \eta_{bd}$ = Pressure normal coefficients, taken as:

= 1 when the considered pressure is applied on the stiffener side,

= −1 otherwise.

f_{NL} = Correction factor for the non-linearity of the wave pressure taken as:

$$f_{NL} = 1 \text{ for } z > T_{LC} + 2h_w$$

$$f_{NL} = 2.5\,\frac{z - T_{LC}}{h_w} - 4 \text{ for } T_{LC} + 1.8h_w < z \leq T_{LC} + 2h_w$$

$$f_{NL} = 0.5\,\frac{z - T_{LC}}{h_w} - 0.4 \text{ for } T_{LC} + 1.fh_w < z \leq T_{LC} + 1.8h_w$$

$$f_{NL} = 0.4 \text{ for } T_{LC} + 1.2h_w < z \leq T_{LC} + 1.6h_w$$

$$f_{NL} = 0.7 - 0.25\,\frac{z - T_{LC}}{h_w} \text{ for } T_{LC} + 0.6h_w < z \leq T_{LC} + 1.2h_w$$

$$f_{NL} = 1 - 0.75\,\frac{z - T_{LC}}{h_w} \text{ for } T_{LC} - 0.2h_w < z \leq T_{LC} + 0.6h_w$$

$$f_{NL} = 0.1875\,\frac{z - T_{LC}}{h_w} + 1.1875 \text{ for } T_{LC} - h_w < z \leq T_{LC} - 0.2h_w$$

$$f_{NL} = 1 \text{ for } z \leq T_{LC} - h_w$$

h_w = Water head equivalent to the pressure at waterline, in [m].

X_e = Distance, in [m], to the hot spot from the closest end of the span ℓ_{bdg}, as defined in Figure 3.5.1.

$Z_{eff-n50}$= Net section modulus [cm^3], of the considered stiffener calculated considering an effective breadth b_{eff} of attached plating and taken at the stiffener flange.

b_{eff} = Effective breadth [mm], of attached plating specified at the ends of the span and in way of end brackets and supports, taken as:

$$b_{eff} = s . \min\left(\frac{\frac{1.04}{3}}{1 + \frac{3}{\left(\frac{\ell_{bdg}}{s}\left(1 - \frac{1}{\sqrt{3}}\right).10^3\right)^{1.35}}}; 1.0\right)$$

for $\frac{\ell_{bdg}}{s}\left(1 - \frac{1}{\sqrt{3}}\right).10^3 \geq 1$

$$b_{eff} = 0.26\ell_{bdg}\left(1 - \frac{1}{\sqrt{3}}\right).10^3$$

for $\frac{\ell_{bdg}}{s}\left(1 - \frac{1}{\sqrt{3}}\right).10^3 < 1$

s = Stiffener spacing in [m].

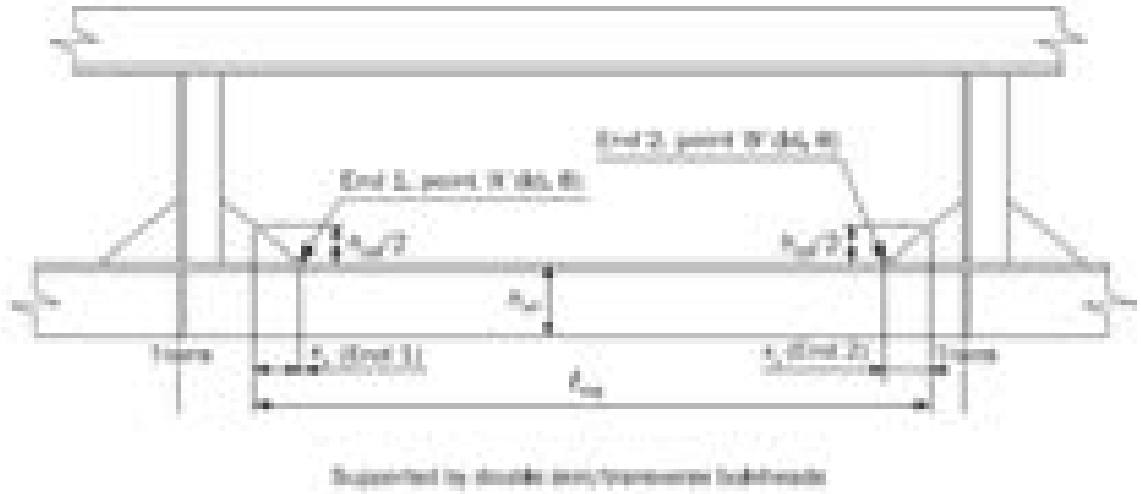

Figure 3.5.1: Definition of effective span and X_e for hot spot

3.5.1.2 Stress due to static pressure

The hot spot stress due to local static pressure [N/mm^2], for loading condition (j) is obtained from the following formula:

$$\sigma_{LS,(j)} = \frac{K_b . K_n . s . \ell_{bdg}{}^2 . \left(\eta_S . P_{S(j)} + \eta_{ls} . P_{ls(j)} + \eta_{bs} . P_{bs(j)}\right)\left(1 - \frac{6X_e}{\ell_{bdg}} + \frac{6X_e^2}{\ell_{bdg}{}^2}\right)}{12Z_{eff-n50}}$$

where:

$P_{S(j)}$ = Static external pressure [kN/m^2], in loading condition (j) as given in Chapter 5.

$P_{ls(j)}$ = Static liquid tank pressure [kN/m^2], in loading condition (j) as given in Chapter 5.

Pressure acting on both sides could be simultaneously considered if relevant in the loading condition.

$P_{bs(j)}$ = Static dry bulk cargo pressure [kN/m^2], in loading condition (j) as given in Chapter 5.

$\eta_S, \eta_{ls}, \eta_{bs}$ = Pressure normal coefficients, taken as:

= 1 when the considered pressure is applied on the stiffener side,

= −1 otherwise.

3.6 Stress due to relative displacements of primary supporting members

3.6.1 The additional hot spot stress due to the relative displacement of primary supporting members is to be considered for longitudinal stiffener end connections fitted on transverse web frames or floors located:

- in way of plane transverse bulkheads (including swash bulkheads in cargo holds), or

- in way of transverse stools and cofferdam bulkheads.

3.6.2 The relative displacement is defined as the lateral displacement of the longitudinal measured at the frame forward (Fwd) or afterward (Aft) relative to the displacement at the transverse bulkhead (or restrained frame).

3.6.3 Displacement of primary supporting members

The displacement of primary supporting members is to be evaluated using a FE model. The displacement of a primary supporting member is the displacement of the point located at the intersection of the stiffener flange, the stiffener web and the supporting member web. This displacement is measured along the line defined by the intersection between the stiffener web and the primary supporting member web in the non-deformed state of the finite element model.

3.6.4 Sign convention

Where the stress at the hot spot location, i.e. at the flange of longitudinal at the transverse

bulkhead (or restrained frame), due to relative displacement is in tension, the sign of the relative displacement is positive.

3.6.5 Stress due to relative displacement derived using FE method

The relative displacement stress can be calculated based on relative displacement derived from FE analysis. If the relative displacement is derived from FE analysis, the local rotation at the position of the hot spot needs to be accounted for.

The stress due to relative deflection, in [N/mm2], for load case i_1 and i_2 of loading condition (j) for both locations 'a' and 'f' is to be calculated directly using the following expression:

$$\sigma_{dD,ik(j)} = \begin{pmatrix} K_b.\sigma_{dFwd-a,ik(j)} + K_b.\sigma_{dAft-a,ik(j)} \text{ for location "a"} \\ K_b.\sigma_{dFwd-f,ik(j)} + K_b.\sigma_{dAft-f,ik(j)} \text{ for location "f"} \end{pmatrix}$$

(k=1,2)

$$\sigma_{dFwd-a,ik(j)} = \frac{3.9\,\delta_{Fwd,ik(j)}.EI_{Aft-n50}.I_{Fwd-n50}}{Z_{Aft-n50}.\ell_{Fwd}(\ell_{Aft}I_{Fwd-n50} + \ell_{Fwd}I_{Aft-n50})}\left(1 - 1.15\frac{|X_{eAft}|}{\ell_{Aft}}\right)10^{-5}$$

$$\sigma_{dAft-a,ik(j)} = \left[\frac{3.9\,\delta_{Aft,ik(j)}.EI_{Aft-n50}.I_{Fwd-n50}}{Z_{Aft-n50}.l_{Aft}(l_{Aft}I_{Fwd-n50} + l_{Fwd}I_{Aft-n50})}\left(1 - 1.15\frac{|X_{eAft}|}{l_{Aft}}\right) - \frac{0.9\delta_{Aft,ik(j)}.EI_{Aft-n50}|X_{eAft}|}{Z_{Aft-n50}\ell_{Aft}^3}\right]10^{-5}$$

$$\sigma_{dFwd-f,ik(j)} = \left[\frac{3.9\,\delta_{Fwd,ik(j)}.EI_{Aft-n50}.I_{Fwd-n50}}{Z_{Fwd-n50}.l_{Fwd}(l_{Aft}I_{Fwd-n50} + l_{Fwd}I_{Aft-n50})}\left(1 - 1.15\frac{|X_{eFwd}|}{l_{Fwd}}\right) - \frac{0.9\delta_{Fwd,ik(j)}.EI_{Fwd-n50}|X_{eFwd}|}{Z_{Fwd-n50}\ell_{Fwd}^3}\right]10^{-5}$$

$$\sigma_{dAft-f,ik(j)} = \frac{3.9\,\delta_{Aft,ik(j)}.EI_{Aft-n50}.I_{Fwd-n50}}{Z_{Fwd-n50}.\ell_{Aft}(\ell_{Aft}I_{Fwd-n50} + \ell_{Fwd}I_{Aft-n50})}\left(1 - 1.15\frac{|X_{eFwd}|}{\ell_{Fwd}}\right)10^{-5}$$

where:

a, f = Suffix which denotes the location as indicated in Figure 3.6.5.

Aft, Fwd = Suffix which denotes the direction, afterward (Aft) or forward (Fwd), from the transverse bulkhead as shown in Figure 3.6.5.

K_b = Stress concentration factor due to bending for the location 'a' or 'f' which may correspond to points 'A' or 'B' as defined in Table 3.7.2.

$\sigma_{dFwd-a,ik(j)}, \sigma_{dAft-a,ik(j)}, \sigma_{dFwd-f,ik(j)}, \sigma_{dAft-f,ik(j)}$ = Additional stress at location 'a' and 'f', in [N/mm^2], due to the relative displacement between the transverse bulkhead including swash bulkhead or floors in way of stool and the forward (Fwd) and afterward (Aft) transverse web or floor respectively for load case i_1 and i_2 of loading condition (j), taken as:

$I_{Aft-n50}, I_{Fwd-n50}$ = Net moment of inertia, in [cm^4], of forward (Fwd) and afterward (Aft) longitudinal.

$Z_{Aft-n50}, Z_{Fwd-n50}$ = Net section modulus in [cm^3], of forward (Fwd) and afterward (Aft) stiffener.

ℓ_{Aft}, ℓ_{Fwd} = Span, in [m], of forward (Fwd) and afterward (Aft) longitudinal, as shown in Figure 3.6.5.

X_{eAft}, X_{eFwd} = Distance, in [m], as shown in Figure 3.5.1, to the hot spot in location 'a' or 'f' from the closest end of ℓ_{Fwd} and ℓ_{Aft} respectively.

$\delta_{Aft,ik(j)}, \delta_{Fwd,ik(j)}$ = Relative displacement in the direction perpendicular to the attached plate, in [mm], between the transverse bulkhead (including swash bulkhead or floor in way of stools) and the forward (Fwd) or afterward (Aft) transverse web (or floor) as shown in Figure 3.6.5.

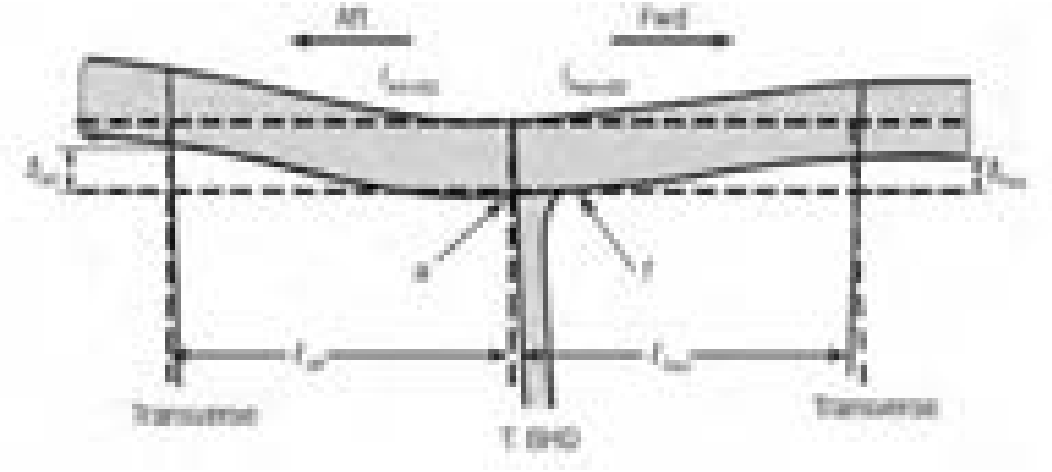

Figure 3.6.5: Definition of the relative displacement (example of the side longitudinal)

3.6.6 Stress due to relative displacement in still water

The additional hot spot stress, in [N/mm^2], in still water, due to the relative displacement is to be obtained according to Cl.3.6.5, replacing dynamic local stress σ_{LD} and dynamic pressure with static local stress σ_{LS} and static pressure.

3.7 Stress concentration factor

3.7.1 Unsymmetrical stiffener

3.7.1.1 The stress concentration factor K_n for unsymmetrical flange of built-up and rolled angle stiffeners under lateral load, calculated at the web's mid-thickness position, as shown in Figure 3.7.1.1, is to be taken as:

$$K_n = \frac{1 + \lambda\,\beta^2}{1 + \lambda\,\beta^2\,\Psi_z}$$

where,

$$\lambda = \frac{3\left(1 + \frac{\eta}{280}\right)}{1 + \frac{\eta}{40}}$$

$$\eta = \frac{\ell_{bdg}^4 . 10^{12}}{b_{f-n50}^3 . t_{f-n50} . {h_{stf-n50}}^2 . \left(\frac{4 . h_{stf-n50}}{t_{w-n50}^3} + \frac{s}{t_{p-n50}^3}\right)}$$

$$\beta = 1 - \frac{2b_{g-n50}}{b_{f-n50}} \text{ for built} - \text{up profiles}$$

$$\beta = 1 - \frac{t_{w-n50}}{b_{f-n50}} \text{ for rolled angle profiles}$$

b_{g-n50} = Eccentricity of the stiffener equal to the distance from flange's edge to web's centreline, in [mm], as shown in Figure 3.7.1.2.

b_{f-n50} = Net breadth of flange, in [mm], as shown in Figure 3.7.1.2.

t_{f-n50} = Net flange thickness, in [mm], as shown in Figure 3.7.1.2.

$h_{stf-n50}$ = Net stiffener height, including face plate, in [mm], as shown in Figure 3.7.1.2.

t_{w-n50} = Net web thickness, in [mm], as shown in Figure 3.7.1.2.

h_{w-n50} = Net web's height stiffener, in [mm], as shown in Figure 3.7.1.2.

t_{p-n50} = Net thickness of attached plating, in [mm], as shown in Figure 3.7.1.2.

Ψ_z = Coefficient given as:

$$\Psi_z = \frac{h_{w-n50}^2 t_{w-n50}}{4Z_{n50}} 10^{-3}$$

Z_{n50} = Net section modulus, in [cm^3], of stiffener with an attached plating breadth equal to the stiffener spacing.

Figure 3.7.1.1: Bending stress in stiffener with symmetrical and unsymmetrical flange

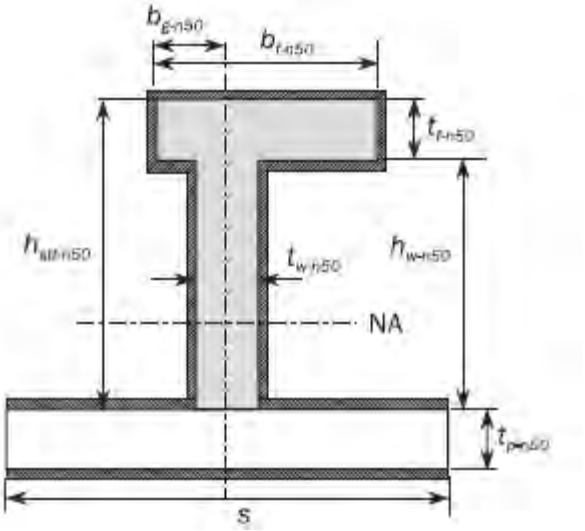

Figure 3.7.1.2: Stiffener - Net scantling

3.7.1.2 Bulb profiles

For bulb profiles K_n factor is to be calculated using the equivalent built-up profile as shown in Figure 3.7.1.3. The flange of the equivalent built-up profile is to have the same properties as the bulb flange, i.e. same cross sectional area and moment of inertia about the vertical axis and neutral axis position. For HP bulb profiles, examples of the equivalent built up profile dimensions are listed in Table 3.7.1.

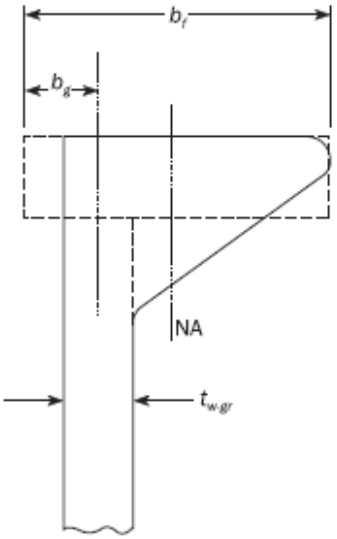

Figure 3.7.1.3: Bulb profile and equivalent built-up profile

Table 3.7.1: HP equivalent built-up profile dimensions				
HP-bulb		**Equivalent built-up flange in gross thickness**		
Height (mm)	**Gross web thickness, t_{w-gr} (mm)**	**b_f (mm)**	**t_{f-gr} (mm)**	**b_0 (mm)**
200	9 – 13	$t_{w-gr} + 24.5$	22.9	$(t_{w-gr} + 0.9)/2$
220	9 – 13	$t_{w-gr} + 27.6$	25.4	$(t_{w-gr} + 1.0)/2$
240	10 – 14	$t_{w-gr} + 30.3$	28.0	$(t_{w-gr} + 1.1)/2$
260	10 – 14	$t_{w-gr} + 33.0$	30.6	$(t_{w-gr} + 1.3)/2$
280	10 – 14	$t_{w-gr} + 35.4$	33.3	$(t_{w-gr} + 1.4)/2$
300	11 – 16	$t_{w-gr} + 38.4$	35.9	$(t_{w-gr} + 1.5)/2$
320	11 – 16	$t_{w-gr} + 41.0$	38.5	$(t_{w-gr} + 1.6)/2$
340	12-17	$t_{w-gr} + 43.3$	41.3	$(t_{w-gr} + 1.7)/2$
370	13-19	$t_{w-gr} + 47.5$	45.2	$(t_{w-gr} + 1.9)/2$
400	14-19	$t_{w-gr} + 51.7$	49.1	$(t_{w-gr} + 2.1)/2$
430	15-21	$t_{w-gr} + 55.8$	53.1	$(t_{w-gr} + 2.3)/2$

3.7.2 Longitudinal stiffener end connections

3.7.2.1 The stress concentration factors K_a and K_b are given in Table 3.7.2 for end connection of stiffeners subjected to axial and lateral loads. The values given in Table 3.7.2 for soft toe are valid provided that toe geometry complies with the requirements given in Cl.3.7.2.5. The stress concentration factor K_b given for lateral loads are to be used also for stress due to relative displacements.

3.7.2.2 Other connection types

When connection types other than those given in Table 3.7.2 are proposed, the fatigue strength for the proposed connection type is to be assessed either by performing a very fine mesh FE analysis as described in Section 4 to obtain directly the hot spot stress, or by calculating the stress concentration factor using FE analysis according to Cl.3.7.3.

3.7.2.3 Overlapped connection

Overlapped connection types for longitudinal stiffeners, i.e. attachments welded to the web of the longitudinals, are to be avoided in areas where fatigue might be critical e.g. in way of cargo hold region. If overlap is used an additional factor of 1.15 should be used.

3.7.2.4 End stiffener without connection to web stiffener: Where the web stiffener is omitted or not connected to the longitudinal flange in way of:

- Side shell below $1.1T_{sc}$

- Bottom.

- Inner hull longitudinal bulkhead below $1.1T_{sc}$

- Hopper.

- Topside tank sloping plating below $1.1T_{sc}$

- Inner bottom.

the following is required:

-A complete collar as defined in Figure 3.7.2.1 (i.e. connection type ID 31 of Table 3.7.2.) or,

-A detail design for cut-outs as described in **Appendix A**.

Equivalence to cut-outs given in **Appendix A**, A.2.1 may be accepted provided it is assessed for fatigue by using comparative FE analysis which is based on hot spot stress around the cut-out in the web plate of the primary supporting member inclusive of the collar, as given in **Appendix A**, A.2.2.

3.7.2.5 Soft toe of web stiffener and backing bracket

The toe geometry end connection of web stiffener and backing bracket is to comply with the following:

$$\theta \leq 20$$

$$h_{toe} \leq \max(t_{bkt-gr}, 15)$$

where:

θ = Angle of the toe in [deg], as shown in Figure 3.7.2.2.

h_{toe} = Height of the toe in [mm], as shown in Figure 3.7.2.2.

t_{bkt-gr} = Gross thickness of the bracket in [mm].

Recommended detail designs for longitudinal end connections with soft toes and backing brackets are given in Figure 3.7.2.2.

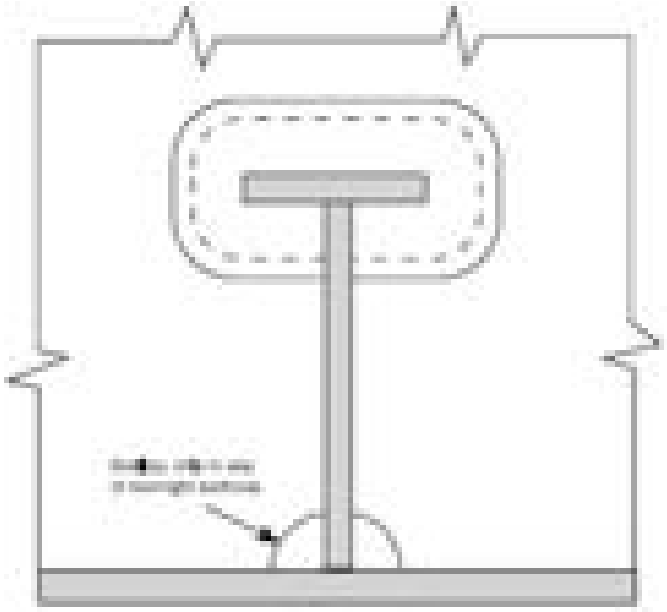

Figure 3.7.2.1: Complete collar fitted before the stiffener is pulled through the web frame

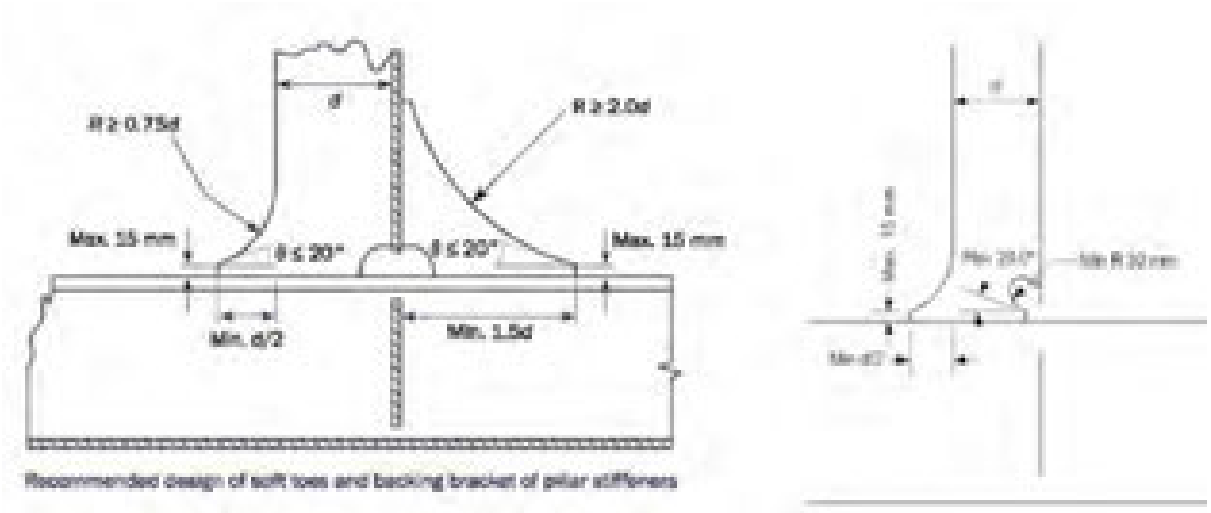

Recommended design of soft toes and backing bracket of pillar stiffeners

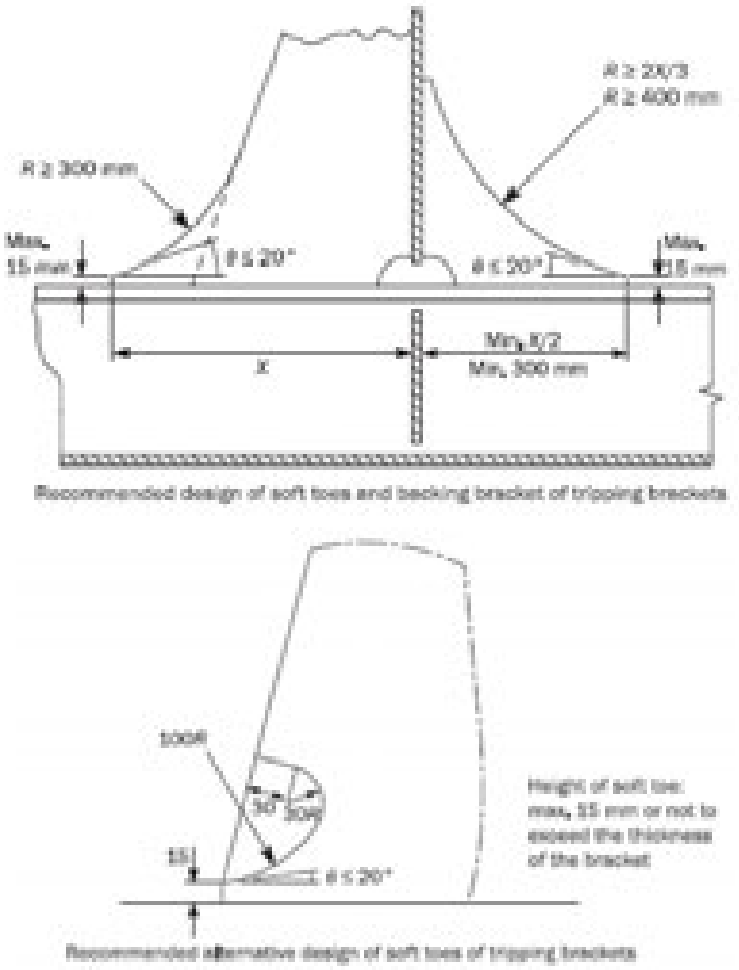

Figure 3.7.2.2: Detail design for soft toes and backing brackets

(1) The attachment length d [mm], is defined as the length of the welded attachment on the longitudinal stiffener flange without deduction of scallop.

(2) Where the longitudinal stiffener is a flat bar and there is a web stiffener/bracket welded to the flat bar stiffener, the stress concentration factor listed in the table (excluding detail 31 and 32) is to be multiplied by a factor of 1.12 when the thickness of attachment is thicker than the 0.7 times thickness of flat bar stiffener. This also applies to unsymmetrical profiles where there is less than 8[mm] clearance between the edge of the stiffener flange and the attachment, e.g. bulb or angle profiles where the clearance of 8[mm] cannot be achieved.

(3) Designs with overlapped connection / attachments, see Cl.3.7.2.3.

(4) ID. 31 and 32 refer to details where web stiffeners are omitted or not connected to the longitudinal stiffener flange. See Cl.3.7.2.4 For detail 31, however, the collar is assumed welded to the stiffener flange.

(5) For connection type ID. 32 with no collar and/or web plate welded to the flange, the stress concentration factors provided in this table are to be used irrespective of slot configuration.

(6) The fatigue assessment point ‘A’ is located at the connection between the stiffener web and the transverse web frame or lug plate. The stress concentration factor represents the hot spot related to the longitudinal stress.

3.7.3 Alternative design

3.7.3.1 Derivation of alternative stress concentration factors

The stress concentration factors for alternative designs are to be calculated by a very fine mesh FE analysis according to the requirements given in Section 4. Additional requirements for derivation of geometrical stress concentration factors for stiffener end connections using very fine mesh FE analysis are given below:

3.7.3.2 FE model extent: the FE model, as shown in Figure 3.7.3, is to cover at least four web frame spacings in the longitudinal stiffener direction with the detail to be considered located at the middle frame. The same type of end connection is to be modelled at all the web frames. In the transverse direction, the model may be limited to one stiffener spacing.

3.7.3.3 Load application: in general, two loading cases are to be considered:

- Axial loading by enforced displacement applied to the model ends and

- Lateral loading by unit pressure load applied to the shell plating.

3.7.3.4 Boundary conditions applied in the FE model considered:

- Symmetry conditions are applied along the longitudinal cut of the plate flange, along transverse and vertical cuts on web frames and on top of the web stiffener.

- For lateral pressure loading: the model is to be fixed in all degrees of freedom at both forward and aft ends.

- For axial loading: the model is to be fixed for displacement in the longitudinal direction at the aft end of the model while enforced axial displacement is applied at the forward end, or vice versa.

3.7.3.5 FE mesh density: At the location of the hot spots under consideration, the element size is to be in the order of the thickness of the stiffener flange or 10[mm] depending on the type of stiffener. In the remaining part of the model, the element size is to be in the order of s/10, where s is the stiffener spacing.

3.7.3.6 The geometric stress concentration factor is defined as the ratio of the hot spot stress derived from FE analysis up on nominal stress calculated according to analytical stress analysis for longitudinal stiffener connections.

3.7.3.7 Two geometric stress concentration factors K_a and K_b are to be determined, for 2 loading cases specified above, and are determined as follows:

- For the axial loading case:

$$K_a = \frac{\sigma_{HSAx}}{\sigma_{NomAx}}$$

- For the bending loading case:

$$K_b = \frac{\sigma_{HSBd}}{\sigma_{NomBd}}$$

σ_{HSAx} = Hot spot stress, [N/mm^2], determined at the stiffener flange for the axial load.

σ_{NomAx} = Nominal axial stress, [N/mm^2], calculated at the stiffener flange according to Cl.3.4.1 for the axial load applied for the FE calculation.

σ_{HSBd} = Hot spot stress, [N/mm^2], determined at the stiffener flange for the unit pressure load.

σ_{NomBd} = Nominal bending stress, [N/mm^2], calculated at the stiffener flange according to Cl.3.5.1 in way of the hot spot for the unit pressure load applied for the FE calculation.

The derivation of geometrical stress concentration factors for alternative designs is to be documented and provided to IRS.

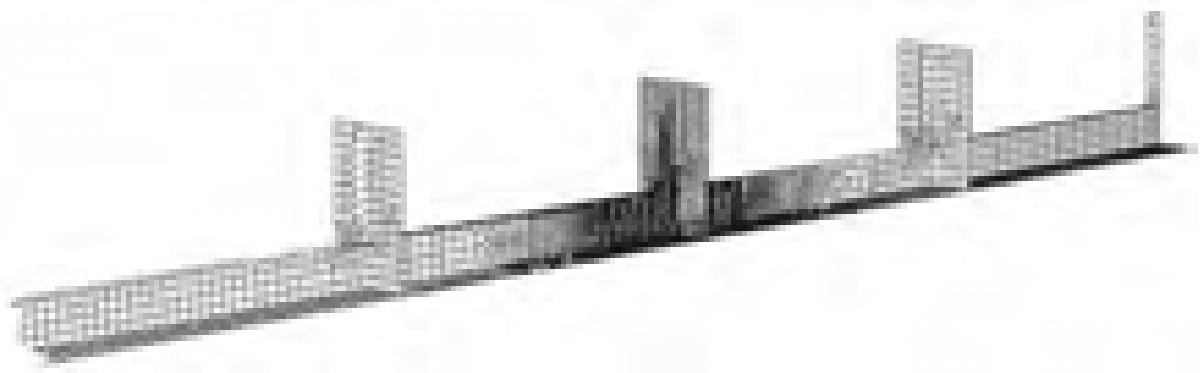

Figure 3.7.3: Fine mesh finite element model for derivation of geometrical stress concentration factor (example of stiffener with flange)

Section 4

Finite Element Stress Analysis

4.1 General

4.1.1 Application

4.1.1.1 This section applies to fatigue assessment by finite element stress analysis. The methods are based on the hot spot stress approach and requirements are given for both plated welded joints and for non-welded hot spots. The hot spot stress takes into account structural discontinuities due to the structural detail of the welded joint, but not taking into account the notch effect at the weld toe.

4.1.1.2 The local nominal stress for non-welded area at cut plate edge requires a specific finite element model and a well specified method for the calculation, Refer Cl.4.2.4.

4.1.1.3 The stress at hot spot for welded joints is generally highly dependent on the finite element model used for the representation of the structure. Where other methods than those described in this Section are adopted for calculation of FEA based hot spot stress, these methods are to be submitted to IRS for review.

4.1.1.4 Limitations of the hot spot stress methodology for simple connections is given in 4.7.

4.1.1.5 Some typical structural details to be assessed for fatigue by very fine mesh analysis according to 4.2 to 4.6 are given below, irrespective of their compliance with the design standard given in **Appendix A**.

- Welded/radiused hopper knuckle (lower/upper) connection (intersection of hopper sloping plate, knuckled inner bottom plate, longitudinal girder, floor and transverse web, inner hull longitudinal bulkhead, transverse web and side stringer) at the most critical frame location.

- Connections of bulkhead (transverse/ corrugated) to the adjoining structures.

- Bracket at the heel of horizontal stringer.

- Large openings

- Upper side frame bracket toe in case of flat bottom of top wing

- Deck plating and longitudinal hatch coaming end bracket toe.

- Side frame end brackets and lower hopper knuckle for single side bulk carrier

The selection of critical locations on the structural members and the fine mesh structural models is to be in accordance with the requirements given in IRS *Guidelines on Structural Assessment of Ships based on Finite Element Method.* Additional specific details may be requested to be checked on a case-by-case basis by IRS.

4.2 Type of details

4.2.1 General

4.2.1.1 The method for calculation of hot spot stress at weld toe for any welded details is given in 4.5 and for web stiffened cruciform joints given in 4.6. The method for calculation of local stress for non-welded area is given in Cl.4.5.4.

4.2.1.2 Two types of hot spots denoted ‘a’ and ‘b’ are described in Table 4.2.1 at weld toe of ordinary welded joints. These are defined depending location on the plate and their orientation to the weld toe as illustrated in Figure 4.2.1.

Table 4.2.1: Types of hot spots

Type	Description
a	Hot spot at the weld toe on plate surface
b	Hot spot at the weld toe around the plate edge

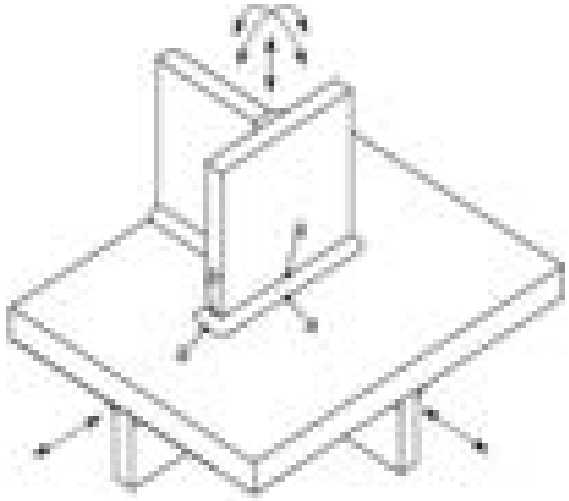

Figure 4.2.1: Types of hot spots

4.2.2 Web-stiffened cruciform joints

A standard cruciform joint corresponds to the intersection of two plates (Figure 4.2.2). A web-stiffened cruciform joint corresponds to a cruciform joint where the two plates are stiffened by another plate perpendicular to the first ones and acting as a web. The method for calculation of the hot spot stress at the weld toes of web-stiffened cruciform joints is given in 4.6.

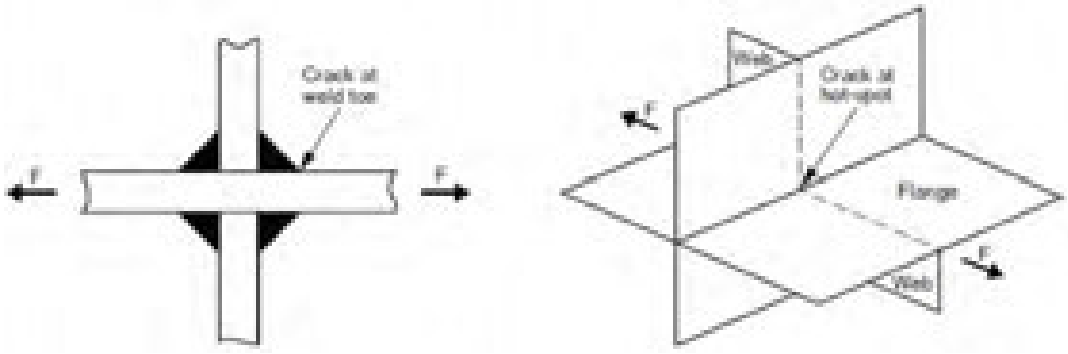

Figure 4.2.2: Standard cruciform joint (left hand side) and web-stiffened cruciform joint (right hand side)

4.2.3 Bent hopper knuckle details

Methods for the calculation of the hot spot stresses for bent hopper knuckles are given in Cl.4.5.5.

4.2.4 Non welded details

Methods for the calculation of the local nominal stress for non-welded area such as cut plate edges, cut-outs for stiffeners connections at web frames, hatch corners, etc. are given in Cl.4.5.4.

4.3 FE model

4.3.1 Three types of FE models are generally used:

- Full ship model

- Partial ship model, like cargo hold model for ships with cargo holds

- Local models, like hot spot models for welded details and local stress models for free plate edges

Evaluation of hot spot stresses for fatigue assessment requires FE models with very fine finite element meshes in way of areas of high stress concentration. These very fine mesh zones are either incorporated into the global FE model (Figure 4.3.1) or by use of sub-modelling technique. The coarse mesh model of cargo holds is to be made according to IRS *Guidelines on Structural Assessment of Ships based on Finite Element Method*. In sub-modelling technique, a separate local finite element model with very fine mesh zones in conjunction with the boundary conditions obtained from a coarse mesh global model is used. Typical examples of local finite element models with very fine mesh are shown in Figure's.4.3.2, 4.3.3 and 4.3.4.

4.3.2 Corrosion model

The thickness to be used in FE analysis is net thickness, t_{n50} together with stress correction factor, f_c, as given in Section 1.

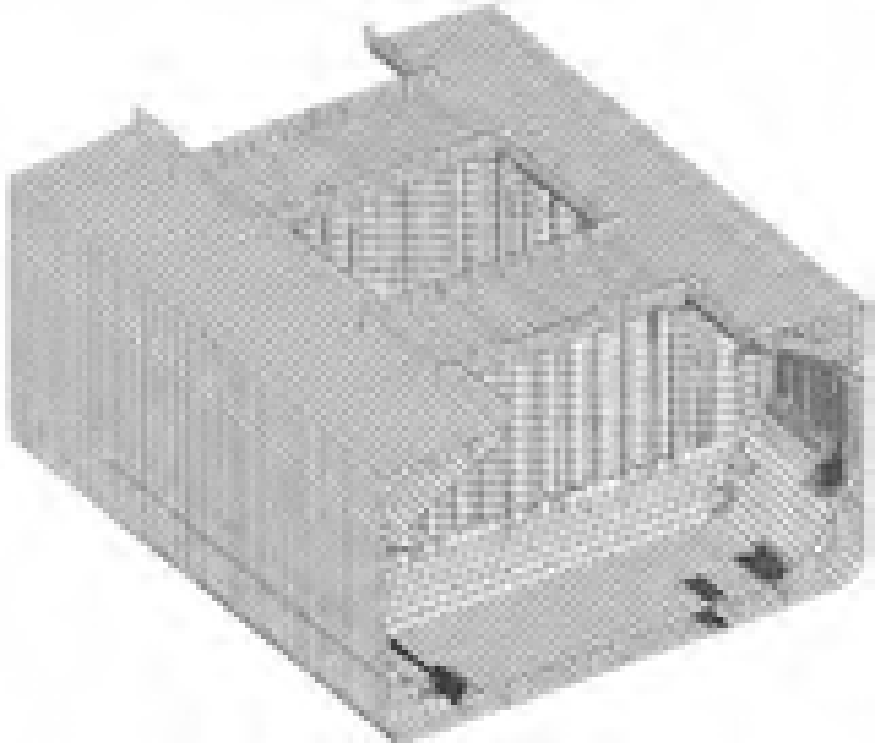

Figure 4.3.1: Very fine mesh areas incorporated directly into the FE model

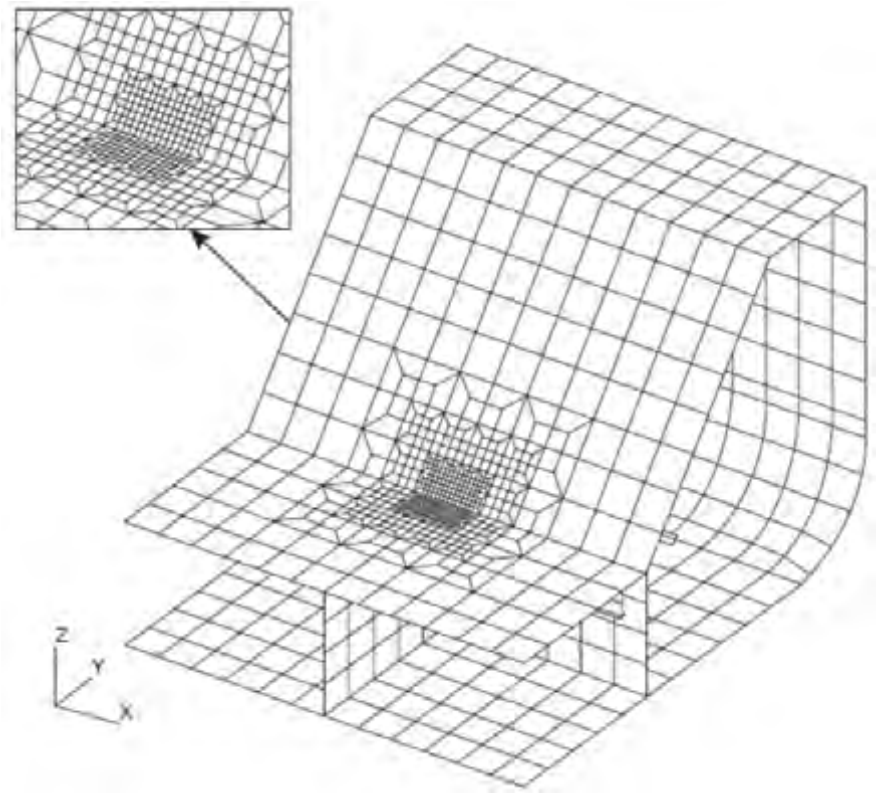

Figure 4.3.2: Local very fine mesh model of hopper knuckle connection between inner bottom and hopper plate

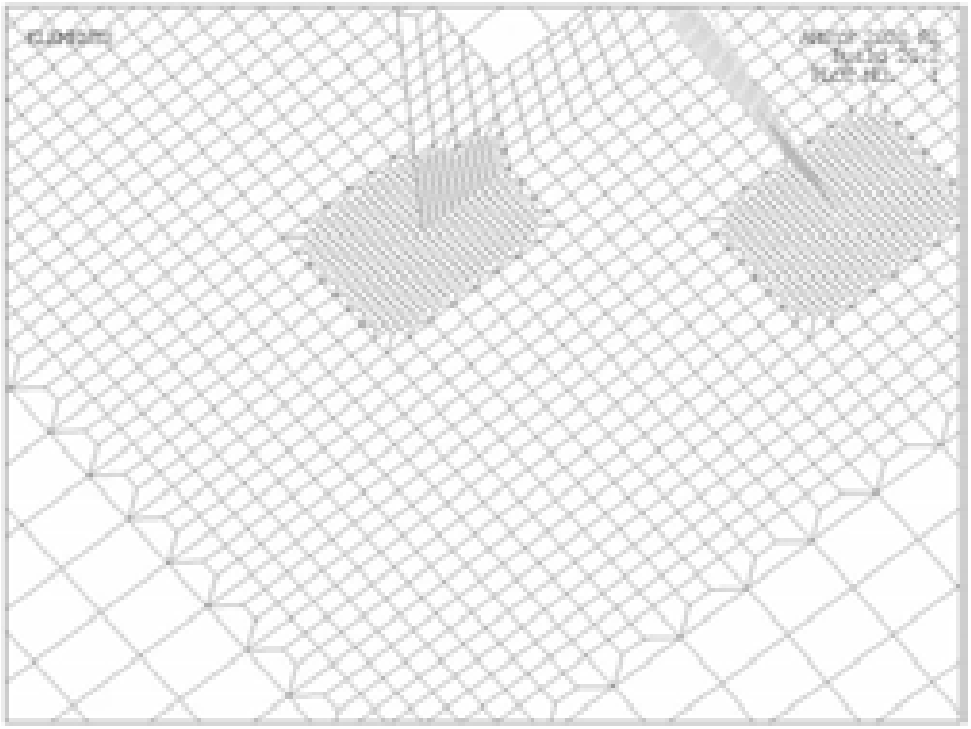

Figure 4.3.3: Local very fine mesh model in LPG carriers

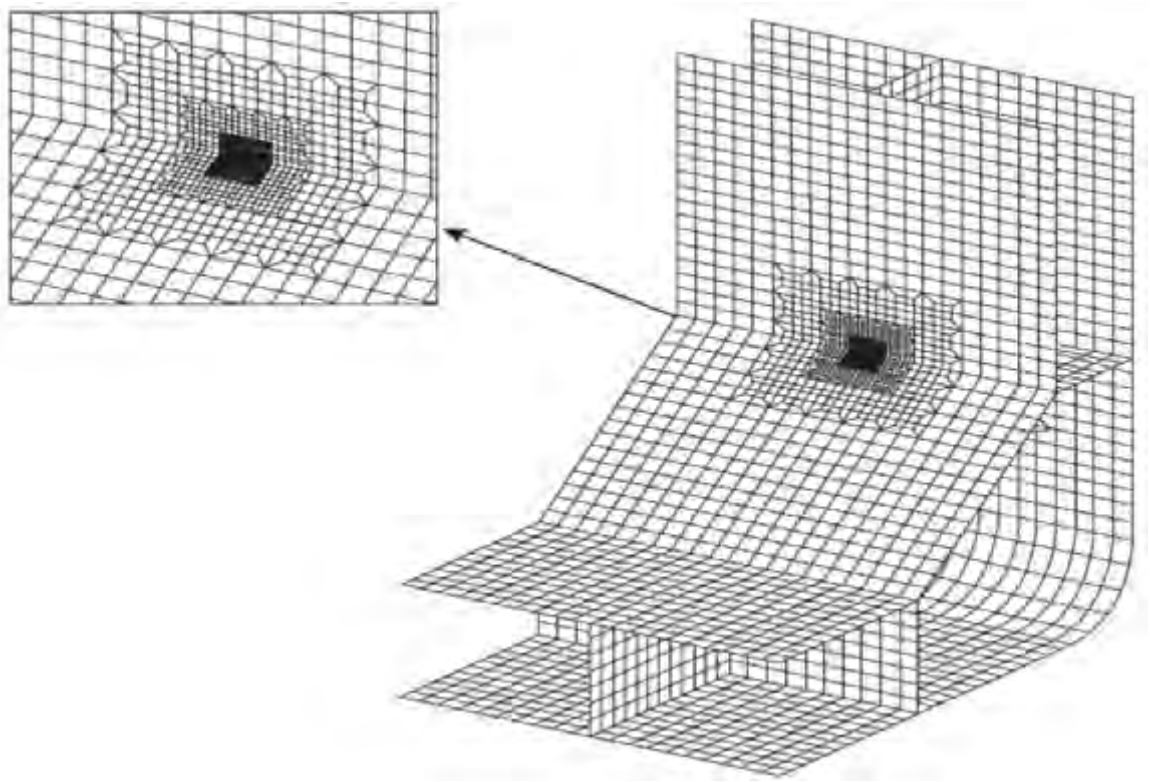

Figure 4.3.4: Local very fine mesh model of upper hopper knuckle connection between inner side shell and hopper plate in Bulk carriers

4.4 FE modelling for hot spot stress calculation

4.4.1 Separate local FE model (Sub-modelling technique)

4.4.1.1 Where a separate local finite element model is used for evaluating the hot spot stress range, the extent of the local model is to be such that the calculated stresses are not significantly affected by the imposed boundary conditions and the applied loads are far enough from the very fine mesh zones.

4.4.1.2 Where a separate local finite element model is used for evaluating the hot spot stress range, the boundary conditions and application of loads are to be in accordance with IRS *Guidelines on Structural Assessment of Ships based on Finite Element Method*.

4.4.1.3 The boundary of the fine mesh model is to be taken at adjacent primary supporting members such as girders, stringers and floors in the cargo hold model as far as practicable. Transverse web frames, stringer plates and girders at the boundaries of the local model need not be represented in the local model.

4.4.2 Mesh size

The evaluation of hot spot stress for 'a' type hot spot is to be based on shell element of mesh size $t_{n50} x\, t_{n50}$, where t_{n50} is the net thickness of the plate in way of the considered hot spot. The evaluation of hot spot stress for a 'b' type hot spot is to be based on shell element of mesh size 10×10[mm]. The aforementioned mesh size is to be maintained within the very fine mesh zone, extending over at least 10 elements in all directions from the fatigue hot spot position. The transition of element size between the coarser mesh and the very fine mesh zone is to be done gradually and an acceptable mesh quality is to be maintained. This transition mesh is to be such that a uniform mesh with regular shape gradually transitions from smaller elements to larger ones. An example of the mesh transition in way of the side frame bracket toe is shown in Figure 4.4.1. Mesh transitions should not be arranged close to the hot spot location.

For efficient read out of element stresses a mesh density in the order of size $t_{n50} x\, t_{n50}$ is generally preferred at the hot spot region.

4.4.3 Four node shell elements with adequate bending and membrane properties are to be used inside the very fine mesh zone. The four node element is to have a complete linear field of in-plane stresses and hence pure in-plane bending of the element can be exactly represented. In case of steep stress gradients, 8 node thin shell elements may be used, if deemed practical. The shell elements are to represent the mid plane of the plating. For practical purposes, adjoining plates of different thickness may be assumed to be median line aligned, i.e. no staggering in way of thickness change is required. The geometry of the weld and construction misalignment is not required to be modelled. The shell elements are to represent the mid plane of the plating as represented in Figure 4.5.1.

4.4.4 All structure in close proximity to the very fine mesh zones is to be modelled explicitly with shell elements. Quadrilateral elements are to have 90[deg] angles as much as possible or angles between 60[deg] and 120[deg]. The aspect ratio is to be close to 1. Triangular elements are to be avoided where possible. Use of extreme aspect ratio (e.g. aspect ratio greater than 3) and distorted elements (e.g. element's corner angle less than 60[deg] or greater than 120[deg]) are to be avoided.

4.4.5 Where stresses are to be evaluated on a free edge, such as cut-outs for stiffener connections at web frames, edge of plating and hatch corners, beam elements having the same depth as the adjoining plate thickness and negligible width is to be used to obtain the required local edge stress values.

Figure 4.4.1: Transition area between coarse and very fine mesh

4.4.6 Hatch corners and hatch coaming end bracket

4.4.6.1 In addition to the general requirements in Cl.4.4.1 to Cl.4.4.4, the modelling requirements in this subsection are applicable to the modelling of hatch corners/ hatch coaming end bracket. The selection of hatch corners/ hatch coaming end bracket for fatigue analysis is to be determined based on the level of stresses obtained from the cargo hold FE analysis.

4.4.6.2 Where separate local finite element models are used, the model extents are to be according to the following:

- Transversely, over the half-breadth of the ship,

- Longitudinally, from the midpoint of the cargo hold in which the concerned hatch corners/hatch coaming end bracket is located to the adjacent cargo hold up to and including the full width of the cross deck nearest to the concerned hatch corners/hatch coaming end bracket.

- Vertically, from the top plate of coaming to the intersection of the topside tank sloping plate with the side or inner side shell.

4.4.6.3 The primary supporting members and coaming stays are to be represented by shell finite elements having both membrane and bending properties. Figure 4.4.6.1 shows a typical FE model of the toe connection of a longitudinal hatch coaming end bracket to the deck plating with the very fine mesh zone having $t_{n50} x\, t_{n50}$ mesh size.

4.4.6.4 The hatch corner area is to be meshed using elements with a sufficiently small size to capture the local stress on the edge. In general, a minimum of 15 elements in 90[deg] arc are to be used to describe the curvature of the hatchway radius plating for a rounded corner (Figure 4.4.6.2). For an elliptical or parabolic corner, a minimum of 15 elements are to be used from the inboard radius end to a point on the edge located at half the longitudinal distance of the semi- major axis. A total of 20 elements are to be used at the elliptical edge of the hatch corner (Figure 4.4.6.3). However, the element edge dimensions along the free edge of the radius need not be less than the thickness of the plating being represented and also not to be greater than 5 times the thickness of the plating being represented. Mesh transitions should not be arranged close to bracket toes.

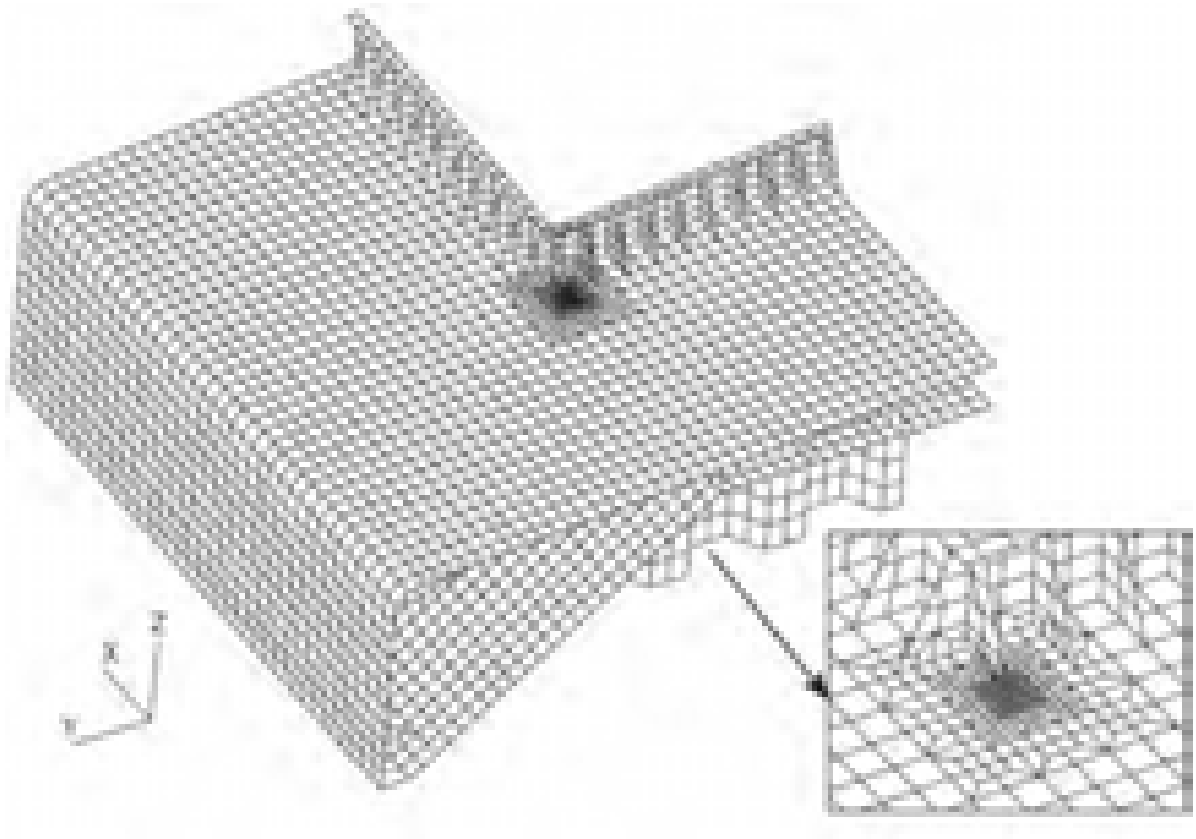

Figure 4.4.6.1: Local FE model of longitudinal hatch coaming end bracket to the deck plating with very fine mesh zone, $t_{n50} \times t_{n50}$ mesh

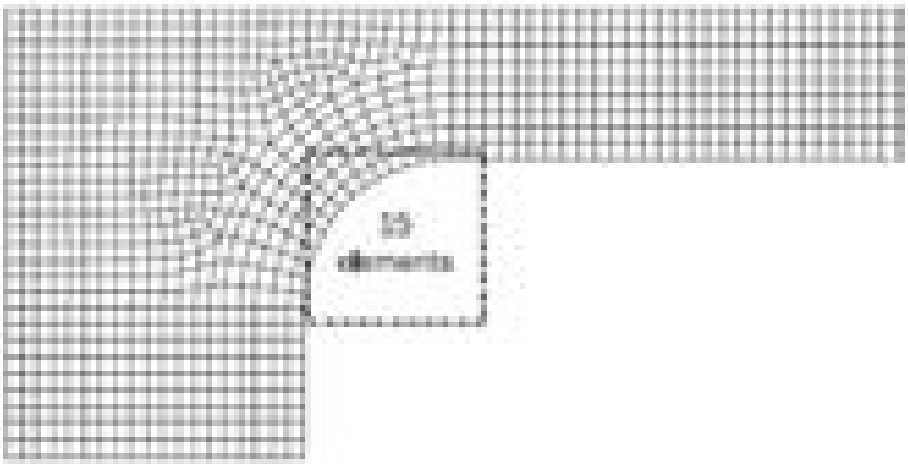

Figure 4.4.6.2: Mesh density for rounded hatch corner

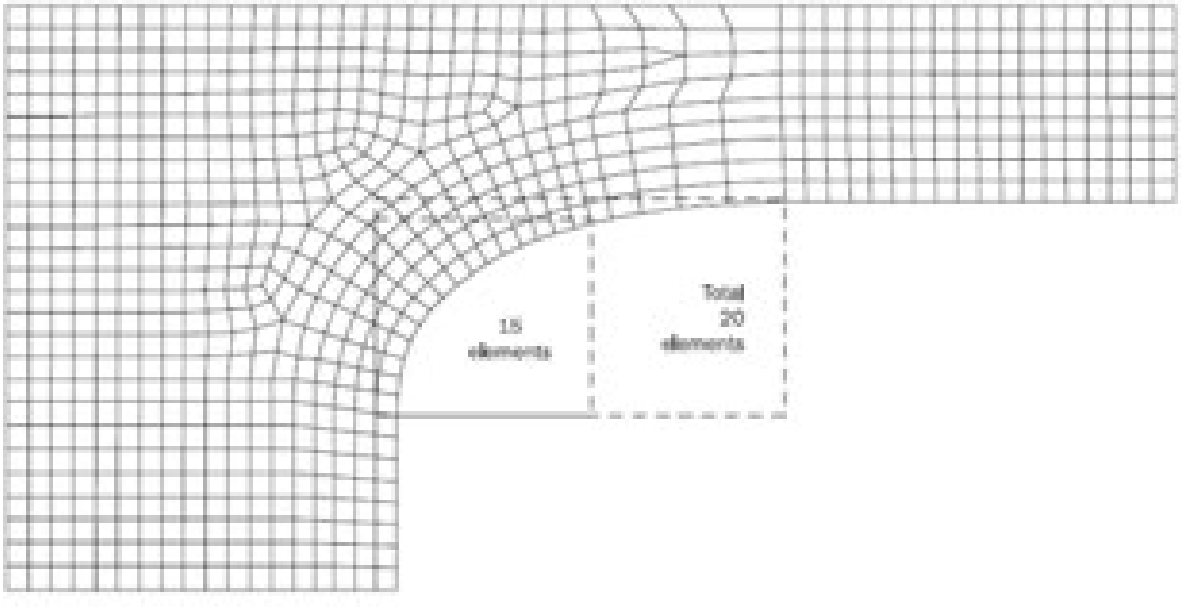

Figure 4.4.6.3: Mesh density for elliptical hatch corner

4.5 Hot spot stress for ordinary details different from web-stiffened cruciform joints

4.5.1 Types of welded details

This section applies to ordinary welded details: butt welds, fillet welds of T joints and ordinary cruciform joints. They do not apply to web-stiffened cruciform joints and bent hopper knuckles.

4.5.2 Welded details

For hot spot type 'a', the structural hot spot stress, σ_{HS}, is calculated from a finite element analysis with $t_{n50} x\, t_{n50}$ mesh density and is obtained by the following formula:

$$\sigma_{HS} = 1.12\sigma$$

where:

σ = Surface principal stress, in [N/mm^2], read out at a distance $t_{n50}/2$ away from the intersection line.

t_{n50} = Plate net thickness, in [mm], in way of the weld toe.

At structural details where the hot spot type 'a' is classified as a web-stiffened cruciform joint, the stress read out procedure of 4.6 is to be applied.

For hot spot type 'b', the stress distribution is not dependent on the plate thickness; the structural hot spot stress, σ_{HS} is derived from a finite element analysis with mesh density 10×10[mm] and is obtained by the following formula:

$$\sigma_{HS} = 1.12\sigma$$

where:

σ = Surface principal stress, [N/mm^2], read out at a distance from the intersection line of 5[mm]. The maximum of the surface principal stress from the two surfaces (edges) should be used.

4.5.3 Stress read out methods

4.5.3.1 The stress evaluation points are located at distances t/2 from the hot spot, where 't' is the plate thickness at the weld toe. This location is denoted as the stress read out point. For hot spot 'b' it would be 5[mm] from the hot spot. For modelling with shell elements without any weld the hot spot stress is taken as the principal stress within an angle ± 45[deg] to the normal to the weld and at the read-out point t/2 away from the intersection line.

4.5.3.2 Depending on the element type, one of the following stress read out methods are to be used:

- With 4-node shell element: Element surface stress (surface where the weld is located)

components at the centre points are linearly extrapolated to the line A-A as shown in Figure 4.5.1 to determine the stress components for load case 'i_1' and 'i_2' at the stress read out point located at a distance $t_{n50}/2$ from the intersection line for type 'a' hot spot. Two principal hot spot stresses are determined at the stress read out point the stress components tensor differences (between load case 'i_1' and 'i_2' in case of EDW approach) calculated from each side (side L, side R) of line A-A. The average from both sides of line A-A is taken. The angle θ between the direction x of the element co-ordinate system and the principal direction pX of the principal hot spot stress range coordinate system has to be determined.

- With 8-node shell element: With a $t_{n50} x\, t_{n50}$ element mesh using 8-node element type, the element mid-side node is located on the line A-A at a distance $t_{n50}/2$ for type 'a' hot spot. This node coincides with the stress read out point. The element surface stress components can be used directly without extrapolation within each adjacent element located on each side (side L, side R) of the line A-A as illustrated in Figure 4.5.2. Two principal hot spot stresses are determined at the stress read out point from the stress components tensor difference (between load case 'i_1' and 'i_2' in case of EDW approach) calculated from each side (side L, side R) of line A-A. The average from both sides of line A-A is taken. The angle θ between the direction x of the element coordinate system and the principal direction pX of the principal hot spot stress range coordinate system has to be determined.

4.5.3.3 For fatigue assessment of type 'b' hot spots, a beam element is to be used to obtain the fatigue stress range at the read out point 5[mm] from the hot spot. The stress range is to be based on axial and bending stress in the beam element. The beam element is to have the same depth as the connecting plate thickness while the in-plane width is negligible, i.e. it should not contribute to the strength and it should be compatible with the shell elements and read out the bending stress correctly.

4.5.3.4 The above read out procedure is based on element surface stresses. Generally, in FE software the element stresses are calculated at the Gaussian integration points located inside the element. Depending on the element type implemented in the FE software, it may be necessary to perform several interpolations in order to determine the actual stress at the considered stress read out point at the surface of the element mid-point or element edge.

4.5.4 Base material free plate edges

For fatigue assessment at a free plate edge, a beam element is to be used to obtain the fatigue stress range. The beam element is to have the same depth as the connecting plate thickness while the in-plane width should be negligible.

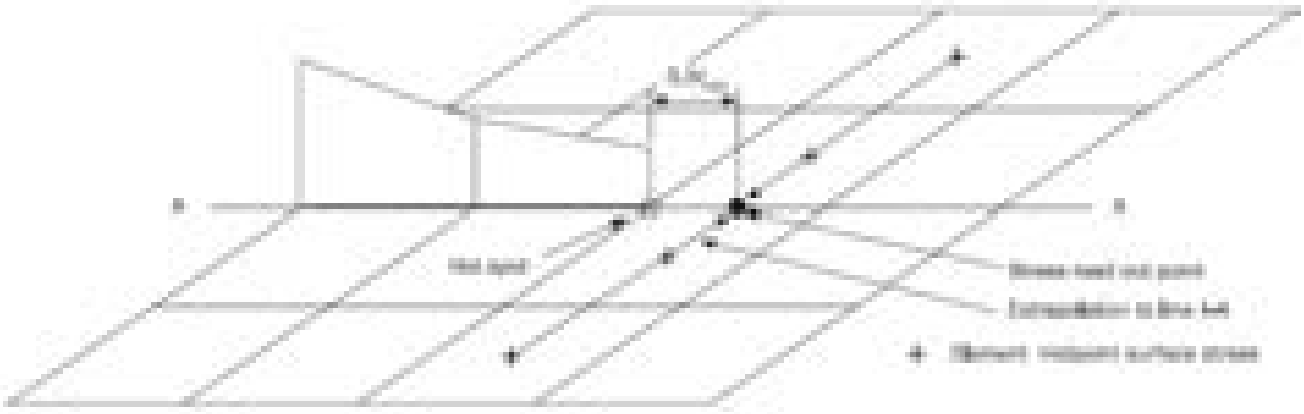

Figure 4.5.1: Determination of stress read out points and hot spot stress for 4-node element

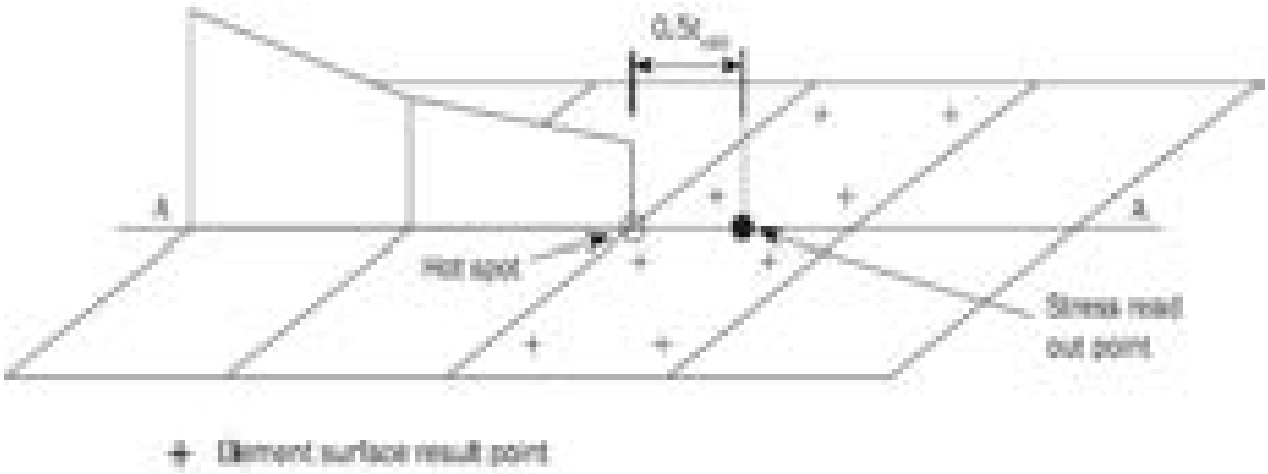

Figure 4.5.2: Determination of stress read out points and hot spot stress for 8-node element

4.5.5 Hot spot stress for bent hopper knuckle details

4.5.5.1 The hot spot stress at the inner bottom/hopper sloping plate in transverse and longitudinal directions of a bent hopper knuckle is to be taken as the surface principal stress read out from a point shifted away from the intersection line between the considered member and abutting member by the weld leg length.

The hot spot stress, in [N/mm^2], is to be obtained as:

$$\sigma_{HS} = \sigma_{shift}$$

where:

σ_{shift} = Surface principal stress, [N/mm^2], at the shifted read out position as defined in Cl.4.6.2.2 and taken as:

$$\sigma_{shift} = \sigma_{membrane}(x_{shift}) + \sigma_{bending}(x_{shift})$$

where,

$\sigma_{membrane}(x_{shift})$ = Membrane stress, in [N/mm^2], at position x_{shift}

$\sigma_{bending}(x_{shift})$ = Bending stress, in [N/mm^2], at position x_{shift}.

The procedure for calculation of hot spot stress at flange such as inner bottom /hopper sloping plate is the same that for web-stiffened cruciform joints as described in Cl.4.6.2.2. The procedure that applies for hot spots on the ballast tank side of the inner bottom/hopper plate in way of a bent hopper knuckle is in principle the same as that applied on the cargo tank side of the inner bottom plate for welded knuckle in Figure 4.6.2.1 and Figure 4.6.2.2. The intersection line is taken at the mid-thickness of the joint assuming median alignment. The plate angle correction factor and the reduction of bending stress as applied for a web-stiffened cruciform joint in Cl.4.6.2.3 are not to be applied for the bent hopper knuckle type.

4.5.5.2 The stress at hot spots located in way of the web (such as transverse web and side girder) of a bent hopper knuckle type is to be derived as described for web-stiffened cruciform joints in Cl.4.6.3.

4.6 Hot spot stress for web-stiffened cruciform joint

4.6.1 Application

4.6.1.1 Concerning the web-stiffened cruciform joint, at the intersection of plates corresponding to the hot spot, there is a high local stress concentration with large gradients. The following structural details are typically considered as a web-stiffened cruciform joint:

- Welded hopper knuckle connection

- Heel of horizontal stringer

- Lower stool – inner bottom connection.

Two kinds of hot spots relative to the web-stiffened cruciform joints are to be assessed:

- Hot spots at the flange of web-stiffened cruciform joint,

- Hot spots in way of the web of web-stiffened cruciform joint.

4.6.1.2 The procedure for calculating hot spot stress at flange of web-stiffened cruciform joint is given in Cl.4.6.2.

4.6.1.3 The procedure for calculating hot spot stress in way of the web of the web-stiffened cruciform joint is given in Cl.4.6.3.

4.6.1.4 Different examples of web stiffened cruciform joints are illustrated in Figure 4.6.1.

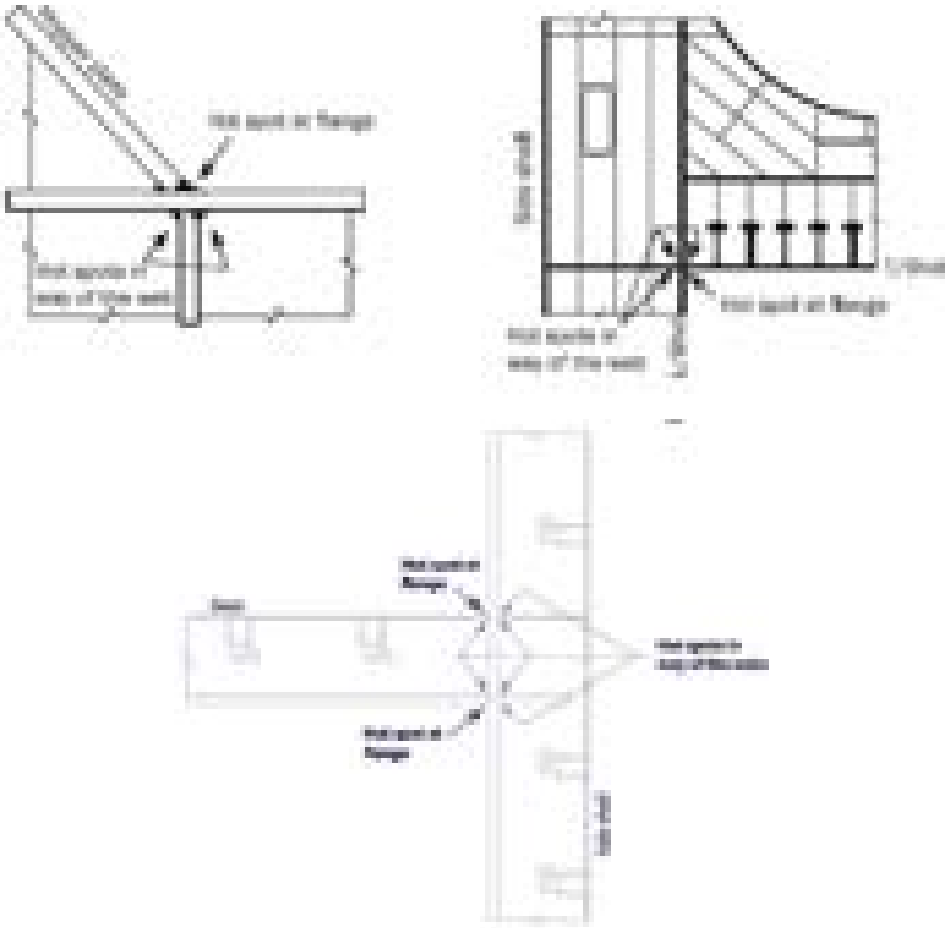

Figure 4.6.1: Web-stiffened cruciform joints

4.6.2 Calculation of hot spot stress at the flange

4.6.2.1 For hot spot at the flange of web-stiffened cruciform joints, the surface principal stress is to be read out from a point shifted away from the intersection line between the considered member and abutting member to the position of the actual weld toe and multiplied by 1.12. The intersection line is taken at the mid-thickness of the cruciform joint assuming a median alignment.

4.6.2.2 The hot spot stress, in [N/mm^2], is to be obtained as:

$$\sigma_{HS} = 1.12\sigma_{shift}$$

where:

σ_{shift} = Surface principal stress, [N/mm^2], at shifted stress read out position.

The stress read out point shifted away from the intersection line is obtained as:

$$x_{shift} = \frac{t_{1-n50}}{2} + x_{wt}$$

where:

t_{1-n50} = Net plate thickness of the plate number 1, in [mm], as shown in Figure 4.6.2.1 associated with hot spot on plate number 1. For hot spot and read out position on plate number 2, t_{1-n50} should be replaced with t_{2-n50} in estimating x_{shift}.

x_{wt} = Extended fillet weld leg length, in [mm], as defined in Figure 4.6.2.1, not taken larger than t_{1-n50} for plate number 1, or t_{2-n50} for plate number 2.

4.6.2.3 The stress at the shifted position is derived according to the following formula and illustrated in Figure 4.6.2.2:

$$\sigma_{shift} = \left(\sigma_{membrane}(x_{shift}) + 0.6\,\sigma_{bending}(x_{shift})\right).\beta$$

where:

$\sigma_{bending}(x_{shift})$ = Bending stress, [N/mm^2], at the shifted position taken as:

$$\sigma_{bending}(x_{shift}) = \sigma_{surfce}x_{shift} - \sigma_{membrane}x_{shift}$$

$\sigma_{surfce}x_{shift}$ = Total surface stress at x_{shift} position (including membrane stress and bending stress) in [N/mm^2].

$\sigma_{membrane}x_{shift}$ = Membrane stress at x_{shift} position in [N/mm^2].

β = Plate angle hot spot stress correction factor, taken as:

For $\alpha = 135[deg]$

$$\beta = 0.96 - 0.13\frac{x_{wt}}{t_{1-n50}} + 0.20\left(\frac{x_{wt}}{t_{1-n50}}\right)^2$$

For $\alpha = 120[deg]$

$$\beta = 0.97 - 0.14\frac{x_{wt}}{t_{1-n50}} + 0.32\left(\frac{x_{wt}}{t_{1-n50}}\right)^2$$

For $\alpha = 90[deg]$

$$\beta = 0.96 - 0.031\frac{x_{wt}}{t_{1-n50}} + 0.24\left(\frac{x_{wt}}{t_{1-n50}}\right)^2$$

α = Angle, in [deg], between the plates forming a web-stiffened cruciform joint as shown in Figure 4.6.2.2.

The procedure is valid for $0 \le x_{wt}/t_{1-n50} \le 1.0$ and correction factors for connections with plate angles intermediate to those given should be derived based on a linear interpolation of the above values. The calculated hot spot stress is to be used in conjunction with the hot spot S-N curve for weld toe connections according to Section 2.

4.6.2.4 Surface principal stresses at the centre point of the two first elements (independent of 4- or 8-node elements) on left and right side of the line A-A are averaged and taken as the surface principal stresses in way of the web position (line A-A). The surface principal stresses for load case 'i_1' and 'i_2' are linearly interpolated along the line A-A in order to determine hot spot principal stresses at the stress read out point located at the x_{shift} position as shown in Figure 4.6.2.3. The two principal hot spot stress ranges are determined at the stress read out point between load case 'i_1' and 'i_2'.

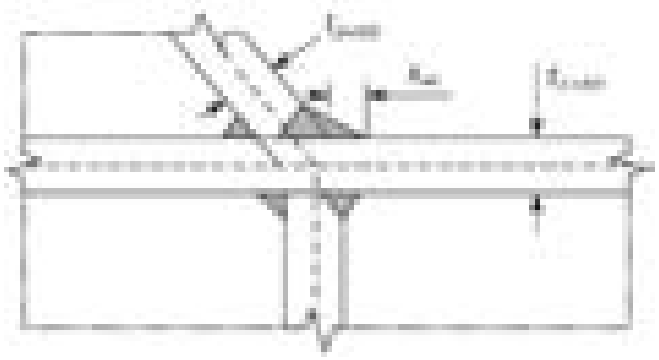

Figure 4.6.2.1: Geometrical parameters of web-stiffened cruciform connections

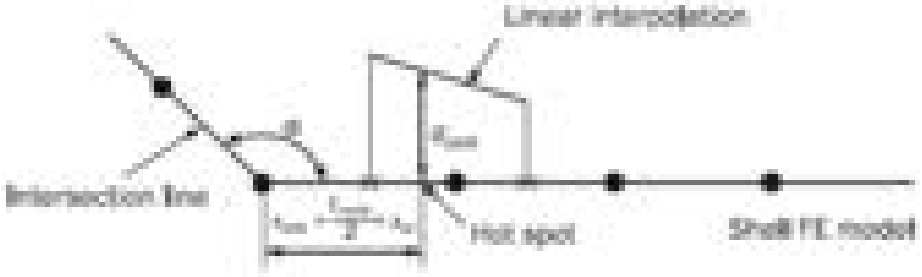

Figure 4.6.2.2: Procedure for calculation of hot spot stress at web-stiffened cruciform connections

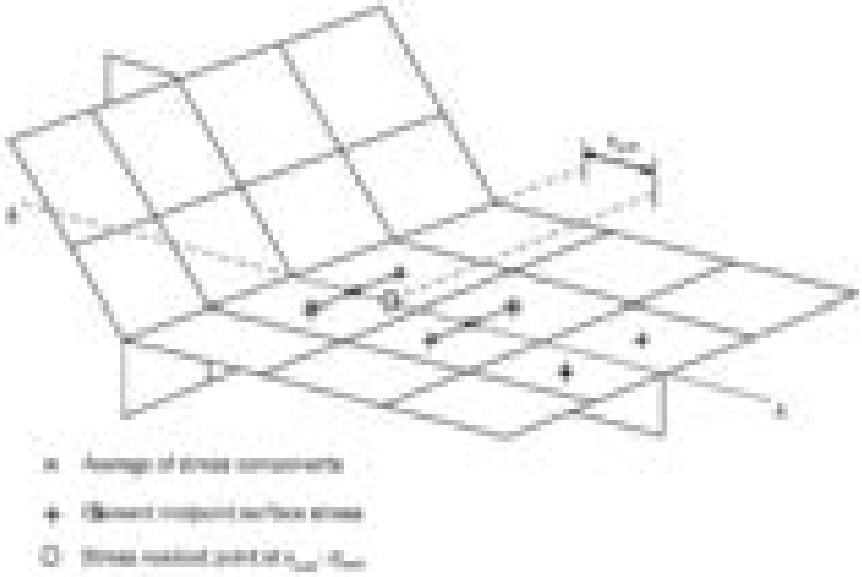

Figure 4.6.2.3: Determination of stress read out points for the flange of web-stiffened cruciform connections

4.6.3 Calculation of hot spot stress in the web

4.6.3.1 Hot spots located in way of the web as indicated in Figure 4.6.3 are to be checked with the hot spot stress defined from the maximum principal surface stress at the intersection offset by the distance x_{shift} from the vertical and horizontal element intersection lines as illustrated in Figure 4.6.3. The intersection line is taken at the mid thickness of the cruciform joint assuming a median alignment.

4.6.3.2 The hot spot stress in [N/mm^2], is to be obtained as:

$$\sigma_{HS} = \sigma_{shift}$$

where:

σ_{shift} = Maximum surface principal stress in [N/mm^2], at the intersection offset by the distance x_{shift}.

The stress read out point at the intersection offset is obtained as:

$$x_{shift} = \frac{t_3}{2} + x_{wt}$$

where:

t_3 = Net plate thickness of the web, in [mm], as shown in Figure 4.6.3.

x_{wt} = Extended fillet weld leg length in [mm], taken as

$$x_{wt} = \min(\ell_{leg1}, \ell_{leg2})$$

ℓ_{leg1}, ℓ_{leg2} = Leg length in [mm], of the vertical and horizontal weld lines as shown in Figure 4.6.3.

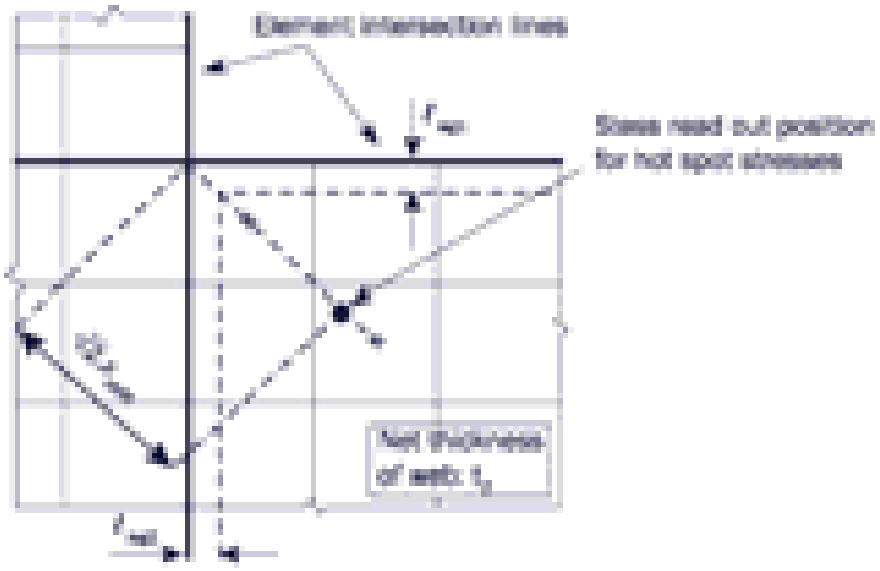

Figure 4.6.3: Hot spots in way of web

4.7 Limitations of hot spot stress approach

4.7.1 Scope of application of hot spot stress approach

The hot spot stress approach given in Section 1, Cl.1.2.5 is not applicable for simple cruciform joints and simple T-joints or simple butt joints when the stress flow in direction I as shown in Figure 4.7.1 is considered. Analysing such connections with shell elements will result in a hot spot stress equal to the nominal stress. The hot spot stress approach is therefore not directly applicable when the stress flow in direction I, is considered. For stresses in the direction normal to the weld at hot spot location “c” (direction I) there is no stress flow into the transverse plating as it is represented only by one plane in the shell model. However, it attracts stresses for in-plane direction (direction II) at hot spot location “a”.

In situations where a bracket (or web) is fitted behind the transverse plate as shown in Figure 4.7.1, acting with stiffness in the direction normal to the transverse plate, stresses flow also into the transverse plate and the hot spot methodology is considered applicable.

4.7.2 Correction of hot spot stress approach for simple cruciform joints

The hot spot stress at position ‘c’ for simple cruciform joints and simple T-joints is to be determined by the stress read out procedure given in 4.5 multiplied by a geometrical stress concentration factor of 1.3 and is taken as:

$$\sigma_{HS} = 1.3 \times 1.12\sigma$$

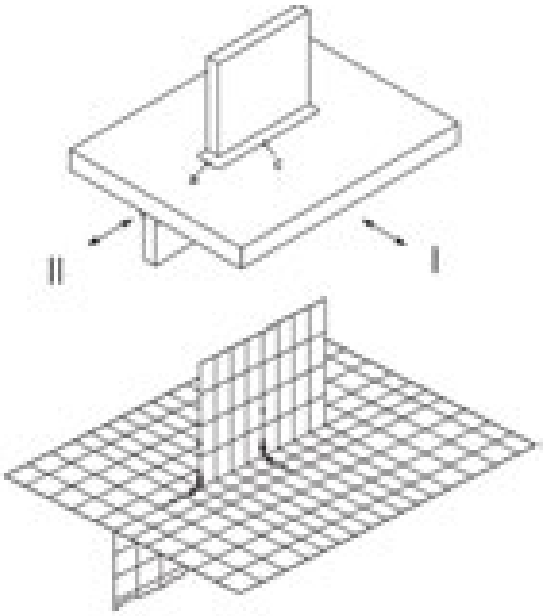

Figure 4.7.1: Illustration of check points in way of a welded attachment under orthogonal applied in plane loads

4.8 Method for hot spot stress extraction

4.8.1 Hot spot extraction method used to obtain hot spot stress from the stress readout points is by linearly extrapolating from two or three readout points to the structural intersection line. (IIW-1823-07) recommendations for fatigue design of welded joints is utilized for this method of hot spot stress extraction.

4.8.2 In case of biaxial stress state at the plate surface, the principal stress which acts approximately in line with the perpendicular to weld toe (within ±60[deg]) are to be used. The other principal stress may need to be analyzed, if necessary, using the fatigue class in the nominal stress approach for welds parallel to the stress (IIW-1823-07).

4.8.3 While using this method of stress extraction, meshing size and the limitation to weld configurations are to be referred from the IIW recommendation

.

End of Chapter

Appendix A – Detail Design Standard

A.1 General

A.1.1 Purpose

A.1.1.1 This detail design standard is provided to ensure improved fatigue performance of structural details. Design standard provides fatigue resistant detail design at an early stage in the structural design process by giving considering the following:

- Application of fatigue design principles.

- Construction tolerances and other practical considerations.

- In-service experience and fatigue performance.

A.1.1.2 The design standard is to be applied to the design of ship structural details in following steps:

- Highlighting potential critical areas within the ship structure.

- Identification of the fatigue hot spot locations for each of the critical structural details.

- Provision of a set of alternative improved configurations from which a suitable solution can be selected.

- Requirements on geometrical configurations, scantlings, welding requirements and construction tolerances.

- Post fabrication method of improving fatigue life, such as weld toe grinding.

A.1.1.3 The detail design standard may provide requirements in order to prevent the following types of fatigue cracks initiating from the:

- Weld toe and propagating into the base material.

- Weld root and propagating into the plate section under the weld.

- Weld root and propagating through the weld throat.

- Surface irregularity or notch at the free plate edge and propagating into the base material

A.1.2 Application

The structural details described in this Appendix are to be designed according to the given design standard. Alternative detail design configurations may be accepted by IRS, subject to demonstration of satisfactory fatigue performance.

A.2 Stiffener-frame connections

A.2.1 Design standard A

A.2.1.1 Designs for cut outs in cases where web stiffeners are omitted or not connected to the longitudinals are required to adopt tight collar or the improved design standard “A” as shown in Table A.2.1 or equivalent, for the following members:

- Side shell below $1.1T_{sc}$

- Bottom.

- Inner hull longitudinal bulkhead below $1.1T_{sc}$

- Topside tank sloping plating below $1.1T_{sc}$

- Hopper.

- Inner bottom.

A.2.1.2 Designs that are different from those shown in Table A.2.1 are acceptable subject to demonstration of satisfactory fatigue performance, e.g. by using comparative finite element analysis. The comparative FE analysis is to be performed following the modelling guidance given in Figure A.2.1.

Table A.2.1: Design standard A – stiffener-frame connection	
Cut outs for longitudinals in transverse webs where web stiffeners are omitted or not connected to the longitudinal flange	
Design standard A	
1	2
	3	4
	Note 1: Soft toes marked "*" are to be dimensioned to suit the weld leg length such that smooth transition from the weld to the curved part can be achieved. Maximum 15[mm] or thickness of transverse web/collar plates/lug plates whichever is the greater. Note 2: Configurations 1 and 4 indicate acceptable lapped lug plate connections.	
Critical location	Locations around cut-out with high stress concentration and locations in way of weld terminations.
Detail design standard	Improved slot shape to avoid high stress concentrations in transverse webs due to shear loads and local pressure loads transmitted via welded joints.
Building tolerances	Ensure alignment of all connecting members and accurate dimensional control of cut-outs according to IACS Recommendation No.47.
Welding requirements	A wraparound weld, free of undercut or notches, around the transverse web connection to longitudinal stiffener web.

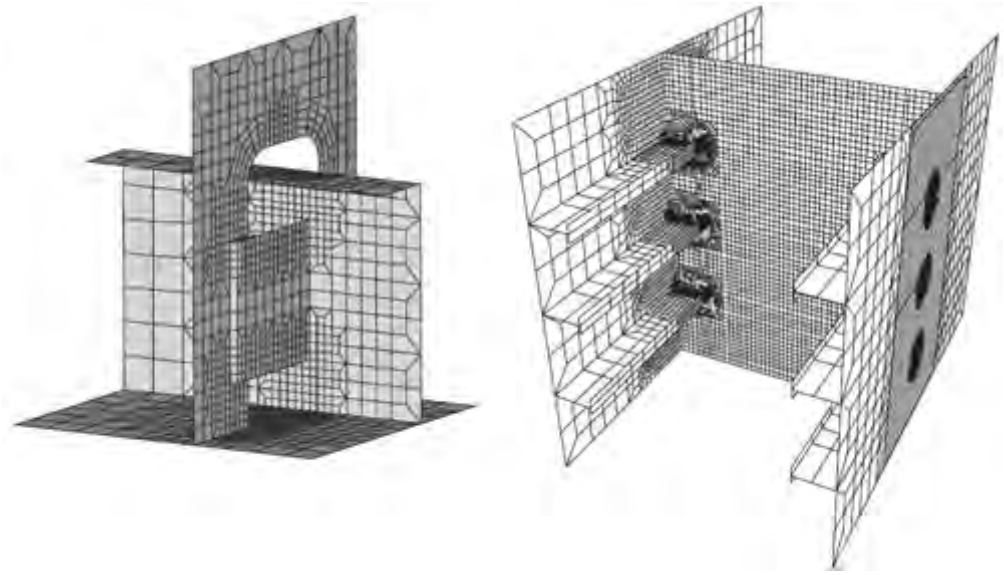

Figure A.2.1: Finite element model for verification of equivalent design

A.2.2 Equivalent design of stiffener-frame connections

(a) If the required designs for stiffener-frame connections A.2.1 are not followed, the alternative design is to be verified to have equivalent fatigue strength to the design standard “A” or to be verified to have satisfactory fatigue performance. The alternative design is to be verified according to the procedure given in A.2.2(b) to A.2.2(e) and documentation of results is to be submitted to IRS.

(b) The procedure in A.2.2(c) and A.2.2(d) is provided to verify the alternative design to have equivalent fatigue strength with respect to any position in the transverse ring, i.e. double bottom and double side. The hot spot stress as well as the stress at the free plate edge of the alternative design and that of the required design is to be compared to the critical hot spots in way of the cut-out. The critical hot spots depend on the detail design and are to be selected in agreement with *IRS.* The hot spot stress is to be derived according to Section 4, Cl.4.5.2 and Cl.4.5.3. It is to be noted that welded hot spots at the free edge are classified as hot spot type “b”.

(c) The very fine mesh finite element models are made to analyze the behavior in way of double side or double bottom. The models should have an extent of 3 stiffeners in cross section, i.e. 4 stiffener spacings, and the longitudinal extent is to be one half frame spacing in both forward and aft direction. A typical model is shown in Figure A.2.1. No cut-outs for access openings are to be included in the models. Connection between the lug or the web-frame to the longitudinal stiffener web, connections of the lug to the web-frame and free edges on lugs and cut-outs in web-frame are to be modelled with elements of net plate thickness size ($t_{n50} x\, t_{n50}$). The mesh with net plate thickness size should extend at least five elements in all directions. Outside this area, the mesh size may gradually be increased in accordance with the requirements in Section 4, 4.3 and 4.4. The eccentricity of the lapped lug plates is to be included in the model. Transverse web and lug plates are to be connected by eccentricity elements (transverse plate elements). The height of eccentricity element is to be the distance between mid-layers of transverse web and lug plates having a thickness equal to 2 times the net thickness of web-frame plate t_{w-n50}. Eccentricity elements representing fillet welds are shown in Figure A.2.2(a).

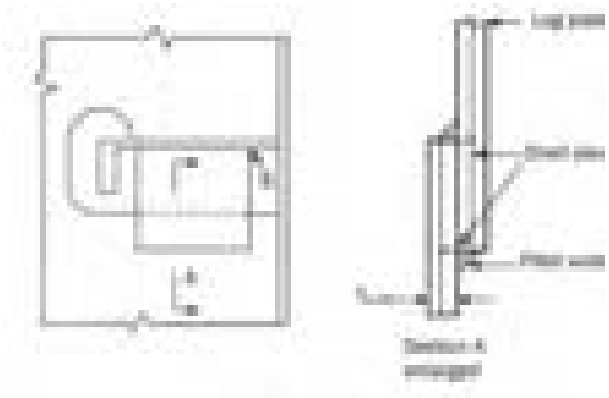

Figure A.2.2(a): Modelling of eccentric lug plate by shell elements

(d) Three load cases are to be applied to the models of the design standard and alternative designs:

- External pressure of unit value, fixed boundary conditions at top and bottom of model.

- Shear stress by prescribed unit displacement at the model top and fixed boundary conditions at the model bottom.

- Axial load by prescribed unit displacement at the model top and fixed boundary conditions at the model bottom.

The forward and aft part of the model is to have symmetry condition describing the behavior in a double hull structure. Load application and boundary conditions are provided in Figure A.2.2(b).

(e) The alternative design may also be verified to have satisfactory fatigue performance using sub-modelling technique where a very fine mesh model of the alternative design located at the actual position of the stiffener-frame connection is analyzed. The alternative design is considered acceptable if the fatigue acceptance criterion given in Section 2 is achieved. The fatigue acceptance criterion is checked by applying the methodology described in Sections 1, 2 and 4. The alternative design is considered acceptable only for the particular position where it is analyzed.

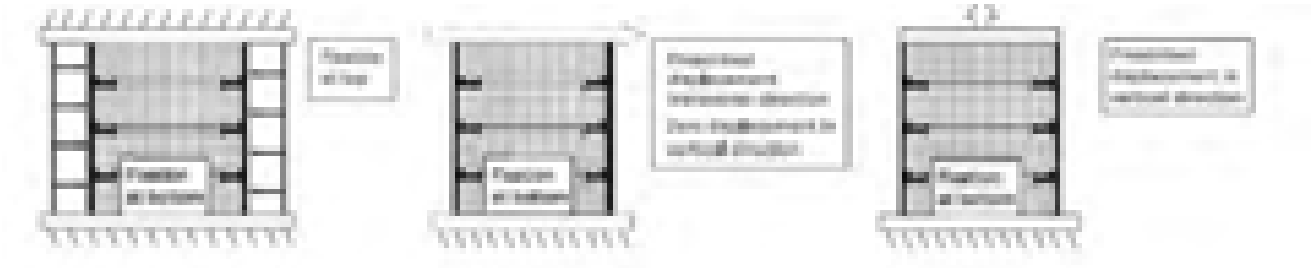

Figure A.2.2(b): Load application and boundary conditions – FE model for verification of alternative design

A.3 Scallops in way of block joints

A.3.1 Design standard B

Scallops in way of block joints in the cargo tank/hold region, located on the stiffeners fitted on strength deck, and side above 0.9D from the baseline, are required to be designed according to the design standard B as shown in Table A.3.1.

General

Symbols

For symbols not defined in this section, Refer to Chapter 1, Section 2.

1.1 Application

1.1.1 For ships with various Ice Class notations, additional requirements given in Part 5, Chapter 21 are to be complied with.

1.2 Materials

1.2.1 All steel plates and sections, castings and forgings used in the constructions are to be tested and approved in accordance with the requirements of Part 2, Chapter 3, Chapter 4 and Chapter 5 respectively. Material grades for plates and sections are to be selected as defined in Part 3, Chapter 2.

1.2.2 Bar keels and stems may either be steel castings or steel forgings.

1.2.3 Stern frames, rudder horns and shaft brackets may be constructed of cast or forged steel or may be fabricated from plates.

Section 2

Bow Flare Impact

Symbols

For symbols not defined in this section, Refer to Chapter 1, Section 2.

f_{bdg} = Bending moment factor.

$$f_{bdg} = 8\left(1 + \frac{n_s}{2}\right)$$

n_s = End fixation factor taken as:

For both ends with low-end fixity (simply supported), $n_s = 0$

For one end fixed and one end simply supported $n_s = 1$

For continuous members or members with bracketed fitted at both ends, $n_s = 2$

λ_w = Wave length in [m].

ζ_a = Average wave amplitude in [m].

x_g = The distance in [m], of the station under consideration from the LCG of the ship.

X = The distance of a section from AP in [m].

θ = Extreme pitching motion in [deg], i.e., Pitch angle as per Chapter 5, Section 2.

$$\theta' = \theta.\frac{\pi}{180}$$

H_s = Significant wave height in [m] $= C.C_w$

where, C is as defined in Cl.2.2.1.

For Coastal vessels, H_s need not be taken more than 5[m].

F_n = Froude number $= V/\sqrt{gL}$

V = Design speed of vessel in [m/s].

V_{th}= Threshold bow flare slamming speed in [m/s] = $0.29\sqrt{L}$

AC-III = Acceptance criteria set as defined in Chapter 1, Section 1.

2.1 Application

2.1.1 Bow flare slamming requirements given in this section are applicable to vessels of L≥ 60[m] on unrestricted or coastal service.

2.1.2 Bow flare slamming impact pressure defined in Cl.2.2.1 is applicable when $V \geq V_{th}$ and $F_n \leq 0.41$. For vessels, when $V \geq V_{th}$ and $F_n > 0.41$, bow flare slamming impact pressure defined in Cl.2.2.1 is not applicable and needs to be specially considered.

2.1.3 The side structure in the region forward of 0.25L abaft of F.P. and vertically above the summer load waterline, is to be strengthened for bow impact pressure 'P_{BOW}'. Refer Figure 2.1.1.

2.1.4 Outside the strengthening area the requirements are to be gradually tapered to the ordinary requirements to maintain adequate continuity of strength in both longitudinal and transverse directions.

2.1.5 The requirements given below are to be applied in addition to applicable scantling requirements in Chapter 7. Local scantling increases due to impact loads are to be made with due consideration given to details and avoidance of hard spots, notches and other harmful stress concentrations.

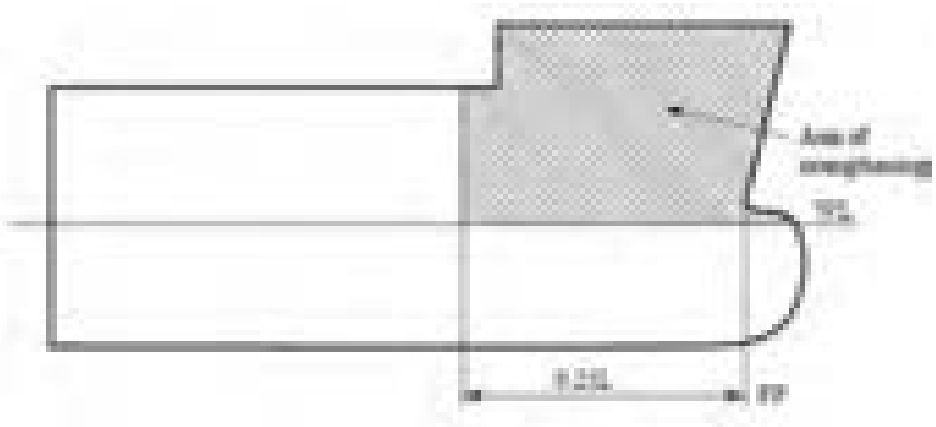

Figure 2.1.1: Extent of strengthening against bow impact

2.2 Design bow impact pressure

2.2.1 The design bow impact pressure, P_{BOW} in [kN/m^2], is to be taken as:

$$P_{BOW} = \frac{1}{2}\rho\, k_b\, U_i^2$$

where,

$k_b = 0.028\alpha^2 - 1.68\alpha + 30 \quad \text{for } \alpha \leq 30°$

$k_b = 7.2 - 0.08\alpha \quad \text{for } 30° < \alpha \leq 75°$

$k_b = 1.2 \quad \text{for } \alpha > 75°$

Impact velocity in [m/s] for finding out Bow flare pressure is the resultant of the normal velocity (U_n) and the tangential velocity (U_t) as given below:

$$U_i = \sqrt{U_n^2 + U_t^2}$$

where,

$$U_n = 2\sqrt{abs(-\omega_{ext}\{z_{ext}\cos(\theta') + x_g\theta' + +\zeta_{ext}\sin(\frac{\left(1.25 - 2.5(1 - \frac{X}{L}\right)\pi}{2})\cos(\theta')\})}$$

$U_t = U/\cos(\beta) \quad \text{for } \beta \leq 60[\text{deg}]$

$U_t = 2.U \text{ for } \beta > 60[\text{deg}]$

$U = (-134F_n^2 + 31F_n + 3)\omega_{ext}\,\zeta_a \text{ for } 0 \leq F_n < 0.16$

$U = (-105F_n^2 + 65F_n - 3)\omega_{ext}\,\zeta_a \text{ for } 0.16 \leq F_n \leq 0.41$

ω_{ext} = Encounter wave frequency, rad/s

$\omega_{ext} = \omega(1 + \frac{\omega V}{g})$

ω = Wave frequency in $[\text{rad/s}]$

$\omega = \sqrt{\frac{2\pi g}{\lambda_w}}$

z_{ext} = Extreme heave motion = $7.2 - 0.012L$

ζ_a =Average wave amplitude in [m].

$\zeta_a = \frac{1}{1.41}(H_s/2)$

ζ_{ext} = Extreme wave amplitude = $0.95(C.C_w)$

$C = \min\left[\sqrt{\frac{L + \lambda_w - 25}{L}}\ ,1.3\right]$

$\lambda_w = 1.05L \text{ for } 0 \leq F_n < 0.16$

$\lambda_w = 1.57L \text{ for } 0.16 \leq F_n < 0.41$

C_w is the wave coefficient as defined in Chapter 5, Section 2

α = Flare angle in [deg] between a tangential plane of side plating and a vertical line, measured at the point considered. (Refer Figure 2.2.1).

β = Local waterline angle, i.e., the angle in degrees made by tangent at a point under consideration with the centreline in the x-y plane (water plane). (Refer Figure 2.2.1).

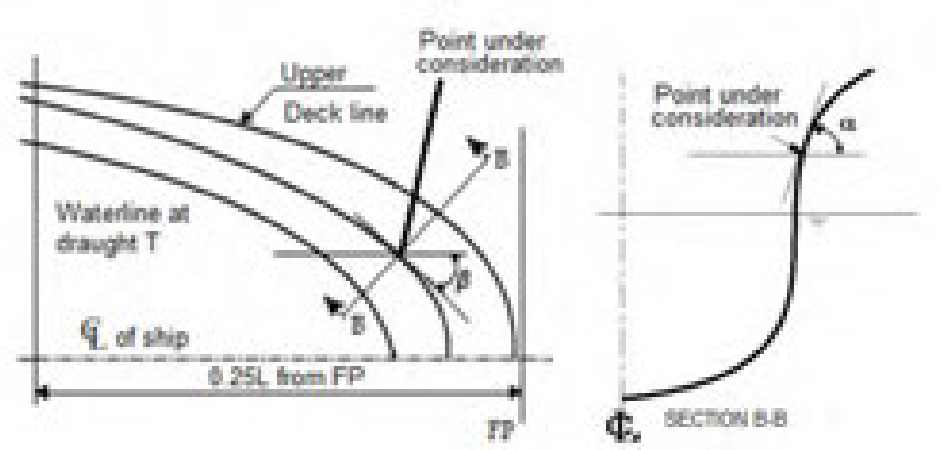

Figure 2.2.1: Local waterline angle and Local body plan angle

2.3 Scantling requirements

2.3.1 Side shell plating

2.3.1.1 The net thickness of the side shell plating, in [mm], subjected to impact pressures from bow flare slamming is not to be less than:

$$t = \frac{0.0158.\alpha_p.b}{C_d}\sqrt{\frac{P_{BOW}}{R_{eH}}}$$

where:

C_d = Plate capacity correction coefficient = 1.3

α_p = correction factor for the panel aspect ratio to be taken as below but not to be greater than 1.0:

$$\alpha_p = 1.2 - \frac{b}{2.1\,a}$$

a,b = Length and breadth of plate panel, in [mm], as defined in Chapter 3 Section 7, Cl.7.5.1.

2.3.2 Side shell stiffeners

2.3.2.1 The design of end connections of stiffeners in the bow impact region is to ensure end fixity, either by making the stiffeners continuous through supports or by providing end brackets complying with Chapter 3, Section 6, Cl.6.2.2.

Where it is not practical to comply with this requirement, the net plastic section modulus, Z_{pl_alt}, in [cm^3], for alternative end fixity arrangements is not to be less than:

$$Z_{pl_alt} = \frac{16\,Z_{pl}}{f_{bdg}}$$

where:

Z_{pl} **=** Effective net plastic section modulus, in [cm^3], required by Cl.2.3.2.3.

2.3.2.2 Scantlings and arrangements of primary supporting members, including decks and bulkheads, in way of the stiffeners, are to comply with Cl.2.5.3. In areas of the greatest bow impact load, the web stiffeners arranged perpendicular to the hull envelope plating and the double-sided lug connections are to be provided.

2.3.2.3 The side shell stiffeners within the strengthening area defined in Cl.2.1.3 are to comply with the following criteria:

(a) The effective net plastic section modulus, Z_{pl}, in [cm^3], calculated in accordance with Chapter 3, Section 7, Cl.7.4.6, is not to be less than:

$$\mathbf{Z_{pl} = \frac{P_{BOW}.s.\ell_{bdg}^2}{f_{bdg}.C_s.R_{eH}}}$$

where:

C_s = Permissible bending stress coefficient taken as:

= 0.9 for acceptance criteria set AC-III.

(b) The net web thickness, $\mathbf{t_w}$, in [mm], is not to be less than:

$$\mathbf{t_w = \frac{\sqrt{3}.P_{BOW}.s.\ell_{shr}}{2.d_{shr}.C_t.R_{eH}}}$$

where:

C_t = Permissible shear stress coefficient taken as:

= 1.0 for acceptance criteria set AC-III.

$\boldsymbol{\ell_{shr}}$ = Effective shear span of the stiffener, in [m], as defined in Chapter 3, Section 7, Cl.7.1.3.

$\mathbf{d_{shr}}$ = Effective shear depth of stiffener, in [mm], as defined in Chapter 3, Section 7, Cl.7.4.3.

2.3.2.4 The slenderness ratio is to comply with Chapter 9, Section 2.

2.3.2.5 Stiffeners are to be connected at ends. For side shell stiffeners, located in the strengthening area as defined in Cl.2.1.3, with the length exceeding 4 times that of the stiffener spacing, tripping brackets are to be fitted for stiffeners with web angle less than 75[deg].

2.3.3 Connection area

Shell stiffeners are to be connected to supports, e.g. stringers, web frames, decks or bulkheads. The connection area is generally obtained through fitting supporting members such as collar plates, lugs, end brackets or web stiffeners. The connection area of stiffeners to PSM and the welding size at the connection are to comply with Chapter 7, Section 7, 7.2, based on design pressure taken equal to P_{BOW}.

2.4 Bow impact load area for primary supporting members

2.4.1 The scantlings of primary supporting members according to Cl.2.5.3 are based on the application of the bow impact pressure, as defined in Cl.2.2.1, to an idealised bow impact load area of hull envelope plating, A_{BL} in [m^2], given by:

$$A_{BL} = 1.1.L.B.C_b.10^{-3}$$

2.5 Primary supporting members, decks and transverse bulkheads

2.5.1 Application

The requirements given in Cl.2.5.2 to Cl.2.5.4 apply for ships as defined in 2.1 and for other ships the evaluation of primary supporting members as described in Cl.2.5.2 to Cl.2.5.4 can be omitted provided the net web thickness of primary support members and decks or bulkheads fitted in lieu of a stringer or a web frame, in [mm], is not less than:

$$t_w = \frac{b}{75}\sqrt{\frac{R_{eH}}{235}}$$

2.5.2 General structural requirements

2.5.2.1 The section modulus of the primary supporting member is to apply along the bending span clear of end brackets. Requirements of the cross-sectional areas of the primary supporting member are to be applied at the ends/supports and may be gradually reduced along the span and clear of the ends/supports following the distribution of f_{dist} indicated in Figure 2.4.3.1.

2.5.2.2 Primary supporting members in the bow impact strengthening area are to be configured to provide effective continuity of strength and the avoidance of hard spots.

2.5.2.3 Web frames supporting side longitudinals in the bow impact region are to be connected to deck transverses in way of decks and platforms.

2.5.2.4 End brackets of primary supporting members are to be suitably stiffened along their edge. Consideration is to be given to the design of bracket toes to minimize abrupt changes of cross-section.

2.5.2.5 Tripping arrangements are to comply with Chapter 9, Section 2. In addition, tripping brackets are to be fitted at the toes of end brackets and at locations where the primary supporting member flange is knuckled or curved.

2.5.3 Scantlings of Primary supporting members

2.5.3.1 Section Modulus of the primary supporting member

The net section modulus of each primary supporting member (stringer and web frames), Z in [cm^3], calculated in accordance with Chapter 3, Section 7, Cl.7.4.7, is not to be less than:

$$\mathbf{Z = \frac{f_{CB}.P_{BOW}.b_{BI}.\ell_{bdg}^2.f_{BL}}{f_{bdg}.C_s.R_{eH}}.10^3}$$

where,

f_{CB} = Correction factor for the bending moment at the ends and considering the patch load taken as:

$$\mathbf{f_{CB} = 3f_{BL}{}^3 - 8\, f_{BL}{}^2 + 6f_{BL}}$$

f_{BL} = Patch load modification factor is taken as:

$$\mathbf{f_{BL} = \frac{\ell_{BL}}{\ell_{bdg}}}$$

$\boldsymbol{\ell_{BL}}$ = Extent of bow impact load area along the span, in [m], taken as:

$\boldsymbol{\ell_{BL}} = \sqrt{\mathbf{A_{BL}}}$ but not to be greater than $\boldsymbol{\ell_{bdg}}$

b_{BI} = Breadth of the impact load area, in [m], supported by the primary supporting member, to be taken as the spacing between primary supporting members, S as defined in Chapter 3, Section 7, but not to be taken as greater than ℓ_{BL}

$\mathbf{A_{BL}}$ = Load area as defined in Cl.2.4.1.

$\mathbf{f_{bdg}}$ = Bending moment factor taken as:

= 12 for primary supporting members with end fixed continuous flange or where brackets at both ends are fitted in accordance with Chapter 3, Section 6, Cl.6.3.5.

C_s = Permissible bending stress coefficient is taken as:

= 0.9 for acceptance criteria set AC-III.

2.5.3.2 Web thickness of the primary supporting member

The net web thickness, t_w in [mm], of primary supporting members including decks/bulkheads in way of the side shell is not to be less than:

$$\mathbf{t_w = \frac{P_{BOW} \cdot b_{BI}}{\sin \varphi_w\, \sigma_{crb}}}$$

where:

$\boldsymbol{\varphi_w}$ = Angle, in [deg], between the primary supporting member web and the shell plate, refer to Figure 2.4.3.2.

σ_{crb} = Critical buckling stress, in [N/mm^2], in compression of the web of the primary supporting member or deck/bulkhead panel in way of the applied load given in Chapter 9. In the calculation, both σ_x and σ_y as given in Chapter 9, Section 5 are to be considered and UP-B is to be applied.

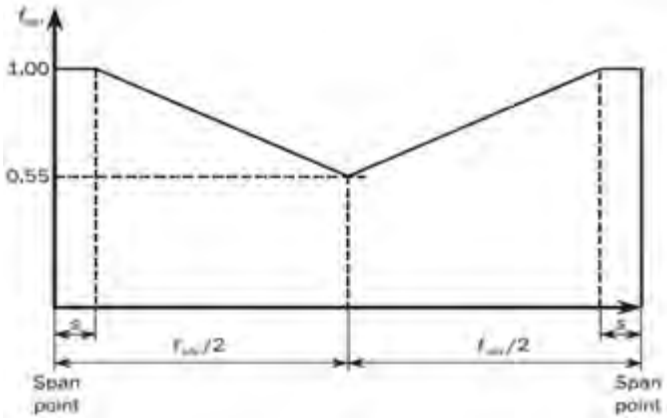

Figure 2.4.3.1: Distribution of $\mathbf{f_{dist}}$ along the span of simple primary supporting members

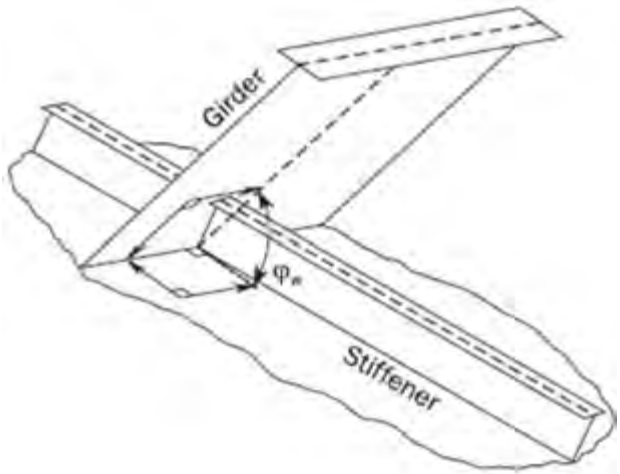

Figure 2.4.3.2: Angle between shell primary member and shell plate

2.5.3.3 Net shear area

The net shear area of the web, $\mathbf{A_{shr-n50}}$, in [cm^2], of each primary supporting member at the support /toe of end brackets, calculated in accordance with Chapter 3, Section 7, Cl.7.4.7, is not to be less than:

$$\mathbf{A_{shr-n50}} = \frac{\mathbf{5}.\sqrt{\mathbf{3}}.\mathbf{P_{BOW}}.\mathbf{b_{BI}}.\boldsymbol{\ell}_{\mathbf{shr}}.\mathbf{f_{BL}}}{\mathbf{C_t}.\mathbf{R_{eH}}}$$

where,

f_{BL} = Patch load modification factor taken as:

$$\mathbf{f_{BL}} = \frac{\boldsymbol{\ell}_{\mathbf{BL}}}{\boldsymbol{\ell}_{\mathbf{shr}}}$$

$\boldsymbol{\ell}_{\mathbf{BL}}$ = Extent of bow impact load area along the span, in [m], taken as:

$\boldsymbol{\ell}_{\mathbf{BL}} = \sqrt{\mathbf{A_{BL}}}$ but not to be greater than $\boldsymbol{\ell}_{\mathbf{shr}}$

C_t = Permissible shear stress coefficient taken as:

= 0.75 for acceptance criteria set AC-III.

2.5.4 Direct calculations

2.5.4.1 Alternative to the formulae in CL.2.2.1, IRS may accept the evaluation of the effects of bow flare impact from direct calculations also, when justified based on the ship's characteristics and intended service. In such cases, the calculations are to be submitted to IRS for approval.

2.5.4.2 Alternative to the requirements given in Cl.2.5.3, for complex arrangements of primary supporting members (grillage system) or for primary supporting members having variable cross sections, the scantling requirements/calculations can be based on direct strength analysis. The procedure for finite element modeling and load application is given in IRS Guidelines on Structural Assessment of Ships based on Finite Element Method.

2.5.4.3 In FE analysis, the equivalent stress, σ_{vm}, as defined in Chapter 8, Section 3, is not to exceed the yield stress, R_{eH}. In the case of beam assessment, the nominal bending stress is not to exceed $0.9R_{eH}$ and the nominal shear stress is not to exceed $0.9\,\tau_{eH}$. Permissible buckling utilization factor for AC-III according to Chapter 9 Section 1, Cl.1.3.3 is to be applied.

Section 3

Bottom Slamming

Symbols

For symbols not defined in this section, Refer to Chapter 1, Section 2.

P_{thr} = Theoretical slamming pressure, [kN/m^2] as defined in Cl.3.3.1.

P_{max} = Peak slamming pressure, [kN/m^2] as defined in Cl.3.3.1.

T_{BF} = Draft of the vessel in [m], at forward perpendicular (FP) in ballast condition.

b' = Full breadth in [m], at 1/10th of local draft of a section at 0.25L from FP.

V_{th}= Threshold slamming speed as defined in Section 2.

x_g = The distance in [m], of the station under consideration from the LCG of the ship.

X = The distance of a section from AP in [m].

AC-III = Acceptance criteria set as defined in Chapter 1, Section 1.

3.1 Application

3.1.1 Bottom slamming requirements given in this section are applicable to vessels of L≥ 60[m] on unrestricted or coastal service.

For 'Restricted Service' or 'Sheltered water service', the requirements given in this section are not applicable.

3.1. Bottom slamming pressure defined in Cl.3.3.1 is applicable when V≥ V_{th} and F_n≤ 0.41. For vessels, when V ≥ V_{th} and F_n> 0.41, bottom slamming pressure defined in Cl.3.3.1 are not applicable and needs to be specially considered.

3.1.3 Where the minimum design ballast draught at F.P. is more than 0.045L[m], additional strengthening to resist bottom slamming pressures is not required.

3.1.4 The bottom slamming pressure is significant along the flat bottom forward of approximately 0.3L measured from FP and vertically up to 0.1T_{BF}. This region is to be strengthened for bottom impact pressure 'P_{SL}'. Refer Figure 3.1.1.

The scantlings of bottom plating, stiffeners and girders up to (0.1T_{BF}) above the baseline (up to bilge curvature in case of ships with rise of floor) are to be based on the design slamming pressure P_{SL} given in Cl.3.3.1.

3.1.5 Outside the strengthening area the requirements are to be gradually tapered to the ordinary requirements to maintain adequate continuity of strength in both longitudinal and transverse directions.

3.1.6 The requirements given below are to be applied in addition to applicable scantling requirements in Chapter 7. Local scantling increases due to impact loads are to be made with due consideration given to details and avoidance of hard spots, notches and other harmful stress concentrations.

3.1.7 The draughts for which the bottom has been strengthened are to be indicated on the shell expansion plan and loading guidance information, as required in Chapter 1, Section 4.

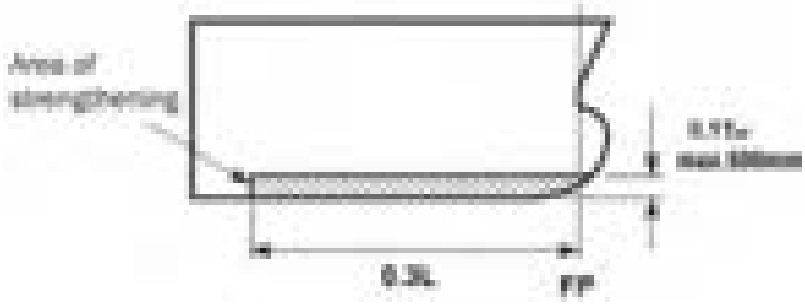

Figure 3.1.1: **Extent of strengthening against bottom slamming**

3.2 Arrangement of floors and girders

3.2.1 The floors and girders in the region forward of 0.3L abaft of F.P. are to be spaced as given below.

3.2.2 Where transverse framing is adopted, floors are to be fitted at every frame. The spacing of longitudinal girders is not to exceed 2.5[m]. In addition, intermediate half height girders or equivalent longitudinals are to be fitted.

3.2.3 Where a longitudinal framing system is adopted, the plate floors are to be fitted at alternate frames. The spacing of longitudinal girders is not to exceed 3 times the longitudinal frame spacing. In the case of longitudinally stiffened single bottoms, the arrangements, and scantlings will be specially considered.

3.3 Design bottom slamming pressure

3.3.1 The design bottom slamming pressure at any point on the keel, P_{SL} in [kN/m^2], is to be taken as:

$$P_{SL} = \mathrm{Min}(P_{thr}, P_{max})$$

where,

$$P_{thr} = \frac{1}{2}\rho\, k_H\, U_r^2$$

$$P_{max} = C_l\, \rho\, g\, h_{max}$$

k_H = Hull shape coefficient

$k_H = 0.028\beta_{DA}{}^2 - 1.68\beta_{DA} + 30$ for $\beta_{DA} \leq 30^0$;

$k_H = 4.8$ for $\beta_{DA} > 30^0$

β_{DA} = The angle made by the line joining the bottommost point, i.e., the intersection of the centreline and the section under consideration) with 60% of the girth at 1/10th of the local draft. Refer to Figure 3.3.1.1.

Relative velocity in [m/s] can be determined as shown below:

$$U_r = 2\sqrt{\mathrm{abs}(-\omega_{ext}\{z_{ext}\cos(\theta') + x_g\theta' + \zeta_{ext}\sin(\frac{\left(1.25 - 2.5\left(1 - \frac{X}{L}\right)\right)\pi}{2})\cos(\theta')\}) + V_{th}\sin(\theta_{sig})}$$

ζ_{ext} = Extreme wave amplitude = $0.95(C.C_w)$

z_{ext} = Extreme heave motion =T_{BF}

ω_{ext} = Encounter wave frequency in [rad/s] as defined in Section 2, Cl.2.2.1

θ_{sig} = Significant pitch angle = $0.33\theta'$

$$h_{max} = \left(\frac{k'}{2\sqrt{g}}\right)\left(\frac{U}{\sqrt{L}}\right)F_n L$$

$$k' = k_1 k_2 k_3$$

$k_1 = -14.6\ln\left(\frac{T_{BF}}{L}\right) - 40.5$ for $0.01 \leq T_{BF}/L \leq 0.045$

$k_1 = 28$ for $T_{BF}/L < 0.01$

$k_1 = 4.8$ for $T_{BF}/L > 0.045$

$k_2 = \frac{10b'}{L}$

Limiting range for k_2: $0.5 \leq k_2 \leq 1.3$

$k_3 = 1.57\exp(-0.01L^{2/3})$

Limiting range for k_3: $0.84 \leq k_3 \leq 1.25$

$U = (-134F_n^2 + 31F_n + 3)\omega_{ext}\zeta_a$

for $0 \leq F_n < 0.16$; [m/s]

$U = (-105F_n^2 + 65F_n - 3)\omega_{ext}\zeta_a$

for $0.16 \leq F_n \leq 0.41$ [m/s]

ζ_a =Average wave amplitude in [m].

$$\zeta_a = \frac{1}{1.41}(H_s/2)$$

C, C_w = Coefficients defined in Section 2, Cl. 2.2.1.

C_l is the coefficient of variation of slamming pressure along the length of the vessel as given in Figure 3.3.1.2 and Figure 3.3.1.3.

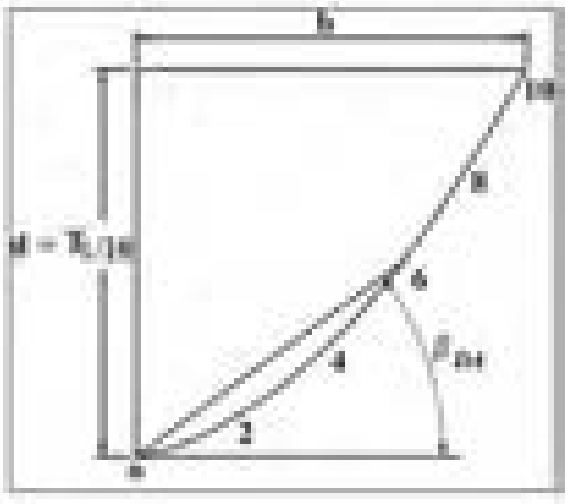

Figure 3.3.1.1: Angle β_{DA} (Cl.3.3.1)

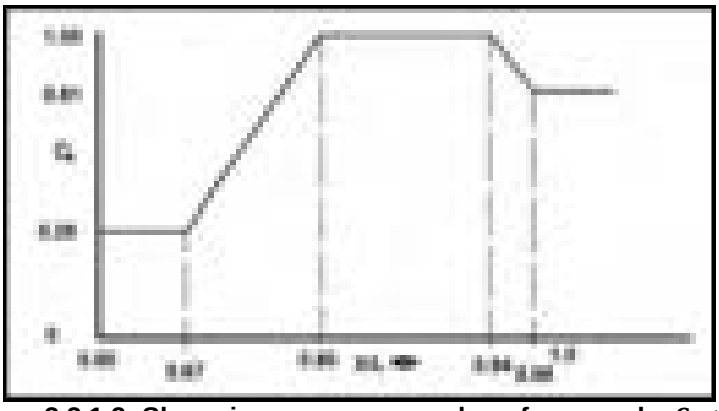

Figure 3.3.1.2: Slamming pressure envelope for vessels, C_b<0.75

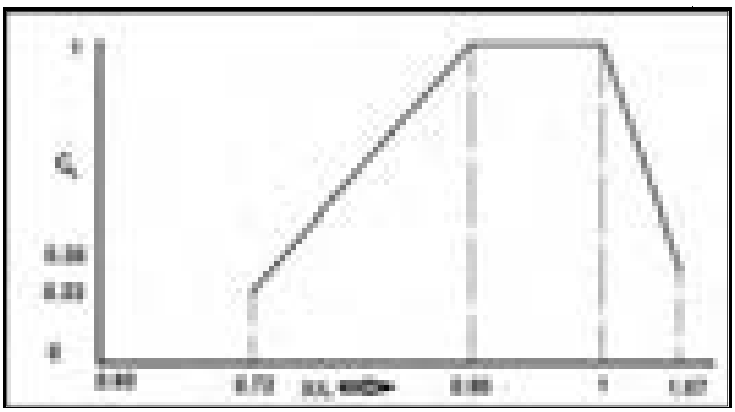

Figure 3.3.1.3: Slamming pressure envelope for vessels, $C_b \geq 0.75$

If the minimum design ballast draught T_{BF} is achieved by means of full ballast tanks in the forebody resulting in internal loads on bottom shell panels, the design slamming pressure P_{SL} on the corresponding panels may be reduced by (14h) [kN/m^2], where, 'h' is the height of the ballast tank [m].

For strength assessment of double bottom floors and girders, h is not to be taken greater than the double bottom height.

3.4 Scantling requirements

3.4.1 Shell plating

The net thickness of the hull envelope plating 't' in [mm], subjected to impact pressures from bottom slamming is not to be less than:

$$t = \frac{0.0158.\alpha_p.b}{C_d}\sqrt{\frac{P_{SL}}{R_{eH}}}$$

where:

C_d = Plate capacity correction coefficient = 1.3

C_a = Permissible bending stress coefficient taken as:

= 1.0 for acceptance criteria set AC-III

α_p = correction factor for the panel aspect ratio to be taken as below but not to be greater than 1.0:

$$\alpha_p = 1.2 - \frac{b}{2.1\,a}$$

a,b = Length and breadth of plate panel, in [mm], as defined in Chapter 3 Section 7, Cl.7.5.1.

3.4.2 Stiffeners

3.4.2.1 The design of end connections of stiffeners in the bottom slamming region is to ensure end fixity, either by making the stiffeners continuous through supports or by providing end brackets complying with Chapter 3, Section 6, Cl.6.2.2. Where it is not practical to comply with this requirement, the net plastic section modulus, Z_{pl_alt}, in [cm^3], for alternative end fixity arrangements is not to be less than:

$$\mathbf{Z_{pl_alt} = \frac{16\,Z_{pl}}{f_{bdg}}}$$

where:

Z_{pl} **=** Effective net plastic section modulus, in [cm^3], required by 3.4.2.2.

Scantlings and arrangements of primary supporting members, including bulkheads in way of stiffeners, are to comply with 3.6.

3.4.2.2 The stiffeners within the strengthening area defined in 3.1 are to comply with the following criteria:

(a) The effective net plastic section modulus, $\mathbf{Z_{pl}}$, in [cm^3], calculated in accordance with Chapter 3, Section 7, Cl.7.4.6, is not to be less than:

$$\mathbf{Z_{pl} = \frac{P_{SL}.s.\ell_{bdg}^2}{f_{bdg}.C_s.R_{eH}}}$$

where:

C_s = Permissible bending stress coefficient taken as:

= 0.9 for acceptance criteria set AC-III.

(b) The net web thickness, t_w, in [mm], is not to be less than:

$$\mathbf{t_w = \frac{\sqrt{3}.P_{SL}.s.\ell_{shr}}{2.d_{shr}.C_t.R_{eH}}}$$

where:

C_t = Permissible shear stress coefficient taken as:

= 1.0 for acceptance criteria set AC-III.

$\boldsymbol{\ell_{shr}}$ = Effective shear span of the stiffener, in [m], as defined in Chapter 3, Section 7, Cl.7.1.3.

$\mathbf{d_{shr}}$ = Effective shear depth of stiffener, in [mm], as defined in Chapter 3, Section 7, Cl.7.4.3.

3.4.2.3 The slenderness ratio is to comply with Chapter 9, Section 2.

3.4.3 Connection area

Bottom stiffeners are to be connected to supports, e.g., floors, girders or bulkheads. The connection area is generally obtained through fitting supporting members such as collar plate, end bracket or web stiffener. The requirements for the net connection area of the supporting members and its welding size are to be according to Section 2, Cl.2.3.3 using $\mathbf{P_{SL}}$.

3.5 Bottom slamming load area for primary supporting members

3.5.1 The scantlings of primary supporting members according to 3.6 are based on the application of slamming pressure, as defined in Cl.3.3.1, to an idealised slamming load area of hull envelope plating, A_{SL} in [m^2], given by:

$$A_{SL} = 1.1.L.B.C_b.10^{-3}$$

3.6 Primary supporting members

3.6.1 Scantlings of Primary supporting members

The size and number of openings in web plating of the floors and girders are to be minimised considering the required shear area as given below in Cl.3.6.1.1:

3.6.1.1 Net shear area

The net shear area $A_{shr-n50}$, in [cm^2], of each primary supporting member web at any position along its span is not to be less than:

$$\mathbf{A_{shr-n50} = \frac{10.\sqrt{3}.Q_{SL}}{C_t.R_{eH}}}$$

where:

$\mathbf{Q_{SL}}$ = The greatest shear force due to slamming for the position being considered, in [kN], based on the application of a patch load, $\mathbf{Q_{SL}}$ to the most onerous location, as determined in accordance with Cl.3.6.1.2 and Cl.3.6.1.3.

C_t = Permissible shear stress coefficient taken as:

= 0.9 for acceptance criteria set AC-III.

3.6.1.2 Simplified calculation of slamming shear force

For simple arrangements of primary supporting members, where the grillage effect may be ignored the shear force, Q_{SL}, in [kN], is given by:

$$Q_{SL} = f_{pt}.f_{dist}.F_{SL}$$

where,

f_{pt} = Correction factor for the proportion of patch load acting on a single primary supporting member, taken as

$$f_{pt} = 0.5({f_{SL}}^3 - 2{f_{SL}}^2 + 2)$$

f_{SL}= Patch load modification factor taken as:

$$\mathbf{f_{SL} = 0.5\frac{b_{SL}}{S}}$$

f_{dist} = Factor for the greatest shear force distribution along the span, according to Figure 3.6.1.

F_{SL} = Patch load, in [kN], taken as:

$$F_{SL} = P_{SL}.\ell_{SL}.b_{SL}$$

$\boldsymbol{\ell_{SL}}$ = Extent of slamming load area along the span, in [m], taken as:

$\boldsymbol{\ell_{SL} = \sqrt{A_{SL}}}$ but not to be greater than $\mathbf{0.5\ell_{shr}}$

$\mathbf{b_{SL}}$ = Breadth of the impact load area, in [m], supported by the primary supporting member, taken as:

$\mathbf{b_{SL} = \sqrt{A_{SL}}}$ but not to be greater than S.

$\mathbf{A_{SL}}$ = Load area as defined in Cl.3.5.1.

3.6.1.3 Direct calculation method for slamming shear force

For complex arrangements of primary supporting members, the greatest shear force, Q_{SL}, at any location along the span of each primary supporting member is to be derived by direct calculation in accordance with Table 3.6.1.

3.6.1.4 Web thickness of the primary supporting member

The net web thickness, t_w, in [mm], of primary supporting members adjacent to the shell, is not to be less than:

$$t_w = \frac{S_w}{100}\sqrt{\frac{R_{eH}}{235}}$$

where,

S_w = Plate breadth, in [mm], taken as the spacing between the web stiffening.

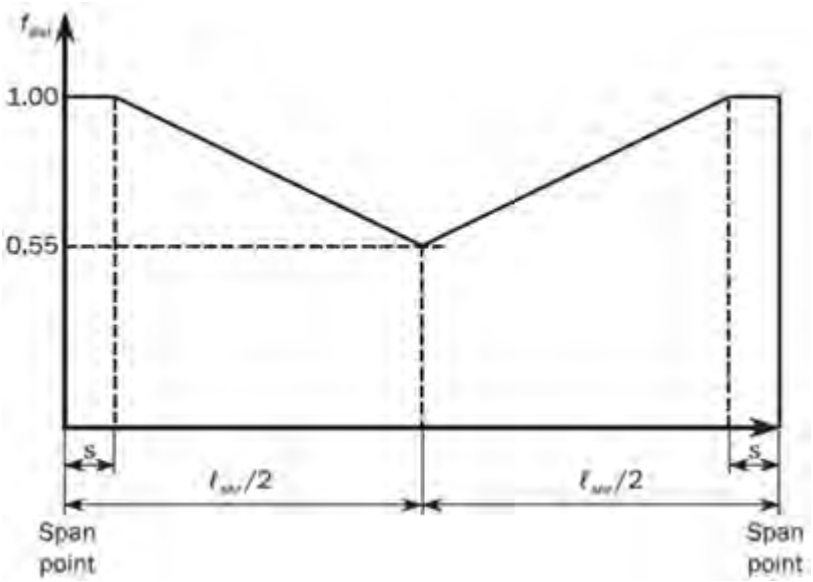

Figure 3.6.1: Distribution of f_{dist} along the span of simple primary supporting members

Table 3.6.1: Direct calculation methods for the derivation of Q_{SL}		
Type of analysis	**Model extent**	**Assumed end fixity of floors**
Beam theory	Overall span of member between effective bending supports.	Fixed at ends
Double bottom grillage	Longitudinal extent to be one cargo tank length. Transverse extent to be between inner hopper knuckle and centreline.	Floors and girders to be fixed at the boundaries of the model.
Note 1: The envelope of greatest shear force along each primary supporting member is to be derived by applying the load patch on a square area as defined in Cl.3.5.1, to several locations along the span. Note 2: A more extensive model in length and breadth can be considered. The procedure for finite element modeling and load application is given in IRS Guidelines on Structural Assessment of Ships based on Finite Element Method. In FE analysis, the equivalent stress, σ_{vm}, as defined in Chapter 8, Section 3, is not to exceed the yield stress, R_{eH}. In the case of beam assessment, the nominal bending stress is not to exceed $0.9R_{eH}$ and the nominal shear stress is not to exceed $0.9\ \tau_{eH}$.		

3.6.2 Direct calculations

Alternative to the formulae in Cl.3.3.1, IRS may accept the evaluation of the effects of bottom slamming from direct calculations also, when justified on the basis of the ship's characteristics and intended service. In such cases, the calculations are to be submitted to IRS for approval.

Section 4

Stern Slamming

4.1 Application

4.1.1 Where the shape of the after sections is such that there are large flat areas of the bottom shell, additional stiffening and/or increased shell plate thickness may be required.

Section 5

Wheel Loading

Symbols

For symbols not defined in this section, Refer to Chapter 1, Section 2.

AC-I = Acceptance criteria set as defined in Chapter 1, Section 1 for harbour condition.

AC-II = Acceptance criteria set as defined in Chapter 1, Section 1 for sea going condition.

5.1 General

5.1.1 Application

5.1.1.1 Where it is proposed either to stow wheeled vehicles on the deck or to use wheeled vehicles for cargo handling, the requirements of this section are to be complied with in addition to those given in the relevant chapters.

5.1.1.2 The requirements given below assume that the considered element (Deck plating and/or stiffener) is subjected to one load area only and that the element is continuous over several evenly spaced supports.

5.1.1.3 A "load area" is the tyre print area of individual wheels; for closely spaced wheels it may be taken as the enveloped area of the wheel group as given in Table 5.2.1.

5.1.1.4 The details of wheel loadings are to be forwarded by the shipbuilder. These details are to include the proposed arrangement and dimensions of tyre prints, type of tyre, axle and wheel spacings, maximum axle load and tyre pressure.

5.1.1.5 Signboards stating the maximum permissible axle load, the maximum tyre pressure of pneumatic tyres, wheel arrangement on axles, and specially approved vehicles are to be stated in the Loading Manual and displayed in a notice on each deck fitted in suitable positions.

For decks covered with protection plates, such as wooden plating, an increased footprint area may be considered for the scantling requirements for plates and stiffeners, considering the load spreading through the cover plate.

5.1.1.6 The deck and supporting structure are to be designed based on the maximum loading to which they may be subjected in service. Where applicable, the hatch covers are to be similarly designed. In no case, however, are the scantlings to be less than would be required as a weather or cargo deck or hatch cover, as applicable.

5.2 Wheel loads

5.2.1 The design pressure 'P_{wl}', in [kN/m^2], from the wheels of individual vehicles on deck with specified arrangement and dimension of footprints is to be taken as:

5.2.1.1 In harbour condition:

$$P_{wl-h} = \frac{W}{n.a.b}.\left(g + \frac{3}{\sqrt{W}}\right)10^6$$

5.2.1.2 In sea going condition:

$$P_{wl-s} = \frac{W}{n.a.b}.(g + a_v)10^6$$

where,

W = Maximum axle load in [t]. For fork lift trucks, the total weight is to be taken as the axle load.

n = Number of "load areas" per axle

a = Extent in [mm], of the load area parallel to the stiffeners (Refer Table 5.2.1).

b = Extent in [mm], of the load area perpendicular to the stiffeners (Refer Table 5.2.1).

a_v = Combined vertical acceleration in [m/s^2] as defined in Chapter 5 Section 2, Cl.2.2.3.3 using y = B/2.

5.2.2 If the arrangement and dimensions of footprints are not available for vehicles with pneumatic tyres, the design pressure, in [kN/m^2], may normally be taken as:

5.2.2.1 In harbour condition

$$P_{wl-h} = \frac{P_T}{n_0}.\left(1 + \frac{3}{g\sqrt{W}}\right)$$

5.2.2.2 In sea going condition

$$P_{wl-s} = \frac{P_T}{n_0}.\left(1 + \frac{a_v}{g}\right)$$

where:

P_T = Tyre pressure for pneumatic tyres, in [kN/m^2]. Refer Cl.5.1.1.4.

n_0 = Number of wheels on the plate panel, taken equal to:

= 1 in general

= 1.20 when double wheels are specified

= 1.27 when triple wheels are specified

The load area as indicated in Table 5.2.1 is defined as:

- the footprint area of individual wheels or

- the rectangular enveloped area of footprints of a wheel group.

Table 5.2.1: Load area definition

Number of wheels in a group	Wheel print dimensions (Imprint area between tyre and deck)	Design load area Axle perpendicular to stiffeners	Design load area Axle parallel to stiffeners
Single wheel			Two wheels			
Triple wheels			
NOTE: In general the scantlings are to be checked according to both individual wheel area and wheel group area. If, however, the distance 'c' between individual footprints is less than the breadth 'b' of the prints, the load area may be calculated for the group of wheels only.

5.3 Tyre print area

5.3.1 When the tyre print area (arrangement and dimensions of footprints) is not available for vehicles with pneumatic tyres, it may be taken equal to:

$$A_t\,[m^2] = \frac{9.81 n_0 . W}{n . P_T}$$

where,

P_T = Tyre pressure for pneumatic tyres, in [kN/m^2].

n_0 = Coefficient taken equal to:

= 1 in the case of a single wheel

= 1.20 when double wheels are specified

= 1.27 when triple wheels are specified

n = Number of wheels for the axle considered

= 2, otherwise specified.

5.3.2 The load area dimensions, in [mm], are in general to be taken as:

$$a_1 = \sqrt{k A_t} . 10^3$$

$$b_1 = \sqrt{A_t / k} . 10^3$$

where,

$k = k_1$ in general

$= k_2$ for plating when $k_2 < k_1$ and

$$\frac{n_0 W}{n\, b^2} 10^6 \geq 100$$

k_1 = 2.0 for a single wheel

= 2.0 for multiple wheels with axle parallel to stiffener

= 0.8 for double wheels with axle perpendicular to stiffeners

= 0.5 for triple wheels with axle perpendicular to stiffeners

$$k_2 = \frac{\sqrt{A_t}}{2b} 10^3$$

A_t, n_0, n = As defined in Cl.5.3.1.

5.3.3 For heavy vehicles with axle load, W, exceeding 15t, the footprint data is to be provided.

5.3.4 For heavy vehicles where the stowing and lashing arrangement may significantly affect the load distribution at sea, the design pressure for individual load areas will be specially considered.

5.3.5 Deck areas for wheel loads from cargo handling vehicles, which are frequently operating in all directions, shall be checked for design loads with axle parallel and perpendicular to stiffeners.

5.4 Scantling requirements

5.4.1 Deck plating

The net thickness, 't' in [mm], of deck plating subjected to wheel loadings, is not to be less than;

$$t = 77.4.f_a\sqrt{\frac{c_2.b.c.P_{wl}}{m.c_a.R_{eH}}}10^{-3}$$

where,

$f_a = (1.2 - s/2.1\ell)$, maximum 1.0

c_2 = coefficient taken as:

c_2 = Maximum 1.0 for $a_1/s \geq 1.94$

$$c_2 = 1.3 - \frac{4.2}{(a_1/s + 1.8)^2} \text{ for } a_1/s < 1.94$$

c = coefficient taken as:

= b_1 for $b_1 \leq s$

= s for $b_1 > s$

a_1, b_1 = Extents, in [mm], of the load area as defined in Cl.5.2.1.

P_{wl} = Design pressure in [kN/m^2] as defined in Cl.5.2.1 or Cl.5.2.2, considering the design load set defined in Chapter 7, Section 2.

m = Bending moment factor taken as:

$$m = \frac{38}{(b_1/s)^2 - 4.7(b_1/s) + 6.5} \text{ for } b_1 \leq s$$

$m = 13.57$ for $b_1 > s$

c_a = Permissible bending stress coefficient for plate taken as:

$$c_a = \beta_a - \alpha_a\frac{|\sigma_{hg}|}{R_{eH}}$$

not to be taken greater than c_{a-max}

σ_{hg} = Hull girder longitudinal stress, in [N/mm^2], as defined in Chapter 6, Section 3.

c_{a-max}= Maximum permissible bending stress coefficient for AC-I and AC-II as defined in Table 5.4.1.

α_a, β_a = Coefficient as defined in Table 5.4.1.

Table 5.4.1: Definition of β_a, α_a, and $C_{a\text{-}max}$

Acceptance criteria	Structural member		β_a	α_a	$C_{a\text{-}max}$
AC-I	Longitudinal member	Longitudinal stiffened plating	1.9	0.5	1.8
		Transverse stiffened plating	1.9	1.0	1.8
	Other member		1.8	0	1.8
AC-II	Longitudinal member	Longitudinal stiffened plating	2.1	0.5	2.0
		Transverse stiffened plating	2.1	1.0	2.0
	Other member		2.0	0	2.0

5.4.2 Deck stiffeners

The net section modulus ' Z ' in [cm^3] of deck beams and longitudinal subjected to wheel loading is not to be less than:

$$Z = \frac{c_3.c.d.\ell_{bdg}.P_{wl}}{m.R_{eH}.C_s}10^{-3}$$

where,

P_{wl} = Design pressure in [kN/m^2] as defined in Cl.5.2.1 or Cl.5.2.2, considering the design load set defined in Chapter 7, Section 2.

$c_3 = 1.0$ for $b_1/s \leq 0.6$

$= (1.15 - 0.25\,b_1/s)$ for $0.6 < b_1/s \leq 1.0$

$= (1.15 - 0.25\,b_1/s)\,b_1/s$ for $1.0 < b_1/s < 3.4$

$= 1.0$ for $b_1/s \geq 3.4$

a_1, b_1 = Extents, in [mm], of the load area as defined in Cl.5.2.1.

c = coefficient defined in Cl.5.4.1.

d = coefficient taken as:

$= a_1$ for $a_1 \leq \ell$

$= \ell$ for $a_1 > \ell$

ℓ_{bdg} = Effective bending span, in [m] as defined in Chapter 3.

m = Bending moment factor

$$m = \frac{r}{\left(\frac{a_1}{1000\ell}\right)^2 - 4.7\left(\frac{a_1}{1000\ell}\right) + 6.5}$$

for $\frac{a_1}{1000\ell} \leq 1.0$

$$m = \frac{87}{\left(\frac{a_1}{1000\ell}\right)^2\left[\left(\frac{a_1}{1000\ell}\right)^2 - 6.3\left(\frac{a_1}{1000\ell}\right) + 10.9\right]}$$

for $1.2 < \frac{a_1}{1000\ell} \leq 2.5$

$m = 12$ for $\frac{a_1}{1000\ell} \geq 3.5$

r = Factor depending on the rigidity of girders supporting continuous stiffeners

= 29 for continuous stiffeners supported at girders.

= 38 when the continuous stiffeners can be considered as rigidly supported at girders against rotation.

C_s = Permissible bending stress coefficient for stiffeners taken as:

$$C_s = \beta_s - \alpha_s \frac{|\sigma_{hg}|}{R_{eH}}$$

$C_{s-max.}$= Maximum permissible bending stress coefficient as defined in Table 5.4.2.

β_s = Coefficient as defined in Table 5.4.2.

α_s = Coefficient as defined in Table 5.4.2.

Table 5.4.2: Definition of α_s, β_s, $C_{s-max.}$

Acceptance criteria set	Structural member	β_s	α_s	$C_{s-max.}$
AC-I	Longitudinal strength member	0.85	1.00	0.75
	Transverse or vertical member	0.75	0.00	0.75
AC-II	Longitudinal strength member	1.00	1.00	0.90
	Transverse or vertical member	0.90	0.00	0.90

5.4.3 Web plating

5.4.3.1 The net web thickness, in [mm], of stiffeners subjected to wheel loading, is not to be taken less than:

$$t_w = \frac{\sqrt{3}.f_{shr}.c_3.c.d.P_{wl}}{d_{shr}.c_t.R_{eH}}10^{-3}$$

where:

f_{shr} = Shear force distribution factor taken as:

$$f_{shr} = 1 - 0.5\frac{a_1}{1000\ell} \text{ for } a_1 \leq 1000\ell$$

$$f_{shr} = 0.5 - 0.25\left(\frac{a_1}{1000\ell} - 1\right) \text{ for } a_1 > 1000\ell, \text{Minimum } 0.25$$

P_{wl} = Design pressure in [kN/m^2] as defined in Cl.5.2.1 or Cl.5.2.2 considering the design load set being defined in Chapter 7, Section 2.

c_3 = Coefficient as defined in Cl.5.4.2.

c = Coefficient as defined in Cl.5.4.2.

d = Coefficient as defined in Cl.5.4.2.

d_{shr} = Effective web depth of stiffener, in [mm] as defined in Chapter 3, Section 7.

c_t = Permissible shear stress coefficient as defined in Chapter 7, Section 5 for the design load set being considered.

5.4.3.2 If more than one load area can be positioned simultaneously on the same stiffener span or adjacent spans, the section modulus will be specially considered, based on finite element analysis.

5.4.4 Deck girders

5.4.4.1 Vehicle loads

The scantlings of girders will be specially considered based on the most severe condition of moving or stowed vehicles. Also, see Cl.5.1.1.4. Allowable stresses to be taken as given in Chapter 7, Section 6,6.2. The envelope vertical acceleration, a_{z-env}, in combination with maximum hull girder stress, σ_{hg} are to be considered in the calculation of design concentrated force calculation.

5.4.4.2 The girder structure is to be based on Chapter 5, Section 4, Cl.4.2.3.1 corresponding to the most severe of the uniform deck load, UDL (evenly and unevenly distributed), and the vehicle axle load (cargo handling vehicle and vehicles to be carried). The position of the vehicles is to be taken as the most unfavorable for the girder strength.

5.4.4.3 The scantlings of girders are also to be considered based on the most severe condition of cargo handling or stowed vehicles. Unless otherwise specified, the girder system is to be designed for a condition where the axles of several trailers side by side are acting on the same transverse girder also.

Section 6

Special Hull Structures

Symbols

For symbols not defined in this section, Refer to Chapter 1, Section 2.

6.1 Stems, Keel, Breasthooks, Diaphragm plating, and Bulbous bow

6.1.1 Plate stem thickness

6.1.1.1 The net thickness, t_{Stm} in [mm], is not to be less than:

$$t_{Stm} = (0.6 + 0.4S_B)(0.08L + 2.7)\sqrt{k}$$

but need not be greater than $22\sqrt{k} - 1$

where:

S_B = Spacing, in [m], between horizontal stringers (partial or not), breasthooks, or equivalent horizontal stiffening members.

Starting from 0.6[m] above the summer load waterline up to $T_{SC} + C_w$, the net thickness may gradually be reduced to $0.8t_{Stm}$.

The extension in [mm] of the stem plate from its leading edge and aftwards shall not be smaller than determined by the following formula:

$$\ell = 70\sqrt{L}$$

6.1.1.2 Arrangement

The expanded width of the stem is not to be less than the rule breadth of the plate keel, defined in Chapter 3, Section 5, Cl.5.3.7.

The plating forming the stems is to be supported by horizontal diaphragms spaced not more than 1.0[m] apart and connected, as far as practicable, to the adjacent frames and side stringers. The webs are to be extended aft to at least beyond the butts of stem plates and shell plating.

If considered necessary, and particularly where the stem radius is large, a centreline stiffener or web of suitable scantlings is to be fitted.

Continuity of strength is to be ensured at the connection of stems to the surrounding structure.

6.1.2 Bar stem

6.1.2.1 Bar stem area

The cross-sectional area, A_{Stm}, in [cm^2], of a bar stem below the summer load waterline, is not to be less than:

$$A_{Stm} = 1.25L$$

Above the summer load waterline, the cross-sectional area of the bar stem may be gradually reduced to $0.75A_{Stm}$ at the stem head.

6.1.2.2 Arrangement

The lower part of the stem may be constructed of cast steel subject to the examination by IRS; where necessary, a vertical web is to be fitted for welding of the centre keelson.

The bar stem is to be welded to the bar keel generally with butt welding. The shell plating is also to be welded directly to the bar stem with butt welding.

6.1.3 Bar keel

6.1.3.1 The depth and thickness of bar keel, in [mm] are not to be less than:

$$D_{keel} = 100 + 1.5L$$

$$T_{keel} = 10 + 0.6L$$

The scantlings of bar keels at the aft and fore-end are to be the same as in the midship region as given above.

6.1.3.2 Minor deviations from the above values may be accepted provided the required sectional area is maintained.

6.1.4 Breasthooks and diaphragm plating

The net thickness of breasthooks/diaphragm plates, t_w, in [mm], is not to be less than:

$$t_w = \frac{s}{70}\sqrt{\frac{R_{eH}}{235}}$$

where:

s = Spacing of stiffeners on the web, as defined in Chapter 1, Section 2, Table 2.6.5, in [mm]. Where no stiffeners are fitted, s is to be taken as the depth of the web.

6.1.5 Bulbous Bow

6.1.5.1 General

Where a bulbous bow is fitted, the structural arrangements are to be such that the bulb is adequately supported and integrated into the fore peak structure.

6.1.5.2 Diaphragm plates

At the forward end of the bulb, the structure is generally to be supported by horizontal diaphragm plates spaced not more than 1.0[m] apart in conjunction with a deep centreline web. In general, vertical transverse diaphragm plates are to be arranged in way of the transition from the peak framing to the bulb framing.

6.1.5.3 Special bulbous bow designs

Additional strengthening in the form of a centreline wash bulkhead is generally to be fitted in way of wide bulbs. Similarly, transverse wash bulkheads or substantial web frames spaced approximately 5 frame spaces apart are to be fitted in way of long bulbs.

6.1.5.4 Strengthening for anchor and chain cable contact

The shell plating thickness at the fore end of the bulb and in other areas likely to be damaged by the anchors and chain cables during anchor handling is not to be less than that required for plate stems as defined in Section 6, Cl.6.1.1.

6.2 Stern Frames and appendages

6.2.1 General

6.2.1.1 Stern frames, rudder horns, shaft brackets, etc. are to be designed such that they are effectively integrated into the ship's structure.

6.2.1.2 In castings, sudden changes of section or possible constrictions to the flow of metal during castings are to be avoided. All fillets are to have adequate radii, which in general should not be less than 50[mm], depending on the size of the casting.

6.2.1.3 Cast steel and fabricated stern frames are to be strengthened by adequately spaced plates with gross thickness not less than 80% of the required thickness for stern frames as defined in Cl.6.2.3. In way of the upper part of the stern frame arch, these webs are to line up with the floors.

Abrupt changes of the section are to be avoided in castings; all sections are to have an adequate tapering radius.

6.2.1.4 Stern frames may be fabricated from steel plates or made of cast steel with a hollow section. For applicable material specifications and steel grades, Refer Chapter 2, Section 2. Stern frames of other materials or construction will be specially considered.

6.2.1.5 Plating materials for stern frames supporting the rudder and propeller boss, rudders, rudder horns and shaft brackets are not to be of lower grades than those corresponding to the material classes given in Chapter 2, Section 2.

6.2.1.6 It is recommended that the after body of the ship be so shaped as to ensure adequate flow of water to the propeller to prevent the uneven formation of eddies, as far as possible. For a moderately cavitating propeller, the following minimum values of propeller hull clearances may be used as guidance. (Refer Figure 6.2.1)

- For single screw ships:

$$a \geq 0.2R \text{ in [m]}$$

$$b \geq (0.7 - 0.04N_b)R \text{ in [m]}$$

$$c \geq (0.48 - 0.02N_b)R \text{ in [m]}$$

$$d \geq 0.07R \text{ in [m]}$$

- For twin screw ships:

$$b \geq (0.5 - 0.03N_b)R \text{ in [m]}$$

$$c \geq (0.6 - 0.02N_b)R \text{ in [m]}$$

where,

R = Propeller radius, in [m].

N_b = Number of propeller blades.

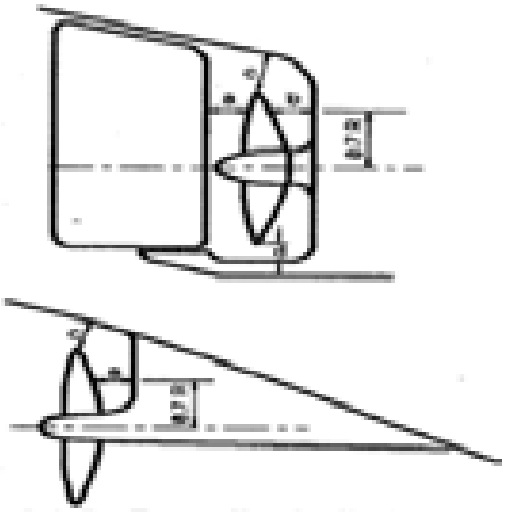

Figure 6.2.1: Propeller hull clearances

6.2.2 Connections

6.2.2.1 Connections with hull structure

Stern frames are to be effectively attached to the aft structure and the lower part of the stern frame is to be extended forward of the propeller post to a length not less than 1500 + 6L[mm], in order to provide an effective connection with the keel. However, the stern frame need not extend beyond the aft peak bulkhead.

The net thickness of shell plating connected with the stern frame is not to be less than that obtained, in [mm], from the following formula:

$$t = 0.094(L_2 - 43) + 0.009b$$

In way of the boss and heel plate, the net thickness of shell plating, in [mm], shall not be less than:

$$t = 0.105(L_2 - 47) + 0.011b$$

where:

b = Breadth of plate panel, in [mm].

L_2 = Rule length but need not be taken greater than 300[m].

The net thickness of the aft peak bulkhead plating in way of the stern tube penetration is to be at least 1.6 times the required thickness for the bulkhead plating.

6.2.2.2 Connection with keel plate

The thickness of the lower part of the stern frames is to be gradually tapered to that of the solid bar keel or keel plate. Where a keel plate is fitted, the lower part of the stern frame is to be designed to ensure an effective connection with the keel.

6.2.2.3 Connection with transom floors

Rudder posts and, in the case of ships greater than 90[m] in length, propeller posts are to be connected with transom floors having height not less than that of the double bottom height and a net thickness not less than that obtained, in [mm], from the following formula:

$$t = 9 + 0.023Lk^{1/2}$$

where:

L = Rule length but need not be taken greater than 250[m]

6.2.2.4 Connection with centre girder

Where the stern frame is made of cast steel, the lower part of the stern frame is to be fitted, as far as practicable, with a longitudinal web for connection with the centre girder.

6.2.3 Propeller posts

6.2.3.1 Gross scantlings of propeller posts

The gross scantlings of propeller posts are not to be less than those obtained from the formulae in Table 6.2.3 for single screw ships.

Where the scantlings and proportions of the propeller post differ from Table 6.2.3, the section modulus of the propeller post about the longitudinal axis is not to be less than that calculated with the propeller post scantlings in Table 6.2.3.

Fabricated and cast propeller posts and rudder posts of twin-screw ships are to be strengthened at intervals by webs. In way of the upper part of the stern frame arch, these webs are to line up with the floors.

Rudder posts and propeller posts are to be connected to floors.

Table 6.2.3: Single screw ships - Gross scantlings of propeller posts

Gross scantlings of Propeller posts, in [mm]	Fabricated propeller post	Cast propeller post	Bar propeller post, cast or forged, having rectangular section
			a	$50L_1^{1/2}$	$33L_1^{1/2}$	$10\sqrt{2.5L + 25}$ for $L \leq 60$ $10\sqrt{7.2L - 256}$ for $L > 60$
b	$35L_1^{1/2}$	$23L_1^{1/2}$	$10\sqrt{1.6L + 16}$ for $L \leq 60$ $10\sqrt{4.6L - 164}$ for $L > 60$
t_1	$2.5L_1^{1/2}$	$3.2L_1^{1/2}$ and to be taken not less than 19[mm]	NA
t_2	NA	$4.4L_1^{1/2}$ and to be taken not less than 19[mm]	NA
t_w	$1.3L_1^{\frac{1}{2}}$	$2.0L_1^{1/2}$	NA
NOTE: L_1 is not to be taken more than 250[m].			

6.2.3.2 Section modulus below the propeller shaft bossing

In the case of a propeller post without a sole piece, the section modulus of the propeller post may be gradually reduced below the propeller shaft bossing down to 85% of the value calculated with the scantlings in Table 6.2.3.

In any case, the thicknesses of the propeller posts are not to be less than those obtained from the formulae in Table 6.2.3.

The scantlings below the boss of stern frames with sole pieces are to be gradually increased to provide strength and stiffness in proportion to those of sole pieces.

6.2.3.3 Scantlings above the propeller boss

In the upper part of the propeller aperture, where the hull form is full and centreline supports are provided, the thickness of stern frames and internal members may be reduced

to 80% of the applicable requirement of propeller posts given in Table 6.2.3.

6.2.4 Propeller boss

6.2.4.1 The gross wall thickness of the boss 't_b', in [mm], in the propeller post is not to be less than:

$$t_b = 0.16d_{ts} + 30 \text{ for } d_{ts} \leq 300[\text{mm}]$$

$$t_b = 5\sqrt{d_{ts} - 60} \text{ for } d_{ts} > 300[\text{mm}]$$

where,

d_{ts} = Rule diameter of the tail shaft in [mm].

6.2.4.2 In fabricated stern frames the connection of the propeller post to the boss is to be by full penetration welds.

6.2.4.3 In single screw ships, the thickness of the propeller shaft bossing, included in the propeller post, is not to be less than 60% of the dimension 'b' required in Cl.6.2.3 for bar propeller posts with a rectangular section.

6.3 Rudder post and rudder shaft

6.3.1 The section modulus of the rudder post 'Z_T', in [cm^3] about the longitudinal axis is not to be less than:

$$Z_T = \frac{F_r \ell}{1000}$$

where,

F_r = Rudder force in [N] as defined in Part 3, Chapter 13, Section 3.

ℓ = Unsupported span of the rudder post in [m]. (Refer Figure 6.3.1).

Where, due to low rigidity of the sole piece in the transverse direction, the bottom support for the rudder post cannot be regarded as efficient, direct calculations are to be carried out and the section modulus of the rudder post is increased to limit the bending stress to 85[N/mm^2].

6.3.2 The rudder shaft diameter, d_ℓ, in [mm], at the lower bearing is not to be less than:

$$d_\ell = 3.9\sqrt[3]{\left(\frac{F_r . c . k(\ell - c)}{\ell}\right)}$$

where,

F_r = Rudder force in [N] as defined in Part 3, Chapter 13, Section 3.

ℓ, a, b = Refer Figure 6.3.1

$$c = \frac{a + b}{2}$$

6.3.3 The diameter 'd_ℓ' may have to be increased on account of the low rigidity of the sole piece, as described for the rudder post in Cl.6.3.1. The diameter d_f below the coupling, the flange is to be 10% greater than d_ℓ unless the rudder axle is protected by a corrosion-resistant composition above the upper bearing. Where the corrosion-resistant composition is not provided then d_f may be equal to d_ℓ.

6.3.4 The details of the taper, nut, etc. at the lower end of the rudder axle are to be similar to those of rudder stock cone couplings given in Part 3, Chapter 13.

6.3.5 The scantlings and arrangements of vertical coupling at the upper end of the rudder axle are to be similar to those of horizontal bolted couplings of the rudder given in Part 3, Chapter 13, Section 6. In the formula the axle diameter 'd_ℓ' is to be used in place of rudder stock diameter 'd_s'.

6.3.6 The bearing depth l_2 is not to be less than $1.2\ d_\ell$ [mm].

6.4 Sole piece

6.4.1 Requirements for structural strength of sole pieces are given in Part 3, Chapter 13.

6.4.2 The sole piece is to extend at least two frame spaces forward of the forward edge of the propeller boss and beyond this, the cross-section of the extension is to be gradually reduced to that necessary for an efficient connection to the keel plate. Fabricated sole pieces are to have adequate internal stiffening.

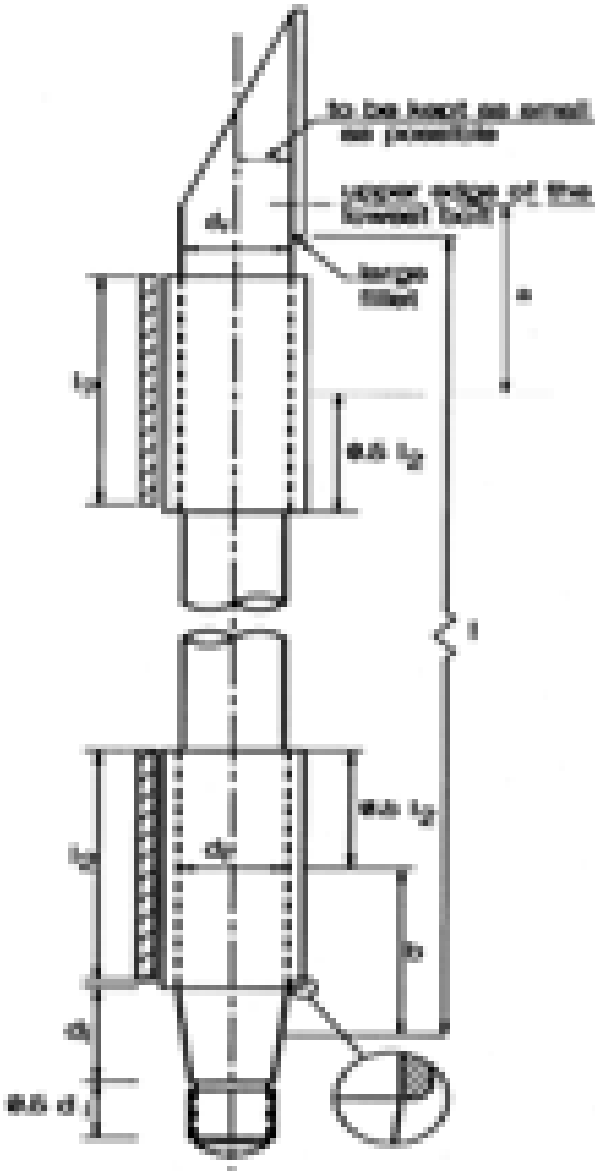

Figure 6.3.1: Rudder shaft details

6.5 Propeller shaft brackets

Propeller shafting is either enclosed in bossing or independent of the main hull and supported by shaft brackets.

6.5.1 Single-arm propeller shaft brackets

6.5.1.1 General

The following requirements are applicable to single arm propeller shaft brackets.

6.5.1.2 Scantling requirement

The moment in a single arm bracket, in [kN-m], is to be obtained from the following formula:

$$M = 0.75\, d_2 F_c \, L/l$$

where,

d_2 = Length of the arm, in [m], measured between the propeller shaft axis and the hull.

L = Length in [m], defined in Figure 6.5.1.

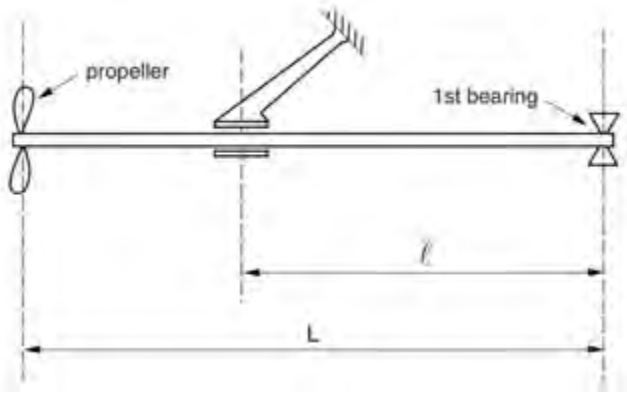

Figure 6.5.1: Schematic showing lengths L and l

F_c = Force, in [kN],

$$= \left(\frac{2\pi N}{60}\right)^2 R_p P$$

N = Number of revolutions per minute of the propeller.

R_p = Distance, in [m], of the centre of gravity of a blade in relation to the rotation axis of the propeller.

P = Mass of a propeller blade, in [t].

6.5.1.3 Checking criteria

The bending stress σ_F and the shear stress τ, is to comply with the following formula:

$$\sqrt{\sigma_F{}^2 + 3\tau^2} \leq \sigma_{all}$$

where,

σ_F = Bending stress to be taken as:

$$\sigma_F = 1000 \frac{M}{z_a}$$

τ = Shear stress

$$\tau = \frac{10.\, F_c.\, L}{A_s l}$$

z_a = Section modulus of the arm, in [cm^3], at the level of the connection to the hull with respect to a longitudinal axis.

A_s = Shear sectional area of the arm, in [cm^2].

σ_{all} = Allowable stress, taken as 70/k [N/mm^2]; where 'k' is the material factor

6.5.2 Double arm propeller shaft brackets

6.5.2.1 General

The following requirements are applicable to propeller shaft brackets having two struts to support the propeller tail shaft boss. The struts are to be of solid or fabricated type. The angle between the struts is not to be less than 50[deg]. It is recommended that the angle included between the arms differs from the angle included between the propeller blades.

6.5.2.2 Arrangement

Solid struts are to be carried continuously through the shell plating and are to be given satisfactory support by the internal ship structure. Fabricated struts may be welded to the shell plating. The shell plating is to be reinforced, and internal brackets in line with strut plating are to be fitted. If the struts are built with a longitudinal centre plate, this plate is to be carried continuously through the shell plating. The struts are to be well-rounded at the fore and aft end at the transition to the hull.

The connection of the arms to the shaft bracket boss is to be by full penetration welding. The strut structure inside the shell needs to terminate within a compartment of limited volume in order to reduce the effect of flooding in the case of damage.

6.5.2.3 Scantling requirement

The scantlings of solid or fabricated shaft brackets are to comply with the following:

$$h \geq 0.4 d_{ts} \text{ [mm]}$$

$$A \geq 0.4 d_{ts}^2 \text{ [mm}^2\text{]}$$

$$Z_T \geq 0.12 d_{ts}^3 \text{ [mm}^3\text{]}$$

where,

d_{ts} = Propeller tail shaft diameter, in [mm].

d_{ts} should be taken as the provided value with a specified minimum tensile strength of 450[N/mm^2] if it is more than the actual value.

h = Thickness of the strut section, in [mm] as given in Figure 6.5.2.

A = Gross area of the strut section, in [mm^2].

Z_T = Gross section modulus of the strut against transverse bending, in [mm^3]. Z_T is to be calculated with reference to the neutral axis YY as indicated in Figure 6.5.2.

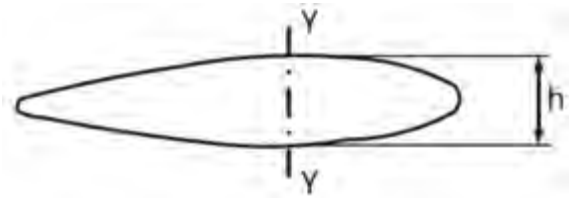

Figure 6.5.2: Sectional view of the strut

6.6 Propeller shaft bossing

6.6.1 Where the propeller shafting is enclosed in bossings extending back to the bearings supporting the propellers, the aft end of the bossings and the bearings are to be adequately supported. End supports are to be designed to transmit the loads from the shaft efficiently to the ship's internal structure.

6.6.2 The boss plating is generally to be radiused into the shell plating and supported at the aft end by diaphragms at every frame. These diaphragms are to be suitably stiffened and connected to floors of increased scantlings or a suitable arrangement of main and deep web frames. At the fore end, the main frames may be shaped to fit the bossing, but deep webs are generally to be fitted not more than four frame spaces apart.

6.6.3 The region where the shafting enters the ship, and the bearing in way, are to be adequately supported by floors or deep webs.

6.7 Shaft Bracket Boss

6.7.1 The length of the shaft bracket boss, ℓ_b, is to be sufficient to support the length of the required bearing and to allow the proper connection of the shaft bracket. Recommendations from the bearing manufacturer are also to be taken into consideration. In general, ℓ_b is recommended

to be not less than $4d_{ts}$, where d_{ts} is the propeller tail shaft diameter, in [mm] and in no case to be less than $2d_{ts}$.

6.7.2 When the shaft and the shaft bracket boss are made of the same material the thickness,t_b [mm] of the shaft bracket boss is to be not less than $(d_{ts}/4)$, where d_{ts} is the propeller tail shaft diameter, in [mm].

6.7.3 Where the shaft and the shaft bracket boss are of dissimilar materials, the thickness of the boss, t_b in [mm] is to be not less than:

$t_b = 0.75\, d_{ts}\, (u^{0.33} - 0.667)$ and in no case is t_b to be less than 12[mm].

where,

d_{ts} = Propeller tail shaft diameter, in [mm] in way of the boss, in the appropriate screw shaft material.

u = Coefficient taken as below but not less than 0.825

$$u = \frac{f_{u-s}}{f_{u-b}}$$

f_{u-s} = Ultimate tensile strength of the shaft material, in [N/mm^2].

f_{u-b} = Ultimate tensile strength of the boss material, in [N/mm^2].

6.8 Rudder horns

6.8.1 Requirements for the structural strength of rudder horns are given in Part 3, Chapter 13.

6.8.2 Rudder horns supporting semi-spade type rudders are to be efficiently integrated into the main hull structure, and additional web frames or side transverses may be required in the 'tween deck above.

6.8.3 The shell plating is to be increased in thickness in way of the horn, and the radius at the shell connection is not to be less than (150 +0.8L)[mm].

6.9 Propeller nozzles

6.9.1 General

6.9.1.1 The requirements for scantlings and arrangements of propeller nozzles given in this section apply, in general, to nozzles of numeral N_N, not greater than 200. Nozzles of numeral greater than 200 will be specially considered.

Nozzle numeral, $N_N = 0.01\ P.D$

where,

P = Power transmitted to the propeller [kW].

D = Diameter of the propeller, in [m].

6.9.1.2 Additional requirements for scantlings and arrangements applicable to steerable nozzles and fixed nozzles are given in Cl.6.9.3 and Cl.6.9.4 respectively.

6.9.1.3 For additional requirements applicable to Azimuth Thrusters see Part 4, Chapter 4, Section 9.

6.9.1.4 All materials used in the construction of the nozzle-body, stocks, pintles, keys, and bolts are to be similar to rudders as per Part 3, Chapter 13, Section 1.

6.9.2 Nozzle scantlings and construction details

6.9.2.1 Nozzle scantlings are to be as per Table 6.9.2. (Refer Figure 6.9.2).

6.9.2.2 If the ship has ice-class notation, nozzle scantlings will be specially considered; however, the part of the outer shell of the nozzle which is situated within the ice belt is to have a plate thickness not less than that of the shell plating in the way.

6.9.2.3 The shroud plating in way of the propeller tips is to be carried well forward and aft of the propeller tips, due to allowance being made on steering nozzles for the rotation of the nozzle in relation to the propeller, however, shroud plate width is not to be less than (L_N/4), where L_N is the length of the nozzle (Refer Figure 6.9.2).

6.9.2.4 The transverse strength of the nozzle is to be maintained by fitting the adequate number of ring webs. At least two ring webs are to be fitted in way of shroud plating, spaced approximately 400[mm]. Fore and aft of these webs the spacing of ring webs are generally not to exceed 600[mm]. Ring webs are to be increased in thickness in way of the headbox and pintle support structure in accordance with Table 6.9.2 and the increased thickness is to be maintained to the adjacent fore and aft web.

Table 6.9.2: Nozzle scantling requirements		
Sl.No	**Item**	**Requirement**
1)	Shroud plating in way of propeller blade tips	• For $N_N \leq 63$ $t_s = (11 + 0.1N_N)$ in [mm] • For $N_N > 63$ $t_s = (14 + 0.052N_N)$ in [mm]
2)	Shroud plating clear of blade tips, flare and cone plating, wall thickness of leading and trailing edge members	$t_p = (t_s - 7)$ in [mm] but not less than 8 [mm].
3)	Webs and ring webs	• In way of the head box and pintle support $t_w = (t_s + 4)$ in [mm] • Elsewhere As for item (2)
Symbols		
N_N = Nozzle numeral as given in Cl.6.9.1. t_s = Thickness of shroud plating in way of propeller tips, in [mm]. t_p = Thickness of plating, in [mm]. t_w = Thickness of webs and ring webs in way of the headbox and pintle support, in [mm].		
NOTE: The thickness given is for mild steel. When corrosion-resistant material is used, the plate thicknesses may be reduced by 15%, however, thickness is not to be less than the minimum thickness as applicable.		

6.9.2.5 Local stiffening is to be fitted in way of the top and bottom supports which are to be integrated with the webs and ring webs. Continuity of bending strength is to be maintained in these regions.

6.9.2.6 Weld details of nozzle plating, webs, coupling flanges, etc. are to be as given in Chapter 13, Section 4 and also as per Chapter 16 'Welding'.

6.9.2.7 Leak testing of the nozzle is to be as required for rudders as per Chapter 17.

6.9.2.8 Arrangement is to be provided to drain the nozzle completely. Drain plugs are to be provided with efficient packing.

6.9.2.9 Internal surfaces of nozzles are to be efficiently coated for corrosion protection after completion of fabrication and testing. Where it is intended to fill the nozzle with plastic foam, details of the foam material are to be submitted.

6.9.2.10 The web plates and shell plates of the support structure are to be in line with the web plates in the nozzle.

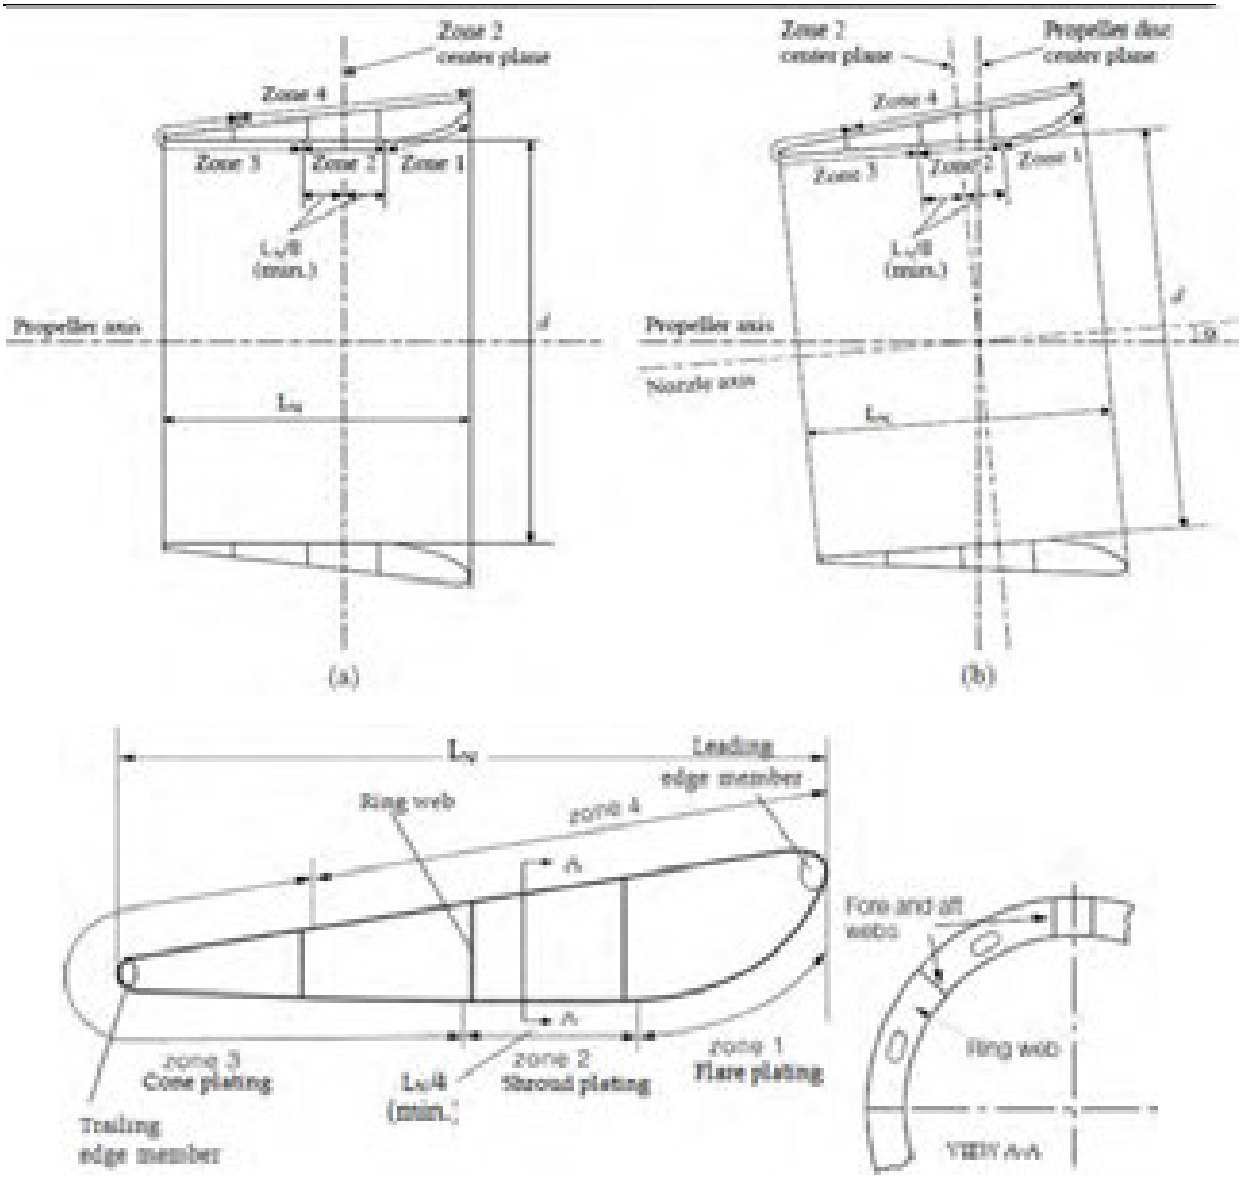

Figure 6.9.2: Propeller Nozzle Section View

where,

L_N = Nozzle length

d = Nozzle inner diameter

Zone 1 = Zone of nozzle inner skin from nozzle leading edge to the fore end of Zone 2.

Zone 2 = Zone of nozzle inner skin in way of propeller tips with two ring webs within the zone, = $L_N/4$ (min)

The minimum length on each side of the Zone 2 centre plane is to be:

= $L_N/8$, where Zone 2 centre plane and propeller disc centre plane coincide as shown in Figure 6.9.2.

= $L_N/8 \cos\alpha + d/2 \tan\alpha$, where Zone 2 centre plane and propeller disc centre plane does not coincide as shown in Figure 6.9.2.

Zone 3 = Zone of nozzle inner and outer skin covering the tail vicinity, from the aft end of Zones 2 to the aft end of Zone 4.

Zone 4 = Zone of nozzle outer skin from the leading edge to the fore end of Zone 3.

6.9.3 Steerable nozzles

6.9.3.1 The nozzle stock, couplings, pintles and bearings are to be designed analogously with the requirements given in Chapter 13, Sections 5 and 6 using the design values of lateral force, F_r, in [N] and turning moment Q_r, in [N-m], as given below:

$$F_r = 376\ A.V^2$$

$$Q_r = F_r.r$$

where,

A = Projected area of the nozzle, in [m^2].

V = Maximum service speed in [knots] with the ship on summer load waterline. When the speed is less than 10[knots], V is to be replaced by the expression

$$V_{min} = \frac{(V + 20)}{3}$$

r = The horizontal distance from the centre line of stock to the centre of pressure of the nozzle, but not to be taken less than 10% of the chord length of the nozzle.

6.9.3.2 Effective means are to be provided for supporting the weight of the nozzle. Where the support is provided by a carrier bearing attached to the nozzle head, the structure in way of the bearing is to be adequately strengthened. The shell plating in way of the nozzle head is to be increased in thickness by 50%.

6.9.3.3 All nozzle bearings are to be accessible for measuring wear without lifting or unshipping the nozzle.

6.9.3.4 Satisfactory arrangement is to be provided to prevent water from entering the steering gear compartment and lubricant from being washed away from the nozzle carrier. A seal or stuffing box is to be fitted above the deepest load water line for this purpose, however, two separate seals or stuffing boxes are to be provided when the nozzle carrier is below the deepest load water line.

6.9.4 Fixed nozzles

6.9.4.1 The nozzle is to be adequately supported preferably by closed box structures of the necessary enclosed area to withstand the lateral force F_r and Torque Q_r given in Cl.6.9.4 and its own weight.

The resultant stresses are not to exceed the following:

Bending stress, $\sigma_b = 75/k\ \text{in}\ [N/mm^2]$

Torsional shear stress, $\tau_t = 50/k\ \text{in}\ [N/mm^2]$

Shear stress, $\tau = 50/k\ \text{in}\ [N/mm^2]$

Equivalent stress,

$$\sigma_{e1} = \sqrt{\sigma^2 + 3\tau^2} = 100/k\ [N/mm^2]$$

$$\sigma_{e2} = \sqrt{\sigma + 3\tau^2} = 90/k\ [N/mm^2]$$

6.9.4.2 The nozzle support box structure is to be well integrated to the webs and ring webs in the nozzle and to the hull structure. Structural continuity is to be maintained between the webs in the nozzle, the top box structure and local girders/floors inside the hull.

6.10 Sea chest

6.10.1 Sea chest plating

In the case where a sea chest is provided in the shell plating for sea suction or discharge, the thickness of the sea chest is not to be less than that obtained from the following formula and to be suitably stiffened to provide sufficient rigidity as necessary. The thickness, however, is not to be less than the thickness of shell plating where the sea chest is installed.

$$t_{sc} = \sqrt{L} + 1[mm]$$

Stiffeners attached to the shell in way of sea chest openings are to be connected at their ends.

The sea water inlet openings in the shell are to be protected by gratings.

6.11 Thruster tunnel

6.11.1 Following requirements apply to transverse thrusters for maneuvering, which are integrated into the ship structure and which can produce transverse thrust at very slow ship speeds. Retractable rudder propellers are not transverse thrusters in the context of these requirements.

6.11.2 Transverse thruster tunnels are to be completely integrated into the ship structure and welded to it.

6.11.3 Where the outboard ends of the tunnel are provided with bars or grids, the bars or grids are to be effectively secured.

6.11.4 The thruster units are to be framed to the same standard as the surrounding shell plating and are to be adequately supported and stiffened.

6.11.5 Thrust element housing structures holding fixtures for propulsion units are to be effectively connected to the tunnel structure.

6.11.6 Welding of structural elements which are part of the watertight integrity of the ship hull is generally to be carried out as welds with full penetration welding. For structural elements where the stress level is low, partial penetration welding may be accepted.

6.11.7 If suction or draining ducts are arranged in the ship's bottom the bottom slamming loads according to Section 3 are to be considered.

6.11.8 Tunnel plate thickness

6.11.8.1 In general, the wall thickness of the thrust (bow and stern) unit is to be in accordance with the manufacturer's recommendation, if any, and is to be not less than 1.1 times more than the thickness of the surrounding shell plating.

6.11.8.2 In addition,t_{tun} is not to be taken less than:

$$t_{tun} = 0.008d_{tun} + 1.8$$

where:

d_{tun} = Inside diameter of the tunnel, in [mm], but not to be taken less than 970[mm].

6.11.8.3 In addition, for ships with L≤ 200 [m], t_{tun} is not to be taken less than:

$$t_{tun} = \sqrt{L.k} + 2.5$$

6.12 Machinery foundations

6.12.1 General

6.12.1.1 Main engines and thrust bearings are to be effectively secured to the hull structure by foundations of strength that can adequately resist the various gravitational, thrust, torque, dynamic, and vibratory forces which may be imposed on them. The recommendations given by the engine manufacturer are also to be considered.

6.12.1.2 In the case of higher power oil engines or turbine installations, the seating should generally be integral with the double bottom structure. The tank top plating in way of the engine foundation plate or the turbine gear case and the thrust bearing is to be substantially increased in thickness, Refer Type 1 of Figure 6.12.1.1.

6.12.1.3 For the main machinery supported on foundations of Type 2, as shown in Figure 6.12.1.2, the forces from the engine into the adjacent structure are to be distributed as uniformly as possible. Longitudinal members supporting the foundation are to be aligned with girders in the double bottom, and transverse stiffening is to be arranged in line with the floors, Refer Type 2 of Figure 6.12.1.2.

They are to be so arranged as to ensure sufficient accessibility for the welding of joints and for surveys and maintenance.

6.12.1.4 For ships with open floors in the machinery space, the foundations are generally to be arranged above the level of the top of the floors and securely bracketed.

6.12.1.5 Lightening holes in engine foundations are to be kept as small as practicable and the edges are to be suitably reinforced.

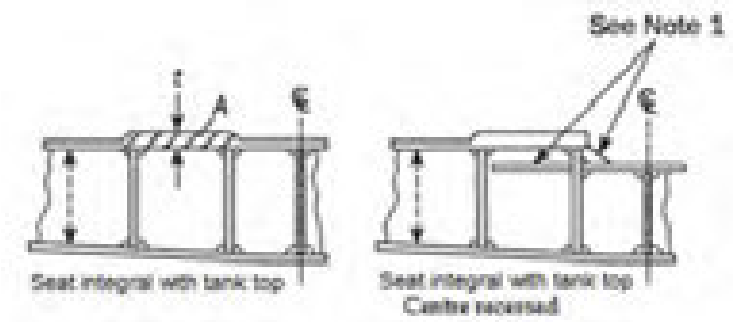

Figure 6.12.1.1: Machinery foundations Type 1-Seat integral with tank top

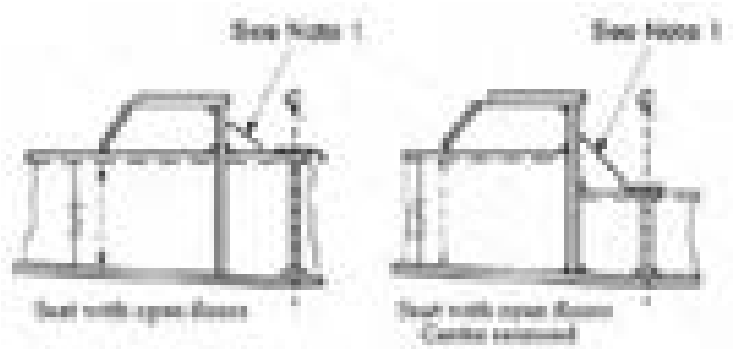

Figure 6.12.1.2: Machinery foundations Type 2-Built up seat

Note 1: Brackets are to be as large as possible. Brackets may be omitted to avoid interference with the girders of the engine foundation, in accordance with the recommendations of the engine manufacturer.

6.12.2 Foundations for internal combustion engines and thrust bearings

6.12.2.1 In determining the scantlings of foundations for internal combustion engines and thrust bearings, consideration is to be given to the general rigidity of the engine and its design characteristics with regard to the out-of-balance forces.

6.12.2.2 Thrust blocks are to be bolted to efficient foundations extending well beyond the thrust blocks and arranged to distribute the loads effectively into the adjacent structure. Extra intercostal girders, effectively attached, are to be fitted in way of the foundations, as may be required.

6.12.3 Auxiliary foundations

6.12.3.1 Auxiliary machinery is to be secured on foundations that are of suitable size and arrangement to distribute the loads from the machinery evenly into the supporting structure.

6.12.4 Boiler foundations

6.12.4.1 Boiler bearers are to be of substantial construction and efficiently supported by transverse and horizontal brackets. These should generally be arranged in line with plate floors and girders in a double bottom or with suitable deep beams or transverses and girders at boiler flats. Suitable allowance is to be made in the design of the supporting structure for the variation in loading due to thermal expansion effects.

6.12.5 Heavy equipment

6.12.5.1 Where heavy equipment is mounted directly on the inner bottom, the thickness of the floors and girders are to be suitably increased.

6.12.6 Recommended scantlings

6.12.6.1 Hold-down bolts are to be arranged as close as possible to floors and longitudinal girders. Plating thickness and the arrangements of hold-down bolts should also consider the manufacturer's recommendations.

6.12.6.2 The scantlings of seating of main engines and thrust bearings are to be adequate in relation to the weight and power of engines and the static and dynamic forces transmitted by the propulsive installation.

6.12.6.3 In general, at least two longitudinal members are to be fitted in way of seating of main engines.

6.12.6.4 One longitudinal member may be fitted only where the following three conditions are complied with:

$$L < 150[m]$$

$$P < 7100[kW]$$

$$P < 2.3\ R\ell$$

6.12.6.5 In general, the scantlings of engine girder face plate, web and floors in way of engine seating may be calculated as given below.

- The minimum top plate area, A in [cm^2], for one side of the seat:

$$A = 50 + 85\left(\frac{P}{Rl}\right) \text{for} \left(\frac{P}{Rl}\right) \geq 2.0$$

$$A = 90 + 65\left(\frac{P}{Rl}\right) \text{ for} \left(\frac{P}{Rl}\right) < 2.0$$

Where twin engines are fitted, a continuous top plate is to be arranged in general if the engines are coupled to one propeller shaft. For elastically mounted engines the sectional area may be adequately reduced.

- The minimum top plate thickness, t_p in [mm],

Where two girders are fitted on each side

$$t_p = \left(300 + 220\left(\frac{P}{Rl}\right)\right)^{0.5}$$

Where one girder is fitted on each side

$$t_p = \left(300 + 220\left(\frac{P}{Rl}\right)\right)^{0.5} + 6$$

where,

P = Maximum power of the engine, in [kW].

R = Rpm of the engine at maximum power.

l = Effective length of engine foundation plate, in [m], required for bolting the engine to the seating.

- The minimum girder web thickness, t_g in [mm],

The sum of the girder web thicknesses (t_{g2}), where two girders are fitted is to be not less than:

$$t_{g2} = \left(400 + 270\left(\frac{P}{Rl}\right)\right)^{0.5}$$

Where a single girder is fitted on each side, the thickness t_{g1}, is to be not less than:

$$t_{g1} = 0.55 t_{g2}$$

- The minimum thickness of floor plates $t_{f,}$ in [mm], below the bed plate

$$t_f = \left(65 + 52\left(\frac{P}{Rl}\right)\right)^{0.5}$$

6.12.6.6 For high-speed engines of less than 1500[kW] and medium speed engines of less than 750[kW] the following may be used instead of the values specified in Cl.6.12.6.5 above.

Top plate area, $A = 20 + 120\frac{P}{R}$ in $[cm^2]$

Top plate thickness, $t_p = 0.1A + 14$ in $[mm]$

Girder web thickness, $t_{g1} = 0.043A + 7$ in $[mm]$

Floor web thickness, $t_f = 0.02A + 6$ in $[mm]$

6.13 Bilge keel

6.13.1 Material

6.13.1.1 The bilge keel and ground bar material are to be of the same yield stress as the material to which they are attached.

6.13.1.2 In addition, when the bilge keel extends over a length more than 0.15L, the material of the bilge keel and ground bar is to be of the same grade as the bilge strake.

6.13.2 Design

6.13.2.1 The design of single web bilge keels is to be such that failure to the web occurs before failure of the ground bar. This may be achieved by ensuring the web thickness of the bilge keel does not exceed that of the ground bar.

Bilge keels are often damaged or ripped off in the ice. The connection of bilge keels to the hull is to be so designed that the risk of damage to the hull, in case a bilge keel is ripped off, is minimized. To limit damage when a bilge keel is partly ripped off, it is recommended that bilge keels are cut up into several shorter independent lengths.

6.13.2.2 Bilge keels of a different design, from that shown in Figure 6.13.2.1, are specially considered. Alternative arrangement as shown in Figure 6.13.2.2 may also be accepted.

6.13.3 Ground bars

6.13.3.1 Bilge keels are not to be welded directly to the shell plating. A ground bar, or doubler, is to be fitted on the shell plating as shown in Figure 6.13.2.1 and Figure 6.13.3. In general, both the bilge keel and the ground bar are to be continuous.

6.13.3.2 It is recommended that bilge keels should not be fitted in the forward 0.3L region on ships intended to navigate in severe ice conditions.

6.13.3.3 The gross thickness of the ground bar is not to be less than the gross thickness of the bilge strake or 14[mm], whichever is the lesser.

6.13.4 End details

6.13.4.1 The ground bar and bilge keel ends are to be tapered or rounded and are to terminate on an internal stiffening member.

6.13.4.2 Tapering is to be gradual with a minimum ratio of 3:1, Refer items (a), (b), (d) and (e) in Figure 6.13.3 and Figure 6.13.4. Rounded ends are to be as shown in item (c) of Figure 6.13.3. Cut-outs on the bilge keel web, within zone 'A' (Refer item (b) of Figure 6.13.3 and item (e) of Figure 6.13.4) are not permitted.

6.13.4.3 The end of the bilge keel web is to be not less than 50[mm] and not greater than 100[mm] from the end of the ground bar, Refer item (a) of Figure 6.13.3 and item (d) of Figure 6.13.4.

6.13.4.4 Ends of the bilge keel and ground bar are to be supported by either transverse or longitudinal members inside the hull, as indicated below:

- Transverse support member is to be fitted at mid length between the end of the bilge keel web and the end of the ground bar, Refer items (a), (b) and (c) of Figure 6.13.3.

- Longitudinal stiffener is to be fitted in line with the bilge keel web, it is to extend to at least the nearest transverse member forward and aft of zone 'A' (Refer item (b) of Figure 6.13.3 and item (e) of Figure 6.13.3). In this case, the requirement of Cl.6.13.4.3 does not apply.

6.13.4.5 Alternative end arrangements may be accepted, provided that they are considered equivalent.

6.13.5 Welding

6.13.5.1 Welding of bilge keel and intermediate plate connections is to be in accordance with Chapter 16, Table 3.2.1.

6.13.5.2 The connections of the bilge keel to the ground bar and the bilge ground bar to the side shell, are to be by double continuous fillet welds

6.13.5.3 Butt welds in shell plating, ground bar and bilge keels are to be staggered. Butt welds in the bilge keel and doubler are to be full penetration.

6.13.5.4 Butt welds, in the bilge keel and ground bar, are to be well clear of each other and of butts in the shell plating. In general, shell butts are to be flush in way of the ground bar and ground bar butts are to be flush in way of the bilge keel.

6.13.5.5 Direct connection between ground bar butt welds and shell plating is not permitted. This may be obtained by the use of removable backing.

6.13.5.6 In general, scallops and cut-outs are not to be used.

6.13.5.7 For ships over 65[m] in length, holes are to be drilled in the bilge keel butt welds. The diameter of the hole is to be greater than the width W of the butt weld and is to be a minimum of 25[mm] (Refer Figure 6.13.2.1.

6.13.5.8 Where the butt weld has been subject to non-destructive examination, the crack arresting hole may be omitted.

6.13.5.9 Within zone 'B', welds at the end of the ground bar and bilge plating, and at the end of the bilge keel web and ground bar, are to have weld factors of 0.44 and 0.34 respectively and they are to be grounded and blended smoothly with the base materials. (Refer Figure 6.13.3 and Figure 6.13.4).

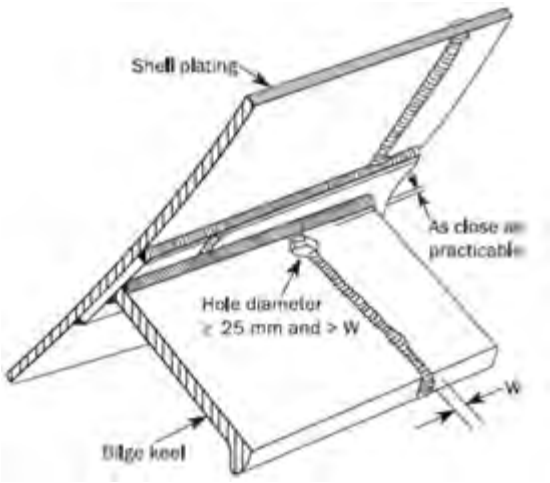

Figure 6.13.2.1: Bilge keel arrangement

Section 7

Tanks Subject to Sloshing

Symbols

For symbols not defined in this section, Refer to Chapter 1, Section 2.

α_p = Correction factor for the panel aspect ratio to be taken as:

$$\alpha_p = 1.2 - \frac{b}{2.1a}$$

but not to be taken as greater than 1.0

a = Length of plate panel, in [mm], as defined in Chapter 3, Section 7.

b = Breadth of plate panel, in [mm], as defined in Chapter 3, Section 7.

ℓ_{slo} = Effective sloshing length, in [m], as defined in Cl.7.4.2.

P_{slo-l} = Sloshing pressure in [kN/m^2] due to longitudinal liquid motion as defined in Cl.7.4.2.

P_{slo-t} = Sloshing pressure in [kN/m^2] due to transverse liquid motion as defined in Cl.7.4.3.

b_{slo} = Effective sloshing breadth, in [m], as defined in Cl.7.4.3.

ρ_L = Density of liquid in the tank and ballast hold, in [t/m^3], but not less than:

For strength assessment:

= 1.025 for all liquids including oil and product cargoes. If a tank filled at 98% is intended to carry heavier liquid cargoes than 1.025 (i.e.$\rho_{max-LM} > 1.025$), then $\rho_L = \rho_{max-LM}$

For fatigue assessment*:*

= 0.9 for oil and oil product cargoes

= 1.025 for ballast tanks

= ρ_{max-LM} for the cargo tank intended to carry liquid other than oil products for cargo tanks intended to carry oil products with a density exceeding 1.025 [t/m^3].

ρ_{max-LM} = Maximum liquid cargo density in [t/m^3], associated with a full tank at 98%, from any loading condition in the ship's loading manual or the value specified by the designer

ρ_{part} = Maximum permissible high liquid cargo density, in [t/m^3], associated with a partially filled cargo tank but not taken less than ρ_L considered for strength assessment

ρ_{slo} = Liquid density, in [t/m^3], to be used for sloshing assessment, taken as:

= ρ_{part} For heavy liquid cargo density associated with partial filling of cargo tank

= ρ_L For all other cases

h_{max} = Maximum permissible filling level, in [m], taken as:

For ballast tanks: Maximum tank height,

For cargo tanks with cargo density equal to ρ_L: Maximum tank height

For cargo tanks with heavy liquid cargo density equal to ρ_{part} associated with a partially filled cargo tank: h_{part} as defined in Cl.7.2.1.

f_{CD} = Factor for joint probability of occurrence of liquid cargo density and maximum sea state in 25 years design life, to be taken as:

For strength assessment with FE analysis of cargo tanks filled with oil or oil products cargo

$$f_{CD} = 0.88 \text{ for } \rho_L \leq 1.025[t/m3]$$

$$f_{CD} = 1.0 \text{ for } \rho_L > 1.025[t/m3]$$

For other cases: $f_{CD} = 1.0$

7.1 Application

7.1.1 The requirements of this section cover the strengthening requirements for localized sloshing loads that occur in tanks carrying liquid.

7.1.2 The requirements of this section apply to all liquid cargo, ballast tanks, and other tanks with volume exceeding 100[m^3], but does not

apply to the water ballast cargo hold of bulk carriers.

7.1.3 Where the effective sloshing length, ℓ_{slo} is less than 0.03L, calculations involving P_{slo-l} are not required and where the effective sloshing breadth b_{slo} is less than 0.32B, calculations involving P_{slo-t} are not required.

7.1.4 The minimum sloshing pressure, $P_{slo-min}$ for small tanks with a volume less than 100[m^3] and for tanks of cellular construction, i.e., double hull construction with internal structures restricting the fluid motion, is to be taken equal to 12 [kN/m^2]. This pressure is only applicable to plates, stiffeners and tripping brackets at all internal surfaces such as web frames, girders and stringers. No other sloshing requirements are applicable to such tanks.

7.1.5 The minimum sloshing pressure, $P_{slo-min}$ for tanks other than those defined in Cl.7.1.4, is to be taken equal to 20[kN/m^2]. This pressure is only applicable to plates, stiffeners and tripping brackets at all internal surfaces such as web frames, girders, stringers and wash bulkheads.

7.1.6 For larger tanks with an effective sloshing breadth, b_{slo} as defined in Cl.7.4.3, greater than 0.56B or an effective sloshing length, ℓ_{slo}, as defined in Cl.7.4.2, greater than 0.13L, sloshing is to be specially considered.

7.1.7 Dry bulk cargo holds intended for the carriage of ballast water are assumed either full or empty in seagoing condition and are not required to be assessed for sloshing.

7.2 General requirements

7.2.1 Filling heights of tanks

The scantlings of all tanks are to comply with the sloshing requirements given in this section for the following cases:

- Unrestricted filling height for all tanks, except for cargo tanks,

- Unrestricted filling height for cargo tanks with cargo density equal to ρ_L.

- All filling levels up to h_{part} for cargo tanks with cargo density equal to ρ_{part} taken as:

$$h_{part} = \frac{h_{tk} . \rho_L . f_{CD}}{\rho_{part}}$$

where:

h_{part} = Maximum permissible filling height, in [m], associated with a partial filling of the considered cargo tank with a high liquid density equal to ρ_{part}.

h_{tk} = Maximum tank height, in [m].

7.2.2 Structural details

Local scantling increases due to sloshing loads are to be made with due consideration given to details and avoidance of hard spots, notches and other harmful stress concentrations.

7.3 Application of sloshing pressure

7.3.1 General

The structural members of the following tanks are to be assessed for the design sloshing pressures P_{slo-l} and P_{slo-t} in accordance with Cl.7.3.3 and Cl.7.3.4.

- Cargo and slop tanks.

- Fore peak and aft peak ballast tanks.

- Other tanks which allow free movement of liquid, e.g. ballast tanks, fuel oil bunkering tanks and freshwater tanks, etc.

7.3.2 Structural members to be assessed

The following structural members are to be assessed:

- Plates and stiffeners forming boundaries of tanks.

- Plates and stiffeners on wash bulkheads.

- Web plates and web stiffeners of primary supporting members located in tanks.

- Tripping brackets supporting primary supporting members in tanks.

7.3.3 Application of design sloshing pressure due to longitudinal liquid motion

7.3.3.1 The design sloshing pressure due to longitudinal liquid motion, P_{slo-l} as defined in Cl.7.4.2 is to be applied to the following members as shown in Figure 7.3.3.

- Transverse tight bulkheads.

- Transverse wash bulkheads.

- Stringers on transverse tight and wash bulkheads.

- Plating and stiffeners on the longitudinal bulkheads, deck and inner hull within a distance from the transverse bulkhead taken as:

- $0.25\ell_{slo}$,

- The distance between the transverse bulkhead and the first web frame if located inside the tank at the considered level, whichever is less.

7.3.3.2 In addition, the first web frame next to a transverse tight or wash bulkhead if the web frame is located within $0.25\ell_{slo}$ from the bulkhead, as shown in Figure 7.3.3, is to be assessed for the web frame reflected sloshing pressure, P_{slo-wf} as defined in Cl.7.4.2.

7.3.3.3 The minimum sloshing pressure, $P_{slo-min}$ as defined in 7.1 is to be applied to all other members.

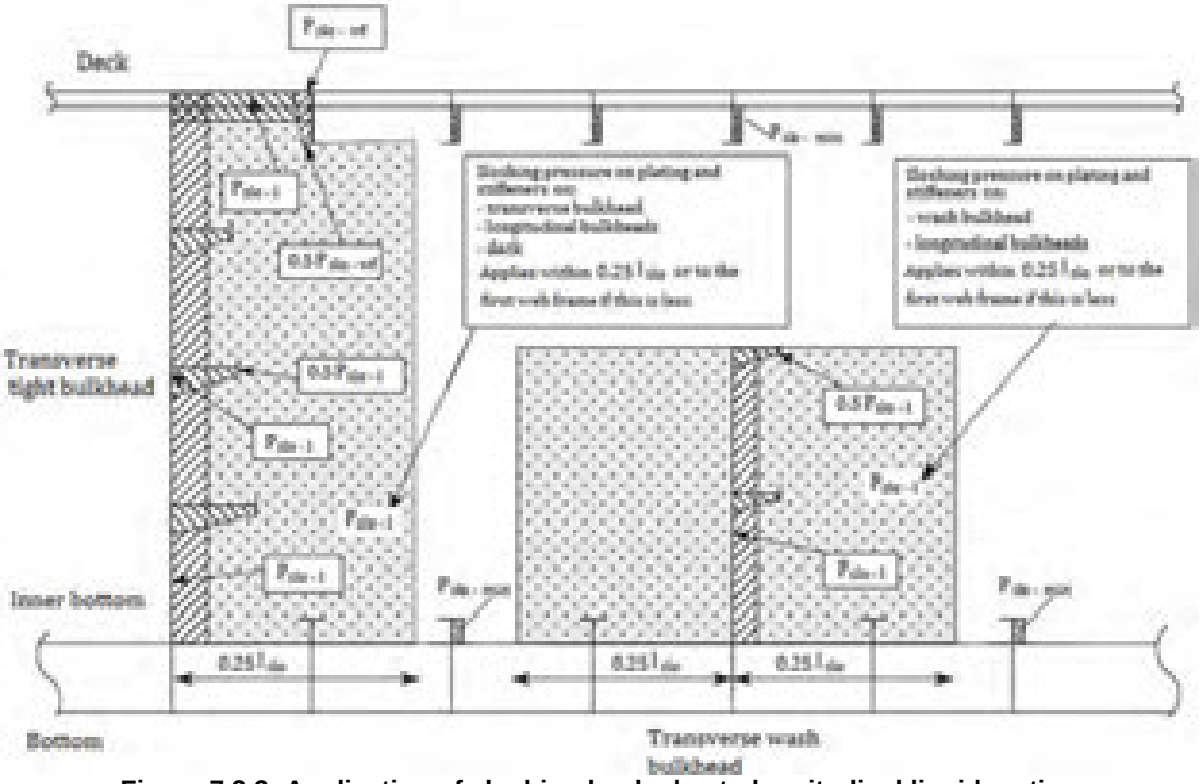

Figure 7.3.3: Application of sloshing loads due to longitudinal liquid motion

7.3.4 Application of design sloshing pressure due to transverse liquid motion

7.3.4.1 The design sloshing pressure due to transverse liquid motion, P_{slo-t} as defined in Cl.8.4.3, is to be applied to the following members as shown in Figure 7.3.4.

- Longitudinal tight bulkhead.

- Longitudinal wash bulkhead and longitudinal girders.

- Horizontal stringers on longitudinal tight and wash bulkheads, and vertical webs on transverse tight and wash bulkheads.

- Plating and stiffeners on the transverse tight bulkheads including stringers and deck within a distance from the longitudinal bulkhead taken as:

- $0.25b_{slo}$,

- The distance between the longitudinal bulkhead and the first girder if located inside the tank at the considered level, whichever is less.

7.3.4.2 In addition, the first girder next to a longitudinal tight or wash bulkhead if the girder is located within $0.25b_{slo}$ from the longitudinal bulkhead, as shown in Figure 7.3.4, is to be assessed for the reflected sloshing pressure, $P_{slo-grd}$ as defined in Cl.7.4.3.

7.3.4.3 The minimum sloshing pressure, $P_{slo-min}$ as defined in 7.1 is to be applied to all other members.

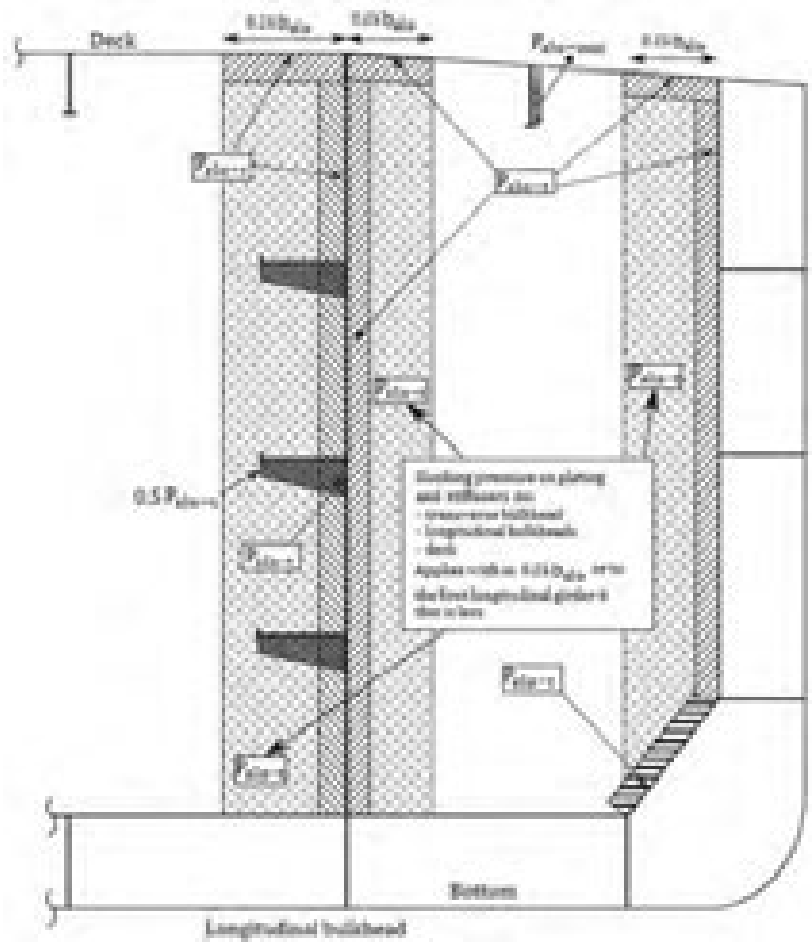

Figure 7.3.4: Application of sloshing loads due to transverse liquid motion

7.3.5 Combination of transverse and longitudinal fluid motion

The sloshing pressures due to transverse and longitudinal fluid motion are assumed to act independently. Structural members are therefore to be evaluated based on the greatest sloshing pressure due to longitudinal and transverse fluid motion.

7.4 Sloshing loads

7.4.1 Sloshing pressure on tank boundaries and internal divisions

The sloshing pressure due to liquid motions in a tank P_{slo} acting on any load point of a tank boundary or internal divisions, in [kN/m^2], for the sloshing design load scenario, given in Cl.7.6.1, is to be taken as follows, but not less than $P_{slo-min}$ as defined in 7.1

$P_{slo} = P_{slo-l}$ for transverse bulkheads, as defined in Cl.7.4.2.

$P_{slo} = P_{slo-wf}$ for web frames and transverse stringers, as defined in Cl.7.4.2.

$P_{slo} = P_{slo-t}$ for longitudinal bulkheads, as defined in Cl.7.4.3.

$P_{slo} = P_{slo-grd}$ for longitudinal girders and stringers, see Cl.7.4.3.

7.4.2 Sloshing pressure due to longitudinal liquid motion

7.4.2.1 Application

The sloshing pressure due to longitudinal liquid motion P_{slo-l} is to be taken as a constant value over the full tank depth and is to be taken as the greater of the sloshing pressures calculated for filling levels from $0.05h_{max}$ to $0.95h_{max}$, and/or $0.05h_{max}$ to h_{part}, typically in 0.05 h_{max} increments.

7.4.2.2 Effective sloshing length

The effective sloshing length, ℓ_{slo} in [m], is to be taken as defined in Table 7.4.2.

Table 7.4.2: Effective sloshing length [ℓ_{slo}]

Type of transverse bulkhead	ℓ_{slo}
Transverse tight bulkheads	$\ell_{slo} = \frac{(1 + n_{WT}\alpha_{WT})(1 + f_{wf}\alpha_{wf})\ell_{tk-h}}{(1 + n_{WT})(1 + f_{wf})}$
Transverse wash bulkheads	$\ell_{slo} = \frac{[1 + (n_{WT} - 1)\alpha_{WT}](1 + f_{wf}\alpha_{wf})\ell_{tk-h}}{(1 + n_{WT})(1 + f_{wf})}$

where:

n_{WT} = Number of transverse wash bulkheads in the tank.

α_{WT} = Transverse wash bulkhead coefficient, to be taken as (Refer Figure 7.4.2.1):

$$\alpha_{WT} = \frac{A_{OWT}}{A_{tk-t-h}}$$

α_{wf} = Transverse web frame coefficient, to be taken as (see Figure 7.4.2.2):

$$\alpha_{wf} = \frac{A_{O-wf-h}}{A_{tk-t-h}}$$

For tanks with changing shape along the length and/or with web frames of different shape the transverse web frame coefficient,α_{wf}, may be taken as the weighted average of all web frame locations in the tank given as:

$$\alpha_{wf} = \frac{\sum_{i=1}^{n_{wf}} \frac{A_{O-wf-h}}{A_{tk-t-h}}}{n_{wf}}$$

A_{OWT} = Total area of openings, in [m^2], in the transverse section in way of the wash bulkhead below the considered filling height.

A_{tk-t-h} = Total transverse cross sectional area, in [m^2], of the tank below the considered filling height.

A_{O-wf-h} = Total area of openings, in [m^2], in the transverse section in way of the web frame below the considered filling height.

f_{wf} = Factor to account for the number of transverse web frames and transverse wash bulkheads in the tank, to be taken as:

$$f_{wf} = \frac{n_{wf}}{1 + n_{WT}}$$

n_{wf} = Number of transverse web frames, excluding wash bulkheads, in the tank

ℓ_{tk-h} = Length of the tank, in [m], at considered filling height.

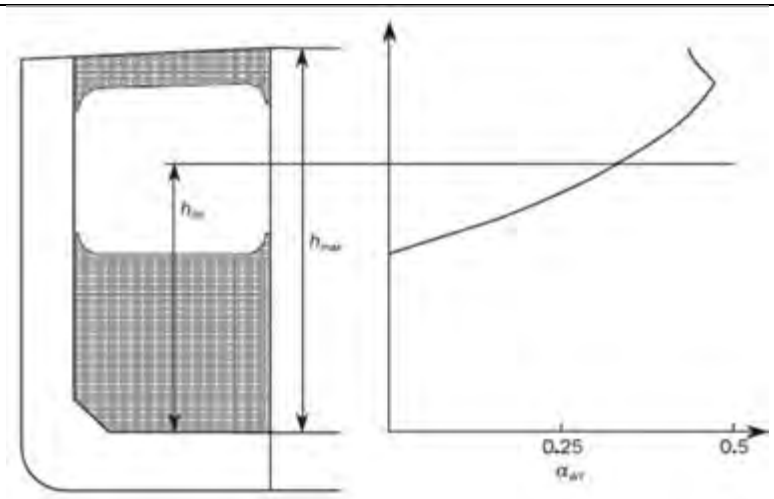

Figure 7.4.2.1: Transverse wash bulkhead coefficient

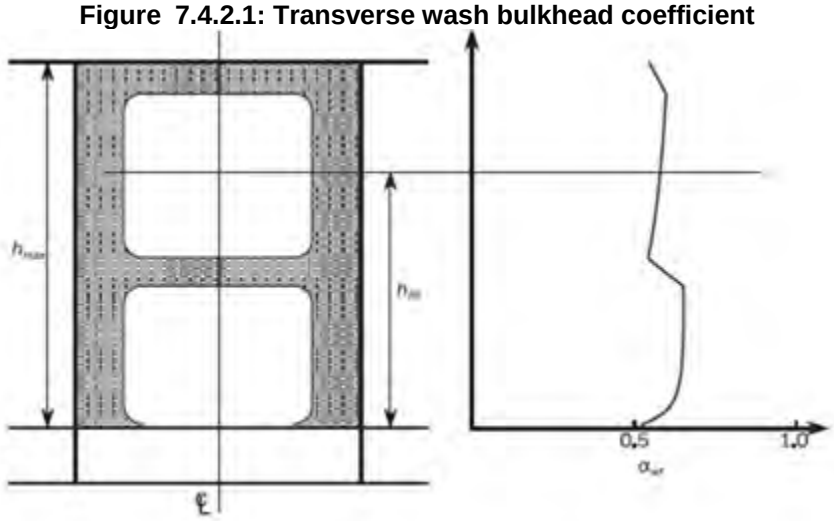

Figure 7.4.2.2: Transverse web frame coefficient

7.4.2.3 Sloshing pressure in way of transverse bulkheads

The sloshing pressure in way of transverse bulkheads including wash bulkheads due to longitudinal liquid motion, P_{slo-l} in [kN/m^2], for a particular filling level, is to be taken as:

$$P_{slo-l} = \rho_{slo} . g . \ell_{slo} . f_{slo} \left[0.4 - \left(0.39 - \frac{1.7 \ell_{slo}}{L} \right) \frac{L}{350} \right]$$

where:

f_{slo} = Coefficient taken as:

$$f_{slo} = 1 - 2 \left(0.7 - \frac{h_{fill}}{h_{max}} \right)^2$$

h_{fill} = Filling height, in [m], measured from the tank bottom, Refer Figure 7.4.2.1.

7.4.2.4 Sloshing pressure on internal web frames or transverse stringers adjacent to a transverse bulkhead

For tanks with internal web frames, the sloshing pressure acting on a web frame or transverse stringer adjacent to transverse bulkheads or transverse wash bulkheads due to longitudinal liquid motion, P_{slo-wf} , in [kN/m^2], provided it is located within $0.25\ell_{slo}$ from the bulkhead, is to be taken as:

$$P_{slo-wf} = P_{slo-l} \left(1 - \frac{S_{wf}}{\ell_{slo}} \right)^2$$

where:

S_{wf} = Distance from transverse bulkhead to web frame under consideration, in [m].

ℓ_{slo} = Effective sloshing length, in [m], as defined in Cl.7.4.2.2.

P_{slo-l} = Sloshing pressure due to longitudinal liquid motion acting on the transverse bulkhead, as defined in Cl.7.4.2.3.

The distribution of pressure across web frames and transverse stringers is given in Figure 7.4.2.3.

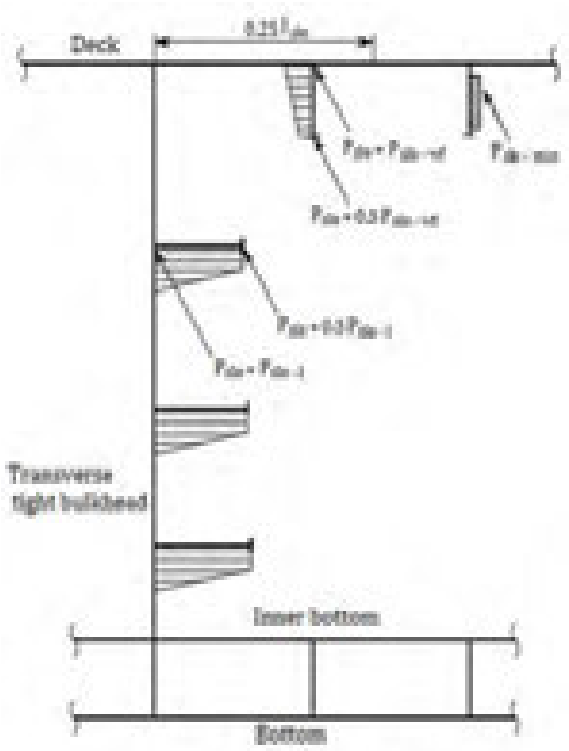

Figure 7.4.2.3: Sloshing pressure distribution on transverse stringers and web frames

7.4.3 Sloshing pressure due to transverse liquid motion

7.4.3.1 Application

The sloshing pressure due to transverse liquid motion, P_{slo-t}, is to be taken as a constant value over the full tank depth and is to be taken as the greater of the sloshing pressures calculated for filling levels from $0.05h_{max}$ to $0.95h_{max}$, and/or $0.05h_{max}$ to h_{part}, typically in $0.05h_{max}$ increments.

7.4.3.2 Effective sloshing breadth

The effective sloshing breadth, b_{slo} in [m], is to be taken as in Table 7.4.3, but not less than 0.3B.

Table 7.4.3: Effective sloshing breadth $[b_{slo}]$

Type of longitudinal bulkhead	b_{slo}
Longitudinal tight bulkheads	$b_{slo} = \frac{(1 + n_{WL}\alpha_{WL})(1 + f_{grd}\alpha_{grd})b_{tk-h}}{(1 + n_{WL})(1 + f_{grd})}$
Longitudinal wash bulkheads	$b_{slo} = \frac{[1 + (n_{WL} - 1)\alpha_{WL}](1 + f_{grd}\alpha_{grd})b_{tk-h}}{(1 + n_{WL})(1 + f_{grd})}$

where:

n_{WL} = Number of longitudinal wash bulkheads in the tank

α_{WL} = Longitudinal wash bulkhead coefficient

$$\alpha_{WL} = \frac{A_{OWL}}{A_{tk-L-h}}$$

α_{grd} = Girder coefficient, to be taken as

$$\alpha_{grd} = \frac{A_{O-grd-h}}{A_{tk-L-h}}$$

A_{OWL} = Total area of openings, in [m^2], in the longitudinal section in way of the wash bulkhead below the considered filling height.

A_{tk-L-h} = Total longitudinal cross-sectional area, in [m^2], of the tank below the considered filling height.

$A_{O-grd-h}$ = Total area of openings, in [m^2], in the longitudinal section in way of the web frame below the considered filling height.

f_{grd} = Factor to account for the number of longitudinal girders and longitudinal wash bulkheads in the tank, to be taken as:

$$f_{grd} = \frac{n_{grd}}{1 + n_{WL}}$$

n_{grd} = Number of longitudinal girders, excluding longitudinal wash bulkheads, in the tank.

b_{tk-h} = Breadth of the tank, in [m], at considered filling height.

7.4.3.3 Sloshing pressure in way of longitudinal bulkheads

The sloshing pressure in way of longitudinal bulkheads including wash bulkheads due to transverse liquid motion, P_{slo-t} in [kN/m^2], for a particular filling level, is to be taken as:

$$P_{slo-t} = 7.\rho_{slo}.g.f_{slo}\left(\frac{b_{slo}}{B} - 0.3\right)GM^{0.75}$$

where:

b_{slo} = Effective sloshing breadth defined in Cl.7.4.3.2.

GM = Metacentric height, in [m], in the considered loading condition.

For the calculation of sloshing pressure in ballast tanks the ‘normal ballast condition’ is to be used. For the calculations of sloshing pressure in cargo tanks, the ‘partial load condition’ is to be used.

f_{slo} = Coefficient as defined in Cl.7.4.3.3.

7.4.3.4 Sloshing pressure on internal girders or longitudinal stringers adjacent to longitudinal bulkheads

For tanks with internal girders or stringers, the sloshing pressure acting on the girder/web frame adjacent to longitudinal bulkheads and longitudinal wash bulkheads, $P_{slo-grd}$ in [kN/m^2], provided it is located within $0.25b_{slo}$ from the bulkhead, is to be taken as:

$$P_{slo-grd} = P_{slo-t}\left(1 - \frac{S_{grd}}{b_{slo}}\right)^2$$

where:

S_{grd} = Distance from longitudinal bulkhead to girder under consideration, in [m].

b_{slo} = Effective sloshing breadth, in [m], as defined in Cl.7.4.3.2.

P_{slo-t} = Sloshing pressure due to transverse liquid motion acting on the longitudinal bulkhead, as defined in Cl.7.4.3.3.

The distribution of pressure across stringers is given in Figure 7.4.3. The distribution of pressure across longitudinal girders is similar to the deck web frame shown in Figure 7.4.2.3.

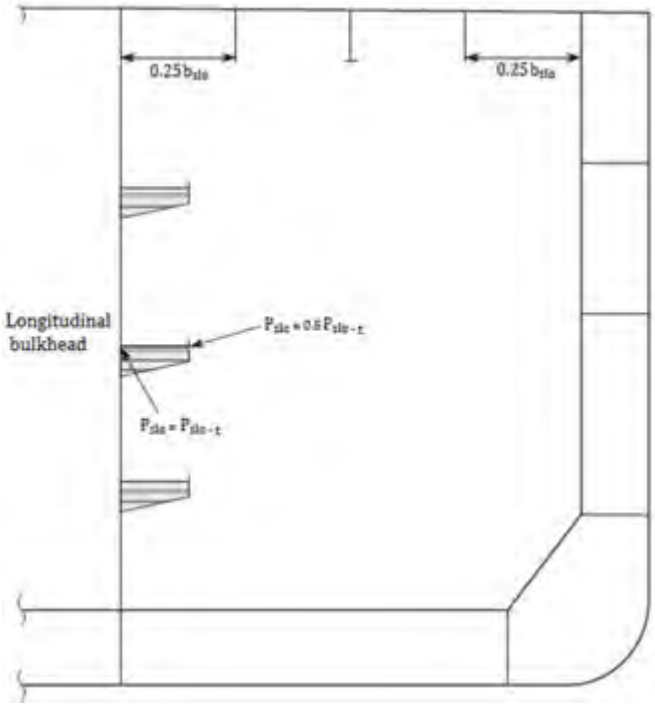

Figure 7.4.3: Sloshing pressure distribution on longitudinal stringers and girders

7.5 Scantling requirements

7.5.1 Plating

The net thickness of the plating, 't' in [mm], subjected to sloshing pressures is not to be less than:

$$t = 0.0158.\alpha_p.b\sqrt{\frac{P_{slo}}{c_a.R_{eH}}}$$

where:

$\mathbf{c_a}$ = Permissible bending stress coefficient for acceptance criteria AC-I as given in Table 7.5.1 but not to be taken greater than c_{a-max}.

$$c_a = \beta_a - \alpha_a \frac{|\sigma_{hg}|}{R_{eH}}$$

Table 7.5.1: Definition of β_a, α_a and $C_{a\text{-}max}$

Acceptance criteria	Structural member		β_a	α_a	$\mathbf{c_{a-max}}$
AC-I	Longitudinal member	Longitudinal stiffened plating	0.9	0.5	0.8
		Transverse stiffened plating	0.9	1.0	0.8
	Other members		0.8	0	0.8

σ_{hg} = Hull girder bending stress, in [N/mm^2], corresponding to the greatest of the sagging and hogging bending moment in absolute value.

P_{slo} = The greater of P_{slo-l}, P_{slo-t} as specified in Cl.7.4.2 and Cl.7.4.3.

For internal members like wash bulkheads the sloshing pressure is not to be taken less than $P_{slo-min}$ as given in 7.1.

7.5.2 Stiffeners

The net section modulus, Z in [cm^3], of stiffeners subjected to sloshing pressures is not to be less than:

$$Z = \frac{P_{slo}.s.\ell_{bdg}^2}{f_{bdg}.C_s.R_{eH}}$$

where:

f_{bdg} = Bending moment factor taken as:

For all continuous horizontal and vertical stiffeners, f_{bdg} is to be taken from Table 7.5.2.1.

For all non-continuous stiffeners, f_{bdg} is taken as:

= 8 For simply supported ends

= 10 For fixed at both ends

C_s = Permissible bending stress coefficient to be taken as:

For members subject to hull girder stress: coefficient for acceptance criteria AC-I as defined in Table 7.5.2.1.

For other cases, Cs = Cs-max.

β_s = Coefficient as defined in Table 7.5.2.2.

α_s = Coefficient as defined in Table 7.5.2.2.

$C_{s-max.}$= Maximum permissible bending stress coefficient as defined in Table 7.5.2.2.

Table 7.5.2.1: Permissible bending stress coefficient C_s

Sign of hull girder bending stress, σ_{hg} (1)	Lateral pressure acting on (2)	Stiffener boundary condition (3)	f_{bdg}	Coefficient C_s
Tension (positive)	Stiffener side	F - F	12	$c_s = \beta_s - \alpha_s \frac{\lvert\sigma_{hg}\rvert}{R_{eH}}$ but not to be taken greater than $c_{s-max.}$
		F - S	8	$c_s = \beta_s - \alpha_s \frac{\lvert\sigma_{hg}\rvert}{R_{eH}}$ but not to be taken greater than $c_{s-max.}$
		S - S	8	$c_s = c_{s-max}$
	Plate side	F - F	24	$c_s = \beta_s - \alpha_s \frac{\lvert\sigma_{hg}\rvert}{R_{eH}}$ but not to be taken greater than c_{s-max}
		F - S	14	$c_s = \beta_s - \alpha_s \frac{\lvert\sigma_{hg}\rvert}{R_{eH}}$ but not to be taken greater than c_{s-max}
		S - S	8	$c_s = \beta_s - \alpha_s \frac{\lvert\sigma_{hg}\rvert}{R_{eH}}$ but not to be taken greater than $c_{s-max.}$
Compression (negative)	Stiffener side	F - F	24	$c_s = \beta_s - \alpha_s \frac{\lvert\sigma_{hg}\rvert}{R_{eH}}$ but not to be taken greater than $c_{s-max.}$
		F - S	14	$c_s = \beta_s - \alpha_s \frac{\lvert\sigma_{hg}\rvert}{R_{eH}}$ but not to be taken greater than $c_{s-max.}$
		S - S	8	$c_s = \beta_s - \alpha_s \frac{\lvert\sigma_{hg}\rvert}{R_{eH}}$ but not to be taken greater than $c_{s-max.}$
	Plate side	F - F	12	$c_s = \beta_s - \alpha_s \frac{\lvert\sigma_{hg}\rvert}{R_{eH}}$ but not to be taken greater than $c_{s-max.}$

		F - S	8	$c_s = \beta_s - \alpha_s \frac{\lvert\sigma_{hg}\rvert}{R_{eH}}$ but not to be taken greater than c_{s-max}.
		S - S	8	$c_s = c_{s-max}$
(1) σ_{hg} is to be considered for hogging and sagging situations. (2) For primary supporting members located inside the considered tank and for wash bulkheads, the sloshing pressure is to be applied both on the stiffener and plate sides. (3) F - F stands for both ends of the stiffener fixed against rotation F - S stands for one end of the stiffener fixed and the other not fixed against rotation S - S stands for both ends of the stiffener not fixed against rotation				

Table 7.5.2.2: Definition of β_s, α_a and $C_{a\text{-}max}$

Acceptance criteria	Structural member		β_s	α_s	$C_{s\text{-}max}$
AC-I	Longitudinal member	Longitudinal stiffeners	0.9	0.5	0.8
		Transverse stiffeners	0.9	1.0	0.8
	Other members		0.8	0	0.8

7.5.3 Primary supporting members

7.5.3.1 Web plating

The net web plating thickness of primary supporting members, 't' in [mm], is not to be less than:

$$t = 0.0158.\alpha_p.b\sqrt{\frac{P_{slo}}{c_a.R_{eH}}}$$

where:

c_a = Permissible plate bending stress coefficient, as given in Cl.7.5.1.

P_{slo} = The greater of P_{slo-l}, P_{slo-t}, P_{slo-wf}, $P_{slo-grd}$ as specified in 8.4 and $P_{slo-min}$ as given in 7.1.

The pressure is to be calculated at the load application point, defined in Chapter 3, Section 7, 7.7, considering the distribution over the height of the member, as shown in Figure 7.3.3 and Figure 7.3.4.

7.5.3.2 Stiffeners on web plating

The net section modulus, Z in [cm^3], of each individual stiffener on the web plating of primary supporting members subjected to sloshing pressures is not to be less than:

$$Z = \frac{P_{slo}.s.\ell_{bdg}^2}{f_{bdg}.C_s.R_{eH}}$$

where:

P_{slo} = The greater of P_{slo-l}, P_{slo-t}, P_{slo-wf}, $P_{slo-grd}$ as specified in 7.4 and $P_{slo-min}$ as given in 7.1.

The pressure is to be calculated at the load application point, defined in Chapter 3, Section 7, 7.6, considering the distribution over the height of the member, as shown in Figure 7.3.3 and Figure 7.3.4.

c_s = Permissible plate bending stress coefficient, as given in Cl.7.5.2.

f_{bdg} = Bending moment factor as given in Cl.7.5.2.

7.5.4 Tripping brackets supporting primary supporting members

The net section modulus, Z in [cm^3], in way of the base within the effective length, d, of tripping brackets and net shear area, A_{shr} in [cm^2], after deduction of cut-outs and slots, of tripping brackets supporting primary supporting members is not to be less than:

$$Z = \frac{1000\, P_{slo}.\, s_{trip}.\, h^2}{2.\, C_s.\, R_{eH}}$$

$$A_{shr} = \frac{\sqrt{3}.\, 10.\, P_{slo}.\, s_{trip}.\, h}{C_t.\, R_{eH}}$$

where:

P_{slo} = The greater of P_{slo-l} , P_{slo-t} , P_{slo-wf} , $P_{slo-grd}$ as specified in 7.4. The average pressure may be calculated at the midpoint of the tripping bracket taking into account the distribution as shown in Figure 7.3.3 and Figure 7.3.4. The sloshing pressure is not being taken less than $P_{slo-min}$ as given in 7.1.

$\mathbf{s_{trip}}$ = Mean spacing, between tripping brackets or other primary supporting members or bulkheads, in [m].

h = Height of tripping bracket, in [m]. Refer Figure 7.5.4

C_s = Permissible bending stress coefficient for tripping brackets to be taken as 0.75.

C_t = Permissible shear stress coefficient for tripping brackets to be taken as 0.75.

The effective breadth of the attached plate to be used for calculating the section modulus of the tripping bracket is to be taken as h/3.

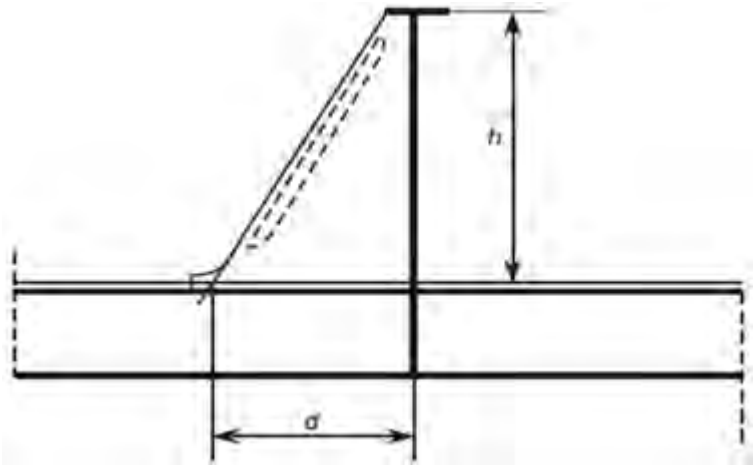

Figure 7.5.4: Effective length and height of tripping bracket

Section 1

General

1.1 Application

1.1.1 The requirement of this Chapter are applicable to all ship types in general. Additional requirements pertaining to special ship types are given in Part 5 of the Rules.

1.1.2 The requirements of this Chapter apply to the arrangement of openings and closing appliances in hull, deckhouse and superstructure. In general, the closing appliances are to have the same strength or scantling corresponding to the part of the hull in which they are fitted.

1.1.3 The requirements conform, where applicable, to those of the International Convention on Load Lines, 1966 (ICLL, 1966) as amended by the 1988 protocol. Reference should also be made to the additional requirements of the National Authority of the country in which the ship is to be registered.

1.1.4 The requirements given in 2.3 apply to small hatch covers fitted on exposed decks.

1.1.5 The requirements given in 2.4 apply to small hatch covers fitted on the exposed fore deck over the forward 0.25L, for ships equal to or greater than 80[m] in length, where the height of the exposed deck in way of the hatch is less than 0.1L or 22[m] above the summer load waterline, whichever is the lesser.

1.1.6 The requirements given in 2.5 apply to small hatch covers fitted on non-exposed decks.

1.2 Definition

1.2.1 Superstructure deck is a deck forming the upper boundary of a superstructure. Where the summer freeboard is increased such that the resulting draught is not more than that corresponding to the minimum summer freeboard for the same ship from an assumed freeboard deck located at a distance equal to or greater than the standard superstructure height below the actual freeboard deck. The actual freeboard deck may be treated as the superstructure deck, while considering the requirements given in this chapter.

1.2.2 The requirements of hatches, doors and ventilators on the weather decks are given with respect to Position 1 and Position 2 as defined below in Cl.1.2.4.

1.2.3 Small hatches are hatches designed for access to spaces below the deck and are capable of being closed weathertight or watertight, as applicable. Their opening is generally equal to or less than 2.5[m^2]. (Refer Section 2).

1.2.4 For the purpose of Load Line assignment, two positions of hatchways, doorways and ventilators are defined as follows (Refer Figure 1.2.1 for Position 1 and Position 2):

(a) Position 1 includes:

- exposed freeboard and raised quarter decks for their entire length

- exposed superstructure decks situated forward of 0.25 L_L from FP_{LL}.

(b) Position 2 includes:

- exposed superstructure decks situated aft of $0.25L_L$ from FP_{LL} and located atleast one standard height of superstructure above the freeboard deck.

- exposed superstructure decks situated forward of $0.25L_L$ from FP_{LL} and located at least two standard heights of superstructure above the freeboard deck.

Note: The upper limit of the vertical extent of Position 2 need not be considered to exceed two standard superstructure heights at locations abaft the $0.25L_L$ from FP_{LL} and three standard superstructure heights forward of $0.25L_L$ from the FP_{LL}.

1.2.5 For the application of Rule requirements, the following specific ship types are categorized as:

(a) Type-1 ship: includes all ships except bulk carriers, self-unloading bulk carriers, ore carriers and combination carriers, as defined in Part 5, Chapter 1.

(b) Type-2 ship: includes all bulk carriers, self-unloading bulk carriers, ore carriers and combination carriers, as defined in Part 5, Chapter 1.

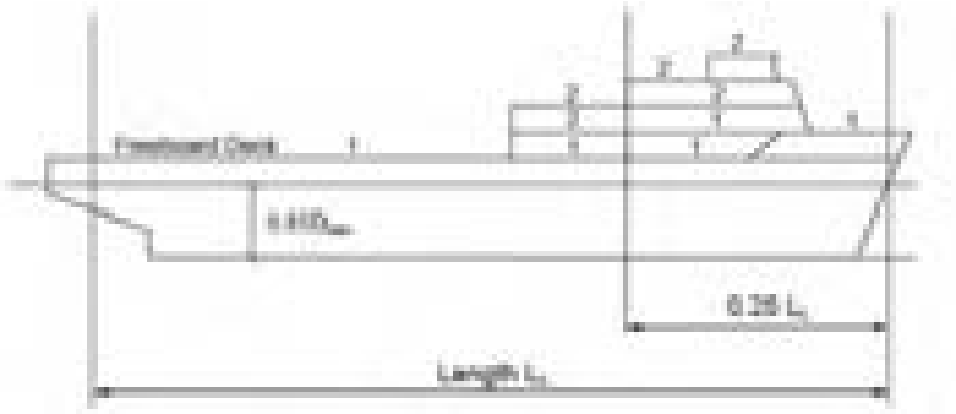

Figure 1.2.1: Position 1 and 2 for general ships

Section 2

Access openings in Freeboard deck and other Exposed decks

2.1 Access openings in Freeboard and Superstructure decks

2.1.1 Manholes and flush scuttles

Manholes and flush scuttles on the decks fitted in position 1 or 2 or within superstructures other than enclosed superstructures are to be closed by substantial covers capable of closing them watertight. Unless secured by closely spaced bolts at a pitch not exceeding 5d, where d is the diameter of bolts, the covers are to be permanently attached.

2.1.2 Companion ways, doors and accesses on weather decks

2.1.2.1 Openings in freeboard decks other than hatchways, machinery space openings, manholes and flush scuttles are to be protected by an enclosed superstructure, or by a deckhouse or companionway of equivalent strength and weather tightness to an enclosed superstructure, effectively secured to deck.

Any such openings:

a) in an exposed superstructure deck, or

b) on top of a deckhouse on the freeboard deck and giving access to space below freeboard deck, or

c) in an exposed position on top of a deckhouse on the enclosed superstructure deck and giving access to space within that enclosed superstructure, is to be protected by an efficient deckhouse or companionway as above.

2.1.2.2 Doorways in such companionways or deckhouses that lead or give access to stairways leading below, need to be fitted with doors complying with the requirements given in Cl.2.2.1.1. Alternatively, if stairways within a deckhouse are enclosed within properly constructed companionways fitted with doors complying with requirements given in Cl.2.2.1.1, the external door need not be weathertight.

2.1.2.3 Regarding the requirement to protect openings in superstructures as described in Cl.2.2.1.1, it is considered that openings in the top of a deckhouse on a raised quarterdeck, or on the deck of a superstructure or on the deck of a deckhouse of less than standard height, having a height equal to or greater than the standard quarterdeck height are to be provided with an acceptable means of closing but need not be protected by an efficient deckhouse or companionway provided the height of the deckhouse is at least the height of superstructure.

The standard height of superstructures is mentioned in Chapter 1 section 2, Table 2.2.5.

2.1.3 Access hatches within enclosed superstructure and tween decks

The requirements of 2.3 are to be complied with as and where applicable.

2.2 Weathertight doors

2.2.1 General

2.2.1.1 All access openings in bulkheads at ends of enclosed superstructures is to be fitted with doors of steel or other equivalent material, permanently and strongly attached to the bulkhead, and framed, stiffened and fitted so that the whole structure is of equivalent strength to the unpierced bulkhead and weathertight when closed. The means for securing these doors weathertight consists of gaskets and clamping devices or other equivalent means and to be permanently attached to the bulkhead or to the doors themselves, and the doors are to be capable of being operated and secured from both sides of the bulkhead. Any fixed lights in the doors are to be provided with hinged steel deadlights fitted internally for maintaining weathertightness.

2.2.1.2 Except pilot doors, which open inwards, weather tight doors are to generally open outwards to provide additional security against the impact of the sea. Doors which open inwards are to be specially approved.

2.2.1.3 Access hatches within a superstructure or deckhouse in Position 1 or 2 need not be provided with means for closing if all openings in the surrounding bulkheads have weather tight closing appliances.

2.2.1.4 Weathertight doors as specified above are to be fitted in all access openings in:

— bulkheads at ends of superstructures

— bulkheads of deckhouses on superstructure deck protecting openings in the superstructure deck

— bulkheads of deckhouses/companionways on freeboard deck protecting openings leading to spaces below the freeboard deck

— bulkheads of deckhouses/companionways protecting openings which give access to spaces within enclosed superstructures.

— companionways and bulkheads of deckhouse upon another deckhouse protecting an opening leading to spaces below the freeboard deck.

— companionways and bulkheads of deckhouse upon another deckhouse which give access to spaces within enclosed superstructures.

2.2.1.5 Weathertight doors in position 1 and 2 are in general to be in accordance with ISO Standards or equivalent.

2.2.2 Sill heights and arrangement

2.2.2.1 The height of doorway sills in companion ways above the deck sheathing, if fitted, is to be at least

— 600[mm] in Position 1

— 380[mm] in Position 2.

2.2.2.2 In the application of Cl.2.1.2.1 and Cl.2.1.2.2 it is understood that:

(i) Where access is provided to the deckhouse, bridge or a poop deck from the deck above as an alternative to the access from the freeboard deck, the height of sill into the deckhouse, bridge or poop can be 380[mm].

(ii) Where access is not provided from above, the height of the sills to doorways in a poop bridge or deckhouse on the freeboard deck should be 600[mm].

(iii) When the closing appliances of openings in superstructures and deckhouses do not comply with the requirements of Cl.2.2.1.1, interior deck openings are to be treated as exposed to the weather deck.

2.2.2.3 The height of sills to doorways in a forecastle if protecting a companionway is to be 600[mm], regardless of whether access is provided from above. If not protecting a companionway the sill height may be 380[mm].

2.2.2.4 Portable sills to be avoided. However, in order to facilitate the loading/unloading of heavy spare parts or similar, portable sills may be fitted on the following conditions:

— They must be installed before the ship leaves port

— Sills are to be gasketed and fastened by closely spaced through bolts.

— Whenever the sills are replaced after removal, the weathertightness of the sills and the related doors must be verified by hose testing. The dates of removal, replacing and hose testing to be recorded in the ship's log book.

2.2.2.5 The height of door sills may be required to be increased on ships of Type 'A', Type 'B-100' or Type 'B-60' where this is shown to be necessary by the floatability calculations required by the ICLL 1966 as amended by the Protocol of 1988. The engine casing in such ships, when not protected by an outer structure will require two weathertight doors in series, with the sill height of the outer and inner door being not less than 600[mm] and 230[mm] respectively.

2.2.2.6 In locations other than those mentioned in 2.2.1.4, doors may be of 50[mm] thick hardwood or equivalent material and strength subject to any requirement of fire protection.

2.2.2.7 Where permitted by the National Authority, reduced companionway sill heights may be accepted on ships engaged on sheltered water service or restricted water service.

2.3 Small hatches on exposed or weather decks

2.3.1 The number and size of access openings are to be kept to the minimum, consistent with the satisfactory operation of the ship.

2.3.2 The height of the coamings for hatches closed by weathertight covers is to be not less than

– 600[mm] in Position 1

– 450[mm] in Position 2

Coaming heights are to be measured from the upper surface of the deck or top of the deck sheathing if fitted.

2.3.3 Lower heights may be considered in relation to operational requirements and the nature of the spaces to which access is given. The height, given in Cl.2.3.2, of hatch coamings closed by steel covers provided with gaskets and securing devices may be reduced or the coamings may be omitted entirely, on condition that the flag administration is satisfied that the safety of the ship is not thereby impaired in any sea conditions. In such cases the scantlings of the covers, their gasketing, their securing arrangements and the drainage of recesses in the deck are considered on a case-by-case basis.

2.3.4 The minimum thickness of the coamings is to be not less than the rule minimum thickness for the deck inside line of openings for that position, or 11[mm], whichever is the lesser. Stiffening of the coaming is to be appropriate to its length and height.

2.3.5 Hatch covers are to be of steel, weathertight and hinged in general. Weathertightness is to be maintained in all sea conditions. Hinges are not to be used as securing devices.

Where toggles are fitted, their diameter and spacing are to be in accordance with or equivalent to, recognized national or international standards.

2.3.6 The thickness of the covers is to be not less than the minimum thickness of the deck, inside the line of opening at that location or (0.01s) where 's' is the spacing of the stiffeners on hatch covers in [mm]. The thickness is not to be less than 6[mm]. The hatch covers are to be adequately stiffened. Stiffeners is to fulfill the requirements in Table 2.4.2.

2.3.7 For hatch covers constructed of materials other than steel, the scantlings are to provide equivalent strength.

2.3.8 Small hatches, including escape hatches, are to be situated clear of cargo containment areas, particularly in the case of offshore supply vessels.

2.3.9 Rope hatches may be accepted with reduced coamings, but generally not less than 380[mm], provided they are well secured and closed before the ship leaves port. A suitable notice is to be displayed at the hatch stating that it is to be closed whilst the ship is at sea.

2.3.10 Where portable plates are required in decks for unshipping machinery, they may be accepted provided they are of equivalent strength to the unpierced deck and are secured by gaskets and closely spaced bolts at a pitch not exceeding 5d, where d is the diameter of bolts. Such portable plates need not be provided with coaming.

2.3.11 Where permitted by the National Authority, access hatch coaming heights may be reduced on ships engaged in sheltered water service or restricted water service. Coaming heights are to be as high as practicable with a minimum height of 230[mm].

2.3.12 Emergency hatch opening

To facilitate a swift and safe means of escape to the lifeboat and life raft embarkation deck, the following provisions apply to overhead hatches fitted along the escape routes addressed by SOLAS Regulation 13 - Means of escape:

– escape hatches and their securing devices are to be capable of being operated and opened from either sides.

– the maximum force needed to open the hatch cover should not exceed 150[N]; and

– the use of a spring equalizing, counterbalance or other suitable device on the hinge side to reduce the force needed for opening is acceptable.

2.3.13 In addition to the requirements, in Cl.2.3.1 to Cl.2.3.12, small hatches on the exposed foredeck of vessels with L≥80[m] are to meet the requirements of 2.4.

2.4 Small hatches fitted on the exposed fore deck

2.4.1 Application

2.4.1.1 These requirements apply to small hatches fitted on the exposed fore deck over the forward 0.25L on ships of L≥80[m], where the height of exposed deck above the summer load waterline in way of the hatch is less than 0.1L or 22[m], whichever is less.

2.4.1.2 For definition of small hatches, Refer Section 1, Cl.1.2.3.

2.4.1.3 Hatches designed for emergency escape need not comply with the requirements given in Cl.2.4.4.2 and Cl.2.4.5.

2.4.1.4 Securing devices of hatches designed for emergency escape are to be of a quick-acting type (e.g. one action wheel handles are provided as central locking devices for latching/unlatching of hatch cover) operable from both sides of the hatch cover. Butterfly nuts and quick acting cleats are not to be used for these hatches.

2.4.1.5 In general, requirements of this subsection do not apply to small hatches on container ships giving access to a cargo hold, which comply with Pt 5, Ch.5, 3.2 for non-weathertight hatch covers. However, the requirements in 2.4.2 for strength and 2.4.3 for primary securing devices, excluding weathertightness, will apply to such small hatch covers. Such hatch covers are considered non-weathertight regardless of whether they are weathertight or not. Requirements for strength in Pt.5, Ch.5, 3.2.7 need not be applied for such small hatch covers.

2.4.2 Strength

2.4.2.1 For small rectangular steel hatch covers, the gross plate thickness, stiffener arrangement and scantlings in [mm], are to be in accordance with Table 2.4.2 and Figure 2.4.2.1. Stiffeners, where fitted, are to be aligned with the metal-to-metal contact points, required in Cl.2.4.4.1 and shown in Figure 2.4.2.1.

2.4.2.2 The primary stiffeners (shown by thick lines) are to be continuous. All stiffeners are to be welded to the inner edge stiffener indicated in Figure 2.4.2.2.

2.4.2.3 The upper edge of the hatchway coaming is to be suitably reinforced by a horizontal section, normally not more than 170 to 190[mm] from the upper edge of the coamings.

2.4.2.4 For small hatch covers of circular or similar shape, the cover plate thickness and reinforcement are to provide strength and stiffness equivalent to the requirements for small rectangular hatches.

2.4.2.5 For small hatch covers constructed of materials other than steel, the required scantlings are to provide equivalent strength and stiffness.

2.4.3 Primary securing devices

2.4.3.1 Small hatches located on exposed fore deck are to be fitted with primary securing devices such that their hatch covers can be secured in place and weathertight by means of a mechanism employing any one of the following methods:

(i) Butterfly nuts tightening onto forks (clamps),

(ii) Quick acting cleats, or

(iii) Central locking device.

2.4.3.2 Dogs (twist tightening handles) with wedges are not acceptable.

2.4.4 Requirement to primary securing

2.4.4.1 The hatch cover is to be fitted with a gasket of elastic material. This is to be designed to allow a metal-to-metal contact at a designed compression and to prevent over compression of the gasket by green sea forces that may cause the securing devices to be loosened or dislodged. The metal-to-metal contacts are to be arranged close to each securing device in accordance with Figure 2.4.2.1 and of sufficient capacity to withstand the bearing force.

2.4.4.2 For a primary securing method using butterfly nuts, the forks (clamps) are to be of robust design. They are to be designed to minimize the risk of butterfly nuts being dislodged while in use; by means of curving the forks upward, a raised surface on the free end, or a similar method. The plate thickness of unstiffened steel forks is not to be less than

16[mm]. An example arrangement is shown in Figure 2.4.2.2.

2.4.4.3 The primary securing method is to be designed and manufactured such that the designed compression pressure is achieved by one person without the need of any tools.

2.4.4.4 For small hatch covers located on the exposed deck forward of the fore-most cargo hatch, the hinges are to be fitted such that the predominant direction of green sea will cause the cover to close, which means that the hinges are normally to be located on the fore edge.

2.4.4.5 On small hatches located between the main hatches, for example between Nos. 1 and 2, the hinges are to be placed on the fore edge or outboard edge, whichever is practicable for protection from green water in beam sea and bow quartering conditions.

2.4.5 Secondary securing device

Small hatches on the fore deck except those designed for emergency escapes are to be fitted with an independent secondary securing device e.g. by means of a sliding bolt, a hasp or a backing bar of slack fit, which is capable of keeping the hatch cover in place, even in the event that the primary securing device became loosened or dislodged. It is to be fitted on the side opposite to the hatch cover hinges.

Table 2.4.2: Gross scantlings for small steel hatch covers on the fore deck

Nominal size [mm x mm]	**Cover plate thickness [mm]**	**Primary stiffeners**	**Secondary stiffeners**
		Flat bar [mm x mm]; number	
630 x 630	8	--	--
630 x 830	8	100 x 8; 1	--
830 x 630	8	100 x 8; 1	--
830 x 830	8	100 x 10; 1	--
1030 x 1030	8	120 x 12; 1	80 x 8; 2
1330 x 1330	8	150 x 12; 2	100 x10; 2

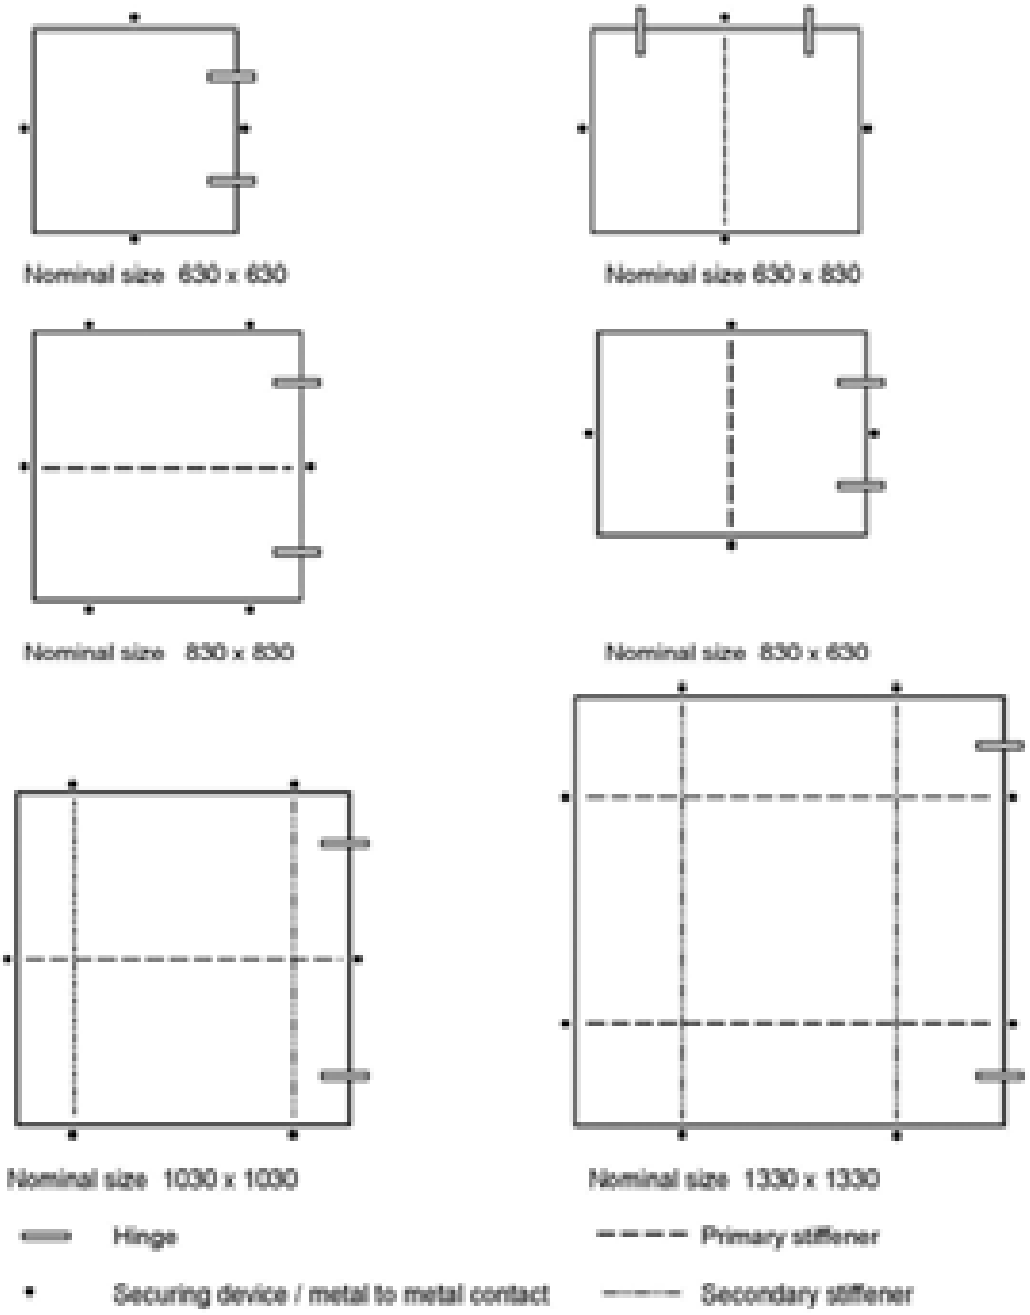

Figure 2.4.2.1: Arrangement of stiffeners

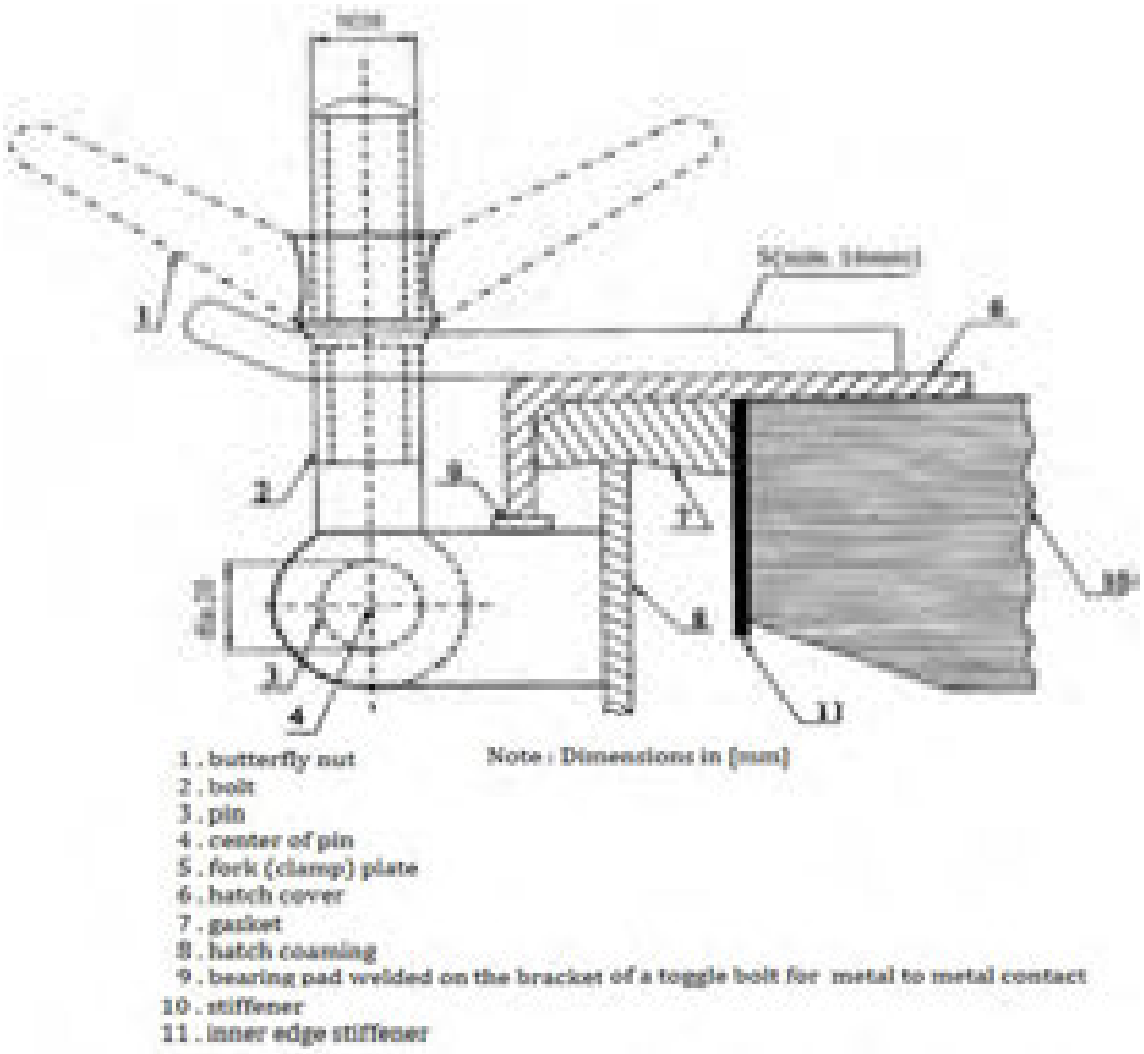

Figure 2.4.2.2: Example or primary securing device

2.5 Small hatch covers fitted on non-exposed decks

2.5.1 Hatch covers on non-exposed decks need not be weathertight.

2.5.2 Small hatch covers fitted on non-exposed decks are to have strength equivalent to that required for the adjacent deck plating.

2.5.3 Small hatch covers fitted on non-exposed decks are to have a level of tightness equivalent to that required for adjacent compartment(s).

2.5.4 If the hatch cover is weathertight or watertight and non-bolted, metal-to-metal contacts are to be provided in order to prevent over compression of the gasket. They are to be designed in order to withstand the bearing force induced by any lateral load on the hatch cover.

Section 3

Machinery Space Openings

3.1 Arrangements

3.1.1 Openings

3.1.1.1 Machinery space openings in position 1 or 2 are to be properly framed and efficiently enclosed by steel casings of ample strength, and where the casings are not protected by other structures their strength are to be specially considered. Access openings in such casings to be fitted with doors complying with the requirements of Section 2.2, Cl.2.2.1.1, the sills to be at least 600[mm] above the deck in position 1, and at least 380[mm] above the deck in position 2. Other openings in such casings are to be fitted with equivalent covers, permanently attached in their proper positions.

3.1.1.2 Machinery space ventilator coamings in an exposed position are to be in accordance with Section 13, Cl.13.5.

3.1.1.3 Machinery space openings in Position 1 or 2 are to have efficient closing appliances. The openings and coamings for fiddley, funnel and machinery space ventilators in the casing in those positions are to be provided with strong covers of steel or other equivalent material permanently attached in their proper positions and capable of being secured weathertight.

3.1.1.4 Skylights are to be of substantial construction and secured firmly to the deck. For skylights in position 1 or 2 the coaming height is not to be less than that of the hatch coaming. Efficient means are to be provided for closing and securing the hinged scuttles, if any. The thickness of glasses in fixed or opening skylights is to be appropriate to their position and size as required for side scuttles. Glasses in any position are to be protected against mechanical damage, and where fitted in Positions 1 and 2 are to be fitted with deadlights or storm covers permanently attached.

3.1.1.5 Side scuttles/skylights in the engine casings are to be provided with fireproof glass.

3.1.2 Special requirements for type 'A' ships

3.1.2.1 Machinery casings on type 'A' ships are to be protected by one of the following arrangements:

- an enclosed poop or bridge of at least standard height; or

- a deckhouse of equal height and equivalent strength.

3.1.2.2 Machinery casings may, however, be exposed if there are no openings giving direct access from the freeboard deck to the machinery space. A door complying with the requirements of Section 2, 2.2 is acceptable in the machinery casing, provided that it leads to a space or passageway which is as strongly constructed as the casing and is separated from the stairway to the engine-room by a second weathertight door or steel or other equivalent material.

Section 4

Windows, Side scuttles and Skylights

Symbols

For symbols not defined in this section, Refer to Chapter 1, Section 2.

4.1 Application and general requirements

4.1.1 The requirements given in this section apply to side scuttles, windows and skylights located on the shell, external bulkheads of superstructures and deckhouse and weather decks of ship structures which are exposed to the action of sea and/or rough weather.

4.1.2 Side scuttles and windows together with their glasses, deadlights and storm covers, if fitted, are to be of an approved design and substantial construction in accordance with, or equivalent to, recognized national or international standards. Non-metallic frames are not acceptable.

The minimum design pressures to which windows and side scuttles are to be designed are to be in accordance with applicable requirements of Chapter 7, Section 8 (Superstructure, Deckhouse and Companionways).

4.1.3 'Deadlights', in accordance with recognized standards, are fitted to the inside of windows and side scuttles while 'storm covers', of comparable specifications to deadlights, are fitted to the outside of windows, where accessible, and may be hinged or portable.

4.1.4 The number of openings in the shell plating is to be reduced to the minimum compatible with the design and proper working of the ship.

4.1.5 A plan showing the location of side scuttles and windows is to be submitted.

4.2 Definitions

4.2.1 Side scuttles are round or oval openings with an area not exceeding 0.16[m^2]. Round or oval openings having areas exceeding 0.16[m^2] are to be treated as windows.

4.2.2 Windows are rectangular openings generally, having a radius at each corner depending on the window size in accordance with recognized national or international standards, and also those associated with round or oval openings with an area exceeding 0.16[m^2].

4.3 Arrangement and positioning

4.3.1 Side scuttles to the following spaces are to be fitted with efficient hinged inside deadlights:

– spaces below freeboard deck

– spaces within the first tier of enclosed superstructures

– first tier deckhouses on the freeboard deck protecting openings leading below

– first tier deckhouses on the freeboard deck considered buoyant in stability calculations.

4.3.2 The deadlights are to be capable of being effectively closed and secured watertight if fitted below the freeboard deck and weathertight if fitted above.

4.3.3 Side scuttles are not to be fitted in such a position that their sills are below a line drawn parallel to the freeboard deck at side and having its lowest point 0.025B or 500[mm], whichever is the greatest distance, above the summer load line (or timber summer load line if assigned).

4.3.4 The sills of all side scuttles which are below the bulkhead deck of passenger ships and the freeboard deck of cargo ships, as permitted in Cl.4.3.3, they are to be of such construction as to prevent effectively any person opening them without the consent of the master of the ship.

4.3.5 Efficient hinged inside deadlights, so arranged that they can be easily and effectively closed and secured watertight, are to be fitted to all side scuttles except that, abaft one eighth

of the ship's length from the forward perpendicular and above a line drawn parallel to the bulkhead deck at side and having its lowest point at a height of (3.7+0.025B)[m] above the deepest subdivision summer load line, the deadlights may be portable in passenger accommodation, unless the deadlights are required by the International Convention on Load Lines in force to be permanently attached in their proper positions. Such portable deadlights are to be stowed adjacent to the side scuttles they serve.

4.3.6 No side scuttles are to be fitted in any spaces which are appropriated exclusively to the carriage of cargo.

4.3.7 Side scuttles may, however, be fitted in spaces appropriated alternatively to the carriage of cargo or passengers, but they are to be of such construction as to prevent effectively any person opening them without the consent of the master of the ship.

4.3.8 Side scuttles are to be of the non-opening type in ships subject to damage stability regulations, if the calculations indicate that they would become immersed by any intermediate stage of flooding or the final equilibrium waterplane in any required damage case.

4.3.9 Windows are not to be fitted in the following locations:

- below the freeboard deck

- in the first-tier end bulkheads or sides of enclosed superstructures

- in first tier deckhouses that are considered buoyant in the stability calculations or protecting openings leading below.

4.3.10 Side scuttles and windows at the side shell in the second tier, protecting direct access below or considered buoyant in the stability calculations, are to be provided with efficient hinged inside deadlights capable of being effectively closed and secured weathertight.

4.3.11 Side scuttles and windows in side bulkheads set inboard from the side shell in the second tier, protecting direct access below to spaces listed in Cl.4.3.1, are to be provided with either efficient hinged inside deadlights or, where they are accessible, permanently attached external storm covers of approved design and of substantial construction and capable of being effectively closed and secured weathertight.

4.3.12 Cabin bulkheads and doors in the second tier and above separating side scuttles and windows from a direct access leading below or the second tier considered buoyant in the stability calculations, may be accepted in place of deadlights or storm covers fitted to the side scuttles and windows.

IR4.3.12 Where an opening in a superstructure deck or in the top of a deckhouse on the freeboard deck which gives access to a space below the freeboard deck or to a space within an enclosed superstructure is protected by a deckhouse, then it is considered that only those side scuttles fitted in spaces which give direct access to an open stairway need be fitted with deadlights. A cabin is considered to provide adequate protection against the minimal account of water which will enter through a broken side scuttle glass fitted on the second tier.

4.3.13 Deckhouses situated on a raised quarter deck or on the deck of a superstructure of less than standard height may be regarded as being in the second tier as far as the provision of deadlights is concerned, provided the height of the raised quarter deck or superstructure is equal to, or greater than, the standard quarter deck height.

4.3.14 Side scuttles and windows facing open or enclosed lifeboat and liferaft embarkation areas and below such areas in such a position that their failure during a fire would impede the launching of or embarkation into lifeboats or liferafts are to have adequate fire integrity.

4.3.15 Fixed or opening skylights are to have glass thickness appropriate to their size and position as required for side scuttles and windows. Skylight glasses in any position are to be protected from mechanical damage and where fitted in positions 1 or 2, are to be provided with permanently attached deadlights or storm covers.

4.3.16 Windows are not to be fitted in machinery space boundaries. However, this does not preclude the use of glass in control rooms within the machinery space.

4.3.17 Where windows are permitted in an exposed bulkhead on the weather deck in the forward $0.25L_L$, strong external storm covers

which may be portable and stored adjacent are to be provided.

4.3.18 If necessary, for practical considerations, the storm covers may be in two parts.

Section 5

Hatch Covers and Hatch Coamings

Symbols

For symbols not defined in this section, Refer to Chapter 1, Section 2.

x = Longitudinal co-ordinate of midpoint of assessed structural member measured from aft end of length L or L_L, as applicable.

5.1 Application

5.1.1 The requirement of this section applies to all ship types in general and is for all cargo hatch covers and coamings on exposed decks. Additional requirements pertaining to special ship types are given in Part 5.

5.1.2 The requirements conform, where applicable, to those of the International Convention on Load Lines, 1966 (ILLC, 1966) as amended by the 1988 protocol, as amended in 2003. Reference should also be made to the additional requirements of the National Authority of the country in which the ship is to be registered.

5.1.3 The strength requirements are applicable to hatch covers and hatch coamings of stiffened plate construction and their closing arrangements.

5.1.4 This section is applicable to hatch covers and hatch coamings made of steel. Use of alternative materials will be specially considered.

5.1.5 This section does not apply to portable covers secured weathertight by tarpaulins and battening devices, or pontoon covers, as defined in ICLL Regulation 15.

5.2 Hatch cover definitions

5.2.1 Single skin cover

A hatch cover made of steel or equivalent material that is designed to comply with ICLL Regulation 16. The cover has continuous top and side plating, but is open underneath with the stiffening structure exposed. The cover is weathertight and fitted with gaskets and clamping devices unless such fittings are specifically excluded.

5.2.2 Double skin cover

A hatch cover as above but with continuous bottom plating such that all the stiffening structure and internals are protected from the environment.

5.3 Hatch cover types

5.3.1 The type of hatch covers a) to e) as described below may be used as per Table 5.3.1 on the weathertight decks of various ship types mentioned in ICLL 1966 as amended by the 1988 protocol, as amended in 2003.

Table 5.3.1: Applicability of hatch cover type					
Types of hatch covers	**Types of ships as per ICLL, 1966**				
	'A'	**'B- 100'**	**'B-60'**	**'B'**	**'B+'**
a	No	Yes	Yes	Yes	Yes
b	No	No	No	Yes	Yes
c	No	No	No	No	Yes
d	Yes	Yes	Yes	Not applicable	
e	Yes	Yes	Yes	Yes	Yes

Type a: Steel plated cargo hatch covers stiffened by webs or stiffeners and secured by clamping devices. Weather tightness is to be ensured by means of gaskets. Hatch covers used for holds containing liquid cargoes are also included in this category.

Type b: Steel plated pontoon type cargo hatch covers with internal webs and stiffeners extending over the full width of the hatchway. Weather tightness is to be achieved by tarpaulins. Refer Section 10.

Note:
Modern hatch cover designs of lift-away-covers are in many cases called pontoon covers. This definition does not fit to the definition above. Modern lift-away hatch cover designs should belong to one of the two categories-single skin covers or double skin cover.

Type c: Wood or steel hatch covers used in conjunction with the portable beams. Weather tightness to be obtained by tarpaulins. Refer Section 10.

Type d: Access hatch covers for cargo oil tanks and adjacent spaces. The hatch covers are to be of steel and gasketed.

Type e: Access hatch covers other than 'd'. For Types 'A', 'B-100' and 'B-60' ships, the covers are to be of steel, and weathertightness is to be ensured by means of gaskets.

5.3.2 Tween deck hatch covers may be any of the types defined in Cl.5.3.1, but need not be weathertight unless fitted to deep tank or water ballast holds or compartments, in which case the covers are to be of type (a) and oil tight or watertight as appropriate.

5.4 Material

5.4.1 Materials for hatch covers and coamings are to be in accordance with the requirements of Part 3, Chapter 2. Material class I is to be applied for top plate, bottom plate and primary supporting members.

5.4.2 For hatch covers, the application of steel with a minimum yield stress of more than 355[N/mm^2], will be specially considered.

5.5 Structural requirements

5.5.1 Primary supporting members and stiffeners of hatch covers are to be continuous over the breadth and length of hatch covers, as far as practical. When this is impractical, sniped end connections are not to be used and appropriate arrangements are to be adopted to provide sufficient load carrying capacity.

5.5.2 The spacing of primary supporting members parallel to the direction of secondary stiffeners is not to exceed 1/3 of the span of primary supporting members. When strength calculation is carried out by FE analysis, this requirement can be waived.

5.5.3 Stiffeners of hatch coamings are to be continuous over the breadth and length of hatch coamings.

5.5.4 Load bearing connections between the hatch cover panels are to be fitted for the purpose of restricting the relative vertical displacements.

5.6 Net Scantling Approach

5.6.1 Unless otherwise noted, the thicknesses ‘t’ of the following sections is net thicknesses.

5.6.2 The net thicknesses, t_{net}, are the member thicknesses necessary to obtain the minimum net scantlings required by Section 7 (Hatch cover strength criteria) and Section 9 (Hatch coaming strength criteria).

5.6.3 The required gross thicknesses are obtained by adding corrosion additions, t_c in [mm], given in Table 5.6.3 to t_{net}.

5.6.4 Strength calculations using FEM are to be performed with net scantlings.

Table 5.6.3: Corrosion additions t_c for hatch covers and hatch coamings

Application	Structure	t_c [mm]
Weather deck cargo hatches of container ships, car carriers, paper carriers, passenger vessels	Hatch covers	1.0
	Hatch coamings	1.0
Weather deck cargo hatches of all other ship types	Hatch covers in general	2.0
	Weather exposed plating and bottom plating of double skin hatch covers	1.5
	Internal structure of double skin hatch covers and closed box girders	1.0
	Hatch coamings not part of the longitudinal hull structure	1.5
	Hatch coamings part of the longitudinal hull structure	1.0
	Coaming stays and stiffeners	1.5
Weather deck cargo hatches of Type-2 ships	Hatch covers in general	2.0
	Top and bottom plating of double skin hatch covers	2.0
	Internal structure of double skin hatch covers	1.5
	Hatch coamings and coaming stays	1.5
Tween deck hatches	Hatch covers in general	1.0

5.7 Steel renewal

5.7.1 Steel renewal is required where the gauged thickness is less than $t_{net} + 0.5$[mm] for:

- Single skin hatch covers
- The plating of double skin hatch covers, and
- Coaming structures for which corrosion additions t_c is provided in Table 5.6.3

5.7.2 Where the gauged thickness is within the range $t_{net} + 0.5$[mm] and $t_{net} + 1.0$[mm], coating (applied in accordance with the coating manufacturer's requirements) or annual gauging may be adopted as an alternative to steel renewal. Coating is to be maintained in GOOD condition.

5.7.3 For the internal structure of double skin hatch covers, thickness gauging is required when hatch cover top or bottom plating renewal is to be carried out or when this is deemed necessary, at the discretion of the individual class society's surveyor, on the basis of the plating corrosion or deformation condition. In these cases, steel renewal for the internal structures is required where the gauged thickness is less than t_{net}.

5.7.4 For corrosion addition $t_c = 1.0$[mm] the thickness for steel renewal is t_{net} and the thickness for coating or annual gauging is when gauged thickness is between t_{net} and $t_{net} + 0.5$ [mm]. For coaming structures, the corrosion additions t_c of which are not provided in Table 5.6.3, steel renewal and coating or annual gauging are to be specially considered.

Section 6

Hatch Covers and Coaming Load Model

Symbols

For symbols not defined in this section, Refer to Chapter 1, Section 2.

x = Longitudinal co-ordinate of midpoint of assessed structural member measured from aft end of length L or L_L, as applicable.

D_{min} = the least moulded depth in [m] as defined in Chapter 1.

h_N = Standard superstructure height in [m].

= $1.05+0.01L_L$, $1.8 \leq h_N \leq 2.3$

6.1 Application

6.1.1 Structural assessment of hatch covers and hatch coamings is to be carried out using the design loads, defined in this section.

6.2 Design Loads on hatch cover and coaming

6.2.1 Vertical weather design load

6.2.1.1 The pressure, P_H in [N/mm²], on the hatch cover panels is given in Table 6.2.1. The vertical design weather load need not be combined with cargo loads given in Cl.6.2.3 and Cl.6.2.4. In Figure 6.2.1.1, the positions 1 and 2 for the purpose of design weather loads are illustrated for an example ship.

6.2.1.2 Where an increased freeboard is assigned, the design load for hatch covers according to Table 6.2.1 on the actual freeboard deck may be as required for a superstructure deck, provided the summer freeboard is such that the resulting draught will not be greater than that corresponding to the minimum freeboard calculated from an assumed freeboard deck situated at a distance at least equal to the standard superstructure height h_N below the actual freeboard deck. (Refer Figure 6.2.1.2).

6.2.1.3 Where two or more panels are connected by hinges, each individual panel is to be considered separately.

6.2.1.4 For hatch covers of cargo holds designed for carriage of ballast or liquid cargo, the internal lateral pressures are also to be considered.

Table 6.2.1: Design load P_H of weather deck hatches

** reduced load upon exposed superstructure decks of vessels with $L_{LL} > 100$ m located at least one superstructure standard height above the lowest Position 2 deck

Figure 6.2.1.2: Positions 1 and 2 for design weather loads for an increased freeboard

6.2.2 Horizontal weather design load

6.2.2.1 General horizontal weather design load

The horizontal design weather load, P_A in [N/mm²], for determining the scantlings of outer edge girders (skirt plates) of weather deck hatch covers and of hatch coamings is not to be taken less than the greater of:

– P_A and

– P_{A-min}, minimum values given in Table 6.2.2

$$P_A = f_n . f_c . (f_b . c_L . C_w - z) 10^{-3}$$

where

f_n = for unprotected front coamings and hatch cover skirt plates

$$= 20 + \frac{L_1}{12}$$

f_n = for unprotected front coamings and hatch cover skirt plates, where the distance from the actual freeboard deck to the summer load line exceeds the minimum non-corrected tabular freeboard according to ICLL by at least one standard superstructure height h_N

$$= 10 + \frac{L_1}{12}$$

f_n = for side and protected front coamings and hatch cover skirt plates

$$= 5 + \frac{L_1}{15}$$

f_n = for aft end of coamings and aft hatch cover skirt plates abaft amidships

$$= 7 + \frac{L_1}{100} - 8.\frac{x'}{L}$$

f_n = for aft end of coamings and aft hatch cover skirt plates forward of amidships

$$= 5 + \frac{L_1}{100} - 4.\frac{x'}{L}$$

L_1 = L, need not be taken greater than 300[m].

f_b = coefficient given by

$$f_b = 1.0 + \left[\frac{\frac{x'}{L} - 0.45}{C_b + 0.2}\right]^2 \text{ for } \frac{x'}{L} < 0.45$$

$$f_b = 1.0 + 1.5\left[\frac{\frac{x'}{L} - 0.45}{C_b + 0.2}\right]^2 \text{ for } \frac{x'}{L} \geq 0.45$$

$0.6 \leq C_b \leq 0.8$, when determining scantlings of aft ends of coamings and aft hatch cover skirt plates forward of amidships, C_b need not be taken less than 0.8.

x' = distance in [m], between the transverse coaming or hatch cover skirt plate considered and aft end of the length L. When determining side coamings or side hatch cover skirt plates, the side is to be subdivided into parts of approximately equal length, not exceeding 0.15L each, and x' is to be taken as the distance between aft end of the length L and the centre of each part considered.

z = Vertical distance in [m] from the summer load line to the midpoint of stiffener span, or to the middle of the plate field.

$$f_c = 0.3 + 0.7\frac{b'}{B'}$$

b' = Breadth of coaming in [m] at the position considered.

B' = Actual maximum breadth of ship in [m] on the exposed weather deck at the position considered.

b'/B' is not to be taken less than 0.25.

C_w = coefficient given by

$$= 4.1 + \frac{L}{25} \qquad \text{for } L < 90[m]$$

$$= 10.75 - \left(\frac{300 - L}{100}\right)^{1.5} \qquad \text{for } 90 \leq L < 300[m]$$

$$= 10.75 \qquad \text{for } 300 \leq L < 350[m]$$

$$= 10.75 - \left(\frac{L - 350}{150}\right)^{1.5} \qquad \text{for } 350 \leq L \leq 500[m]$$

$$c_L = \sqrt{\frac{L}{90}} \quad \text{for } L < 90[m]$$

$$= 1 \qquad \text{for } L \geq 90[m]$$

The minimum values of design load P_{A-min}, in [N/mm²] is given in Table 6.2.2.

Table 6.2.2: Minimum design load, P_{A-min}

L[m]	P_{A-min} in [N/mm²]	
	For unprotected fronts	Elsewhere
$L \leq 50$	30.10^{-3}	15.10^{-3}
$L > 50$	$\left(25 + \frac{L}{10}\right)10^{-3}$	$\left(12.5 + \frac{L}{20}\right)10^{-3}$
$L < 250$		
$L \geq 250$	50.10^{-3}	25.10^{-3}

6.2.2.2 Horizontal weather design load applicable to coamings of Type-2 ships

The pressure P_{Coam}, in [N/mm²], on the No. 1 forward transverse hatch coaming is given by:

$P_{Coam} = 220x10^{-3}$, when a forecastle is fitted in accordance with Part 5, Chapter 1, Cl.1.7.

$= 290x10^{-3}$, in the other cases

The pressure P_{Coam}, in [N/mm²], on the other coamings is given by:

$P_{Coam} = 220x10^{-3}$

Note: The horizontal design weather loads, P_A and P_{Coam} need not be included in the direct strength calculation of the hatch cover, unless it is utilized for the design of substructures of horizontal support according to Cl.9.12.3.

6.2.3 Cargo loads

6.2.3.1 Distributed loads

The load on hatch covers due to distributed cargo loads P_L in [N/mm²], resulting from heave and pitch (i.e. ship in upright condition) is to be determined according to the following formula:

$$P_L = P_{Cargo}(1 + a_v)$$

where:

P_{Cargo} = Uniform cargo load in [N/mm²].

a_v = Vertical acceleration addition as follows:

$$a_v = F.m$$

$$F = 0.11 \times \frac{v_0}{\sqrt{L}}$$

$$m = m_0 - 5(m_0 - 1)\frac{x}{L} \qquad \text{for } 0 \leq \frac{x}{L} \leq 0.2$$

$$m = 1.0 \qquad \text{for } 0.2 < \frac{x}{L} \leq 0.7$$

$$m = 1.0 + \frac{m_0 + 1}{0.3}\left[\frac{x}{L} - 0.7\right] \text{ for } 0.7 < \frac{x}{L} \leq 1.0$$

$$m_0 = 1.5 + F$$

v_0 = Maximum speed in [knots], at summer load line draught, v_0 is not to be taken less than $\sqrt{L}$.

6.2.3.2 Point loads

The load P in [kN], due to a concentrated force P_S in [kN], except for container load, resulting from heave and pitch (i.e. ship in upright condition) is to be determined as follows:

$$P = P_S(1 + a_v)$$

where:

a_v = Vertical acceleration addition according to Cl.6.2.3.1.

6.2.4 Container loads

6.2.4.1 The loads defined in Cl.6.2.4.2 to Cl.6.2.4.4 are to be applied where containers are stowed on the hatch cover.

6.2.4.2 The load P in [kN], applied at each corner of a container stack, and resulting from heave and pitch (i.e. ship in upright condition) is to be determined as follows:

$$F = 9.81\frac{M}{4}(1 + a_v)$$

where:

a_v = Vertical acceleration addition according to Cl.6.2.3.1.

M = Maximum designed mass of container stack in [t].

6.2.4.3 The loads in [kN], applied at each corner of a container stack, and resulting from heave, pitch, and the ship's rolling motion (i.e. ship in heel condition) are to be determined as follows, (Refer Figure 6.2.4):

$$A_z = 9.81\frac{M}{2}(1 + a_v)\left(0.45 - 0.42\frac{h_m}{b}\right)$$

$$B_z = 9.81\frac{M}{2}(1 + a_v)\left(0.45 + 0.42\frac{h_m}{b}\right)$$

$$B_y = 2.4M$$

where:

a_v = Acceleration addition according to Cl.6.2.3.1.

M = Maximum designed mass of container stack, in [t].

$$M = \sum W_i$$

h_m = Designed height of centre of gravity of stack above hatch cover top in [m], may be calculated as weighted mean value of the stack, where the centre of gravity of each tier is assumed to be located at the centre of each container,

$$= \sum (z_i W_i)/M$$

z_i = Distance in [m], from hatch cover top to the centre of i^{th} container.

W_i = Weight of i^{th} container in [t].

b = Distance in [m], between midpoint of foot points.

A_z, B_z = Support forces in [kN] in z-direction at the forward and aft stack corners.

B_y = Support force in [kN] in y-direction at the forward and aft stack corners.

Values of A_z and B_z applied for the assessment of hatch cover strength are to be shown in the drawings of the hatch covers.

Note:
It is recommended that container loads as calculated above are considered as limit for foot point loads of container stacks in the calculations of cargo securing (container lashing).

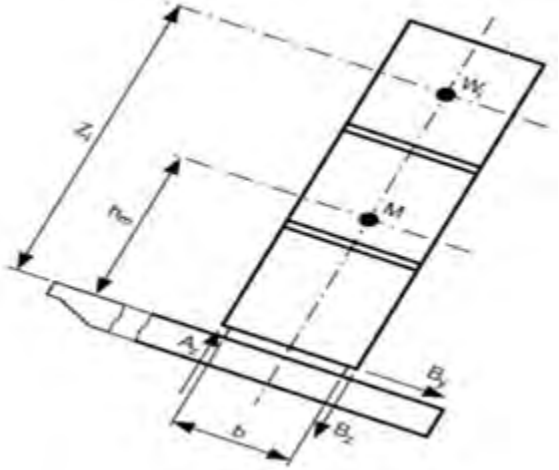

Figure 6.2.4: Forces due to container loads

6.2.4.4 Load cases with partial loading

The load cases defined in Cl.6.2.4.2 and Cl.6.2.4.3 are also to be considered for partial non homogeneous loading which may occur in practice, e.g. where specified container stack places are empty. For each hatch cover, the heel directions, as shown in Table 6.2.4, are to be considered.

The load case *partial loading of container hatch covers* can be evaluated using a simplified approach, where the hatch cover is loaded without the outermost stacks, that are located completely on the hatch cover. If there are additional stacks that are supported partially by the hatch cover and partially by container stanchions then the loads from these stacks are also to be neglected, refer Table 6.2.4, “Partial loading of container hatch covers”. In addition, the case where only the stack places supported partially by the hatch cover and partially by container stanchions are left empty is to be assessed in order to consider the maximum loads in the vertical hatch cover supports. It may be necessary to also consider partial load cases where more or different container stack places are left empty.

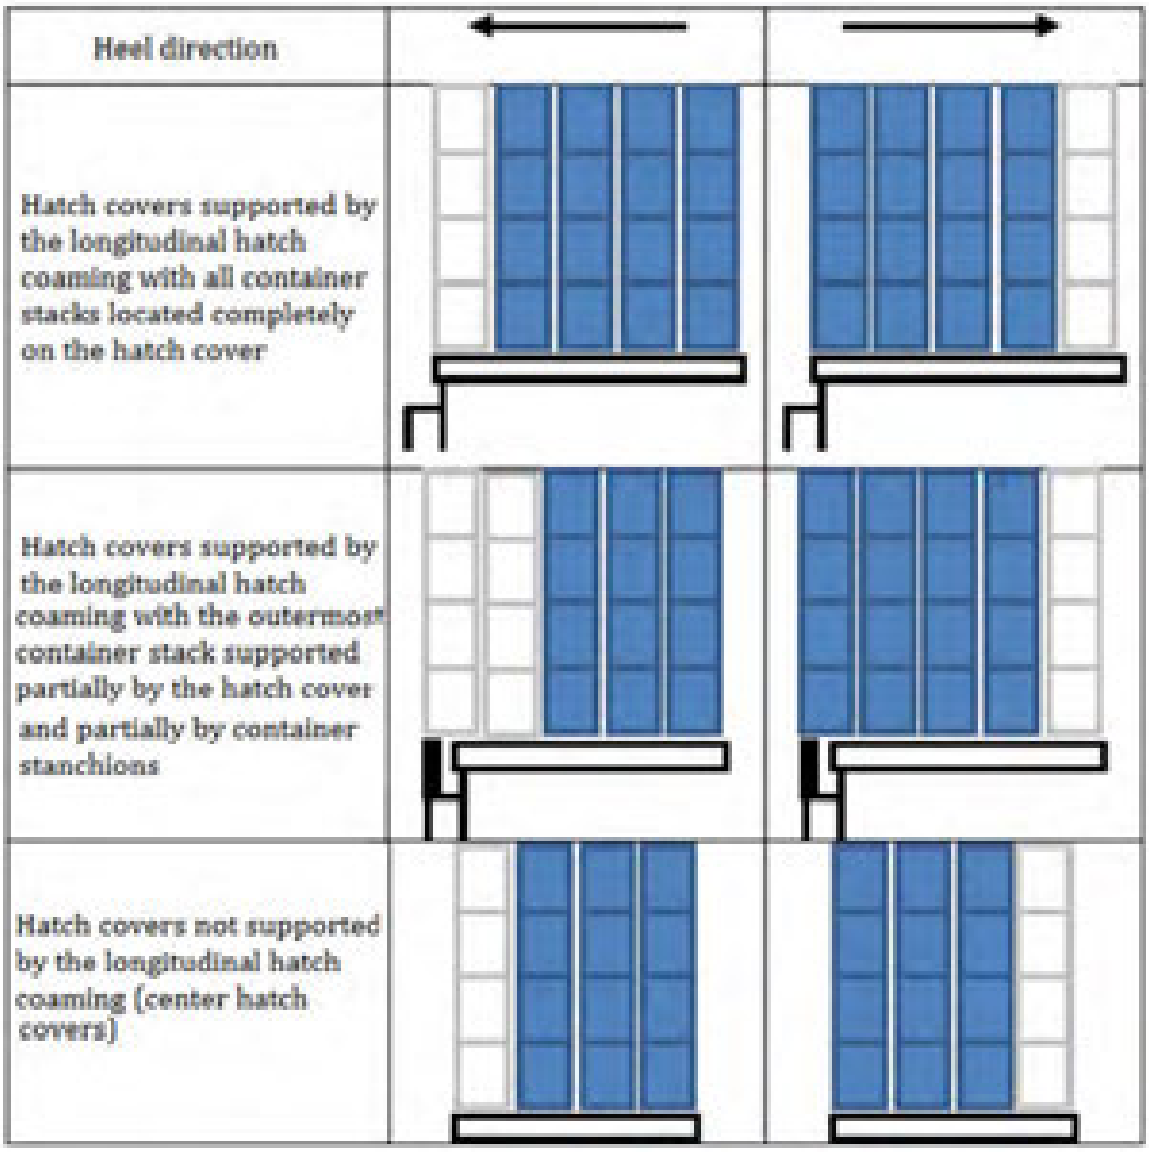
6.2.4.5 Mixed stowage of 20[ft] and 40[ft] containers on hatch covers

In the case of mixed stowage (20[ft] +40[ft] container combined stack), the foot point forces at the fore and aft end of the hatch cover are not to be higher than resulting from the design stack weight for 40[ft] containers, and the foot point forces at the middle of the cover are not to be higher than resulting from the design stack weight for 20[ft] containers.

6.2.5 Loads due to elastic deformations of the ship's hull

Hatch covers, which in addition to the loads according to Cl.6.2.1 to Cl.6.2.4 are loaded in the ship's transverse direction by forces due to elastic deformations of the ship's hull, are to be designed such that the sum of stresses does not exceed the permissible values given in Cl.7.2.1.

Table 6.2.4: Partial loading of container hatch covers



Section 7

Hatch Cover Strength Criteria

Symbols

For symbols not defined in this section, Refer to Chapter 1, Section 2 and Chapter 9.

7.1 General strength criteria

7.1.1 The scantlings of the hatch cover plating, secondary stiffeners and primary supporting members are to be determined as per 7.3, 7.4 and 7.5 respectively using the design loads given in 6.2.

7.1.2 The scantlings specified in the following sections are applicable to covers of mild steel or higher strength steel. Where other materials are used, it is specially considered. The scantlings apply basically to hatch covers of rectangular shapes, assumed to be simply supported with the stiffening members arranged primarily in one direction and carrying a uniformly distributed load.

7.1.3 Hatch covers of special construction and arrangement e.g. covers designed and constructed as a grillage, covers supported along more than two opposite edges and covers supporting other covers, may require submission of direct strength calculation taking into account the arrangement of stiffeners and the supporting members.

7.1.4 Container loads and other point loads are to be additionally taken in to account, in the calculations.

7.2 Permissible stresses and deflections

7.2.1 Yield strength

All hatch cover structural members are to comply with the following formulae:

$\sigma_{vm} \leq \sigma_a$ for shell elements in general.

$\sigma_{axial} \leq \sigma_a$ for rod or beam elements in general.

where

σ_a = Allowable stress, in [N/mm^2] as defined in Table 7.2.1.

σ_{axial} = Axial stress, in [N/mm^2] in rod or beam elements.

R_{eH} = Specified minimum yield stress of the material in [N/mm^2].

σ_{vm} = Von Mises stress, in [N/mm^2] to be taken as follows:

$$\sigma_{vm} = \sqrt{\sigma_x^2 - \sigma_x.\sigma_y + \sigma_y^2 + 3\tau_{xy}{}^2}$$

where:

σ_x = Normal stress in [N/mm^2] in x-direction.

σ_y = Normal stress in [N/mm^2] in y-direction.

τ_{xy} = Shear stress in [N/mm^2] in the x-y plane.

Indices x and y are coordinates of a two-dimensional Cartesian system in the plane of the considered structural element.

In case of finite element (FE) calculations using shell (or plate) elements, the stresses are to be read from the centre of the individual element. It is to be observed that, in particular, at flanges of unsymmetrical girders, the evaluation of stress from element centre may lead to nonconservative results. Thus, a sufficiently fine mesh is to be applied in these cases or, the stress at the element edges is not exceed the allowable stress. Where shell elements are used, the stresses are to be evaluated at the mid plane of the element.

Stress concentrations are to be assessed to the satisfaction of IRS.

For steels with a minimum yield stress of more than 355[N/mm^2], the value of R_{eH} to be applied throughout this requirement is subject to the individual classification society but is not to be more than the minimum yield stress of the material.

Table 7.2.1: Allowable stresses in [N/mm²]		
Members of	**Subject to**	σ_a
Hatch cover structure	External pressure, as defined in 6.2.1	$0.8R_{eH}$
	Other loads, as defined in 6.2.2 to 6.2.5	$0.9R_{eH}$ for Static (S)+Dynamic (D) load case $0.72R_{eH}$ for Static (S) load case

7.2.2 Deflection

The vertical deflection of primary supporting members in [m], due to the vertical design weather load according to Cl.6.2.1 is to be not more than $(\mu.\ell_g)$

where:

μ = Coefficient taken equal to:

= 0.0056 for weathertight hatch covers.

ℓ_g = Greatest span of primary supporting members in [m].

Note:
Where hatch covers are arranged for carrying containers and mixed stowage is allowed, i.e., a 40[ft] container stowed on top of two 20[ft] containers, particular attention is to be paid to the deflections of hatch covers. Further the possible contact of deflected hatch covers within cargo hold has to be observed.

For curved plating, the stiffener spacing, s or the primary supporting member spacing, 'S' is to be measured on the mean chord between members.

7.3 Local net plate thickness

7.3.1 Hatch cover top plating

The local net plate thickness 't' in [mm], of the hatch cover top plating is not to be less than:

$$t = 0.0158\ F_p s \sqrt{\frac{P \times 10^3}{0.95\ R_{eH}}}$$

and to be not less than 1% of the spacing of the stiffener or 6[mm] if that be greater.

F_p = Factor for combined membrane and bending response

= 1.5, in general

$$= 1.9.\frac{\sigma}{\sigma_a} \text{ for } \frac{\sigma}{\sigma_a} \geq 0.8$$

for the attached plate flange of primary supporting members

where:

s = Stiffener spacing in [mm].

P = Pressure P_H and P_L in [N/mm²], as defined in 6.2.

σ = Maximum normal stress in [N/mm²], of hatch cover top plating, determined according to Figure 7.3.1.

σ_a = As defined in Table 7.2.1.

For flange plates under compression sufficient buckling strength according to 7.7 is to be demonstrated.

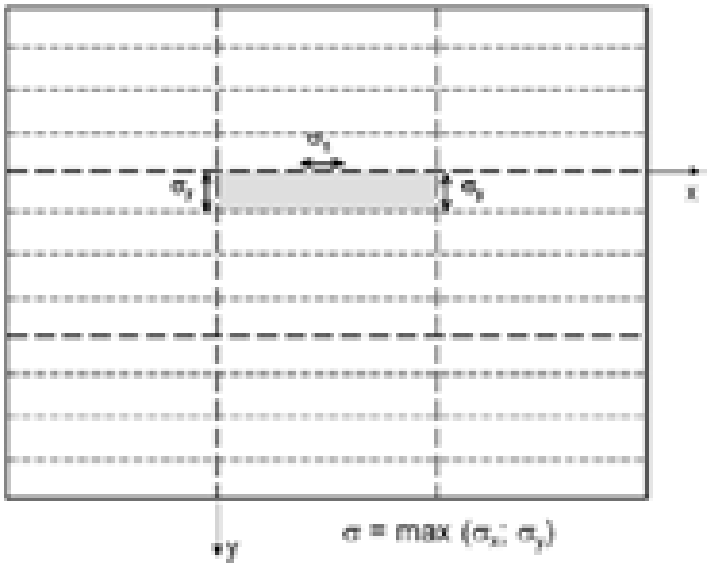


Figure 7.3.1: Determination of normal stress of the hatch cover plating

7.3.2 Local net plate thickness of hatch covers for wheel loading

The local net plate thickness of hatch covers for wheel loading is to be according to Chapter 11, Section 5.

7.3.3 Lower plating of double skin hatch covers and box girders

The thickness to fulfill the strength requirements is to be obtained from the calculation according to 7.6 under consideration of permissible stresses as per Cl.7.2.1. When the lower plating is taken into account as a strength member of the hatch cover, the net thickness in [mm], of lower plating is to be taken not less than 5[mm].

When project cargo is intended to be carried on a hatch cover, the net thickness must not be less than:

$$t = 6.5\, s \times 10^{-3}\ [mm]$$

where,

s = Stiffener spacing in [mm].

Note:
Project cargo means especially large or bulky cargo lashed to the hatch cover. Examples are parts of cranes or wind power stations, turbines, etc. Cargoes that can be considered as uniformly distributed over that hatch cover, e.g., timber, pipes or steel coils need not to be considered as project cargo.

When the lower plating is not considered as a strength member of the hatch cover, the thickness of the lower plating will be specially considered.

7.4 Net scantling of secondary stiffeners

7.4.1 The net section modulus 'Z' in [cm^3] and net shear area A_{shr} in [cm^2] of uniformly loaded hatch cover stiffeners constrained at both ends must not be less than:

$$Z = \frac{P\,.\,s.\ell^2.10^3}{f_{bc}.\sigma_a}$$

$$A_{shr} = \frac{8.7P.\,s.\ell}{\sigma_a}$$

where:

ℓ = Stiffener span in [m], to be taken as the spacing, in [m], of primary supporting members or the distance between a primary supporting member and the edge support, as applicable. When brackets are fitted at both ends of all stiffener spans, the secondary stiffener span may be reduced by an amount equal to 2/3 of the minimum brackets arm length, but not greater than 10% of the unsupported span, for each bracket

s = Stiffener spacing in [mm].

P = Pressure P_H and P_L in [N/mm^2], as defined in 6.2.

f_{bc} = Boundary coefficient of stiffener, taken equal to:

= 8, in the case of stiffener simply supported at both end or simply supported at one end and clamped at the other end

= 12, in the case of stiffener clamped at both ends.

σ_a = Allowable stress as defined in Table 7.2.1.

7.4.2 For stiffeners of lower plating of double skin hatch covers, requirements mentioned above are not applied due to the absence of lateral loads. For double skin hatch covers of holds designed for ballast or liquid cargo, the stiffeners on lower plating are to be strengthened according to Chapter 7, Section 5.

7.4.3 The net thickness, in [mm], of the stiffener (except u-beams/trapeze stiffeners) web is to be taken not less than 4[mm].

7.4.4 The net section modulus of the stiffeners is to be determined based on an attached plate width assumed equal to the stiffener spacing.

7.4.5 Stiffeners parallel to primary supporting members must be continuous at crossing primary supporting member and may be considered for calculating the cross-sectional properties of primary supporting members. It is to be verified that the combined stress of those stiffeners induced by the bending of primary supporting members and lateral pressures does not exceed the permissible stresses according to Cl.7.2.1. The requirements of this paragraph are not applied to stiffeners of lower plating of double skin hatch covers if the lower plating is not considered as strength member.

7.4.6 For hatch cover stiffeners under compression sufficient safety against lateral and torsional buckling according Cl.7.7.3 is to be verified.

7.4.7 For hatch covers subject to wheel loading or point loads stiffener scantlings are to be determined under consideration of the

permissible stresses according to Cl.7.2.1 or are to be determined according to Chapter 11, Section 5.

7.5 Net scantling of primary supporting members

7.5.1 Primary supporting members

7.5.1.1 Scantlings of primary supporting members are obtained from calculations according to 7.6 under consideration of permissible stresses according to Cl.7.2.1.

7.5.1.2 For all components of primary supporting members sufficient safety against buckling must be verified according to 7.7.

7.5.1.3 The net thickness, in [mm], of webs of primary supporting members is not be less than:

$$t = 6.5\, s \times 10^{-3}$$

$$t_{min} = 5.0$$

where,

s = Stiffener spacing [mm]

7.5.2 Edge girders (Skirt plates)

7.5.2.1 Scantlings of edge girders are obtained from the calculations according to 7.6 under consideration of permissible stresses as per Cl.7.2.1.

7.5.2.2 The net thickness, 't' in [mm], of the outer edge girders exposed to wash of sea is not be less than:

$$t = \max\left(\begin{matrix} 0.0158\, s\sqrt{\dfrac{P_A \times 10^3}{0.95 R_{eH}}}; \\ 8.5\, s \times 10^{-3}\,;\ 5.0 \end{matrix}\right)$$

where,

s = Stiffener spacing, in [mm].

p = Horizontal pressure as defined in Cl.6.2.2.

7.5.2.3 The stiffness of edge girders is to be sufficient to maintain adequate sealing pressure between securing devices. The moment of inertia, in [cm^4], of edge girders is not to be less than:

$$I = 6.\, q.\, s_{SD}^4$$

where,

q = Packing line pressure, in [N/mm], minimum 5[N/mm].

s_{SD} = Spacing of securing devices in [m], not to be taken less than 2[m].

7.6 Strength calculations

7.6.1 The stresses in hatch covers are to be determined by FE analysis.

The stress calculation model in this section is to be used for both yielding and buckling strength assessments in accordance with 7.2 and 7.7, respectively.

The net scantlings as defined in Section 5, 5.6 are to be used.

7.6.2 General requirements for FEM calculations

7.6.2.1 For the strength assessments of hatch covers by means of FE analysis, the hatch cover geometry shall be idealized as realistically as possible. In no case element width is to be larger than stiffener spacing. In way of force transfer points and cutouts the mesh has to be refined where applicable. The ratio of element length to width is not exceed 3.

7.6.2.2 The element size along the height of webs of primary supporting member is not to exceed one-third of the web height. Stiffeners, which support plates subjected to lateral pressure loads, are to be included in the FE model idealization. Stiffeners may be modelled by using beam elements, or shell/plate elements. Buckling stiffeners may be disregarded for the stress calculation.

7.6.2.3 Hatch covers fitted with U-type stiffeners as shown in Figure 7.6.2, are to be assessed by means of FE analysis. The geometry of the U-type stiffeners is to be accurately modelled using shell/plate elements. Nodal points are to be properly placed on the intersections between the webs of a U-type stiffener and the hatch cover plate, and between the webs and flange of the U-type stiffener.

7.6.2.4 Wherever applicable the following boundary conditions are to be applied to the FE model:

- Boundary nodes in way of a bearing pad on the hatch coamings are to be fixed against displacement in the direction perpendicular to the pad.
- Lifting stoppers are to be fixed against displacements in the direction determined by the stoppers.
- For a folding type hatch cover, the FE nodes connected through a hinge are to have the same translational displacement in the direction perpendicular to the hatch cover top plating.

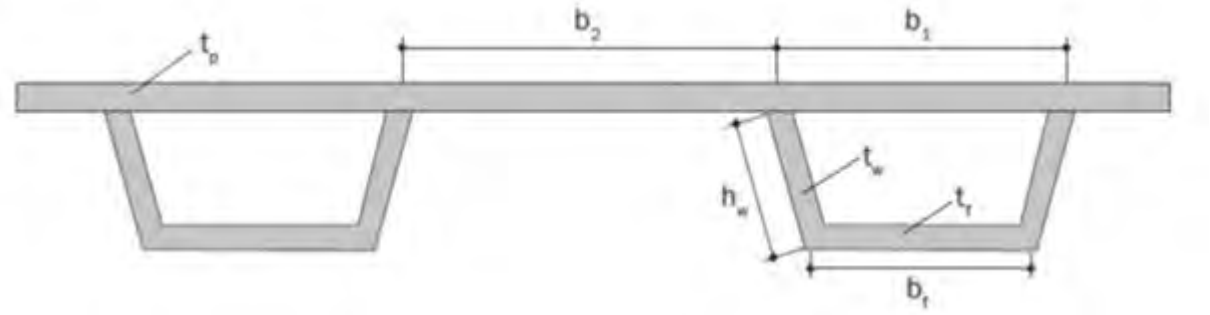

Figure 7.6.2: Example of hatch cover fitted with U-type stiffeners

7.7 Buckling strength of hatch cover structures

7.7.1 General

Buckling strength of all hatch cover structures is to be checked. Buckling assessments are to be done according to Chapter 9 for the conditions specified in 7.7.2 and 7.7.3.

The net scantlings as defined in Section 5, 5.6 are to be used for buckling check.

7.7.2 Slenderness requirements

7.7.2.1 The slenderness requirements are to be in accordance with Chapter 9, Section 2. The slenderness requirements need not be applied to the lower boundary of double skin hatch covers unless the cargo hold is designed for carriage of ballast or liquid cargo.

7.7.2.2 The breadth of the primary supporting member flange is to be not less than 40% of their depth for laterally unsupported spans greater than 3.0[m]. Tripping brackets attached to the flange may be considered as a lateral support for primary supporting members.

7.7.3 Buckling requirements

7.7.3.1 Application

These requirements apply to the buckling assessment of hatch cover structures subjected to compressive and shear stresses and lateral pressures.

The buckling assessment is to be performed for the following structural elements:

- Stiffened and unstiffened panels, including curved panels and panels stiffened with U type stiffeners.
- Web panels of primary supporting members in way of openings.

The buckling strength assessment of coaming parts is to be done according to Chapter 9.

For rule application, the panel types and assessment methods, the applied lateral pressure and stresses, safety factors and buckling check criteria are defined in Cl.7.7.3.2, Cl.7.7.3.3, Cl.7.7.3.4 and Cl.7.7.3.5, respectively.

The procedure and detailed requirements for buckling assessment including idealization of irregular plate panels, definition of reference stresses and buckling criteria, are given in Chapter 9, Section 4.

7.7.3.2 Panel types and assessment methods

The plate panel of a hatch cover structure is to be modelled as stiffened panel (SP) or unstiffened panel (UP) as defined in Chapter 9, Section 4.

Assessment Method A (-A) and Method B (-B) as defined in Chapter 9, Section 1, Cl.1.3.1 are to be used in accordance with Table 7.7.3.1, Figure 7.7.3.1 and Figure 7.7.3.2.

For a web panel with opening, the procedure for opening should be used for its buckling assessment.

For a hatch cover fitted with U-type stiffeners, the additional buckling assessment requirements specific for panels with U-type stiffeners in Chapter 9, Section 5, 5.5 are also to be applied.

Table 7.7.3.1: Structural members and assessment methods

Structural elements	Assessment method (1)(2)	Normal panel definition
Hatch cover top/bottom plating structures, Refer Figure 7.7.3.1		
Hatch cover top/bottom plating	SP-A	Length: between transverse girders Width: between longitudinal girders
Irregularly stiffened panels	UP-B	Plate between local stiffeners/PSM
Hatch cover web panels of primary supporting members, Refer Figure 7.7.3.2		
Web of transverse/longitudinal girder (single skin type)	UP-B	Plate between local stiffeners/face plate/PSM
Web of transverse/longitudinal girder (double skin type)	SP-B (3)	Length: between PSM Width: full web depth
Web panel with opening	Procedure for opening	Plate between local stiffeners/face plate/PSM
Irregularly stiffened panels	UP-B	Plate between local stiffeners/face plate/PSM

Note 1: SP and UP stand for stiffened and unstiffened panel respectively.
Note 2: A and B stand for Method A and Method B respectively.
Note 3: In case that the buckling carlings/brackets are irregularly arranged in the web of transverse/longitudinal girder, UP-B method may be used

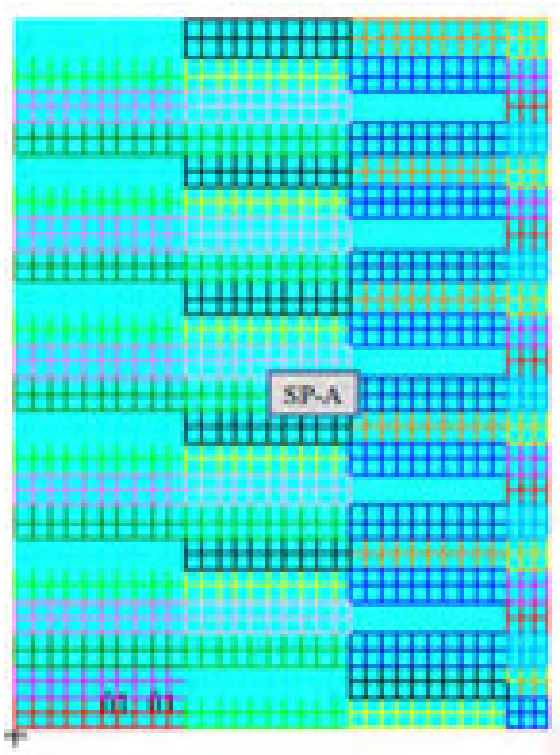

Figure 7.7.3.1: Hatch cover top/bottom plating structures

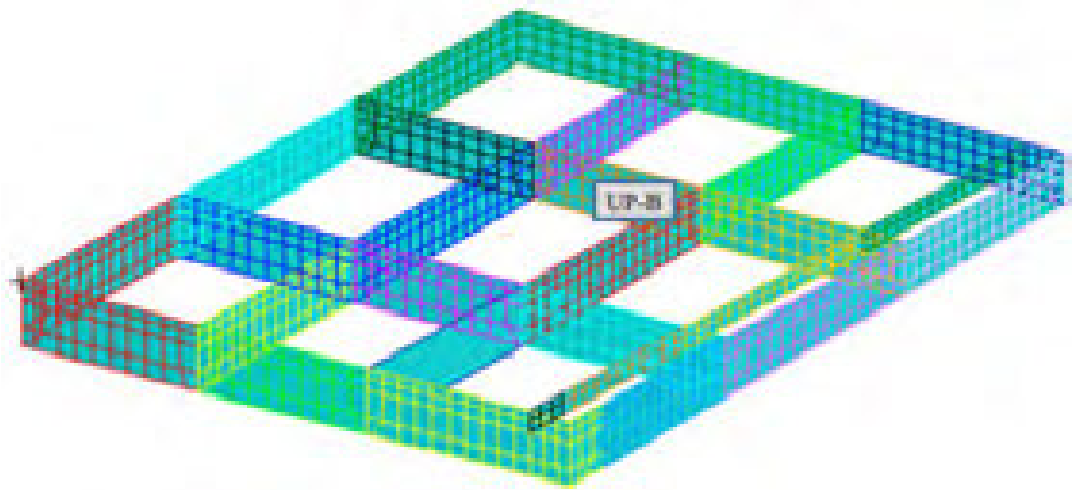

Figure 7.7.3.2: Hatch cover webs of primary supporting members

7.7.3.3 Applied lateral pressure and stresses

The buckling assessment of hatch covers is based on the lateral pressure as defined in 6.2.1 and 6.2.2, and stresses obtained from FE analysis, Refer to 7.6.

7.7.3.4 Safety factors

For all hatch cover structural members, safety factor S=1.0 is to be applied to both of the plating and stiffener buckling capacity formulas as defined in Chapter 9, Section 5, 5.2.

7.7.3.5 Buckling acceptance criteria

A structural member is considered to have an acceptable buckling strength if it satisfies the following criterion

$$\eta_{act} \leq \eta_{all}$$

where,

η_{act} = Buckling utilisation factor based on the applied stress as per Chapter 9, Section 1, Cl.1.3.2, and Chapter 9, Section 4, and calculated per Chapter 9, Section 5.

η_{all} = Allowable buckling utilisation factor as defined in Table 7.7.3.5.

Table 7.7.3.5: Allowable buckling utilisation factor (η_{all})

Structural component	Subject to	Design Load set	η_{all}
Plates and stiffeners	External pressure, as defined in 6.2.1		0.80
Web of PSM	Other loads, as defined in 6.2.2 to 6.2.5	S	0.72
		S + D	0.90

7.8 Hatch covers with variable cross-section

Hatch covers with Z and I gradually reducing towards the ends of the span are to be designed so that the maximum bending stresses and deflections are not increased.

7.8.1 When the section shape is reduced towards the ends (Refer Figure 7.8.1) the requirements of the section modulus Z and the moment of inertia I of the section in the middle uniform part are to be increased by the factors C1 and C2 respectively where C1 and C2 are given below.

7.8.2 The net section modulus *Z*, in [cm^3], of stiffeners and primary supporting members with a variable cross section is to be taken not less than the greater of the values given by the following formulae:

$$Z = Z_{cs}$$

$$Z = \left(1 + \frac{3.2\alpha - \beta - 0.8}{7\beta + 0.4}\right) Z_{cs}$$

where:

Z_{cs} = Net section modulus in [cm^3], for a constant cross section, complying with the checking criteria in Cl.7.4.1.

α = Coefficient taken equal to:

$$\alpha = \frac{\ell_1}{\ell_0}$$

β = Coefficient taken equal to:

$$\beta = \frac{Z_1}{Z_0}$$

ℓ_1 = Length of the variable section part in [m], as shown in Figure 7.8.1.

ℓ_0 = Span measured in [m], between end supports, as shown in Figure 7.8.1.

Z_1 = Net section modulus at end in [cm^3], as shown in Figure 7.8.1.

Z_0 = Net section modulus at mid-span in [cm^3], as shown in Figure 7.8.1.

7.8.3 The net moment of inertia in [cm^4], of stiffeners and primary supporting members with a variable cross section is to be taken not less than the greater of the values given by the following formulae:

$$I = I_{cs}$$

$$I = \left(1 + 8\alpha^3 \left(\frac{1 - \delta}{0.2 + 3\sqrt{\delta}}\right)\right) I_{cs}$$

where:

I_{cs} = Net moment of inertia with a constant cross-section in [cm^4], calculated with wave pressure, as given in Cl.6.2.1 or distributed load as given in Cl.6.2.3.1. It is to be such that the deflection does not exceed (μ α), with μ as defined in Cl.7.2.2.

Δ = Coefficient taken equal to:

$$\delta = \frac{I_1}{I_0}$$

I_1 = Net moment of inertia at end in [cm^4], (Refer Figure 7.8.1)

I_0 = Net moment of inertia at mid-span in [cm^4], (Refer Figure 7.8.1).

The use of these formulae is limited to the determination of the strength of stiffeners and primary supporting members in which abrupt changes in the cross section do not occur along their length.

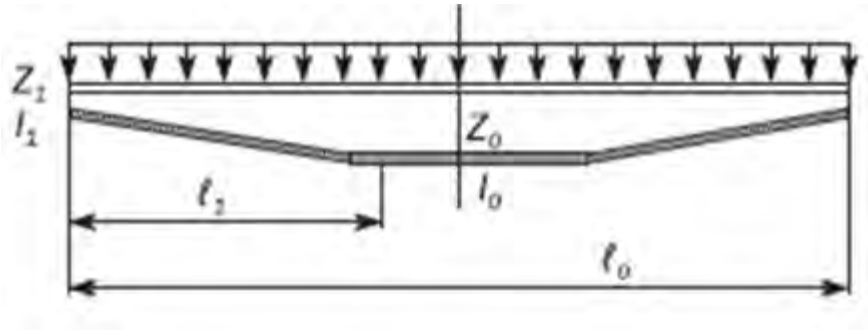

Figure 7.8.1: Variable cross-section stiffener

7.8.4 The net web area, 'A' in [cm^2] of the primary supporting members at any point is not to be less than:

$$A = 10\frac{\left(0.5 - \frac{x}{\ell}\right)}{\tau_a} P.s.\ell$$

where:

τ_a = $0.46R_{eH}$ [Allowable shear stress in [N/mm^2].

x is the distance [m] from the end of the span to the section considered. The value of x is not to be taken more than 0.25ℓ.

Section 8

Details of Hatch Covers

Symbols

For symbols not defined in this section, Refer to Chapter 1, Section 2.

8.1 Container foundations on hatch covers

8.1.1 Container foundations and substructures are to be designed for cargo and container loads according to Section 6, Cl.6.2.3 and Cl.6.2.4, applying the permissible stresses according to Section 7, 7.2.

8.2 Weather tightness

8.2.1 General

8.2.1.1 Where the hatchway is exposed, the weather tightness is to be ensured by gaskets and clamping devices sufficient in number and quality. Weather tightness may also be ensured by means of tarpaulins.

8.2.1.2 In general, a minimum of two securing devices or equivalent is to be provided on each side of the hatch cover.

8.2.1.3 The weight of covers and any cargo stowed thereon, together with inertial forces generated by ship motions, are to be transmitted to the ship structure through suitable contact, such as continuous steel to steel contact of the cover skirt plate with the ship's structure or by means of defined bearing pads.

8.2.2 Weathertight Hatch Covers

8.2.2.1The arrangement of weathertight hatch covers is to be such that weather tightness can be maintained in all sea conditions.

8.2.2.2 Weathertight sealing is to be achieved by a continuous gasket of relatively soft elastic material compressed to provide the necessary weather tightness. Similar sealing is to be arranged between cross-joint elements. Where fitted, compression flat bars or angles are to be well rounded where in contact with the gasket and are to be made of a corrosion-resistant material.

8.2.3 Tightness Testing/Operation and maintenance of Weathertight Hatch Covers

8.2.3.1 The tightness testing is to be carried out as per the requirements of Chapter 17, Section 3, Cl.3.4.4.3.

Upon completion of installation of hatch covers, a hose test is to be carried out with a water pressure in the hose nozzle not less than 2 bar. The nozzle is to have a minimum inside diameter of 12[mm] and nozzle is to be held at a perpendicular distance from the hatch cover to be tested not exceeding 1.5[m]. Water pressure is to be sufficient for a free height of water with the stream directed upwards maximum of 10[m]. During frost periods equivalent tightness tests may be carried out to the satisfaction of the surveyor. Alternative methods of tightness testing will be specially considered.

8.2.3.2 All hatch covers are to be tested for proper functioning and operation in presence of the surveyor.

8.2.3.3 It is recommended that ships with steel hatch covers are supplied with an operation and maintenance manual including:

- opening and closing instructions;
- maintenance requirements and specifications for packings, securing devices and operating items;
- cleaning instructions for the drainage system;
- corrosion prevention instructions;
- list of spare parts.

8.2.4 Gaskets

8.2.4.1 Packing material

- For weather deck hatch covers packings are to be provided, for exceptions Refer Cl.8.2.5.
- The gasket material is to be of a quality suitable for all environmental conditions likely to be experienced by the ship, and is to be compatible with the cargoes carried. The material and form of gasket selected is

to be considered in conjunction with the type of cover, dimensions, the securing arrangement and the expected relative movement between cover and ship structure. The gasket is to be effectively secured to the cover. Forces are to be carried by the steel structure only.

- The packings are to be compressed so as to give the necessary tightness effect for all expected operating conditions. Special consideration is to be given to the packing arrangement in ships with large relative movements between hatch covers and coamings or between hatch cover sections. If necessary, suitable devices are to be fitted to limit such movements. The specification or grade of the packing material is to be indicated on the drawings.

- The hatch coamings and steel parts of hatch covers in contact with gaskets are to have no sharp edges and are to be well rounded where necessary.

- Metallic contact is required for an earthing connection between the hatch cover and the hull structures. If necessary, this is to be achieved by means of a special connection for the purpose.

- The gasket material is to be of satisfactory air, seawater and if necessary oil resistant quality. It is to be effectively secured along the edges of the cover in a manner as to ensure that the forces from the hatch covers or cargo stowed on top of the hatch covers are transferred to the coaming or to the deck by direct contact. The sealing is to be achieved by relatively soft packing.

8.2.5 Dispensation of weather tight gaskets

8.2.5.1 For hatch covers of cargo holds solely for the transport of containers, upon request by the owners and subject to compliance with the following conditions the fitting of weather tight gaskets according to Cl.8.2.4 may be dispensed with:

- The hatchway coamings is not to be less than 600[mm] in height;

- The exposed deck on which the hatch covers are located is situated above a depth $H(x)$ in [m]. H(x) is to be shown to comply with the following criteria:

$$H(x) \geq T_{fb} + f_b + h$$

T_{fb} = Draught in [m] corresponding to the assigned summer load line.

f_b = Minimum required freeboard in [m], determined in accordance with ICLL Regulation 28 as modified by further regulations as applicable.

h = Distance, in [m], taken equal to:

$$h = 4.6 \text{ for } x/L_L \leq 0.75$$

$$h = 6.9 \text{ for } x/L_L > 0.75$$

8.2.5.2 Labyrinths, gutter bars or equivalents are to be fitted proximate to the edges of each panel in way of the coamings to minimize the amount of water that can enter the container hold. The clear profile of these opening is to be kept as small as possible.

8.2.5.3 Where a hatch is covered by several hatch cover panels the clear openings of the gap in between the panels is not to be wider than 50[mm].

8.2.5.4 The labyrinths and gaps between hatch cover panels are to be considered as unprotected openings with respect to the requirements of intact and damage stability calculations.

8.2.5.5 With regard to drainage of cargo holds and the necessary fire-fighting system, reference is made to applicable requirements in Piping Systems, Valves and Pumps and Fire Protection and Fire Extinguishing Equipment of Part 4, Chapter 3, Part 6 and Part 5, Chapter 5, Section 2.2 of the Rules.

8.2.5.6 Bilge alarms are to be provided in each hold fitted with non-weathertight covers.

8.2.5.7 Furthermore, Chapter 3 of IMO MSC/Circ. 1087 is to be referred to concerning the stowage and segregation of containers containing dangerous goods.

8.3 Drainage arrangement at the coaming

8.3.1 Drain openings are to be arranged at the ends of drain channels and are to be provided with effective means for preventing ingress of water from outside, such as non-return valves or equivalent. It is unacceptable to connect fire hoses to the drain openings for this purpose.

8.3.2 If drain channels are provided inside the line of gasket by means of a gutter bar or vertical extension of the hatch side and end coaming, drain openings are to be provided at appropriate positions of the drain channels.

8.3.3 Cross-joints of multi-panel covers are to be arranged with drainage of water from the space above the gasket and a drainage channel below the gasket.

8.3.4 If a continuous outer steel contact between cover and ship structure is arranged, drainage from the space between the steel contact and the gasket is also to be provided.

8.3.5 Drain openings in hatch coamings are to be arranged with sufficient distance to areas of stress concentration (e.g. hatch corners, transitions to crane posts).

Section 9

Hatch Coaming Strength Criteria

Symbols

For symbols not defined in this section, Refer to Chapter 1, Section 2.

P_A = Horizontal weather design load, in [N/mm^2], as defined in Section 6, Cl.6.2.2.1.

P_{Coam} = Horizontal weather design load applicable to coamings of Type-2 ships, as defined in Section 6, Cl.6.2.2.2.

9.1 Coaming heights

9.1.1 The height of the coamings for hatchways closed by weathertight covers is to be not less than

— 600[mm] in Position 1

— 450[mm] in Position 2

Coaming heights are to be measured from the upper surface of the deck or top of the deck sheathing, if fitted.

9.1.2 The height of coamings less than that required as per Cl.9.1.1 may be accepted on special consideration provided the construction of the hatch covers is such as to ensure that the safety of the ship is not impaired in any sea condition. Such reduced coaming heights will also have to be approved by the concerned National Authorities.

9.1.3 Height of coamings may be required to be increased on certain ships e.g., ships of Type 'B-100' or Type 'B-60' where it is found necessary to satisfy the requirements of floatability stipulated in the ICLL 1966 as amended by the Protocol of 1988.

9.1.4 Coamings are not required for hatchways below the freeboard deck or within weathertight closed superstructures unless they are required for strength purposes.

9.2 Hatch coaming construction

9.2.1 Hatch side coamings are to extend to the lower edge of the deck beams. Side coamings not forming a part of continuous girders, are to extend two frame spaces beyond the hatch ends below the deck.

9.2.2 Hatch end coamings when not in line with the deck transverses are to extend below the deck, at least three longitudinal frame spaces beyond the side coaming.

9.2.3 Continuous hatchway coamings or coamings forming an effective part of the deck girder system are to be made from steel of same tensile strength as that of the deck plating.

9.2.4 If the junction of hatch coamings forms a sharp corner, the side and end coamings are to be extended in the form of tapered brackets in longitudinal and transverse directions respectively. Alternatively tapered brackets may be omitted, provided that the hatch coamings at the corners of the hatchways are well rounded and are joined to the deck by full penetration welds. Suitable supporting brackets are to be provided if the deck overhang at the corner is excessive.

9.2.5 Extension brackets or rails arranged approximately in line with the cargo hatch side coamings and intended for the stowage of steel hatch covers are not to be welded to deckhouse, mast house or to each other unless

they form a part of the longitudinal strength members. The ends of supporting structures of hatch cover stowage rails are not to end abruptly and are to be tapered by suitable end brackets.

9.2.6 Design of local details not covered in this section are to be suitable for the purpose of transferring the loads on the hatch covers to the hatch coamings and through them, to the deck structures below. Hatch coamings and supporting structures are to be adequately stiffened to accommodate the loading from hatch covers, in longitudinal, transverse and vertical directions.

9.2.7 The stresses in the under-deck structures induced by the load transmitted by the stays are not to be greater than the allowable stresses for coaming stays indicated in Cl.7.2.1.

9.2.8 The coamings are to be satisfactorily stiffened against buckling.

9.2.9 Unless otherwise stated, weld connections and materials for hatch coaming are to be dimensioned and selected in accordance with the requirements of Part 3, Chapter 16 .

9.2.10 Coamings are to be stiffened on their upper edges with a stiffener suitably shaped to fit the hatch cover closing appliances.

9.2.11 Coamings which are 600[mm] or more in height is to be stiffened by a horizontal stiffener. Where the unsupported height of a coaming exceeds 1.2[m], additional stiffeners is to be arranged.

9.2.12 When two hatches are close to each other, under deck stiffeners are to be fitted to connect the longitudinal coamings in order to maintaining the continuity of their strength.

9.2.13 Where watertight metallic hatch covers are fitted, other arrangements of equivalent strength may be adopted.

9.2.14 Cut outs in the top of hatch coamings are to be avoided. They are to be circular or elliptical in shape where it is necessary for the securing devices. Also, any local reinforcements should be given a tapered transition in the longitudinal direction with a taper the rate of which should not exceed 1 in 3.

9.2.15 Cut-outs and drain holes are to be avoided in the hatch side coaming continuation brackets. Where these are necessary the size, shape and position will be specially considered.

9.2.16 On ships carrying deck cargo such as timber, coal or coke, coaming stays are to be spaced not more than 1.5[m] apart.

9.3 Local net plate thickness of coamings

9.3.1 The net thickness of weather deck hatch coamings, in [mm], is not be less than the greater of the following values:

(1) For Type-1 ships:

$$t = 0.0142.s\sqrt{\frac{P_A.10^3}{0.95.R_{eH}}} \text{ with } t \geq t_{min}$$

$$t_{min} = 6 + \frac{L_1}{100}$$

(2) For Type-2 ships:

$$t = 0.016.s\sqrt{\frac{P_{Coam}.10^3}{0.95.R_{eH}}} \text{ with } t \geq t_{min}$$

$$t_{min} = 9.5$$

where

s = Stiffener spacing, in [mm].

L_1 = L need not be taken greater than 300[m].

Longitudinal strength aspects are to be verified according to Chapter 6.

9.4 Net scantling of stiffeners of coamings

9.4.1 The stiffeners of coamings must be continuous at the coaming stays. For stiffeners with both ends constraint, the elastic net section modulus Z [cm^3] and net shear area A_{shr} [cm^2], calculated on the basis of net thickness, is not be less than:

(1) For Type-1 ships:

$$Z = \frac{P_A.s.\ell^2.10^3}{f_{bc}.R_{eH}}$$

$$A_{shr} = \frac{10.P_A.s.\ell}{R_{eH}}$$

where

s = Stiffener spacing, in [mm].

ℓ = Stiffener span, in [m], to be taken as the spacing of coaming stays.

f_{bc} = 12, in general.

= 8, for the end spans of stiffeners sniped at the coaming corners.

(2) For Type-2 ships:

$$Z = \frac{1.21\, P_{Coam}.\, s.\, \ell^2.\, 10^3}{f_{bc}.\, c_p.\, R_{eH}}$$

where:

f_{bc} = 16 in general

= 12 for the end spans of stiffeners sniped at the coaming corners

s = Stiffener spacing, in [mm].

ℓ = Stiffener span, in [m].

c_p = Ratio of the plastic section modulus to the elastic section modulus of the stiffeners with an attached plate breadth, in [mm], equal to 40 t, where 't' is the plate net thickness.

= 1.16 in the absence of more precise evaluation

9.4.2 For sniped stiffeners of coaming at hatch corners, section modulus and shear area at the fixed support have to be increased by 35%. The gross thickness of the coaming plate, in [mm], at the sniped stiffener end is not be less than:

$$t_{gr} = 19.6\sqrt{\frac{P_A.\, s(\ell - 0.0005s)}{R_{eH}}}$$

9.4.3 Horizontal stiffeners on hatch coamings, which are part of the longitudinal hull structure, are to be designed according to Chapter 7, Section 5.

9.5 Coaming stays

Coaming stays are to be designed for the loads transmitted through them and permissible stresses according to Cl.7.2.1.

9.5.1 Coaming stay section modulus and web thickness

At the connection with deck, the net section modulus Z [cm^3] and the net thickness t_w [mm], of the coaming stays designed as beams with flange (examples 1 and 2 are shown in Figure 9.5.1) are to be taken not less than:

$$Z = \frac{P.\, s_c.\, H_c^2.\, 10^3}{1.9\, R_{eH}}$$

$$t_w = \frac{2.\, P.\, s_c.\, H_c}{R_{eH}.\, h_w}$$

where:

s_c = Spacing of coaming stays in [mm].

H_c = Height of coaming stays in [m].

h_w = Depth of coaming stay in [mm], at the connection with the deck.

P = Pressure on coaming, in [N/mm^2], taken as P_A defined in 6.2.2.1 in general and as P_{Coam} defined in 6.2.2.2 for Type-2 ships.

For other designs of coaming stays, such as those shown in Figure 9.5.1, examples 3 and 4, the stresses are to be determined through FEM. The calculated stresses are to comply with the permissible stresses according to Cl.7.2.1.

Coaming stays are to be supported by appropriate substructures. For calculating the section modulus of coaming stays, their face plate area is to be taken into account only when it is welded with full penetration welds to the deck plating and adequate underdeck structure is fitted to support the stresses transmitted by it.

Stay webs are to be connected to the deck plating by fillet welds on both sides with a throat thickness of $a = 0.44 t_w [mm]$ or with a leg length of $t_{leg} = 0.62 t_w [mm]$.

For Type-2 ships, toes of stay webs are to be connected to the deck plating with full or partial penetration double bevel welds extending over a distance not less than 15% of the stay width for $t_w > 10 [mm]$.

9.5.2 Coaming stays under friction load

For coaming stays, which transfer friction forces at hatch cover supports, fatigue strength is to be considered. (Also Refer Cl.9.11.2).

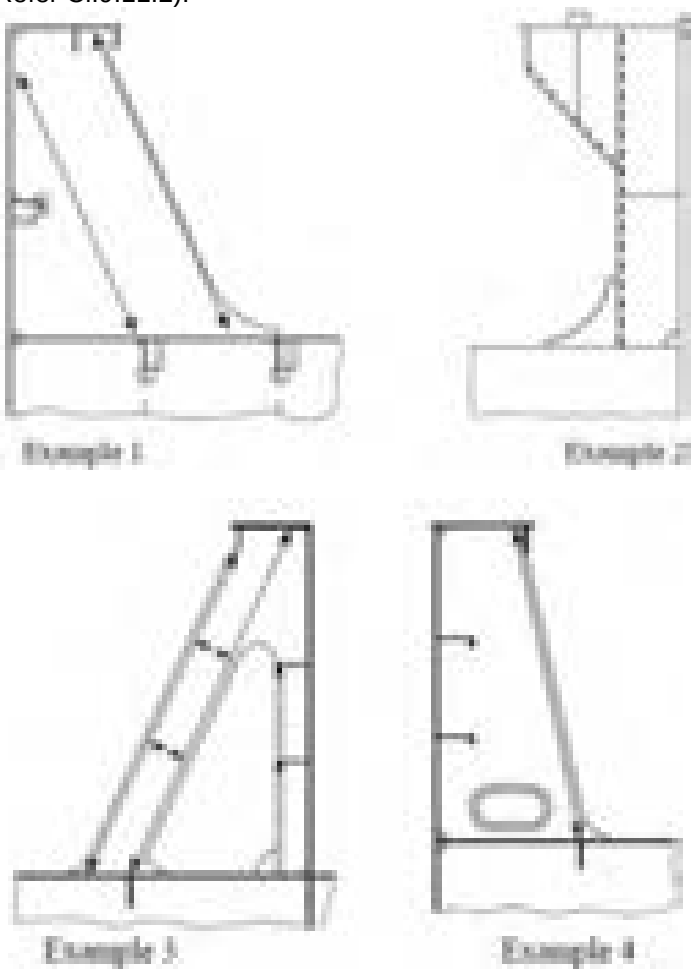

Figure 9.5.1: Examples of coaming stays

9.6 Further requirements for hatch coamings

9.6.1 Longitudinal strength

9.6.1.1 Hatch coamings which are part of the longitudinal hull structure are to be designed according to the requirements of Chapter 6.

9.6.1.2 For structural members welded to coamings and for cutouts in the top of coamings sufficient fatigue strength is to be verified.

9.6.1.3 Longitudinal hatch coamings with a length exceeding 0.1L[m] are to be provided with tapered brackets or equivalent transitions and a corresponding substructure at both ends. At the end of the brackets they are to be connected to the deck by full penetration welds of minimum 300[mm] in length.

9.7 Extend of coaming plates

9.7.1 Coaming plates are to extend to the lower edge of the deck, else hatch side girders are to be fitted that extend to the lower edge of the deck beams. Extended coaming plates and hatch side girders are to be flanged or fitted with face bars or half-round bars. Figure 9.7.1 gives an example.

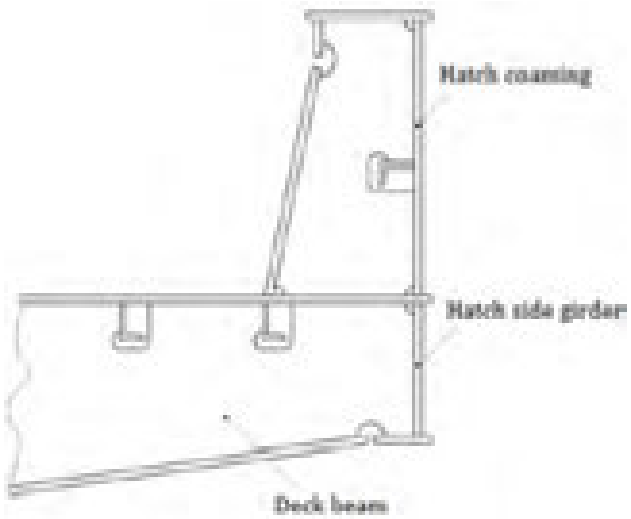

Figure 9.7.1: Example for a hatch side girder

9.8 Closing arrangement

9.8.1 Securing devices

9.8.1.1 Securing devices between cover and coaming and at cross-joints are to be installed to provide weather tightness. Sufficient packing line pressure is to be maintained. Where the packing line pressures is greater than 5[N/mm], it is to be specified in the drawings.

9.8.1.2 Securing devices must be appropriate to bridge displacements between cover and coaming due to hull deformations.

9.8.1.3 Securing devices are to be of reliable construction and effectively attached to the hatchway coamings, decks or covers. Individual securing devices on each cover are to have approximately the same stiffness characteristics.

9.8.1.4 Sufficient number of securing devices is to be provided at each side of the hatch cover considering the requirements of Section 7, Cl.7.5.2. This applies also to hatch covers consisting of several parts.

9.8.1.5 Panel hatch covers are to be secured by appropriate devices (bolts, wedges or similar) suitably spaced alongside the coamings and between cover elements.

9.8.1.6 Hatch covers provided with special sealing devices, insulated hatch covers, flush hatch covers and those having coamings of a reduced height (Refer Cl.9.1.1) are specially considered.

9.8.1.7 In the case of hatch covers carrying containers, the scantlings of the closing devices are to take into account the possible upward vertical forces transmitted by the containers.

9.8.1.8 Securing arrangements with reduced scantlings may be accepted provided it can be demonstrated that the possibility of water reaching the deck is negligible.

9.8.2 Arrangements

9.8.2.1 Securing arrangements together with suitable gasketing material are to ensure weather tightness of the covers to the satisfaction of the surveyors. The arrangements are to be such as to ensure that the weather tightness can be maintained in any sea condition.

9.8.2.2 At cross-joints of multi-panel covers, (male/female) vertical guides are to be fitted to prevent excessive relative vertical deflections between loaded/unloaded panels.

9.8.2.3 The securing and stopping devices are to be arranged so as to ensure sufficient compression on gaskets between hatch covers and coamings and between adjacent hatch covers.

9.8.2.4 The spacing of the securing arrangements is not to be greater than 6[m].

9.8.2.5 Arrangement and spacing are to be determined with due attention to the effectiveness for weather-tightness, depending upon the type and the size of the hatch cover, as well as on the stiffness of the cover edges between the securing devices.

9.8.3 Rod cleats

Where rod cleats are fitted, resilient washers or cushions are to be incorporated.

9.8.4 Hydraulic cleats

In case where hydraulic arrangement is provided for securing the cleats, the system is to remain mechanically locked in closed position in the event of a failure of the hydraulic system.

9.8.5 Materials

Materials used in the manufacturer of stoppers or securing devices including welding electrodes are to be in accordance with relevant requirements given in Part 2. Specifications of the materials are to be shown in the drawings of the hatch covers.

9.9 Cross sectional area of the securing devices

9.9.1 The gross cross-sectional area, in [cm^2] of the securing devices is not to be less than:

$$A = 0.28.q.S_{SD}.k_{\ell}$$

where:

q = Packing line pressure, in [N/mm], not to be less than 5[N/mm].

S_{SD} = Spacing between securing devices in [m], not to be taken less than 2[m].

k_{ℓ} = Material factor, to be taken as:

$$= \left(\frac{235}{R_{eH}}\right)^{e}$$

R_{eH} = The minimum yield strength of the material [N/mm^2], but is not to be taken greater than $0.7\sigma_t$ where σ_t is the tensile strength of the material [N/mm^2].

e = Coefficient taken equal to:

= 0.75 for $R_{eH} > 235$

= 1.00 for $R_{eH} \leq 235$

9.9.2 Where the packing line pressure exceeds 5[N/mm], the cross-sectional area of the securing devices is to be increased in direct proportion.

9.9.3 Rods or bolts are to have a gross diameter not less than 19[mm] for hatchways exceeding 5[m^2] in area.

9.9.4 Securing devices of special design in which significant bending or shear stresses occur may be designed as anti-lifting devices according to 9.10. As load, the packing line pressure 'q' multiplied by the spacing between securing devices 'S_{SD}' is to be applied.

9.10 Anti-lifting devices

9.10.1 The securing devices of hatch covers, on which cargo is to be lashed, are to be designed for the lifting forces resulting from loads according to Cl.6.2.4, refer Figure 9.10.1. Unsymmetrical loadings, which may occur in practice, are to be considered. Under these loadings the equivalent stress, in [N/mm^2], in the securing devices is not to exceed:

$$\sigma_{vm} = \frac{150}{k_{\ell}}$$

Omission of anti-lifting devices will be specially considered.

Note:
The partial load cases given in Table 6.2.4 may not cover all unsymmetrical loadings, critical for hatch cover lifting.

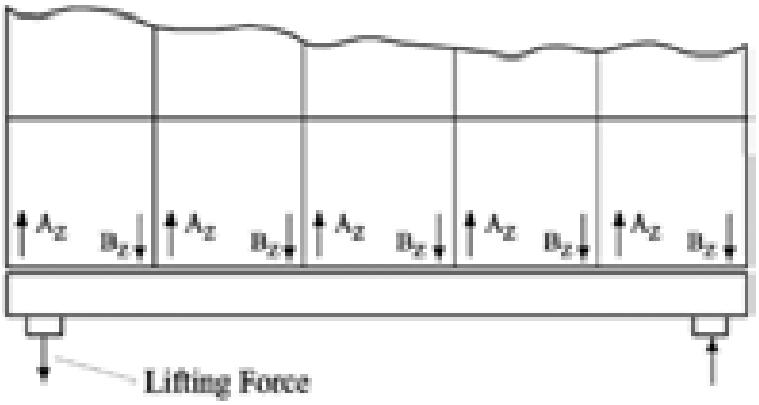

Figure 9.10.1: Lifting forces at a hatch cover

9.11 Hatch cover supports, stoppers and supporting structures

9.11.1 Horizontal mass forces

For the design of hatch cover supports the horizontal mass forces, in [kN], are to be obtained from the following formula.

$$F_h = m.a$$

where:

a = Acceleration, in [m/s^2], to be taken as:

a_x = 0.2g in longitudinal direction

a_y = 0.5g in transverse direction

m = Sum of mass, in [t], of cargo lashed on the hatch cover and of the hatch cover.

The acceleration in longitudinal direction and in transverse direction do not need to be considered as acting simultaneously.

9.11.2 Hatch cover supports

9.11.2.1 For the transmission of the support forces resulting from the load cases specified in Section 6, 6.2 and of the horizontal mass forces specified in Cl.9.11.1, supports are to be provided which are to be designed such that the nominal surface pressures in general do not exceed the following maximum values, P_{n-max} in [N/mm^2]:

In general: $P_{n-max} = d.P_n$

For metallic supporting surfaces not subjected to relative displacements: $P_{n-max} = 3.P_n$

where,

d = Parameter taken equal to:

= 3.75-0.015L, to be taken not greater than, $d_{max} = 3.0$, and not less than d_{min}

d_{min} = Minimum factor, to be taken as:

= 1.0 in general

= 2.0 for partial loading conditions (Refer Cl.6.2.4.4)

P_n = Permissible nominal surface pressure, in [N/mm^2], as defined in Table 9.11.2.

Table 9.11.2: Permissible nominal surface pressure, P_n

Support material	P_n [N/mm²] when loaded by	
	Vertical force	Horizontal force (on stoppers)
Hull structural steel	25	40
Hardened steel	35	50
Plastic materials on steel	50	--

Note:
When the maker of vertical hatch cover support material can provide proof that the material is sufficient for the increased surface pressure, not only statically but under dynamic conditions including relative motion for adequate number of cycles, permissible nominal surface pressure may be relaxed at the discretion of IRS. However, realistic long-term distribution of spectra for vertical loads and relative horizontal motion should be assumed and agreed with IRS.

9.11.2.2 Drawings of the supports are to be submitted. In the drawings of supports the permitted maximum pressure given by the material manufacturer must be specified.

9.11.2.3 Where large relative displacements of the supporting surfaces are to be expected, the use of material having low wear and frictional properties is recommended.

9.11.2.4 The substructures of the supports must be of such a design, that a uniform pressure distribution is achieved.

9.11.2.5 Irrespective of the arrangement of stoppers, the supports must be able to transmit the following force P_h in [kN], in the longitudinal and transverse direction:

$$P_h = \mu . \frac{P_v}{\sqrt{d}}$$

where:

μ =Frictional coefficient, to be taken as:

= 0.50 in general

P_v = Vertical supporting force, in [kN].

9.11.2.6 For non-metallic, low-friction support materials on steel, the friction coefficient may be reduced but not to be less than 0.35 and to the satisfaction of IRS.

9.11.2.7 Supports as well as the adjacent structures and substructures are to be designed such that the permissible stresses according to Cl.7.2.1 are not exceeded.

9.11.2.8 For substructures and adjacent structures of supports subjected to horizontal forces P_h, a fatigue strength analysis is to be carried out.

9.11.3 Hatch cover stoppers

9.11.3.1 Hatch covers are to be sufficiently secured against horizontal shifting. Stoppers are to be provided for hatch covers on which cargo is carried.

9.11.3.2 The greater of the loads resulting from Cl.6.2.2 and Cl.9.11.1 is to be applied for the dimensioning of the stoppers and their substructures.

9.11.3.3 The permissible stress in stoppers and their substructures, in the cover, and of the coamings is to be determined according to Cl.7.2.1. In addition, the provisions in Cl.9.11.2 are to be observed.

9.11.3.4 Specifically for Type-2 ships, the following additional requirements are to be complied with:

- Hatch covers are to be effectively secured, by means of stoppers, against the transverse forces arising from a pressure of 175 [kN/m^2].

- With the exclusion of No.1 hatch cover, hatch covers are to be effectively secured, by means of stoppers, against the longitudinal forces acting on the forward end arising from a pressure of 175[kN/m^2].

- No. 1 hatch cover is to be effectively secured, by means of stoppers, against the longitudinal forces acting on the forward end arising from a pressure of 230[kN/m^2].

- This pressure may be reduced to 175 [kN/m^2] when a forecastle is fitted in accordance with Part 5, Chapter 1, 1.7.

- The equivalent stress is not to exceed the allowable value of $0.8R_{eH}$:

  — in stoppers and their supporting structures, and

  — calculated in the throat of the stopper welds.

Section 10

Hatchways Closed by Portable Covers and Secured Weathertight by Tarpaulins and Battening Devices

Symbols

For symbols not defined in this section, Refer to Chapter 1, Section 2.

10.1 Pontoon Covers

10.1.1 Where steel pontoon covers are used in place of portable beams and covers, the maximum allowable stress and deflection under the minimum design pressures given in Table 10.1.1.1, and the minimum required top plate thickness are as follows:

a) Maximum allowable stress $0.68\ R_{eH}$ [N/mm^2].

b) Maximum allowable deflection 0.0044 times the span of primary supporting member in [m].

c) Top cover plate thickness 0.01s, but not less than 6[mm]

where

s = Stiffener spacing in [mm].

Table 10.1.1.1: Pontoon cover minimum design pressures in [kN/m^2]

1) For ships of 100[m] in length and above: (a) Position 1 hatch covers located in the forward quarter of the ships length is to be designed for wave pressures at the forward perpendicular, calculated from the following equation: $$p = 49.05 + 9.81(L_L - 100)a$$ Where, L_L is L for ships of not more than 340 m but not less than 100 m in length and equal to 340 m for ships of more than 340 m in length: a = 0.0074 for Type B freeboard ships = 0.0363 Ships assigned reduced freeboard The pressure, p, is to be reduced linearly to 34.3[kN/m^2] at the end of the forward quarter's length, as shown in Table 10.1.1.2 Summary of pontoon cover minimum design pressures. The design pressure used for each hatch cover panel is to be determined at its mid-point location. (b) All other position 1 hatch covers is to be designed to 34.3 [kN/m^2]. (c) Position 2 hatch covers is to be designed to 25.51[kN/m^2]. (d) For a position 1 hatchway is located at least one superstructure standard height higher than the freeboard deck, it is to be designed to 34.3[kN/m^2].
2) For ships 24[m] in length: (a) Position 1 hatch covers located in the forward quarter of the ship's length is to be designed for wave pressures of 23.84[kN/m^2] at the forward perpendicular and reduced linearly to 19.6[kN/m^2] at the end of the forward quarter's length, as shown in Table 10.1.1.2 Summary of pontoon cover minimum design pressures. The design pressure used for each hatch cover panel is to be determined at its mid-point location. (b) All other position 1 hatch covers shall be designed to 19.6[kN/m^2].

(c) Position 2 hatch covers shall be designed to 14.7[kN/m^2].

(d) Where a position 1 hatchway is located at least one superstructure standard height higher than the freeboard deck, it may be designed to 19.6[kN/m^2].

3) For ships between 24[m] and 100[m] in length, and for positions between FP and 0,25L, wave pressures is to be obtained by linear interpolation of the values shown in Table 10.1.1.2 Summary of pontoon cover minimum design pressures.

Table 10.1.1.2: Summary of pontoon cover minimum design pressures in [kN/m^2]

Deck Location	**Longitudinal Position**		
	FP	**0.25L**	**Aft of 0.25L**
L_L>100[m]			
Freeboard deck	Equation given in Table 10.1.1.1	34.3	34.3
Superstructure deck	34.3		25.51
L_L=100[m]			
Freeboard deck	49.05	34.3	34.3
Superstructure deck	34.3		25.51
L_L=24[m]			
Freeboard deck	23.84	19.6	19.6
Superstructure deck	19.6		14.7

10.2 Cleats

10.2.1 Cleats are to be of an approved pattern, at least 65[mm] wide, with edges so rounded as to minimize damage to the wedges, and are to be spaced not more than 600[mm] from centre to centre; the first and last cleats along each side or end being not more than 150[mm] from the hatch corners. Cleats are to be so set as to fit the taper of the wedges.

10.3 Wedges

10.3.1 Battens and wedges are to be efficient and in good condition. Wedges are to be of tough wood, generally not more than 200[mm] in length and 50[mm] in width. They should have a taper of not more than 1 in 6 and should not be less than 13[mm] thick at the point.

10.4 Battens and locking bars

10.4.1 For all hatchways in Positions 1 and 2, battens or transverse bars in steel or other equivalent means are to be provided in order to efficiently secure each section of the portable hatch covers and independently after the tarpaulins are battened down. Portable covers of more than 1.5[m] in length are to be secured by at least two such securing devices. Where hatchway covers extend over intermediate supports, steel bars or their equivalent are to be fitted at each end of each section of covers. At all other hatchways in exposed positions on weather decks, ring bolts or other fittings suitable for lashings are to be provided.

10.4.2 Acceptable equivalent means to steel bars are to consist of devices and materials which will provide strength and stiffness equivalent to that of steel. Steel wire ropes cannot be regarded as satisfactory equivalent means. Care is to be taken that tarpaulins are adequately protected from the possibility of damage arising from the usage of securing devices which do not provide a flat bearing surface.

10.5 Tarpaulins

10.5.1 At least two layers of tarpaulin in good condition are to be provided for each hatchway in Positions 1 and 2. Tarpaulins are to be free from jute and are to be waterproof and of ample strength.

The minimum mass of the material before treatment is to be:

— 0.65[kg/m^2] if the material is to be tarred

— 0.60[kg/m^2] if to be chemically dressed

— 0.55[kg/m^2] if to be dressed with black oil

A certificate to this effect is to be supplied by the makers of the tarpaulins. Special consideration will be given to the use of synthetic materials for tarpaulins.

10.6 Wooden hatch covers

10.6.1 Wooden hatch covers are to have a finished thickness of not less than 60[mm] in association with an unsupported span of 1.5 [m] and of not less than 82[mm] with 2[m] unsupported span. The thickness for the intermediate span may be obtained by linear interpolation. Where the tween deck height exceeds 2.6 [m], the thickness of the wood hatch cover is to be increased at the rate of 16.5% per metre of excess tween deck height.

10.6.2 The ends of all wooden hatch covers are to be protected by encircling with galvanized steel bands, about 65[mm] wide and 3[mm] thick, efficiently secured.

10.7 Portable hatch beams

10.7.1 The section modulus and the moment of inertia of the portable hatch beams stiffened at their upper and lower edges by continuous flat bars are to satisfy the requirements of 10.1 for pontoon hatch covers.

10.7.2 Where the cross section of portable beams is not constant along the span, Section 7,7.8 may be used to determine required scantlings.

10.7.3 The ends of the web plates are to be doubled, or inserts fitted for at least 180[mm] along the length of the web.

10.7.4 The beams which carry the ends of wood or steel hatch covers, a 50[mm] vertical flat is to be arranged on the upper face plate. The width of bearing surface for hatch covers is to be not less than 65[mm].

10.7.5 Sliding hatch beams are to be provided with an efficient device for locking them in their correct fore and aft positions when the hatchway is closed.

10.8 Carriers or Sockets

10.8.1 Carriers or sockets, or other suitable arrangements are to be provided as means of the efficient fitting and securing of portable hatch beams. The arrangements are to be of suitable construction and the width of the bearing surface measured along the axis of the beam is not to be less than 75[mm] unless the carriers are of an interlocking type with the beam ends.

10.8.2 Carriers for beams are to extend to the deck level or the coamings are to be fitted with stiffeners or external brackets in way of each beam.

Section 11

Side Shell and Stern Doors

Symbols

For symbols not defined in this section, Refer to Chapter 1, Section 2.

11.1 Application

11.1.1 These rule gives requirements for the arrangement, strength and securing of cargo and service doors in the ship side shell, abaft the collision bulkhead and stern doors leading into enclosed spaces, below the freeboard deck and in enclosed superstructures.

11.2 Arrangement

11.2.1 Stern doors for passenger vessels are to be situated above the freeboard deck. Stern doors for Ro-Ro cargo ships and side shell doors may be either below or above the freeboard deck.

11.2.2 Side shell doors and stern doors are to be so fitted as to ensure tightness and structural integrity commensurate with their location and the surrounding structure.

11.2.3 The sill of any side shell door is, in general, not to be below a line drawn parallel to the freeboard deck at side, with its lowest point 230[mm] above the uppermost loadline.

Special consideration shall be given to preventing the spread of any leakage water over the deck. A flat bar welded to the deck and provision of scuppers would be an acceptable arrangement.

11.2.4 Where the sill of any side shell door is below the line specified in Cl.11.2.3 satisfactory additional features are to be fitted to maintain the watertight integrity. Fitting of a second door of equivalent strength and water tightness is one acceptable arrangement. In that case leakage detection device should be provided in the compartment between the two doors. Further, drainage of this compartment to the bilges controlled by an easily accessible screw down valve, should be arranged.

11.2.5 Doors should preferably open outwards.

11.3 Definitions

11.3.1 *Securing device*: a device used to keep the door closed by preventing it from rotating about its hinges or about pivoted attachments to the ship.

11.3.2 *Supporting devices*: a device used to transmit external or internal loads from the door to a securing device and from the securing device to the ship's structure, or a device other than a securing device, such as a hinge, stopper or other fixed device, that transmits loads from the door to the ship's structure.

11.3.3 *Locking device*: a device that locks a securing device in the closed position.

11.4 Design loads

11.4.1 The design forces, in [N], considered for the scantlings of primary members, securing and supporting devices of side shell doors and stern doors are to be not less than:

11.4.1.1 Design forces for securing or supporting devices of doors opening inwards:

External force: $F_e = AP_e 10^6 + F_p$

Internal force: $F_i = F_0 + 10W$

11.4.1.2 Design forces for securing or supporting devices of doors opening outwards:

External force: $F_e = AP_e 10^6$

Internal force: $F_i = F_0 + 10W + F_p$

11.4.1.3 Design forces for primary members:

External force: $F_e = AP_e 10^6$

Internal force: $F_i = F_0 + 10W$

whichever is the greater,

where,

A = Area, in [m^2], of the door opening.

W = Mass of the door, in [kg].

F_p = Total packing force in [N]. Packing line pressure is normally not to be taken less than 5[N/mm].

F_0 = The greater of F_c and 5000 A [N].

F_c = Accidental force, in [N], due to loose cargo etc., to be uniformly distributed over the area A and not to be taken less than 300000[N]. For small doors such as bunker doors and pilot doors, the value of F_c may be appropriately reduced. However, the value of F_c may be taken as zero, provided an additional structure such as an inner ramp is fitted, which is capable of protecting the door from accidental forces due to loose cargoes.

P_e = External design pressure, in [N/mm^2], determined at the centre of gravity of the door opening and not taken less than:

$$P_e = 0.01(T_1 - Z_G) + 0.025 \text{ for } Z_G < T_1$$

$$P_e = 0.025 \text{ for } Z_G > T_1$$

where,

Z_G = Height of the centre of area of the door in [m], above the baseline.

T_1 = Draught in [m], at the highest subdivision load line.

Moreover, for stern doors of ships fitted with bow doors, P_e in [N/mm^2], is not to be taken less than:

$$P_e = 0.6\lambda C_H\left(0.8 + 0.6\sqrt{L}\right)^2 10^{-3}$$

where,

λ = Coefficient depending on the area where the ship is intended to be operated:

= 1 for sea going ships,

= 0.8 for ships operated in coastal waters,

= 0.5 for ships operated in sheltered waters.

C_H = 0.0125L for L < 80[m]

= 1 for L ≥ 80[m]

L = Ship's length in [m], but need not be taken greater than 200[m].

11.5 Strength Criteria

11.5.1 Scantlings of the primary members, securing and supporting devices of side shell doors and stern doors are to be determined considering simply supported end connections and the design loads defined in 11.4. The following permissible stresses, in [N/mm^2], are not to be exceeded:

$$\text{Shear stress, } \tau = \frac{80}{k}$$

$$\text{Bending stress, } \sigma = \frac{120}{k}$$

$$\text{Equivalent stress, } \sigma_c = \sqrt{\sigma^2 + 3\tau^2} = \frac{150}{k}$$

where k, the material factor, is not to be taken less than 0.72 unless a direct strength analysis with regard to relevant modes of failures is carried out.

11.5.2 The buckling strength of primary members is to be verified as per Chapter 9.

For doors acting as ramps in harbour condition, additional buckling check according to Chapter 9 Section 4, is required.

For steel-to-steel bearings in securing and supporting devices, the nominal bearing pressure, σ_b in [N/mm^2], to follow the formulae below:

$$\sigma_b \leq 0.8\,\sigma_y$$

where,

$$\sigma_b = F/A_b$$

with:

F = Design force, in [N], defined in 11.4.

A_b = Projected bearing area, in [mm^2].

σ_y = Yield stress of the bearing material, in [N/mm^2].

For other bearing materials, the permissible bearing pressure is to be determined according to the manufacturer's specification.

11.5.3 The arrangement of securing and supporting devices is to be such that threaded bolts do not carry support forces. The maximum tension in way of threads of bolts not carrying

support forces is not to exceed 125/k [N/mm^2], where k is defined in Cl.11.5.1.

11.6 Scantlings

11.6.1 General

11.6.1.1 The strength of side shell doors and stern doors is to be commensurate with that of the surrounding structure.

11.6.1.2 Side shell doors and stern doors are to be adequately stiffened and means are to be provided to prevent any lateral or vertical movement of the doors when closed. Adequate strength is to be provided in the connections of the lifting/maneuvering arms and hinges to the door structure and to the ship's structure.

11.6.1.3 Where doors also serve as vehicle ramps, the design of the hinges should take into account the ship's angle of trim and heel which may result in uneven loading on the hinges.

11.6.1.4 Shell door openings are to have well rounded corners and adequate compensation is to be arranged with web frames at sides and stringers or equivalent above and below.

11.6.1.5 Arrangements are to be such that the sea pressure is transferred directly to the hull coamings. For doors with opening area A < 12[m^2], securing bolts or similar devices may be accepted as carriers of sea pressure to the hull coamings.

11.6.1.6 If a door is divided into separate sections, each section is to have full strength independent of the other sections.

11.6.2 Plating and secondary stiffeners

11.6.2.1 The gross thickness of the door plating is not to be less than the required thickness for the side shell plating, using the door stiffener spacing, and not less than the minimum required thickness of shell plating as per Chapter 7, Section 3.

Where doors serve as vehicle ramps, the plating thickness is to be not less than required for vehicle decks.

11.6.2.2 The gross section modulus of secondary horizontal or vertical stiffeners is not to be less than that required for side framing as per Chapter 7, Section 5 for the side, using the door stiffener spacing.

Where doors serve as vehicle ramps, the stiffener scantlings are not to be less than required for vehicle decks. Consideration is to be given, where necessary, to differences in fixity between ship's frames and door stiffeners.

11.6.3 Primary Structure

11.6.3.1 The secondary stiffeners are to be supported by primary members constituting the main stiffening of the door.

11.6.3.2 The primary members and the hull structure in way are to have sufficient stiffness to ensure structural integrity of the boundary of the door.

11.6.3.3 Scantlings of the primary members are to be based on direct strength calculations in association with the design forces given in 11.4 and permissible stresses given in 11.5. In general, formulae for simple beam theory may be used to calculate the loads and stresses in primary supporting members. Members are to be considered to have simply supported end connections.

11.6.3.4 The webs of primary members (girders and stringers) are to be adequately stiffened, preferably in a direction perpendicular to the shell plating.

11.6.3.5 Sufficient stiffness in way of door edges and hull structure are provided, to ensure weathertight integrity. Edge stiffeners/girders are to be adequately stiffened against rotation and are to have a moment of inertia, in [cm^4], not less than:

$$I = 8.P_{\ell}.d^4$$

where:

d = Distance between closing devices in [m].

P_{ℓ} = Packing line pressure along edges in [N/mm], not to be taken less than 5[N/mm].

For edge girders supporting main door girders between securing devices, the moment of inertia is to be increased in relation to the additional force.

11.7 Securing and supporting of doors

11.7.1 General

11.7.1.1 Side shell doors and stern doors are to be fitted with adequate means of securing and

supporting so as to be commensurate with the strength and stiffness of the surrounding structure. The hull supporting structure in way of the doors is to be suitable for the same design loads and design stresses as the securing and supporting devices.

Where packing is required, the packing material is to be of a comparatively soft type and the supporting forces are to be carried by the steel structure only. Other types of packing may be specially considered.

11.7.1.2 Maximum design clearance between securing and supporting devices is not generally to exceed 3[mm]. A means is to be provided for mechanically fixing the door in the open position, taking into account the self-weight of the door and a minimum wind pressure of 1.5[kN/m^2] acting on the maximum projected area in the open position.

11.7.1.3 Only the active supporting and securing devices having an effective stiffness in the relevant direction are to be included and considered to calculate the reaction forces acting on the devices.

11.7.1.4 Small and/or flexible devices such as cleats intended to provide local compression of the packing material are not generally to be included in the calculations in Cl.11.7.2.2. The number of securing and supporting devices are generally to be the minimum practical whilst taking into account the requirement for redundant provision given in Cl.11.7.2.3 and the available space for adequate support in the hull structure.

11.7.1.5 Securing devices are to be equipped with positive locking arrangements. Arrangements are to be such that the securing devices are retained in the closed position within design limits of inclination, vibration and other motion-induced loads and in the event of loss of any actuating power supply.

11.7.2 Scantlings

11.7.2.1 Securing and supporting devices are to be adequately designed so that they can withstand the reaction forces within the permissible stresses given in Cl.11.5.1.

11.7.2.2 The distribution of the reaction forces acting on the securing devices and supporting devices may require direct calculations taking into account the flexibility of the hull structure and the actual position of the supports.

11.7.2.3 The arrangement of securing devices and supporting devices in way of these securing devices is to be designed with redundancy so that in the event of failure of any single securing or supporting device the remaining devices are capable to withstand the reaction forces without exceeding by more than 20% of the permissible stresses as given in Cl.11.5.1.

11.7.2.4 All load transmitting elements in the design load path, from the door through securing and supporting devices into the ship's structure, including pins, support brackets, back-up brackets and welded connections, are to be to the same strength standard as required for the securing and supporting devices.

11.8 Securing and locking arrangement

11.8.1 Systems for operation

11.8.1.1 Securing devices are to be simple to operate and easily accessible. Securing devices are to be equipped with mechanical locking arrangement (self-locking or separate arrangement), or are to be of the gravity type. The opening and closing systems as well as securing and locking devices are to be interlocked in such a way that they can only operate in the proper sequence.

Where hinges are used as closing devices they shall be well integrated into the door structure.

11.8.1.2 Doors which are located partly or totally below the freeboard deck with a clear opening area greater than 6[m^2] are to be provided with an arrangement for remote control, from a position above the freeboard deck of:

— the closing and opening of the doors,

— associated securing and locking devices.

For doors which are required to be equipped with a remote control arrangement, indication of the open/closed position of the door and the securing and locking device is to be provided at the remote control stations. The operating panels for operation of doors are to be inaccessible to unauthorized persons. A notice plate, giving instructions to the effect that all securing devices are to be closed and locked before leaving harbour, is to be placed at each operating panel and is to be supplemented by warning indicator lights.

Alternative means of securing are to be provided for emergency use in case of failure of the power systems.

11.8.1.3 Where hydraulic securing devices are applied, the system is to be mechanically lockable in closed position. This means that in the event of loss of the hydraulic fluid, the securing devices remain locked. The hydraulic system for securing and locking devices is to be isolated from other hydraulic circuits, when in closed position.

11.8.2 Systems for indication/monitoring

11.8.2.1 The requirements in Cl.11.8.2.2 to Cl.11.8.2.5 apply to doors in the boundary of special category spaces or ro-ro spaces, as defined in Part 6, Chapter 1, Section 3, through which such spaces may be flooded.

For cargo ships, where no part of the door is below the uppermost waterline and the area of the door opening is not greater than 6[m^2], the requirements of Cl.11.8.2.2 to Cl.11.8.2.5, need not be applied.

11.8.2.2 Separate indicator lights and audible alarms are to be provided on the navigation bridge and on each operating panel to indicate that the doors are closed and that their securing and locking devices are properly positioned.

The indication panel is to be provided with a lamp test function. It shall not be possible to turn off the indicator light.

11.8.2.3 The indicator system is to be designed on the fail safe principle and is to indicate by visual alarms if the door is not fully closed and not fully locked and by audible alarms if securing devices become open or locking devices become unsecured. The power supply for the indicator and alarm system is to be independent of the power supply for operating and closing arrangements of the doors and is to be provided with a backup power supply from the emergency source of power or other secure power supply such as a UPS with a minimum capacity of 30 minutes.

The sensors of the indicator system are to be protected from water, ice formation and mechanical damages.

The requirements for fail safe design principle are to be similar to those for bow doors as indicated in Cl.12.11.2.4.

11.8.2.4 The indication panel on the navigation bridge is to be equipped with a mode selection function "harbour/sea voyage", so arranged that audible alarm is given if the vessel leaves harbour with side shell or stern doors not closed or with any of the securing devices not in the correct position.

11.8.2.5 For passenger ships, a water leakage detection system with audible alarm and CCTV indication to the navigation bridge and to the engine control room of any leakage through the doors.

For cargo ships, a water leakage detection system with audible alarm is to be arranged to provide an indication to the navigation bridge.

11.8.2.6 For ro-ro passenger ships, on international voyages, the special category spaces and ro-ro spaces are to be continuously patrolled or monitored by effective means, such as CCTV surveillance, so that any movement of vehicles in adverse weather conditions and unauthorized access by passengers thereto, can be detected whilst the ship is underway.

11.9 Operating and maintenance manual

11.9.1 An Operating and Maintenance Manual for the side shell and stern doors is to be provided onboard and contain necessary information on:

11.9.1.1 Main particulars and design drawings

— special safety precautions

— details of vessel

— equipment and design loading (for ramps)

— key plan of equipment (doors and ramps)

— manufacturer’s recommended testing for equipment

— description of equipment for

- bow doors
- inner bow doors
- bow ramp/doors
- side doors

- stern doors
- central power pack
- bridge panel
- engine control room panel

11.9.1.2 Service conditions

— limiting heel and trim of ship for loading/unloading

— limiting heel and trim for door operations

— doors/ramps operating instructions

— doors/ramps emergency operating instructions

11.9.1.3 Maintenance and function testing

— schedule and extent of maintenance

— trouble shooting and acceptable clearances

— manufacturer’s maintenance procedures

11.9.1.4 Register of inspections, including inspection of locking, securing and supporting devices, repairs and renewals.

11.9.2 Documented operating procedures for closing and securing side shell and stern doors are to be kept on board and posted at the appropriate places.

11.9.3 This Manual has to be submitted for approval to verify that the above-mentioned items are contained in the OMM and that the maintenance part includes the necessary information with regard to inspections, troubleshooting and acceptance / rejection criteria.

Note: It is recommended that recorded inspections of the door supporting and securing devices be carried out by the ship's personnel at monthly intervals or following incidents that could result in damage, including heavy weather or contact in the region of side shell and stern doors. A record is to be kept and any damage recorded during such inspections is to be reported to IRS.

Section 12

Bow Doors and Inner Doors

Symbols

For symbols not defined in this section, Refer to Chapter 1, Section 2.

12.1 Application

12.1.1 These requirements cover the arrangement, strength and securing of bow doors and inner doors leading to a complete or long forward enclosed superstructure or to a long non-enclosed superstructure, where fitted to attain minimum bow height equivalence.

12.1.2 Hull supporting structure in way of the bow doors is to be able to withstand the loads imposed by the bow door securing and supporting devices without exceeding the permissible stresses for the devices given in this section.

12.2 Type of Bow doors

12.2.1 Two types of bow doors have been considered:

12.2.1.1 Visor doors opened by rotating upwards and outwards about a horizontal axis through two or more hinges located near the top of the door and connected to the primary structure of the door by longitudinally arranged lifting arms;

12.2.1.2 Side-opening doors opened either by rotating outwards about a vertical axis through two or more hinges located near the outboard edges or by horizontal translation by means of linking arms arranged with pivoted attachments to the door and the ship. It is anticipated that side-opening bow doors are arranged in pairs.

Other types of bow door will be specially considered in association with the applicable requirements of this section.

12.3 Arrangement

12.3.1 Bow doors are to be situated above the freeboard deck. A watertight recess in the freeboard deck located forward of the collision bulkhead and above the deepest waterline fitted for arrangement of ramps or other related mechanical devices may be regarded as a part of the freeboard deck for the purpose of this requirement.

12.3.2 An inner door is to be fitted. The inner door is to be part of the collision bulkhead. The inner door need not be fitted directly above the bulkhead below, provided it is located within the limits specified for the position of the collision bulkhead. A vehicle ramp may be arranged for this purpose, provided its position is within the limits. (Refer Chapter 3, Section 2, Cl.2.2.1.3. If this is not possible, a separate inner weathertight door is to be installed, as far as practicable within the limits specified for the position of the collision bulkhead.

12.3.3 Bow doors are to be so fitted as to ensure tightness consistent with operational conditions and to give effective protection to inner doors. Inner doors forming part of the collision bulkhead are to be weathertight over the full height of the cargo space and arranged with fixed sealing supports on the aft side of the doors.

12.3.4 Bow doors and inner doors are to be arranged so as to preclude the possibility of the bow door causing structural damage to the inner door or to the collision bulkhead in the case of damage to or detachment of the bow door. If this is not possible, a separate inner weathertight door is to be installed, as indicated in Cl.12.3.2.

12.3.5 The requirements for inner doors are based on the assumption that vehicles are effectively lashed and secured against movement in stowed position.

12.4 Definitions

12.4.1 Securing device: a device used to keep the door closed by preventing it from rotating about its hinges or about pivotted attachments to the ship.

12.4.2 Supporting devices: a device used to transmit external or internal loads from the door to a securing device and from the securing device to the ship's structure, or a device other than a securing device, such as a hinge, stopper or other fixed device, that transmits loads from the door to the ship's structure.

12.4.3 Locking device: a device that locks a securing device in the closed position.

12.5 Bow door design loads

12.5.1 External pressure

12.5.1.1 The external sea pressure, in [N/mm^2], to be considered for the scantlings of primary members, securing and supporting devices of bow doors are to be taken as the greater of the following:

$$P_e = P_{ex} \cdot 10^{-3}$$

$$P_e = 2.75\lambda C_H(0.22 + 0.15\tan\alpha)\left(0.4V\sin\beta + 0.6\sqrt{L}\right)^2 10^{-3}$$

where,

P_{ex} = External sea pressure as given in Chapter 5, Section 4, Cl.4.1.1 to Cl.4.1.3 in [kN/m^2].

V = Maximum service speed, in [knots].

λ = Coefficient depending on the area where the ship is intended to be operated:

= 1 for sea going ships,

= 0.8 for ships operated in coastal waters,

= 0.55 for ships operated in sheltered waters.

C_H = 0.0125L for L < 80[m]

= 1 for L ≥ 80[m]

L = Ship's length in [m] but need not be taken greater than 200[m].

α = Flare angle [deg] at the point to be considered, defined as the angle between a vertical line and the tangent to the side shell plating, measured in a vertical plane normal to the horizontal tangent to the shell plating

β = Entry angle [deg] at the point to be considered, defined as the angle between a longitudinal line parallel to the centerline and the tangent to the shell plating in a horizontal plane. (Refer also Figure 12.5.1 for α and β).

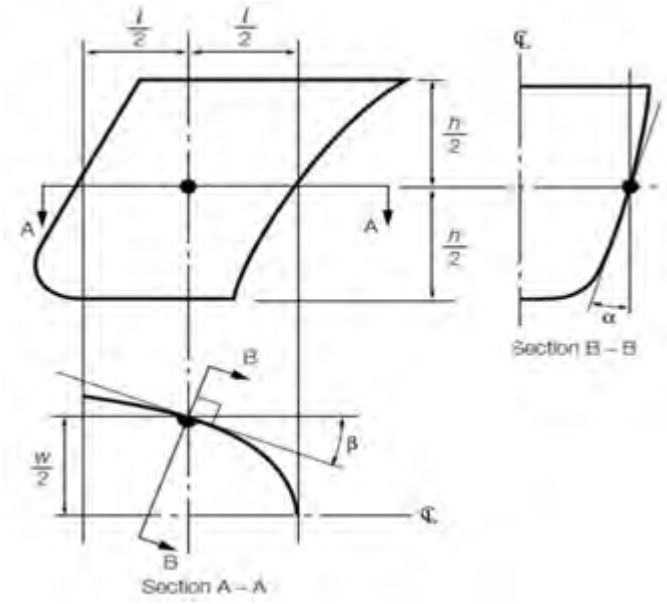

Figure 12.5.1: Definition of α and β angles

12.5.2 External force

12.5.2.1 The design external forces in [kN], considered for the scantlings of securing and supporting devices of bow doors are not to be less than:

$$\text{Longitudinal force, } F_x = P_e A_x 10^3$$

$$\text{Transverse force, } F_y = P_e A_y 10^3$$

$$\text{Vertical force, } F_z = P_e A_z 10^3$$

where,

A_x = Area in [m^2], of the transverse-vertical projection (i.e. in y-z plane) of the door between the levels of the bottom of the door and the top of the upper deck bulwark, or between the bottom of the door and the top of the door, including the bulwark, where it is part of the door, whichever is lesser.

Where the flare angle of the bulwark is at least 15° less than the flare angle of the adjacent shell plating, the height from the bottom of the door may be measured to the upper deck or to the top of the door, whichever is lesser.

In determining the height from the bottom of the door to the upper deck or to the top of the door, the bulwark is to be excluded from the projected area.

A_y = Area in [m^2], of the longitudinal-vertical projection (i.e. in (x-z plane) of the door between the levels of the bottom of the door and the top of the upper deck bulwark, or between the bottom of the door and the top of the door, including the bulwark, where it is part of the door, whichever is lesser.

Where the flare angle of the bulwark is at least 15° less than the flare angle of the adjacent shell plating the height from the bottom of the door may be measured to the upper deck or to the top of the door, whichever is lesser.

A_z = Area in [m^2], of the horizontal projection (i.e. in x-y plane) of the door between the bottom of the door and the top of the upper deck bulwark, or between the bottom of the door and the top of the door, including the bulwark, where it is part of the door, whichever is the lesser.

Where the flare angle of the bulwark is at least 15° less than the flare angle of the adjacent shell plating, the height from the bottom of the door may be measured to the upper deck or to the top of the door, whichever is lesser.

12.5.2.2 If the bulwark is flared inwards such that the horizontal projected area to the top of the bulwark is less than that to the upper deck, then the horizontal projected area to the upper deck is to be considered for the determination of A_z.

h = Height, [m], of the door between the levels of the bottom of the door and the upper deck or between the bottom of the door and the top of the door, whichever is the lesser.

ℓ = Length in [m], of the door at a height h/2 above the bottom of the door.

w = Breadth in [m], of the door at a height h/2 above the bottom of the door.

P_e = External pressure as given in Cl.12.5.1.1 with flare angle and entry angle β measured at a location on the shell h/2 above the bottom of the door and ℓ/2 aft of the intersection of the door with the stem.

12.5.2.3 For bow doors, including bulwark, of unusual form or proportions, e.g. ships with a rounded nose and large stem angles, the areas and angles used for determination of the design values of external forces may require to be specially considered.

12.5.3 Visor door Forces, Moments and Load Cases

12.5.3.1 Closing Moment

For visor doors the closing moment M_y under external loads in [kN-m], is to be taken as:

$$M_y = F_x.a + 10.W.c - F_z.b$$

For visor doors opening outwards, the pivot arrangement are generally to be such that the visor is self-closing under external loads, that is $M_y > 0$. Moreover, the closing moment M_y as given above is to be not less than M_{yo} in [kN-m]:

$$M_{yo} = 10.W.c + 0.1\left(\sqrt{a^2 + b^2}\right)\left(\sqrt{F_x^2 + F_z^2}\right)$$

where:

W = Mass of the visor door in [t].

a = Vertical distance in [m], from visor pivot to the centroid of the transverse vertical projected area of the visor door, as shown in Figure 12.5.3.

b = Horizontal distance in [m], from visor pivot to the centroid of the horizontal projected area of the visor door, as shown in Figure 12.5.3.

c = Horizontal distance in [m], from visor pivot to the centre of gravity of visor mass, as shown in Figure 12.5.3.

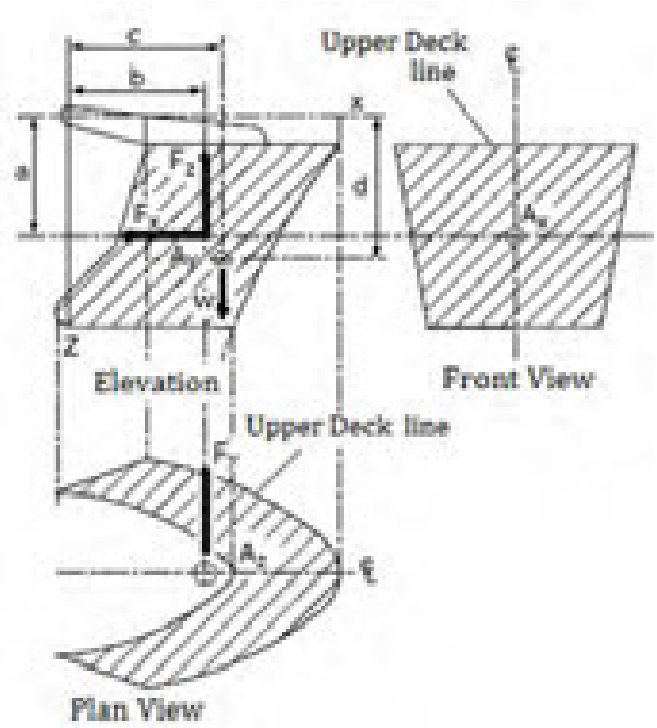

Figure 12.5.3: Bow Door of Visor Type

12.5.3.2 Opening Moment

For visor doors, two securing devices are to be provided at the lower part of the door, each capable of providing the full reaction force required to prevent opening of the door within the permissible stresses given in Cl.12.7.1. The opening moment, M_o in [kN-m], to be balanced by this reaction force, is not to be taken less than:

$$M_o = 5A_x.a + 10.W.d$$

where,

d = Vertical distance [m], from the hinge axis to the centre of gravity of the door, as shown in Figure 12.5.3.

12.5.3.3 Vertical Design Force

For visor doors, the securing and supporting devices excluding the hinges should be capable of resisting the vertical design force F_v in [kN], within the permissible stresses given in Cl.12.7.1 is given below:

$$F_v = F_z - 10W$$

12.5.3.4 Reaction Forces

For visor doors, the reaction forces applied on the effective securing and supporting devices assuming the door as a rigid body are determined for the following combination of external loads acting simultaneously together with the self-weight of the door:

Case 1 : F_x and F_z

Case 2 : $0.7F_y$ acting on each side separately together with $0.7F_x$ and $0.7F_z$

where F_x, F_y and F_z are to be calculated as indicated in Cl.12.5.2 and applied at the centroid of projected areas.

12.5.3.5 Forces acting on the lifting arms

The design of lifting arms of a visor door and its supports is to take into account the static and dynamic forces applied during the lifting and lowering operations, and a minimum wind pressure of 0.0015[N/mm^2].

12.5.4 Side-opening door Reaction forces and Load Cases

12.5.4.1 For side-opening doors, securing devices are to be provided such that in the event of a failure of any single securing device the remaining are capable of providing the full reaction force required to prevent the opening of the door within the permissible stresses given in Cl.12.7.1.

The opening moment about the hinges to be balanced by this reaction force is not to be less than that calculated when the following loads are applied:

— An internal pressure of 5[kN/m^2].

— A force of 10W[kN] acting forward at the centroid of mass.

12.5.4.2 For side-opening doors, the reaction forces applied on the effective securing and supporting devices assuming the door as a rigid body are determined for the following combination of external loads acting simultaneously together with the self-weight of the door:

Case 1 : F_x, F_y and F_z acting on both doors

Case 2 : $0.7F_x$ and $0.7F_z$ acting on both doors and $0.7F_y$ acting on each door separately

where F_x, F_y and F_z are to be calculated as indicated in Cl.12.5.2 and applied at the centroid of projected areas.

12.6 Inner door design loads

12.6.1 External pressure

The design external pressure, P_e in [N/mm^2], considered for the scantlings of primary members, securing and supporting devices and surrounding structure of inner doors is to be taken as the greater of the following:

$$P_e = 0.45.L \times 10^{-3}$$

$$P_h = 0.01h$$

where,

h = The distance in [m], from the load point to the top of the cargo space.

L = Ship's length in [m], but need not be taken greater than 200[m].

12.6.2 Internal pressure

The design internal pressure, P_i in [N/mm^2], considered for the scantlings of securing devices of inner doors is not to be less than:

$$P_i = 0.025$$

12.7 Strength Criteria

12.7.1 Scantlings of the primary members, securing and supporting devices of bow doors and inner doors are to be determined to withstand the design loads defined in 12.5 and 12.6, using the following permissible stresses, in [N/mm^2]:

$$\text{Shear stress}, \tau = \frac{80}{k}$$

$$\text{Bending stress}, \sigma = \frac{120}{k}$$

$$\text{Equivalent stress}, \sigma_c = \sqrt{\sigma^2 + 3\tau^2} = \frac{150}{k}$$

where k, the material factor, is not to be taken less than 0.72 unless a direct fatigue analysis is carried out.

12.7.2 The buckling strength of primary members is to be verified as per Chapter 9.

12.7.3 For steel-to-steel bearings in securing and supporting devices, the nominal bearing pressure, σ_b in [N/mm^2], to follow the formulae below:

$$\sigma_b \leq 0.8\,\sigma_y$$

where,

$$\sigma_b = \frac{F}{A_b}$$

with:

F = Design force in [N], defined in Cl.12.5.2

A_b = Projected bearing area, in [mm^2].

σ_y = Yield stress of the bearing material, in [N/mm^2].

For other bearing materials, the permissible bearing pressure is to be determined according to the manufacturer's recommended value.

12.7.4 The arrangement of securing and supporting devices is to be such that threaded bolts do not carry support forces. The maximum tension in way of threads of bolts not carrying support forces is not to exceed 125/k [N/mm^2], where k is defined in Cl.12.7.1.

12.8 Scantlings of bow doors

12.8.1 General

12.8.1.1 The strength of bow doors is to be commensurate with that of the surrounding structure.

12.8.1.2 Bow doors are to be adequately stiffened and means are to be provided to prevent any lateral or vertical movement of the doors when closed. For visor doors, adequate strength for the opening and closing operations is to be provided in the connections of the lifting arms to the door structure and to the ship's structure.

12.8.2 Plating and secondary stiffeners

12.8.2.1 The gross thickness of the bow door plating is not to be less than the required thickness for the side shell plating, using the door stiffener spacing as per Chapter 7, Section 4, and also not less than the minimum required thickness of fore end shell plating as per Chapter 7, Section 3.

12.8.2.2 The gross section modulus of secondary horizontal or vertical stiffeners is not to be less than that required for end framing as per Chapter 7, Section 5 for the fore end, using the bow door stiffener spacing. Consideration is to be given, where necessary, to differences in fixity between ship's frames and door stiffeners.

12.8.2.3 The net sectional area in [cm^2], of stiffener webs is not to be less than:

$$A = 0.05 P_e . s . \ell . k$$

12.8.3 Primary Structure

12.8.3.1 The bow door secondary stiffeners are to be supported by primary members constituting the main stiffening of the door.

12.8.3.2 The primary members of the bow structure and the hull structure in way are to have sufficient stiffness to ensure structural integrity of the boundary support of the door.

12.8.3.3 Scantlings of the primary members are to be based on direct strength calculations in association with the external pressure given in Cl.12.5.1.1.and permissible stresses given in Cl.12.7.1. In general, formulae for simple beam theory may be applied to determine the bending stresses. Members are to be considered to have simply supported end connections.

12.8.3.4 The webs of primary members (girders and stringers) are to be adequately stiffened, preferably in a direction perpendicular to the shell plating.

12.9 Scantlings of inner doors

12.9.1 Scantlings of the primary members of inner doors are to be based on the external pressure given in Cl.12.6.1 and permissible stresses given in Cl.12.7.1. Supporting calculations for resultant stresses are to be submitted.

12.9.2 Where inner doors serve as vehicle ramps, scantlings are not to be less than those required for vehicle decks.

12.9.3 Calculations to determine the distribution of forces acting on the securing and supporting devices are to take into account the flexibility of the structure and the actual position and stiffness of the supports and are to be submitted for approval.

12.10 Securing and supporting of bow doors

12.10.1 General

12.10.1.1 Bow doors are to be fitted with adequate means of securing and supporting so as to be commensurate with the strength and stiffness of the surrounding structure. The hull supporting structure in way of the bow doors is to be strengthened for the loads and stresses arising from the securing and supporting devices.

Where packing is required, the packing material is to be of a comparatively soft type, and the supporting forces are to be carried by the steel structure only. Other types of packing may be considered. Maximum design clearance between securing and supporting devices is not generally to exceed 3[mm].

12.10.1.2 Only the active supporting and securing devices having an effective stiffness in the relevant direction are to be included and considered while calculating the reaction forces acting on the devices. Small and/or flexible devices such as cleats intended to provide load compression of the packing material are not generally to be included in the calculations in Cl.12.10.2.3. The number of securing and supporting devices is generally to be the minimum practical whilst taking into account the requirements for redundancy given in Cl.12.5.3.2 and Cl.12.10.2.4 and the space

available for adequate support in the hull structure.

12.10.2 Scantlings

12.10.2.1 Scantlings of securing and supporting devices are to be adequately designed so that they can withstand the reaction forces calculated in Cl.12.5.3.4 and Cl.12.5.4.2, within the permissible stresses given in Cl.12.7.1.

12.10.2.2 The support forces as determined according to Cl.12.5.2.1, Case 1 in Cl.12.5.3.4 and Case 1 in Cl.12.5.4.2 are to generally give rise to a zero moment about the transverse axis through the centroid of the area A_X.

For visor doors, longitudinal reaction forces of pin and/or wedge supports at the door base contributing to this moment are not to be in the forward direction.

12.10.2.3 The distribution of the reaction forces acting on the securing and supporting devices may require to be supported by direct calculations taking into account the flexibility of the hull structure and the actual position and stiffness of the supports.

12.10.2.4 The arrangement of securing and supporting devices is to be designed with redundancy so that in the event of failure of any single securing or supporting device the remaining devices are capable to withstand the reaction forces without exceeding the permissible stresses given in Cl.12.7.1, by more than 20%.

12.10.2.5 For side-opening doors, thrust bearing has to be provided in way of girder ends at the closing of the two leaves to prevent one leaf to shift towards the other one under effect of unsymmetrical pressure (Refer Figure 12.10.2). Each part of the thrust bearing has to be kept secured on the other part by means of securing devices. Any other arrangement serving the same purpose may be proposed.

12.10.2.6 All load transmitting elements in the design load path, from door through securing and supporting devices into the ship structure, including pins, supporting brackets, back-up brackets and welded connections, are to be to the same strength standard as required for the securing end supporting devices.

12.10.2.7 Inner doors are to be gasketed and weathertight.

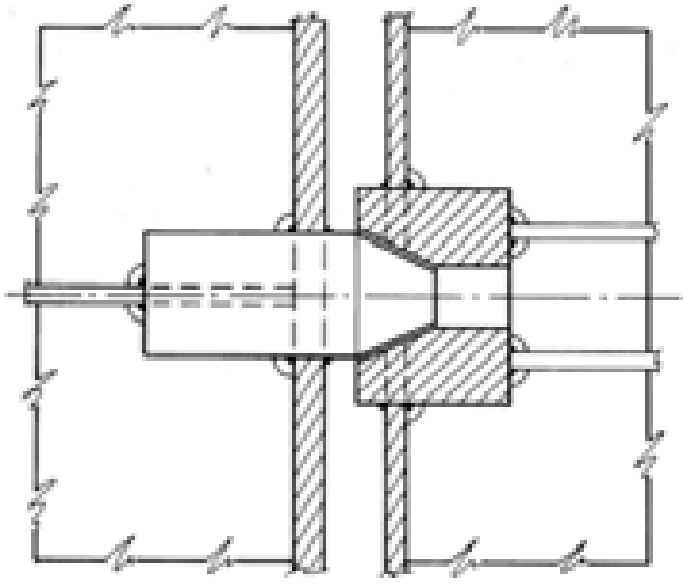

Figure 12.10.2: Thrust bearing

12.11 Securing and locking arrangement

12.11.1 Systems for operation

12.11.1.1 Securing devices are to be simple to operate and easily accessible.

Securing devices are to be equipped with mechanical locking arrangement (self-locking or separate arrangement), or to be of the gravity type.

The opening and closing systems as well as securing and locking devices are to be

interlocked in such a way that they can only operate in the proper sequence.

12.11.1.2 Bow doors and inner doors giving access to vehicle decks are to be provided with an arrangement for remote control of the following from a position above the freeboard deck:

— the closing and opening of the doors, and

— associated securing and locking devices for every door.

Indication of the open/closed position of every door and every securing and locking device is to be available at the remote-control stations.

The operating panels for operation of doors are to be inaccessible to unauthorized persons.

A notice plate, giving instructions to the effect that all securing devices are to be closed and locked before leaving harbour, is to be placed at each operating panel and is to be supplemented by warning indicator lights.

Alternative means of securing are to be provided for emergency use in case of failure of the power systems.

12.11.1.3 Where hydraulic securing devices are applied, the system is to be mechanically lockable in closed position (i.e. in the event of loss of the hydraulic fluid, the securing devices are to remain locked).

The hydraulic system for securing and locking devices is to be isolated from other hydraulic circuits, when in closed position.

12.11.1.4 Securing devices are to be equipped with positive locking arrangements such that the devices are retained in the closed position within design limits of inclination, vibration and other motion-induced or dynamic loads and in the event of loss of any actuating power supply.

12.11.1.5 Means are to be provided to enable the bow doors to be mechanically fixed in the open position taking into account the self-weight of the door and a minimum wind pressure of 1.5[kN/m^2] acting on the maximum projected area in the open position.

12.11.2 Systems for indication/monitoring

12.11.2.1 Separate indicator lights and audible alarms are to be provided on the navigation bridge and on the operating panel to show that the bow door and inner door are closed and that their securing and locking devices are properly positioned.

The indication panel is to be provided with a lamp test function. It shall not be possible to turn off the indicator light.

12.11.2.2 The indicator system is to be designed on the fail-safe principle and is to show by visual alarms if the door is not fully closed and not fully locked and by audible alarms if securing devices become open or locking devices become unsecured.

The power supply for the indicator system is to be independent of the power supply for operating the doors and provided with a back-up power supply from the emergency source of power or other secure power supply such as a UPS.

The sensors of the indicator system are to be protected from water, ice formation and mechanical damages.

12.11.2.3 The indication panel on the navigation bridge is to be equipped with a mode selection function "harbour/sea voyage", so arranged that audible alarm is given on the navigating bridge if vessel leaves harbour with the bow door or inner door not closed and with any of the securing devices not in the correct position.

12.11.2.4 The indicator system is considered designed on the fail-safe principle when the following are satisfied:

• The indication panel is provided with:

— a power failure alarm

— an earth failure alarm

— a lamp test

— separate indication for door closed, door locked, door not closed and door not locked.

• Limit switches electrically closed when the door is closed (when more than one limit switch is provided they may be connected in series).

- Limit switches electrically closed when securing arrangements are in place (when more than one limit switch is provided they may be connected in series).

- Two electrical circuits (may be provided in one multicore cable), one for the indication of door closed/not closed and the other for door locked / not locked.

- In case of dislocation of limit switches, indication to show: not closed / not locked / securing arrangement not in place – as appropriate.

12.11.2.5 A water leakage detection system with audible alarm and CCTV surveillance is to be arranged to provide an indication to the navigation bridge and to the engine control room of leakage through the inner door. The indicator system is considered designed on the fail – safe principle when the requirements of Cl.12.11.2.4 are satisfied.

12.11.2.6 Between the bow door and the inner door a CCTV surveillance system is to be fitted with a monitor on the navigation bridge and in the engine control room.

The system is to monitor the position of doors and a sufficient number of their securing devices.

Special consideration is to be given for lighting and contrasting colour of objects under surveillance. The indicator system is considered designed on the fail – safe principle when the requirements of Cl.12.11.2.4 are satisfied.

12.11.2.7 A drainage system is to be arranged in the area between bow door and ramp, or where no ramp is fitted, between the bow door and inner door.

The system is to be equipped with an audible alarm function to the navigation bridge being set off when the water levels in these areas exceed 0.5[m] above the car deck level or the high water level alarm, whichever is lesser.

12.11.2.8 For ro-ro passenger ships on international voyages, the special category spaces and ro-ro spaces are to be continuously patrolled or monitored by effective means, such as CCTV surveillance, so that any movement of vehicles in adverse weather conditions or unauthorized access by passengers thereto, can be detected whilst the ship is underway.

12.12 Operating and maintenance manual

12.12.1 An Operating and Maintenance Manual for the bow and inner doors is to be provided onboard and contain necessary information on:

12.12.1.1 Main particulars and design drawings

— special safety precautions

— details of vessel

— equipment and design loading (for ramps)

— key plan of equipment (doors and ramps)

— manufacturer's recommended testing for equipment

— description of equipment for

- bow doors
- inner bow doors
- bow ramp/doors
- side doors
- stern doors
- central power pack
- bridge panel
- engine control room panel

12.12.1.2 Service conditions

— limiting heel and trim of ship for loading/unloading

— limiting heel and trim for door operations

— doors/ramps operating instructions

— doors/ramps emergency operating instructions

12.12.1.3 Maintenance and function testing

— schedule and extent of maintenance

— trouble shooting and acceptable clearances

— manufacturer's maintenance procedures

12.12.1.4 Register of inspections, including inspection of locking, securing and supporting devices, repairs and renewals.

12.12.2 Documented operating procedures for closing and securing bow door and inner doors are to be kept on board and posted at the appropriate places.

12.12.3 This Manual has to be submitted for approval to verify that the above-mentioned items are contained in the OMM and that the maintenance part includes the necessary information with regard to inspections, troubleshooting and acceptance / rejection criteria.

Note: It is recommended that recorded inspections of the door supporting and securing devices be carried out by the ship's personnel at monthly intervals or following incidents that could result in damage, including heavy weather or contact in the region of shell doors. A record is to be kept and any damage recorded during such inspections is to be reported to IRS.

Section 13

Ventilators, Air Pipes and Discharges

Symbols

For symbols not defined in this section, Refer to Chapter 1, Section 2.

13.1 General

13.1.1 This section applies to all ships and provides requirements for ventilators, air and sounding pipes and overboard discharges.

13.1.2 The requirements conform, where relevant, to those of the ICLL 1966 as amended by the Protocol of 1988. Reference should also be made to any additional requirements of the National Authority of the country in which the ship is to be registered.

13.2 Definitions

13.2.1 The requirements of ventilators are given with respect to two basic positions – Position 1 and Position 2 as defined in Section 1, Cl.1.2.5.

13.3 Protection

13.3.1 In all cargo spaces and other areas where mechanical damage is likely, all air and sounding pipes, ventilators, scuppers and discharges, including their valves, controls and indicators, are to be well protected. This protection is to be of steel or other equivalent material.

13.4 Strength requirements for fore deck air pipes, ventilator pipes and their closing devices

13.4.1 General

13.4.1.1 The air pipes, ventilators and their closing devices fitted on ships of L ≥ 80[m] on exposed decks in the forward 0.25L are to satisfy the requirements given in Cl.13.4.2 and Cl.13.4.3 if the height of the exposed deck in way of the item is less than 0.1L or 22[m] above the summer load waterline, whichever is the lesser.

However, these requirements need not be applied to cargo tank venting systems and inert gas systems of oil tankers, chemical carriers and liquefied gas carriers.

13.4.2 Design load

13.4.2.1 The green sea pressure 'p' in [kN/m^2] acting on air pipes, ventilators and their closing appliances is to be taken as:

$$p = 0.5\rho V^2 C_d C_s C_p$$

where:

ρ = Density of sea water (1.025 t/m^3)

V = Velocity of water in [m/sec], over the fore deck

= 13.5 for $d \leq 0.5d_1$

= $13.5\sqrt{2\left(1-(d/d_1)\right)}$ for $0.5d_1 < d \leq d_1$

d = Distance in [m], from summer load waterline to exposed deck

d_1 = 0.1L or 22[m] whichever is the lesser

C_d = Shape coefficient

= 0.5 for pipes

= 1.3 for air pipe or ventilator heads in general

= 0.8 for an air pipe or ventilator head of cylindrical form with its axis in the vertical direction.

C_s = Slamming coefficient = 3.2

C_p = Protection coefficient

= 0.7 for pipes and ventilator heads located immediately behind a breakwater or forecastle

= 1.0 elsewhere and immediately behind a bulwark.

13.4.2.2 Forces acting in the horizontal direction on the pipe and its closing device are to be calculated using pressure 'p' and the largest projected area of each component.

13.4.3 Strength criteria

13.4.3.1 Bending moment and stresses: Bending moments and stresses in air pipes and ventilator pipes are to be calculated at critical positions, such as at penetration pieces, weld or flange connections, and toes of supporting brackets. Bending stresses considering the net section (after deduction of 2.0[mm] from the pipes thickness), irrespective of the corrosion protection provided are not to exceed $0.8\sigma_y$, where σ_y is the specified minimum upper yield stress or 0.2% proof stress of the steel at room temperature.

13.4.3.2 Ventilators: For standard ventilators of 900[mm] height closed by heads of not more than the tabulated projected area, the applicable pipe thicknesses and bracket heights are specified in Table 13.4.3.1.

13.4.3.3 For ventilators of height greater than 900[mm], brackets or alternative means of support are to be fitted. Pipe gross thickness is not be taken less than as required in Table 13.4.3.1.

13.4.3.4 For standard air pipes of height 760[mm] closed by heads of not more than the tabulated projected area, the applicable pipe thicknesses and bracket heights are specified in Table 13.4.3.2.

13.4.3.5 For other configurations of air pipes and ventilators, loads according to Cl.13.4.2 are to be applied and means of support determined in order to comply with the requirements of Cl.13.4.3.1.

13.4.3.6 Where brackets are specified for supporting the air pipe or ventilator, three or more radial brackets are to be fitted. These brackets are to have gross thickness of at least 8[mm], minimum length 100[mm] and height according to Table 13.4.3.1 or Table 13.4.3.2 as applicable but need not extend over the joint flange for the head. Bracket toes at the deck are to be suitably supported.

13.4.3.7 Components and Connections: All component parts and connections of the air pipe or ventilator are to be capable of withstanding the green sea pressure 'p' given in Cl.13.4.2.

13.4.3.8 Rotary Heads: Rotating type mushroom ventilator heads are unsuitable for application in the location defined in Cl.13.4.1.1. Screw down type mushroom ventilators may be used in such locations.

Table 13.4.3.1: 900[mm][(a)] ventilator pipe gross thickness and bracket standards			
Standard ventilator details			**Required Height[(b)] of brackets [mm]**
Nominal pipe diameter [mm]	**Minimum fitted gross thickness, [mm]**	**Maximum projected area of head [cm^2]**	
80A	6.3	-	460
100A	7.0	-	380
150A	8.5	-	300
200A	8.5	550	-
250A	8.5	880	-
300A	8.5	1200	-
350A	8.5	2000	-
400A	8.5	2700	-
450A	8.5	3300	-
500A	8.5	4000	-
Notes: (a) For other ventilator heights, the relevant requirements of Cl.13.4.2 and Cl.13.4.3 are to be applied. (b) Brackets need not extend over the joint flange for the head.			

Table 13.4.3.2: 760[mm][(1)] air pipe thickness and bracket standards			
Standard air pipe details			**Required Height[(2)] of brackets [mm]**
Nominal pipe diameter [mm]	**Minimum fitted gross thickness, [mm]**	**Maximum projected area of head [cm^2]**	
65A	6.0	-	480
80A	6.3	-	460
100A	7.0	-	380
125A	7.8	-	300
150A	8.5	-	300
175A	8.5	-	300
200A	8.5[(3)]	1900	300[(3)]
250A	8.5[(3)]	2500	300[(3)]
300A	8.5[(3)]	3200	300[(3)]
350A	8.5[(3)]	3800	300[(3)]
400A	8.5[(3)]	4500	300[(3)]
Notes: (1) For other pipe heights, the relevant requirements of Cl.13.4.2 and Cl.13.4.3 are to be applied. (2) Brackets need not extend over the joint flange for the head. (3) Brackets need not be provided if the as fitted gross thickness of air pipes is not less than 10.5[mm].			

13.5 Ventilators

13.5.1 General

13.5.1.1 Ventilators located on the exposed deck over the forward 0.25L of the rule length, of ships of length 80[m] or more, where the height of the exposed deck in way of the item is less than 0.1L or 22[m] above the summer load waterline, whichever is the lesser, are to comply with the requirements of 13.4. All other ventilators are to comply with the following requirements.

13.5.1.2 Ventilators in position 1 or 2 to spaces below freeboard deck or decks of enclosed superstructures are to have coamings of steel or other equivalent material, substantially constructed and efficiently connected to the deck. Where the coaming of any ventilator exceeds 900[mm] in height it is to be specially supported.

13.5.1.3 Ventilators passing through superstructures other than enclosed superstructures are to have substantially constructed coamings of steel or other equivalent material at the freeboard deck.

13.5.1.4 Special care is to be taken in the design and positioning of ventilator openings and coamings, particularly in the region of the forward end of superstructures and other points of high stress. The deck plating in way of the coamings is to be efficiently stiffened.

13.5.1.5 Ventilators from deep tanks and tunnels passing through 'tween decks are to have scantlings suitable for withstanding the pressures to which they may be subjected, and are to be made watertight.

13.5.1.6 For the requirements of fire precautions on cargo and passenger ships, Refer Part 6, Chapter 2, Section 2.

13.5.2 Coamings

13.5.2.1 The height of ventilator coamings exposed to the weather is to be not less than:

— 900[mm] in position 1

— 760[mm] in position 2

these heights being measured above deck sheathing where fitted.

13.5.2.2 The height of ventilator coamings may be required to be increased on ships of Type 'A', Type 'B-100' and Type 'B-60' where this is shown to be necessary by the floatability criterion required by the ICLL 1966 as amended by the Protocol of 1988.

13.5.2.3 The minimum wall gross thickness of ventilator coamings in position 1 and 2 leading to spaces below the freeboard deck or to spaces within enclosed superstructures, are not to be less than those obtained from Table 13.5.2.

Table 13.5.2: Minimum wall gross thickness of ventilator coamings

Location	External diameter[mm]	Gross thickness[mm]
Position 1 and 2	≤ 80	6.0
	≥ 165	8.5
Above position 2	≤ 155	4.5
	≥ 230	6.0
Note: The thickness for intermediate diameters may be obtained by interpolation.		

13.5.2.4 Where the height of the ventilator exceeds that required by 13.5.2.1, the thickness given in Table 13.5.2 may be gradually reduced, above the required minimum height, to a minimum of 6.0[mm]. The ventilator is to be adequately stayed.

13.5.2.5 For gooseneck ventilators, the coaming height is to be measured to the underside of the bend, this being the lowest point through which water on deck could pass freely to spaces below.

13.5.2.6 Where wall vents are fitted with an internal baffle which rises above the lower edge of the exterior opening, the coaming height is measured to the top of the baffle.

13.5.3 Closing appliances

13.5.3.1 All ventilator openings are to be provided with efficient weathertight closing appliances except where:-

— the height of the coaming is greater than 4.5[m] in position 1, or

— the height of the coaming is greater than 2.3[m] in position 2

in which case closing appliances need not be provided unless unusual features of design make it necessary.

13.5.3.2 The weathertight closing appliance for all ventilators in positions 1 and 2 are to be of steel or other equivalent materials. Wood plugs and canvas covers are not acceptable in these positions.

13.5.3.3 In general, ventilators which are necessary to continuously supply the machinery space and on demand, immediately supply the emergency generator room, should have coamings with sufficient heights specified in Cl.13.5.3.1, without having to fit weathertight closing appliances.

However, where due to vessel size and arrangement this is not practicable, lesser heights for machinery space and emergency generator room ventilator coamings may be considered with provision of weathertight closing appliances in combination with other suitable arrangements to ensure an uninterrupted, adequate supply of ventilation to these spaces.

13.5.3.4 In ships where the load line length, L_L, is not more than 100[m], the closing appliances are to be permanently attached to the ventilator coaming. Whereas in other ships, they may be conveniently stowed near the ventilator to which they are to be fitted.

13.5.3.5 Where, in ferries, ventilators are proposed to be led overboard in an enclosed 'tween deck' the closing arrangements are to be submitted for approval. If such ventilators are led overboard more than 4.5[m] above the main vehicle deck, closing appliances may be omitted, provided that satisfactory baffles and drainage arrangements are provided, as in the case of air intakes or exhaust openings for machinery spaces, which may be arranged in the sides of the ship.

13.5.3.6 On offshore supply ships, to ensure satisfactory operation in all weather conditions, machinery space ventilation inlets and outlets are to be located in such positions that closing appliances will not be necessary.

13.5.3.7 The height of ventilators may be required to be increased depending on where the flooding points in relation to the damaged waterline in the stability calculation.

13.5.3.8 Watertight ventilators and trunks is to be carried at least up to the bulkhead deck in passenger ships and up to the freeboard deck in cargo ships.

13.5.3.9 Where permitted by the National Authority, ventilator coaming heights may be reduced on ships engaged on sheltered water service or restricted water service.

13.6 Air and Sounding pipes

13.6.1 General

13.6.1.1 Air and sounding pipes are to comply with the requirements of Part 4, Chapter 2.

13.6.1.2 Striking plates of suitable thickness, or their equivalent, are to be fitted under all sounding pipes.

13.6.1.3 On offshore supply ships, air pipes are to be situated clear of the cargo containment areas.

13.6.1.4 The venting systems of cargo tanks are to be entirely separated from the air pipes of the other compartments of the ship.

13.6.1.5 All air pipes in cargo spaces are to be well protected.

13.6.2 Height of air pipes

13.6.2.1 The height of air pipes from the upper surface of decks exposed to the weather, to the point where water may have access below is not normally to be less than:

- 760 [mm] on freeboard deck

- 450 [mm] on superstructure decks

these heights being measured above deck sheathing, where fitted. Air pipes with height exceeding 900[mm] are to be additionally supported.

13.6.2.2 Lower heights may be approved in cases where these are essential for the working of the ship, provided that the design and arrangements are otherwise satisfactory. In such cases, efficient, permanently attached closing appliances of an approved automatic type will generally be required.

13.6.2.3 The height of air pipes may be required to be increased on ships of Type 'A', Type 'B-100' and Type 'B-60' where this is shown to be necessary by the floatability calculations required by the ICLL 1966 as amended by the Protocol of 1988.

13.6.2.4 Air pipes are generally to be led to an exposed deck, but alternative arrangements will be considered in the case of ferries where such an arrangement is not practicable.

13.6.2.5 Where air pipes are led through the side of superstructures, the opening is to be at least 2.3[m] above the summer load waterline. Automatic vent heads of approved design are to be provided.

13.6.2.6 The minimum wall gross thickness of air pipe in positions defined in Cl.13.6.2.1 is to be:

• 6.0[mm] for pipes of 80[mm] external diameter or smaller;

• 8.5[mm] for pipes of 165[mm] external diameter or greater.

Intermediate minimum thicknesses are to be determined by linear interpolation.

For other positions not mentioned in Cl.13.6.2.1:

• 4.5[mm] for pipes of 155[mm] external diameter or smaller;

• 6.0[mm] for pipes of 230[mm] external diameter or greater.

Intermediate minimum thicknesses are to be determined by linear interpolation.

13.6.2.7 Where permitted by the National Authority, air pipe coaming heights may be reduced on ships engaged on sheltered water service or restricted water service.

13.6.3 Closing appliances

13.6.3.1 All openings of air and sounding pipes are to be provided with permanently attached, satisfactory means of closing to prevent the free entry of water.

13.6.3.2 Air pipe closing devices are to be of an approved type and so designed that they withstand both ambient and working conditions and be suitable for use at inclinations up to and including 40^{o}.

13.6.3.3 Wooden plugs and trailing canvas hoses are not accepted in Freeboard deck and Superstructure deck.

13.6.3.4 Closing devices shall be automatic if, while the vessel is at its draught corresponding to summer load line, the openings of air pipes to which these closures are fitted submerge at angles up to 40° or up to a lesser angle which may be agreed on the basis of stability requirements. Pressure-vacuum valves (P-V valves) may however, be accepted on tankers.

13.6.3.5 An automatic closing device is to:

• Prevent the free entry of water into the tanks,

• Allow the passage of air or liquid to prevent excessive pressure or vacuum developing in the tank.

13.6.3.6 Air pipe closing devices are to be so constructed as to allow inspection of the closure and the inside of the casing as well as changing of the seals.

13.6.3.7 Efficient ball or float seating arrangements are to be provided for the closures, where fitted. Bars, cage or other devices are to be provided to prevent the ball or float from contacting the inner chamber in its normal state and made in such a way that the ball or float is not damaged when subjected to water impact due to a tank being overfilled.

13.6.3.8 The clear area through an air pipe closing device is to be at least equal to the area of the inlet. Air pipe closing devices are to be self draining.

13.6.3.9 In the case of air pipe closing devices of the float type, suitable guides are to be provided to ensure unobstructed operation. The maximum allowable tolerances for wall thickness of ball floats are not to exceed 10% of the nominal thickness.

13.6.3.10 Casings of air pipe closing devices are to be of approved metallic materials adequately protected against corrosion. The inner and the outer chambers of an automatic air pipe head is to be of a minimum thickness of 6[mm]. Where side covers are provided and their function is integral to providing functions of the closing device as outlined in Cl.13.6.3.5, they are to have a minimum wall thickness of

6[mm]. If the air pipe head can meet the type approval tightness test requirement without the side covers attached, then the side covers are not considered to be integral to the closing device, in which case a wall thickness less than 6[mm] can be considered acceptable for side covers.

13.6.3.11 For galvanized steel air pipe heads, the zinc coating is to be applied by the hot method and the coating thickness is to be 70 to 100 microns. For areas of the head susceptible to erosion (e.g. those parts directly subjected to ballast water impact when the tank is being pressed up, for example the inner chamber area above the air pipe, plus an overlap of 10 ^{o} or more on either side) an additional harder coating such as aluminium bearing epoxy coating or equivalent, is to be applied over the zinc coating.

13.6.3.12 Closures and seats made of non-metallic materials are to be compatible with the media intended to be carried in the tank at temperatures between -25^{o}C and 85^{o}C and sea water.

13.6.3.13 For ships assigned timber freeboards, the air pipes should be provided with automatic closing appliances.

13.7 Scuppers, Inlets and Sanitary Discharges

13.7.1 General

13.7.1.1 Scuppers sufficient in number and size to provide effective drainage are to be fitted in all decks.

13.7.1.2 Scuppers draining weather decks and spaces within superstructures or deckhouses not fitted with efficient weathertight doors are to be led overboard.

13.7.1.3 Scuppers and discharges which drain spaces below the freeboard deck, or spaces within intact superstructures or deckhouses on the freeboard deck fitted with efficient weathertight doors, may be led to the bilges in the case of scuppers.

Alternatively, they may be led overboard provided that the spaces drained are above the load waterline, and the pipes are fitted with efficient and accessible means of preventing water from passing inboard.

13.7.1.4 The drainage arrangements of enclosed 'tween deck spaces in ships with small freeboards are to be specially considered.

13.7.1.5 In the enclosed 'tween deck space on the main vehicle deck of a ferry, which is provided with a drencher fire extinguishing system, scuppers of not less than 150[mm] diameter are to be provided port and starboard, spaced about 9.0[m] apart. The capacity of the scuppers may be required to be increased, dependent on the discharge rate of the drencher system. The mouth of the scupper is to be protected by bars.

13.7.1.6 If a 'tween deck space on the main vehicle deck of a ferry is not totally enclosed, scuppers or freeing ports are to be provided consistent with the requirements of Chapter 7.

13.7.1.7 The following will apply to drainage of enclosed cargo spaces on the bulkhead deck of passenger ships or on the freeboard deck of cargo ships:

• Where the freeboard to the bulkhead deck or the freeboard deck, respectively, is such that the deck edge is immersed when the ship heels more than 5[deg.] the drainage shall be by means of a sufficient number of scuppers of suitable size discharging directly overboard.

• Where the freeboard is such that the edge of the bulkhead deck or the edge of the freeboard deck, respectively, is immersed when the ship heels 5[deg.] or less, the drainage shall be led to a suitable space of adequate capacity, having a high water level alarm and provided with suitable arrangements for discharge overboard.

13.7.1.8 For drainage arrangements of closed vehicle and ro-ro spaces and special category spaces, refer to Part 6, Chapter 7, Cl.3.6.1.4 and Cl.3.6.1.5.

13.7.1.9 Scuppers and discharge pipes should not normally pass through fuel oil or cargo oil tanks. Where scuppers and discharge pipes pass, unavoidably, through fuel oil or cargo oil tanks, and are led through the shell within the tanks, the thickness of the piping should be at least the same thickness as Rule shell plating in way, derived from the appropriate Chapters, but need not exceed 19[mm]. Piping within tanks is to be tested in accordance with Part 4, Chapter 2 and Chapter 3.

13.7.1.10 All piping is to be adequately supported.

13.7.1.11 Where scuppers are carried through watertight bulkheads, arrangements are to be made to ensure the watertight integrity of the bulkheads.

13.7.1.12 For the use of non-metallic pipe, Refer Part 4, Chapter 2, Section 5.

13.7.2 Closing appliances

13.7.2.1 Discharges led through the shell either from spaces below the freeboard deck or from within superstructures and deckhouses on the freeboard deck fitted with doors complying with the requirements given in Section 2, Cl.2.2.1.1, is to be fitted with efficient and accessible means for preventing water from passing inboard. Normally each separate discharge shall have one automatic non-return valve with a positive means of closing it from a position above the freeboard deck. The means for operating the positive action valve shall be readily accessible and provided with an indicator showing whether the valve is open or closed.

It is considered that an acceptable equivalent to an automatic non-return valve with a positive means of closing from a position above the freeboard deck would be one automatic non-return valve and one sluice valve controlled from above the freeboard deck.

Where sanitary discharges and scuppers lead overboard through the shell in way of machinery spaces, the fitting to shell of a locally operated closing valve, together with non-return valve inboard, is considered to provide protection equivalent to above. The controls of the valves is to be in an easily accessible position.

13.7.2.2 Where the vertical distance from the summer load waterline to the inboard end of the discharge pipe exceeds $0.01L_L$, the discharge may be fitted with two automatic non-return valves without positive means of closing, instead of automatic non-return valve with a positive means of closing, provided that the inboard valve is always accessible for examination under service conditions i.e. the inboard valve should be above the level of the tropical load waterline.

If this is not practicable, then, provided a locally controlled sluice valve is interposed between the two automatic non-return valves, the inboard valve need not be fitted above the LWL.

13.7.2.3 Where the vertical distance from the summer load waterline to the inboard end of the discharge pipe exceeds $0.02L_L$, a single automatic non-return valve without positive means of closing may be fitted. Refer Figure 13.7.2.

13.7.2.4 It is considered that the requirements for non-return valves are applicable only to those discharges which remain open during the normal operation of the vessel. For discharges which must necessarily be closed at sea, such as gravity drains from topside ballast tanks, a single screw down valve operated from the deck is sufficient.

The inboard end of a gravity discharge which leads overboard from an enclosed superstructure or space is to be located above the waterline formed by a 5 degree heel, to port or starboard, at a draft corresponding to be assigned summer freeboard.

13.7.2.5 In a ship to which timber freeboards are assigned, the summer load waterline is to be regarded as that corresponding to the timber summer freeboard and the position of the inboard end of discharges is to be regarded as that of timber summer load waterline.

13.7.2.6 Where in an enclosed tween deck space on the main vehicle deck of a ferry, a drencher fire extinguishing system is provided, discharge valve controls are to be operable from spaces above the main vehicle deck and to be protected from mechanical damage.

13.7.2.7 Scuppers and discharge pipes originating at any level which penetrate the shell either more than 450[mm] below the freeboard deck or less than 600[mm] above the summer load waterline, are to be fitted with an automatic non-return valve at the shell. This valve, unless required by Cl.13.7.1.3, may be omitted provided that the pipe is of substantial thickness. Refer Part 4, Chapter 3, Section 3.5.2. However, the thickness need not exceed 12.5[mm], unless greater thickness is required by Cl.13.7.1.8.

13.7.2.8 If, in association with Cl.13.7.1.8, a valve is required by Cl.13.7.1.3, this valve should preferably be fitted as close as possible to the point of entry of the pipe into the tank. If fitted below the freeboard deck, the valve is to be capable of being controlled from an easily

accessible position above the freeboard deck. Local control is also to be arranged, unless the valve is inaccessible. An indicator is to be fitted at the control position showing whether the valve is open or closed

13.7.2.9 Discharges with inboard opening located lower than the ship's uppermost load line may be accepted when a loop of the pipe is arranged between the inboard opening and the outlet in hull. The top of the loop is regarded as the position of the inboard opening, and the pipeline is provided with valves according to Figure 13.7.2.

Refer Figure 13.7.2 for the acceptable arrangements of scuppers, inlets and discharges.

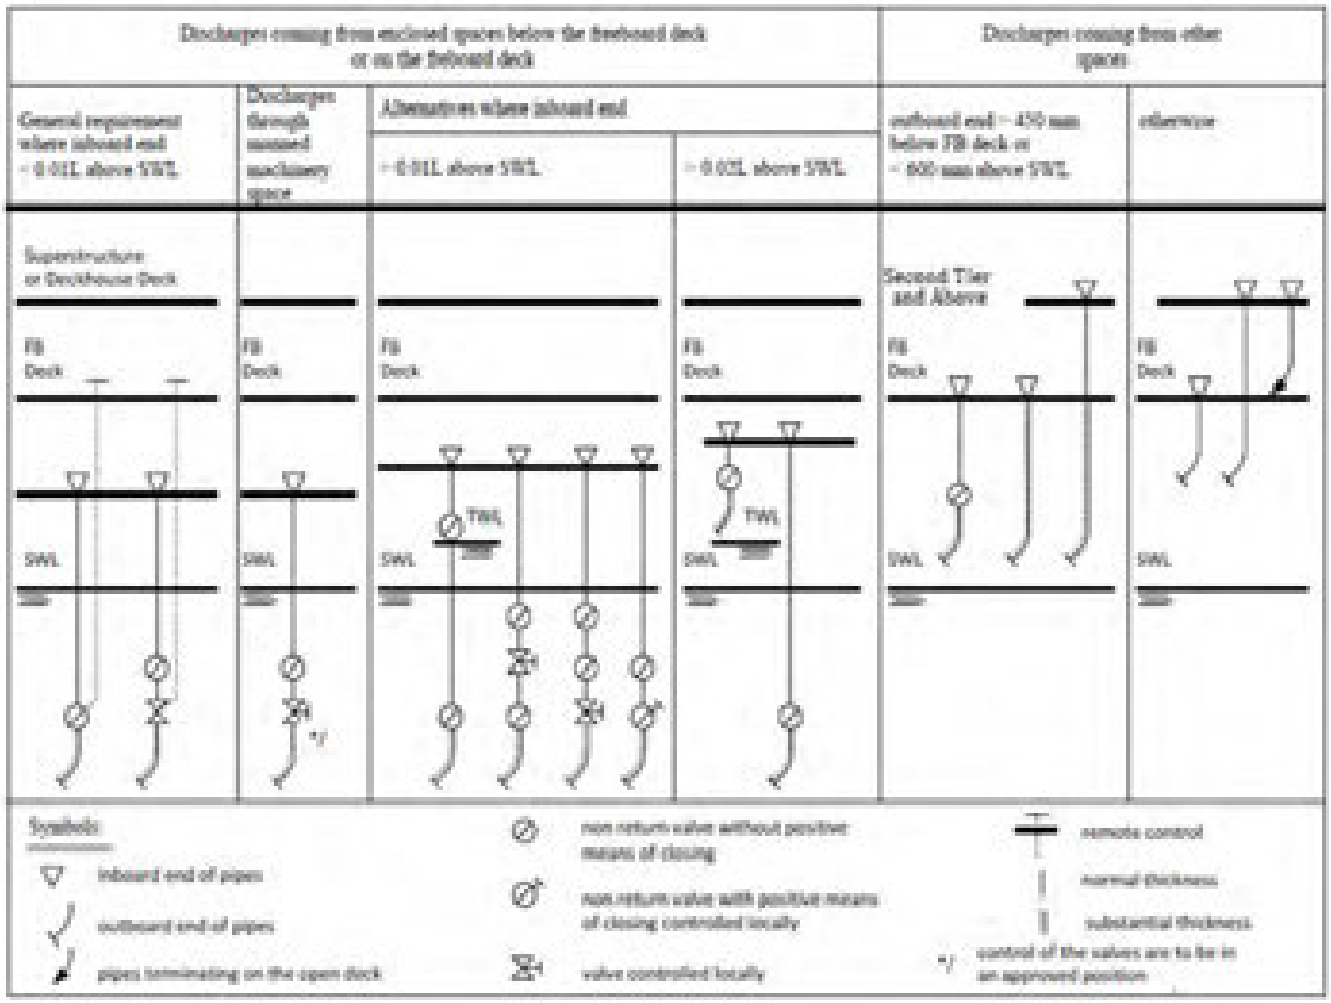

Figure 13.7.2: Discharge Valve Requirements

13.8 Materials for valves, fittings and pipes

13.8.1 All shell fittings, pipes and the valves required by Cl.13.7.2 are to be of steel, bronze or other approved ductile material. Valves of ordinary cast iron or similar material are not acceptable. Materials are to satisfy the requirements of Part 2.

13.8.2 All these items, if made of steel or other approved material with low corrosion resistance, are to be suitably protected against wastage.

13.8.3 The lengths of pipe attached to the shell fittings, elbow pieces or valves are to be of galvanized steel or other equivalent approved material.

13.8.4 Where plastic pipes are used for sanitary discharges and scuppers, they are also subject to the requirement of Figure 13.7.2, and the valve at the shell is to be operated from outside the space in which the valve is located.

Where such plastic pipes are located below the summer waterline, the valve is to be operated

from a position above freeboard deck. The portion of discharge line from the shell to the first valve as well as shell fittings and valves shall be of steel; bronze or other approved ductile material.

The approval of plastic piping in any location will be subject to the consideration of strength and fire hazards involved with special reference to penetrations through bulkheads, decks or other significant compartment boundaries. Attention must be paid to valid fire technical regulations.

13.9 Garbage chutes

13.9.1 General

13.9.1.1 For garbage chutes an acceptable equivalent to the non-return valve with a positive means of closing from a position above the freeboard deck would be two gate valves controlled from the working deck of the chute.

The lowest gate valve should, in addition, be controlled from a position above the freeboard deck. An interlock system is to be arranged between the two valves. The distance between the two gate valves is to be adequate to allow the smooth operation of the interlock system.

13.9.1.2 It is recommended that the inboard end of the garbage chute be located above the waterline formed by an 8.5 deg heel, to port or starboard, at a draft corresponding to the assigned summer freeboard, but not less than 1000[mm] above the summer waterline.

13.9.1.3 Where the inboard end of the garbage chute exceeds $0.01L_L$ above the summer waterline, valve control from the freeboard deck is not required, provided the inboard gate valve is always accessible under service conditions.

13.9.1.4 Alternatively, the upper and lower gate valves may be replaced by a hinged weathertight cover at the inboard end of the chute together with a discharge flap. The cover and the flap are to be arranged with an interlock so that the discharge flap cannot be operated until the hopper cover is closed.

13.9.1.5 The entire chute, including the cover is to be constructed of material of substantial thickness (Refer Part 4, Chapter 3, Section 3.5).

13.9.1.6 The gate valve controls and/or hinged cover are to be clearly marked: “Keep closed when not in use”.

13.9.1.7 Where the inboard end of the chute is below the freeboard deck of a passenger ship or the equilibrium waterlines of a cargo ship to which damage stability requirements apply, then:

— the inboard end hinged cover/valve is to be watertight

— the valve is to be a screw-down non-return valve fitted in an easily accessible position above the deepest load line; and

— the screw-down non-return valve is to be controlled from a position above the bulkhead deck and provided with open/closed indicators. The valve control shall be clearly marked: "Keep closed when not in use".

Section 1

General

1.1 Scope

1.1.1 The requirements of this Chapter apply to arrangement and scantlings of normal streamlined or plate rudders and their supporting structure. Rudders fitted with special features e.g. special profiles, fins, flaps, steering propellers etc. to increase the lift force will be specially considered.

1.1.2 IRS may accept alternatives to requirements given in this Chapter, provided they are deemed to be equivalent.

1.1.3 Direct analyses adopted to justify an alternative design are to take into consideration all relevant modes of failure, on a case by case basis. These failure modes may include, amongst others: yielding, fatigue, buckling and fracture. Possible damages caused by cavitation are also to be considered.

1.1.4 Lab tests, or full scale tests may be requested to validate the alternative design approach, if deemed necessary by IRS,

1.1.5 Additional requirements for various Ice Class notations are given in Pt.5, Ch.21.

1.2 Material

1.2.1 All materials used in the construction of the rudder are to be tested and approved in accordance with Pt.2.

1.2.2 Material grades for plates and sections for the rudder blade are to be selected as per Pt.3, Ch.2.

1.2.3 For rudder stocks, pintles, keys and bolts, the specified minimum yield stress is not to be less than 200 [N/mm^2]. For materials having a specified yield stress differing from 235 [N/mm^2], material factor 'k' as determined below, is to be applied.

$$k = \left(\frac{235}{R_{eH}}\right)^e$$

with e = 0.75 for R_{eH}> 235 [N/mm^2]

= 1.0 for $R_{eH} \leq 235$ [N/mm^2]

R_{eH} = specified minimum yield stress of the material used, but not to be taken greater than 0.7 σ_u or 450 [N/mm^2] whichever is smaller;

where σ_u is the tensile strength [N/mm^2] of the material.

Where high strength steels are used for rudder stock, evaluation of stock deformations may be required, as large deformations can cause excessive edge pressures in way of bearings.

1.2.4 Bearing materials for bushings are to be stainless steel, bronze, white metal, synthetic material or lignum vitae. If stainless steel is proposed to be used for liners or bushes for the rudder stocks and pintles, the chemical composition is to be submitted for approval. Hardness of the material of the bushing is to be at least 65 Brinell lower than that of the liner or the rudder stock or pintle.

Synthetic bush materials are to be of approved type. Arrangement is to be provided for adequate supply of sea-water to these bearings.

1.3 Testing

1.3.1 Bodies of the rudders are to be tested in accordance with the requirements given in Ch.18.

Section 2

Arrangement and Details

2.1 General

2.1.1 Various types of rudder arrangement are shown in Fig.2.1.1, other combinations of couplings and bearings may however be proposed.

2.1.2 Effective means are to be provided for supporting the weight of the rudder. Where the support is provided by a carrier bearing attached to the rudder head, the structure in way of the bearing is to be adequately strengthened. The plating under all rudder head bearings or rudder carriers is to be increased in thickness.

2.1.3 All rudder bearings are to be accessible for measuring wear without lifting or unshipping the rudder.

2.1.4 Satisfactory arrangement is to be provided to prevent water from entering the steering gear compartment and lubricant from being washed away from the rudder carrier. A seal or stuffing box is to be fitted above the water line at scantling draught (without trim), for this purpose, however two separate watertight seals or stuffing boxes are to be provided when the top of the rudder trunk is below the water line at scantling draught (without trim).

2.1.5 Suitable arrangement is to be provided to prevent the rudder from lifting and accidental unshipping.

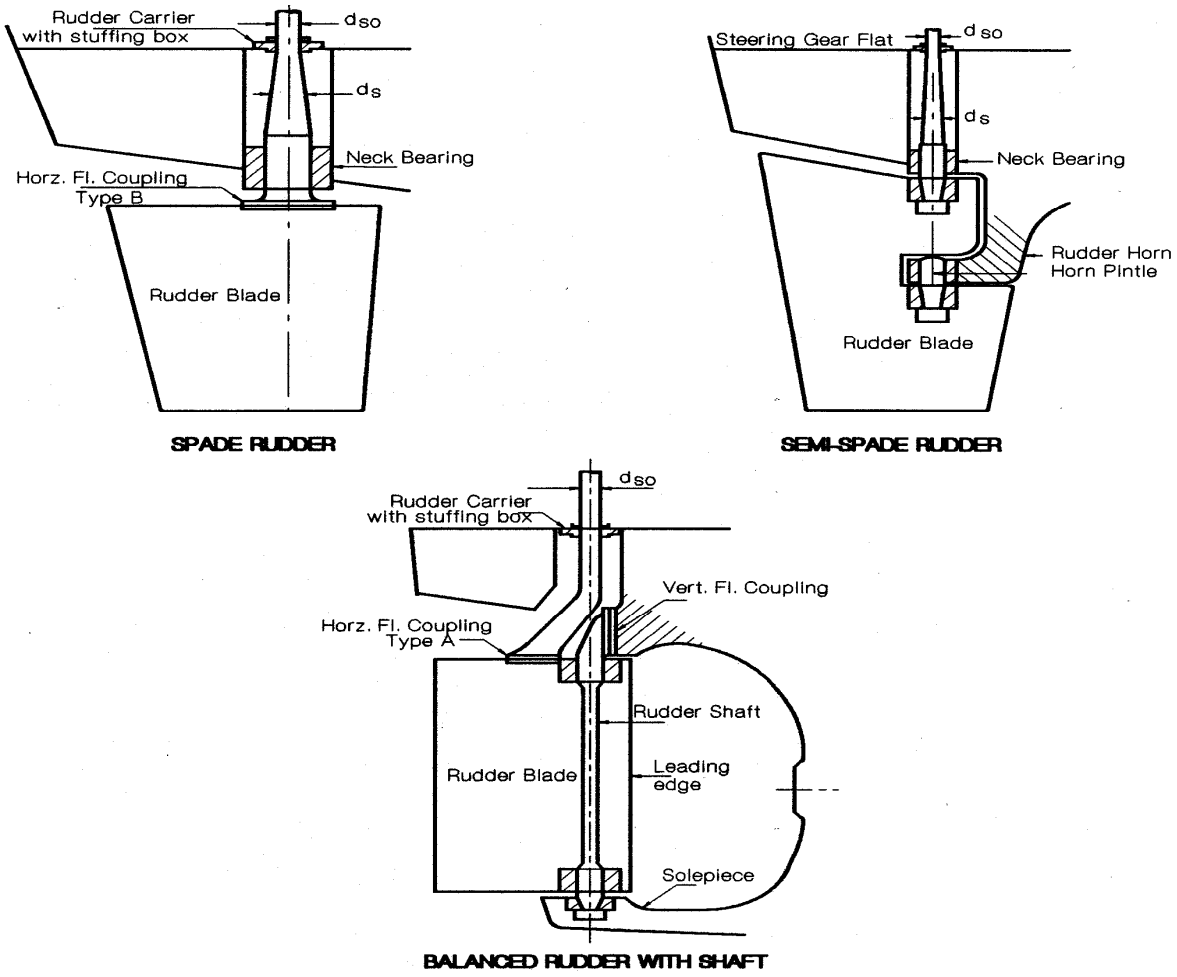

Fig.2.1.1 : Types of rudders

Section 3

Design Loads

3.1 Rudder force

3.1.1 The rudder force upon which rudder scantlings are to be based is to be determined from the following formula:

$F_r = 132 \cdot K_1 \cdot K_2 \cdot K_3 \cdot A \cdot V^2$ [N]

where,

F_r = rudder force [N]

A = area of rudder blade [m^2]

V = Design speed (knots), with vessel running ahead at maximum continuous rated shaft rpm and at the summer load waterline. Special consideration will be given to ships designed to operate at higher speed at a lower draft, and with full immersion of rudder. When the speed is less than 10 knots, V is to be replaced by the expression.

$V_{min} = (V + 20)/3$

For astern condition, the maximum astern speed as defined in SOLAS Regulation II-1/3.15 is to be used, but in no case taken less than:

$V_{astern} = 0.5V$

K_1 = factor based on the aspect ratio, λ of the rudder area;

$K_1 = (\lambda + 2)/3$; with λ not to be taken greater than 2.

$\lambda = b^2/A_t$; where b is the mean height of the rudder area [m] and At, the sum of rudder blade area and area of rudder post or rudder horn, if any, within the height b [m^2]

Mean breadth C [m] and mean height b [m] of rudder are calculated according to the co-ordinate system in Fig.3.1.1.

K_2 = Factor depending on type of the rudder and the rudder profile as per Table 3.1.1.

K_3 = 0.80 for rudders outside the propeller jet

= 1.15 for rudders behind a fixed propeller nozzle

= 1.0 otherwise.

As per Fig, 3.1.1,

$C = \frac{x_2+x_3-x_1}{2}$; Mean Breadth of Rudder

$b = \frac{z_3+z_4-z_2}{2}$; Mean Height of Rudder

Table 3.1.1

Profile Type	K_2	
	Ahead condition	**Astern condition**
NACA-00 series Göttingen 	1.10	0.80
Flat side 	1.10	0.90
Hollow	1.35	0.90
High lift rudders 	1.70*	1.30
Fish tail 	1.40	0.80
Single plate 	1.00	1.00
Mixed profiles (e.g. HSVA)	1.21	0.90

Note :
***** In the case of flap rudder, K_2 values determined by direct calculation methods taking into account geometry of rudder and flap and their angles of turn may be accepted as an alternative to the value indicated in the Table.

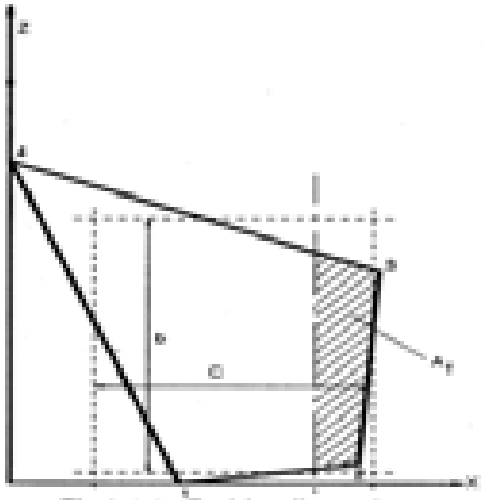

Fig.3.1.1 : Rudder dimensions

3.2 Rudder torque

3.2.1 The rudder torque on regular shaped rudders in both the ahead and astern conditions of travel is to be calculated as follows:

$$Q_r = F_r \cdot r \text{ [N-m]};$$

where,

$r = x_c - f$ [m];

for ahead condition, r is not to be taken less than 0.1C

x_c = the distance of the point of application of the design force F_r from the leading edge

= 0.33 C in ahead condition

= 0.66 C in astern condition.

C = Mean breadth of rudder area [m] See Fig.3.1.1.

$f = C \cdot A_f/A$ where A_f is the portion of the rudder blade area situated ahead of the centre line of the rudder stock.

3.2.2 In case of rudder blades with stepped contours / semi-spade rudders, the total rudder torque is to be obtained as follows:

$$Q_r = \Sigma Q_{ri} \text{ for } i = 1,2,3,.....$$

where,

$Q_{ri} = F_{ri}.r_i$; individual torque component from each part A_i of the total rudder area. See Fig.3.2.2.

The rudder area may be divided into two rectangular or trapezoidal parts with areas A_1 and A_2, so that $A = A_1 + A_2$

A_{1a} = portion of A_1 situated aft of the centre line of the rudder stock.
A_{1f} = portion of A_1 situated ahead of the centre line of the rudder stock.
A_{2a} = portion of A_2 situated aft of the centre line of the rudder stock.
A_{2f} = portion of A_2 situated ahead of the centre line of the rudder stock.

$F_{ri} = F_r . A_i/A$

$r_i = x_{ci} - f_i$; but not to be taken less than $0.1 C_i$.

where,

$f_i = C_i . A_{if}/A_i$

x_{ci}, f_i , A_{if} and C_i are to be taken as x_c, f, A_f and C as in 3.2.1 for each discrete part except that for those rudder parts immediately aft of rudder horn x_{ci} is to be taken as $0.25C_i$ and $0.55C_i$ in ahead and astern conditions respectively.

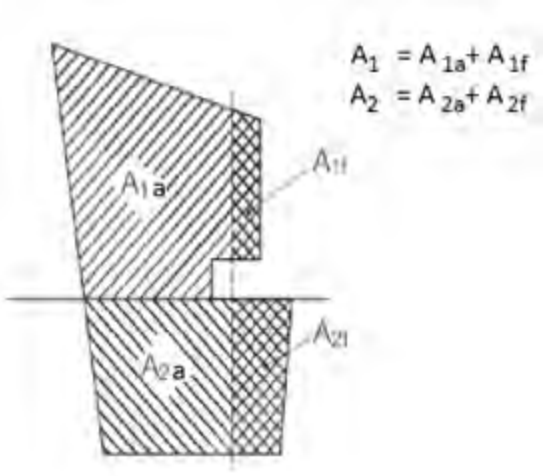

Fig. 3.2.2. Rudder area distribution

3.3 Rudder Strength Calculations

3.3.1 The rudder force and resulting rudder torque as given in 3.1 and 3.2 causes bending

moments and shear forces in the rudder body, bending moments and torques in the rudder stock, supporting forces in pintle bearings and rudder stock bearings and bending moments, shear forces and torques in rudder horns and heel pieces. The rudder body is to be stiffened by horizontal and vertical webs enabling it to act as a bending girder.

3.3.2 The bending moment (BM) and shear force (SF) distributions along the entire height of the rudder blade and rudder stock as well as the bearing reactions may be obtained by direct calculation. The rudder is to be assumed as simply supported at the centres of the upper bearing and the neck bearing. In case of rudders supported by the sole piece or rudder horn the flexibility of the sole piece or rudder horn, and rudder and rudder stock is to be taken into consideration. Guidelines for calculation of bending moment and shear force distribution for various types of rudders are given in Section 8.

Section 4

Rudder Blades

4.1 Construction details

4.1.1 Care is to be taken to avoid notch effects and to maintain continuity of strength around cut-outs and openings in the side plating. The plating thickness is to be increased suitably and corners are to be well rounded and ground smooth.

4.1.2 Side plating and vertical webs transmitting the torque are to be welded to the coupling flange by full penetration welds. Welds in the rudder side plating subjected to significant stresses from rudder bending and welds between plates and heavy pieces (solid parts in forged or cast steel or very thick plating) are to be made as full penetration welds. In way of highly stressed areas e.g. cut-out of semi-spade rudder and upper part of spade rudder, cast or welding on ribs is to be arranged. Two sided full penetration welding is normally to be arranged. Where back welding is impossible, welding is to be performed against ceramic backing bars or equivalent. Steel backing bars may be used and are to be fitted with continuous weld on one side to the bevelled edge, see Figure 4.1.2. The bevel angle is to be at least 15° for one sided welding.

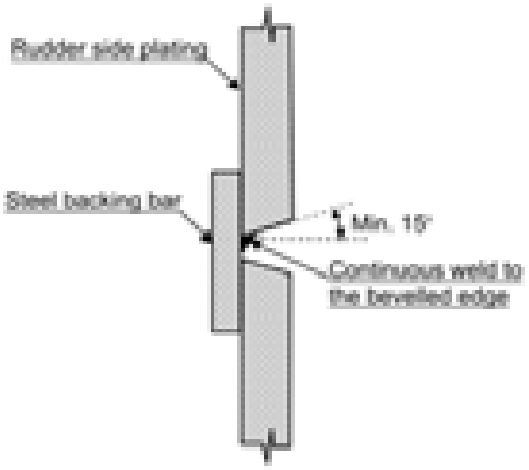

Fig 4.1.2: Use of steel backing bar in way of full penetration welding of rudder side plating

4.1.3 Webs are to be connected to the side plating in accordance with Ch.17. Where fillet welding is not practicable side plating is to be connected by means of slot welding to flat bars welded to the webs. Slot welding is to be limited as far as possible. Slot welding is not to be used in areas with large in-plane stresses transversely to the slots or in way of cut-out areas of semi-spade rudders. Normally slots of

length 75 [mm], breadth at least twice the side plating thickness and spaced 200 [mm] centre to centre will be accepted. The ends of the slots are to be well rounded. The slots are to be fillet welded around the edges and filled with a suitable compound, e.g. epoxy putty. Slots are not to be filled with weld.

4.1.4 Continuous slot welds may be used in lieu of slot welds. When continuous slot welding is used, the root gap is to be between 6-10 [mm] and the bevel angle is to be atleast 15º.

4.1.5 In way of the rudder horn recess of semi-spade rudders, the radii in the rudder plating except in way of solid part in cast steel are not to be less than 5 times the plate thickness, but in no case less than 100 [mm]. Welding in side plate is to be avoided in or at the end of the radii. Edges of side plate and weld adjacent to radii are to be ground smooth.

4.1.6 Requirements for welding and design details of rudder trunks are indicated in 7.3.

4.1.7 Requirements for welding and design details when the rudder stock is connected to the rudder by horizontal flange coupling are indicated in 6.1.6.

4.1.8 Requirements for welding and design details of rudder horns are indicated in 7.2.3.

4.1.9 Arrangement is to be provided to drain the rudders completely. Drain plugs are to be provided with efficient packing.

4.1.10 Internal surfaces of rudders are to be efficiently coated for corrosion resistance after completion of fabrication and testing. Where it is intended to fill the rudder with plastic foam, details of the foam material are to be submitted.

4.2 Double plated rudders

4.2.1 Thickness 't' of the rudder side, top and bottom plating is not to be less than:

$$t = 5.5\, s\, f_a \sqrt{k} \sqrt{\left(T_{SC} + \frac{F_r 10^{-4}}{A}\right)}\, 10^{-3} + 2.5 \ [mm]$$

where,

$$f_a = \sqrt{1.1 - 0.5(s/1000/l)^2};\ \max .1.00$$

s = the smaller of the distances between the horizontal or the vertical web plates/ smallest unsupported width of plating [mm].

l = the larger of the distances between the horizontal or the vertical web plates/ greatest unsupported width of plating [m].

T_{SC} = scantling draught [m]

k = Material factor for the rudder plating.

The thickness 't' is however not to be less than the minimum side shell thickness as per Pt.3, Ch.8.

For nose plates the thickness is to be increased to 1.25 t.

4.2.2 The thickness of the vertical and horizontal webs is not to be less than 70 per cent of the requirement given in 4.2.1 with a minimum of 8 [mm].

4.2.3 Overall strength of the rudder blade (except in way of rudder recess sections where d) applies) based on bending moments (BM) and shear forces (SF) obtained as per Sec.3 is to satisfy the following criteria:

a) bending stress

$$\sigma = \frac{\mathrm{BM}}{\mathrm{Z}_l} \le 110/\mathrm{k}\ [\mathrm{N/mm^2}]$$

b) shear stress $\tau = \dfrac{\mathrm{SF}}{\mathrm{A_w}} \le 50/\mathrm{k}\ [\mathrm{N/mm^2}]$

c) equivalent stresses

$$\sigma_e = \sqrt{\sigma^2 + 3\tau^2} \le 120/\mathrm{k}\ [\mathrm{N/mm^2}]$$

where,

Z_l = Section modulus of the blade cross section against lateral bending obtained considering side plating and web plates within the effective width of the rudder profile. The effective width is to be generally taken as 40 per cent of the net width of the rudder profile; and

A_w = Total Sectional area of the vertical webs.

k = Material factor for the rudder plating

d) In way of cut-outs or openings in the side plating for access to cone coupling or pintle nut:

Bending stress, $\sigma \leq 75$ [N/mm^2]

Torsional stress, $\tau_t \leq 50$ [N/mm^2]

Equivalent stress $\sigma_e = \sqrt{\sigma_b^2 + 3\tau_t^2} \leq 100$ [N/mm^2]

where,

τ_t is torsional stress based on torque arising from the partial rudder force acting on the area below the section in consideration.

Note : The stresses in d) apply equally to high tensile and ordinary steels.

e) In way of the coupling the stresses are to be limited as in d); however for calculation of the stresses only the items within the width of the coupling are to be considered.

4.3 Single plated rudders

4.3.1 Mainpiece diameter

The mainpiece diameter is calculated according to 5.1.1 and 5.1.4 respectively. The diameter of the main piece at top end is not to be less than that of the lower rudder stock, and it may be gradually reduced towards lower end provided stresses are limited as per 4.2.3. For spade rudders the lower third may taper down to 0.75 times stock diameter.

4.3.2 Blade thickness

The blade thickness is not to be less than:

$$t_b = 1.5\, s\, V\sqrt{k} + 2.5 \quad \text{[mm]}$$

where:

s = spacing of stiffening arms, [m], not to exceed 1 m;

V = speed in knots, see 3.1.1.

k = material factor for the rudder plating.

4.3.3 Arms

The thickness of the arms is not to be less than the blade thickness

$t_a = t_b$ [mm]

The section modulus is not to be less than:

$Z_a = 0.5\ s\ C_1^2\ V^2\ k$ [cm^3];

C_1 = horizontal distance from the aft edge of the rudder to the centreline of the rudder stock, [m]

k = material factor

4.3.4 Rudder blade is to be stiffened by horizontal arms spaced not more than 1000 [mm] apart. The arms are to be efficiently attached to the main piece.

4.4 Connection of rudder blade structure with solid parts

4.4.1 Solid parts in forged or cast steel, which house the rudder stock or the pintle, are to be provided with protrusions, except where not required as indicated below.

These protrusions are not required when the web plate thickness is less than:

- 10 [mm] for web plates welded to the solid part on which the lower pintle of a semi-spade rudder is housed and for vertical web plates welded to the solid part of the rudder stock coupling of spade rudders.

- 20 [mm] for other web plates.

4.4.2 The solid parts are in general to be connected to the rudder structure by means of two horizontal web plates and two vertical web plates.

4.4.3 Minimum section modulus of the connection with the rudder stock housing.

The section modulus of the cross-section of the structure of the rudder blade, in [cm^3], formed by vertical web plates and rudder plating, which is connected with the solid part where the rudder stock is housed is to be not less than:

$$Z_s = c_s\, d_c^3 \left(\frac{H_E - H_X}{H_E}\right) \frac{k}{k_s}\ 10^{-4} \quad \text{[cm}^3\text{]}$$

where:

c_s = coefficient, to be taken equal to:

= 1.0 if there is no opening in the rudder plating or if such

openings are closed by a full penetration welded plate

= 1.5 if there is an opening in the considered cross-section of the rudder

d_c = rudder stock diameter, [mm]

H_E = vertical distance between the lower edge of the rudder blade and the upper edge of the solid part, [m]

H_X = vertical distance between the considered cross-section and the upper edge of the solid part, [m]

k = material factor for the rudder blade plating.

k_s = material factor for the rudder stock.

The actual section modulus of the cross-section of the structure of the rudder blade is to be calculated with respect to the symmetrical axis of the rudder.

The breadth of the rudder plating, [m], to be considered for the calculation of section modulus is to be not greater than:

$$b = s_V + 2 H_x / 3 \quad [m]$$

where:

s_V = spacing between the two vertical webs, [m] (see Fig.4.4.3)

Where openings for access to the rudder stock nut are not closed by a full penetration welded plate, they are to be deducted.

4.4.4 The thickness of the horizontal web plates connected to the solid parts, in [mm], as well as that of the rudder blade plating between these webs, is to be not less than the greater of the following values:

$$t_H = 1.2\ t \quad [mm]$$

$$t_H = 0.045\ d_s^2 / s_H \quad [mm]$$

where:

t = defined in 4.2.1

d_S = diameter, [mm], to be taken equal to:

= d_c, as per 5.1.4, for the solid part housing the rudder stock

= d_p, as per 5.2.1, for the solid part housing the pintle

s_H = spacing between the two horizontal web plates, [mm]

The increased thickness of the horizontal webs is to extend fore and aft of the solid part at least to the next vertical web.

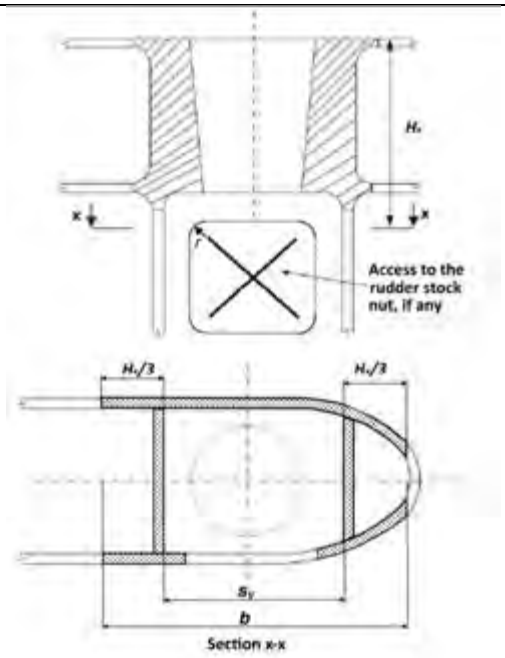

Fig.4.4.3 : Cross-section of the connection between rudder blade structure and rudder stock housing, example with opening in only one side shown

4.4.5 The thickness of the vertical web plates welded to the solid part where the rudder stock is housed as well as the thickness of the rudder side plating under this solid part is to be not less than the values obtained, in [mm], from Table 4.4.5. The increased thickness is to extend below the solid piece at least to the next horizontal web.

Table 4.4.5 : Thickness of side plating and vertical web plates

Type of rudder	Thickness of vertical web plates, [mm]		Thickness of rudder plating, [mm]	
	Rudder blade without opening	Rudder blade with opening	Rudder blade without opening	Area with opening
Rudder supported by sole piece	1.2 t	1.6 t	1.2 t	1.4 t
Semi-spade and spade rudders	1.4 t	2.0 t	1.3 t	1.6 t
t = thickness of the rudder plating, [mm] as defined in 4.2				

Section 5

Rudder Stock and Pintles

5.1 Rudder stock

5.1.1 The rudder stock diameter required for the transmission of the rudder torque is to be dimensioned such that the torsional stress is not exceeding the following value:

$$\tau_T = 68 / k \text{ [N/mm}^2\text{]}$$

The rudder stock diameter for the transmission of the rudder torque is therefore not to be less than:

$$d_t = 4.2\sqrt[3]{Q_r k} \text{ [mm]}$$

Q_r = Total rudder torque [Nm] as calculated in 3.2.

k = Material factor of the rudder stock as given in 1.2.3

5.1.2 If the rudder stock is subjected to combined torque and bending, the Equivalent stress σ_e in the rudder stock is not to exceed 118/k [N/mm^2] i.e.

k = Material factor of the rudder stock as given in 1.2.3

$$\sigma_e = \sqrt{\sigma^2 + 3\tau_t^2} \leq 118 / k \text{ [N/mm}^2\text{]}$$

where,

σ is the bending stress in [N/mm^2],

$\sigma = 10.2 \times 10^3 \, BM / d_c^3$

τ_t is the torsional shear stress in [N/mm^2].

$\tau_t = 5.1 \times 10^3 \, Q_r / d_c^3$

This requirement is regardless of the liners; and both ahead and astern conditions are to be considered.

5.1.3 The diameter of the rudder stock at and above rudder carrier is given by

$$d_t = 4.2\sqrt[3]{(Q_r . k)} \text{ [mm]}$$

5.1.4 The diameter of rudder stock at any other cross section is given by

$$d_c = d_t . \sqrt[6]{\left[1 + \frac{4}{3} . \frac{BM^2}{Q_r^2}\right]} \text{ [mm]}$$

where BM is the bending moment at the cross section under consideration obtained as per 3.3.

For a spade rudder with trunk extending inside the rudder, the rudder stock scantlings are to be checked against the two cases defined in 8.3.

5.1.5 The diameter of the rudder stock at neck bearing is to be maintained to a point as far as practicable above the top of the neck bearing and may subsequently be tapered to that required at the rudder carrier. The length of the taper is to be at least three times the reduction in diameter. Particular care is to be taken to avoid the formation of a notch at the upper end of the taper.

5.1.6 Sudden changes of section or sharp corners in way of the rudder coupling, jumping collars and shoulders for rudder carriers are to be avoided. Jumping collars are not to be welded to the rudder stock. Keyways in the rudder stock are to have rounded ends and the corners at the base of the keyway are to be adequately radiused.

5.1.7 Significant reductions in rudder stock diameter due to the application of steels with specified minimum yield stress exceeding 235 [N/mm^2] are to be granted only after evaluation of rudder stock deformations. Large deformations of the rudder stock are to be avoided in order to avoid excessive pressures in way of bearings.

5.2 Pintles

5.2.1 Scantlings

The diameter d_p of the pintles, is not to be less than

$$d_p = 0.35\sqrt{(B\,k_p)}$$

where,

B = relevant bearing force, [N]

k_p = material factor for pintle as given in 1.2.3

5.2.2 Couplings

Pintles are to have a conical attachment to the gudgeons with a taper on diameter not greater than:
1:8 - 1:12 for keyed and other manually assembled pintles applying locking by slugging nut,

1:12 - 1:20 on diameter for pintles mounted with oil injection and hydraulic nut.

5.2.3 Push-up pressure for pintle

The required push-up pressure for pintle in case of dry fitting, in [N/mm²], is to be determined by *preq1* as given below.

The required push-up pressure for pintle in case of oil injection fitting, in [N/mm²], is to be determined by the maximum pressure of p_{req1} and p_{req2} as given below:

$$p_{req1} = 0.4\,\frac{B d_0}{d_m^2\, l} \quad [N/mm^2]$$

$$p_{req2} = \frac{6\,M_{bp}}{l^2 d_m}\,10^3 \quad [N/mm^2]$$

where:

B = Supporting force in the pintle, [N] e.g., B_1 as defined in Fig 8.5.2 for semi-spade rudder.

d_0, d_m, l = Pintle dimensions, see Fig. 6.3.1

M_{bp} = bending moment in the pintle cone coupling to be determined by:

$$M_{bp} = B l_a\ [Nm]$$

ℓa = length between middle of pintle-bearing and top of contact surface between cone coupling and pintle in m, see Figure 5.2.3.

The required push-up length, $\Delta\ell_1$, is to be calculated similarly as in 6.4.3, using the required push-up pressure as defined above, and properties for the pintle.

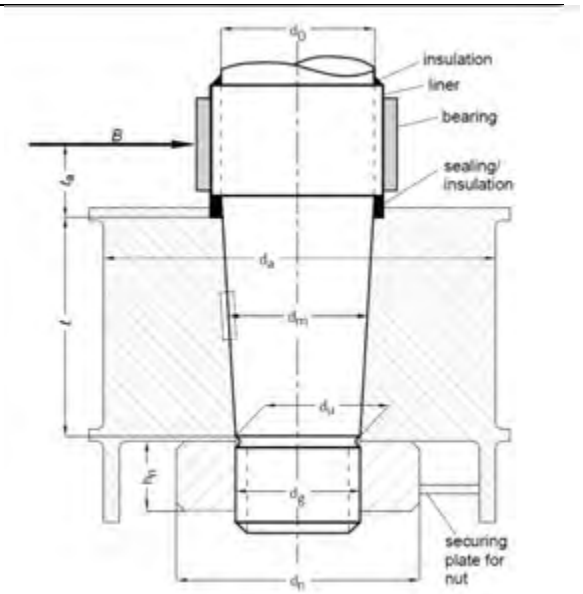

Figure 5.2.3 Pintle cone coupling indicating ℓa

5.2.4 The minimum dimensions of threads and nuts are to be determined according to Cl. 6.3.2. The push-up length is to be calculated similarly as in Cl. 6.4.3, using required push-up pressure and properties for the pintle. An effective sealing against sea water is to be provided at both ends of the cone.

5.2.5 Pintle housing

The length of pintle housing in the gudgeon is not to be less than the pintle diameter d_p. The thickness of the pintle housing is not to be less than 0.25 d_p.

5.2.6 Where liners are fitted to pintles, they are to be shrunk on or otherwise efficiently secured. If liners are to be shrunk on, the shrinkage allowance is to be indicated on the plans. Where liners are formed by stainless steel weld deposit, the pintles are to be of weldable quality steel, and details of the procedure are to be submitted. Bushing is to be effectively secured against movement.

5.3 Bearings of rudder stock, rudder shaft and pintle

5.3.1 Liners and Bushes

5.3.1.1 Rudder stock bearing

Liners and bushes are to be fitted in way of bearings. For rudder stocks and pintles having diameter less than 200 [mm], liners in way of bushes may be provided optionally. The

minimum thickness of liners and bushes is to be equal to:

- t_{min} = 8 [mm] for metallic materials and synthetic material
- t_{min} = 22 [mm] for lignum material

5.3.1.2 Pintle bearing

The thickness of any liner or bush, [mm], is neither to be less than:

$$t = 0.01\sqrt{B}$$

where:

B = relevant bearing force, [N]

nor less than the minimum thickness defined in 5.3.1.1

5.3.2 Minimum Bearing Surface

5.3.2.1 An adequate lubrication is to be provided. The bearing surface A_b (defined as the projected area: length x outer diameter of liner) is not to be less than:

$$A_b = {}^{P}/_{q_a}$$

where:

P = reaction force [N] in bearing as determined in 3.3;

q_a = allowable surface pressure according to the Table 5.3.4.

5.3.3 Bearing clearances are normally to be as given in Table 5.3.3.

Attention is to be paid to the manufacturer's recommendations particularly where bush material requires pre-soaking.

5.3.4 The maximum surface pressure p, for the various combinations is not to exceed the values given in Table 5.3.4. Higher values than given in table may be taken on verification by tests.For the purpose of this calculation, the bearing length is not to be taken greater than 1.2 times the rudder stock or pintle diameter measured outside of liners, if fitted. The bearing length L_p of the pintle is to be such that

$$D_p \leq L_p \leq 1.2\, D_p$$

where,

D_p = Actual pintle diameter measured on the outside of the liners.

Table 5.3.3 : Bearing clearances

- For metal bearing material	Not less than 0.001 d_p + 1.0 [mm]
- For synthetic bearing material	To be specially determined considering the swelling and thermal expansion properties of the material, but not less than 1.5 [mm]#.

A smaller clearance may be accepted if supported by the manufacturer’s recommendation and documented evidence of satisfactory service history with reduced clearance.

Table 5.3.4 : Allowable surface pressure q_a

Bearing material	q_a [N/mm^2]
Lignum vitae	2.5
White metal, oil lubricated	4.5
Synthetic material with hardness greater than 60 shore D(1)	5.5(2)
Steel,(3) bronze and hot pressed bronze- graphite materials	7.0

Note:

(1) Indentation hardness test at 23°C and with 50% moisture, according to a recognised standard. Synthetic bearing materials to be of approved type.

(2)Surface pressures exceeding 5.5 [N/mm^2] may be accepted in accordance with the bearing manufacturer's specification and tests, but in no case more than 10 [N/mm^2]

(3) Stainless and wear resistant steel in an approved combination with stock liner.

Section 6

Rudder Couplings

6.1 Horizontal flange couplings

6.1.1 The diameter of the coupling bolts is not to be less than:

$$d_b = 0.62\left[\frac{d_s^3 . k_b}{n.e_m.k_s}\right]^{1/2} \text{[mm]}$$

where,

d_s = Stock diameter [mm] in way of the coupling flange; equal to the greater of the diameters d_t or d_c according to 5.1.3 and 5.1.4

k_s = material factor for the rudder stock material;

k_b = material factor for the bolt material;

n = total number of bolts;

e_m = mean distance of the bolt axes from the centre of the bolt system [mm].

6.1.2 Coupling bolts are to be fitted bolts and a minimum of six (6) bolts are to be provided. Their nuts are to be effectively locked.

6.1.3 Mean distance e_m from the centre of the bolts to the centre of the bolt system is not to be less than 0.9 d_s [mm]. In addition, where the coupling is subjected to bending stress the mean athwartship distance from the centre of bolts to the longitudinal centreline of the coupling is not to be less than 0.6 d_s [mm].

6.1.4 The thickness of coupling flanges is not to be less than that obtained by the following formula:

$$t_f = d_b\sqrt{\left(\frac{k_f}{k_b}\right)} \text{[mm]}$$

t_f is to be also not less than 0.9 d_b;

d_b = bolt diameter [mm] calculated for a number of bolts not exceeding 8.

k_f = material factor for the flange;

k_b = material factor for the bolt material.

6.1.5 The width of material outside the bolt holes is not to be less than 0.67 d_b [mm].

6.1.6 The welded joint between the rudder stock and the flange is to be made in accordance with Fig.6.1.6 or equivalent.

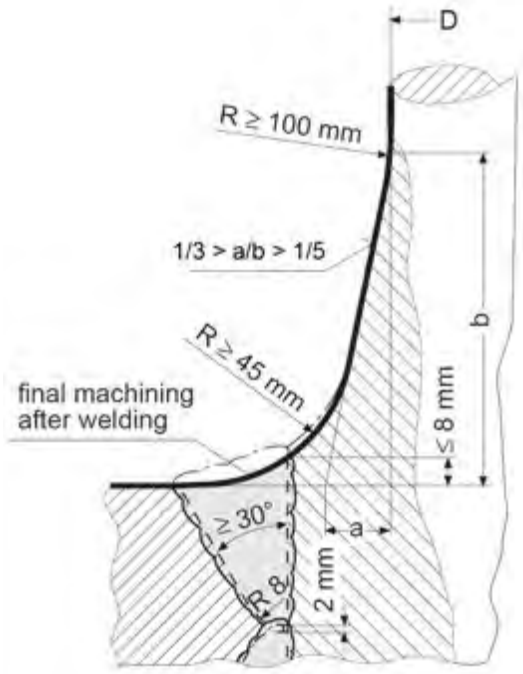

Fig. 6.1.6 : Welded joint between rudder stock and coupling flange

6.2 Vertical flange couplings

6.2.1 The diameter of the coupling bolts is not to be less than:

$$d_b = 0.81\left[\frac{d_s^2 . k_b}{n . k_s}\right]^{1/2} \quad [mm]$$

where,

d_s = Stock diameter [mm] in way of the coupling flange

n = total number of bolts, but not less than 8.

k_b = material factor for bolts.

k_s = material factor for rudder stock.

6.2.2 The first moment of area of the bolts about the centre of the coupling to be not less than:

$$m = 0.00043\ d_s^3\ [cm^3]$$

6.2.3 The thickness of the coupling flanges is to be at least equal to the bolt diameter; and the width of the flange material between the perimeter of the bolt holes and the perimeter of the flange is to be greater than or equal to 0.67 d_b.

6.2.4 Coupling bolts are to be fitted bolts and their nuts are to be locked effectively.

6.3 Cone couplings with key/ Cone couplings without hydraulic arrangement for mounting and dismounting

6.3.1 Cone couplings without hydraulic arrangements for mounting and dismantling the coupling should have a taper 'c' on diameter generally ranging between 1:8 to 1:12.

$c = \frac{d_o - d_u}{l_c}$ according to Fig. 6.3.1 and 6.3.1b)

The diameters d_o in mm, and d_u in mm, are defined in Fig. 6.3.1 and the cone length l_c, in mm, is defined in Fig. 6.3.1 b)

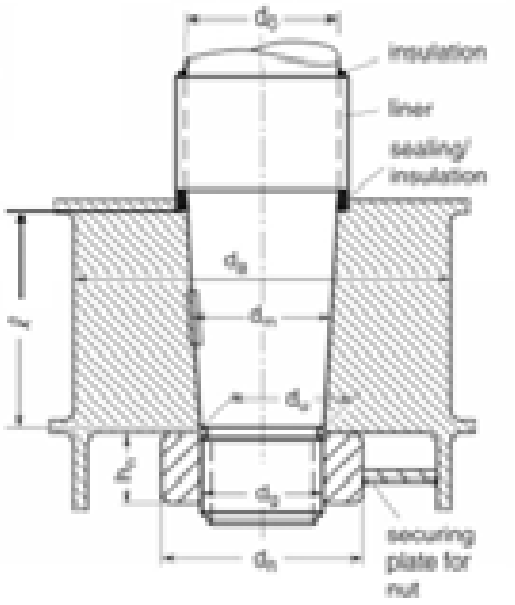

Fig.6.3.1 : Cone coupling with key

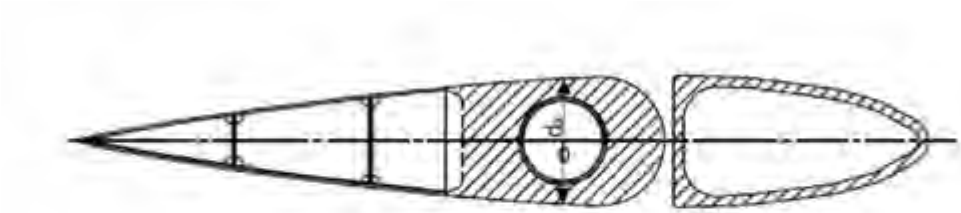

Fig. 6.3.1 a) Gudgeon outer diameter(d_a) measurement

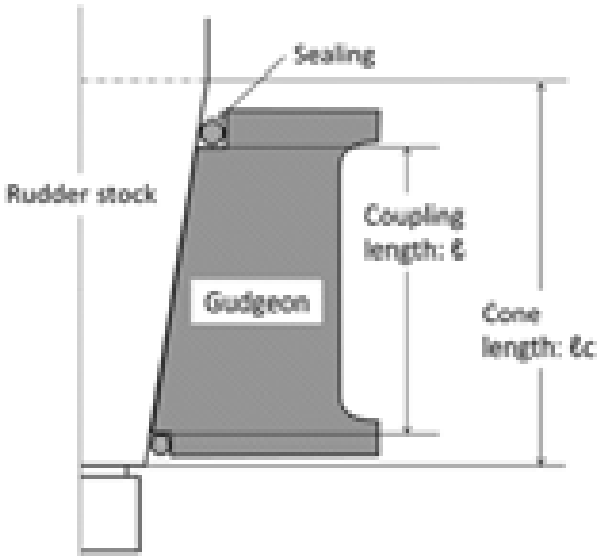

Fig. 6.3.1 b) Cone length and coupling length

The coupling length *l* in mm, is in general not to be less than 1.5 times the rudder stock diameter d_o at the top of rudder.

The cone shape is to be very exact and the slugging nut is to be efficiently secured.

6.3.2 The dimensions of the slugging nut [mm], are not to be less than (See Fig 6.3.1) :

External thread of nut, $d_g \geq 0.65\ d_o$;

Outer diameter of nut, $d_n \geq 1.2\ d_u$ or $1.5\ d_g$, whichever is the greater;

Height of nut, $h_n \geq 0.6\ d_g$

6.3.3 A key is to be fitted in the tapered connection, as close to the nut as possible and ample fillets are to be provided at corners of the keyway.

The shear area of the key is not to be less than:

$$a_s = \frac{17.55\ Q_F}{d_k\ R_{eH1}}$$

where,

Q_F = design yield moment of rudder stock, in [Nm]

$$Q_F = 0.02664\ \frac{d_t^3}{k}$$

Where the actual diameter d_{ta} is greater than the calculated diameter d_t, the diameter d_{ta} is to be used. However, d_{ta} applied to the above formula need not be taken greater than 1.145 d_t.

d_t = stock diameter, [mm], according to 5.1.3.

k = material factor for stock as given in 1.2.3

d_k = mean diameter of the conical part of the rudder stock, [mm], at the key

R_{eH1} = specified minimum yield stress of the key material, [N/mm^2]

The effective surface area, [cm^2], of the key (without rounded edges) between key and rudder stock or cone coupling is not to be less than:

$$a_k = \frac{5\,Q_F}{d_k R_{eH2}}$$

where:

R_{eH2} = specified minimum yield stress of the key, stock or coupling material, [N/mm^2], whichever is less.

6.3.4 Push up

It is to be proved that 50% of the design yield moment is solely transmitted by friction in the cone couplings. This can be done by calculating the required push-up pressure and push-up length according to 6.4.2 and 6.4.3 for a torsional moment $Q'_F = 0.5\ Q_F$.

6.3.5 Notwithstanding the requirements in 6.3.3 and 6.3.4, where a key is fitted to the coupling between stock and rudder and it is considered that the entire rudder torque is transmitted by the key at the couplings, the scantlings of the key as well as the push-up force and push-up length are to be specially considered.

6.4 Cone couplings with hydraulic arrangement for mounting and dismounting (with oil injection and hydraulic nut)

6.4.1 Where the stock diameter exceeds 200 [mm], the press fit is recommended to be achieved by a hydraulic pressure connection. In such cases, the cone diameter is to be, c, generally ranging between 1:12 to 1:20.

In case of hydraulic pressure connections the nut is to be effectively secured against the rudder stock or the pintle.

For the safe transmission of the torsional moment by the coupling between rudder stock and rudder body the push-up pressure and the push-up length are to be determined according to 6.4.2 and 6.4.3 respectively.

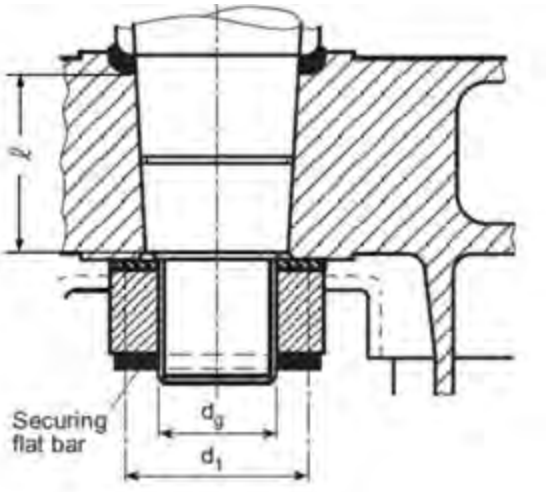

Fig.6.4.1 : Cone coupling without key

6.4.2 Push-up pressure

The push-up pressure is not to be less than the greater of the two following values:

$$p_{req1} = \frac{2Q_F}{d_m^2 \ell \pi \mu_0} 10^3 \quad [\text{N/mm}^2]$$

$$P_{req2} = \frac{6M_C}{l^2 d_m} 10^3 \ [N/mm^2]$$

where:

Q_F = design yield moment of rudder stock, as defined in 6.3.3, [Nm]

d_m = mean cone diameter [mm], see Figure 6.3.1

ℓ = coupling length [mm]

μ_0 = frictional coefficient, equal to 0.15

M_C = bending moment in rudder stock at the top of the cone coupling (e.g. in case of spade rudders), [Nm]

For spade rudder with trunk extending inside the rudder, the coupling is to be checked against the two cases defined in 8.3.

It has to be proved by the designer that the push-up pressure does not exceed the permissible surface pressure in the cone. The permissible surface pressure, [N/mm²], is to be determined by the following formula:

$$p_{perm} = \frac{0.95R_{eH}(1-\alpha^2)}{\sqrt{3+\alpha^2}} - p_b \ [N/mm^2]$$

where:

$$p_b = \frac{3.5M_C}{d_m l^2} 10^3$$

R_{eH} = specified minimum yield stress of the material of the gudgeon [N/mm²]

α = d_m / d_a

d_m = diameter, [mm], see Fig. 6.3.1.

d_a = outer diameter of the gudgeon, [mm], see Fig.6.3.1 and Fig. 6.3.1 a). The least diameter is to be considered.

The outer diameter of the gudgeon in mm is not to be less than $1.25d_o$, with d_o defined in Fig 6.3.1

6.4.3 Push-up length

The push-up length $\Delta\ell$, [mm], $\Delta\ell$ is to comply with the following formula:

$$\Delta\ell_1 \le \Delta\ell \le \Delta\ell_2$$

where:

$$\Delta\ell_1 = \frac{p_{req} d_m}{E\left(\frac{1-\alpha^2}{2}\right)c} + \frac{0.8R_{tm}}{c} \quad \text{[mm]}$$

$$\Delta l_2 = \frac{p_{perm} d_m}{E\left(\frac{1-\alpha^2}{2}\right)c} + \frac{0.8R_{tm}}{c} \ [mm]$$

R_{tm} = mean roughness, [mm] taken equal to 0.01

c = taper on diameter defined in 6.3.1.

Note: In case of hydraulic pressure connections the required push-up force P_e, [N], for the cone may be determined by the following formula:

$$P_e = p_{req} d_m \pi \ell \left(\frac{c}{2} + 0.02\right)$$

The value 0.02 is a reference for the friction coefficient using oil pressure. It varies and depends on the mechanical treatment and roughness of the details to be fixed. Where due to the fitting procedure a partial push-up effect caused by the rudder weight is given, this may be taken into account when fixing the required push-up length, subject to approval by IRS.

Section 7

Sole Pieces and Rudder Horns

7.1 Sole piece

The section modulus around the vertical (z)-axis is not to be less than:

$Z_z = M_b\, k / 80$ [cm^3]

The section modulus around the transverse (y)-axis is not to be less than:

$Z_y = 0.5\, Z_z$

The sectional area is not to be less than:

$A_s = B_1\, k / 48$ [mm^2]

k = material factor as given in 1.2.3

7.1.1 Equivalent stress

At no section within the length ℓ_{50} is the equivalent stress to exceed 115 / k [N/mm^2]. The equivalent stress is to be determined by the following formula (See Fig.8.4.2):

$$\sigma_e = \sqrt{\sigma_b^2 + 3\tau^2} \quad [N/mm^2];$$

where:

$\sigma_b = M_b / Z_z(x)$ [N/mm^2];

$\tau = B_1 / A_s$ [N/mm^2];

M_b = bending moment at the section considered [Nm];

$M_b = B_1\, x$ [Nm];

$M_{bmax} = B_1\, \ell_{50}$ [Nm];

B_1 = supporting force in the pintle bearing [N] (normally $B_1 = F_r / 2$).

k = material factor as given in 1.2.3

7.2 Rudder horn

When the connection between the rudder horn and the hull structure is designed as a curved transition into the hull plating, special consideration is to be given to the effectiveness of the rudder horn plate in bending and to the stresses in the transverse web plates.
The bending moments and shear forces are to be determined by a direct calculation or in line with the guidelines given in Section 8 for semi spade rudder with one elastic support and semi spade rudder with 2-conjugate elastic support respectively.

The section modulus around the horizontal x-axis is not to be less than:

$Z_x = M_b\, k / 67$ [cm^3].

M_b = bending moment at the section considered, [Nm];

The shear stress is not to be larger than:

τ = 48 / k [N/mm^2].

k = material factor as given in 1.2.3

7.2.1 Equivalent stress

At no section within the height of the rudder horn is the equivalent stress to exceed 120 / k N/mm^2. The equivalent stress is to be calculated by the following formula:

$$\sigma_e = \sqrt{\sigma_b^2 + 3\left(\tau^2 + \tau_T^2\right)} \quad [N/mm^2];$$

$\sigma_b = M_b / Z_x$ [N/mm^2];

$\tau = B_1 / A_h$ [N/mm^2];

B_1 = supporting force in the pintle bearing [N];

A_h = effective shear area of rudder horn in y-direction [mm^2];

$\tau_T = M_T\, 10^3 / 2\, A_T\, t_h$ [N/mm^2];

M_T = torsional moment [Nm];

A_T = area in the horizontal section enclosed by the rudder horn [mm^2];

t_h = plate thickness of rudder horn [mm];

k = material factor as given in 1.2.3

7.2.2 Rudder horn plating

The thickness of the rudder horn side plating is not to be less than:

$$t = 2.4\sqrt{Lk} \quad \text{[mm]}$$

where:

L = Rule length as defined in Chapter 1, Cl. 2.1.3;

k = material factor as given in 1.2.3.

7.2.3 Welding and connection to hull structure

.1 The rudder horn plating is to be effectively connected to the aft ship structure, e.g. by connecting the plating to side shell and transverse/ longitudinal girders, in order to achieve a proper transmission of forces, see Figure 7.2.3.

.2 Brackets or stringer are to be fitted internally in horn, in line with outside shell plate, as shown in Figure 7.2.3.

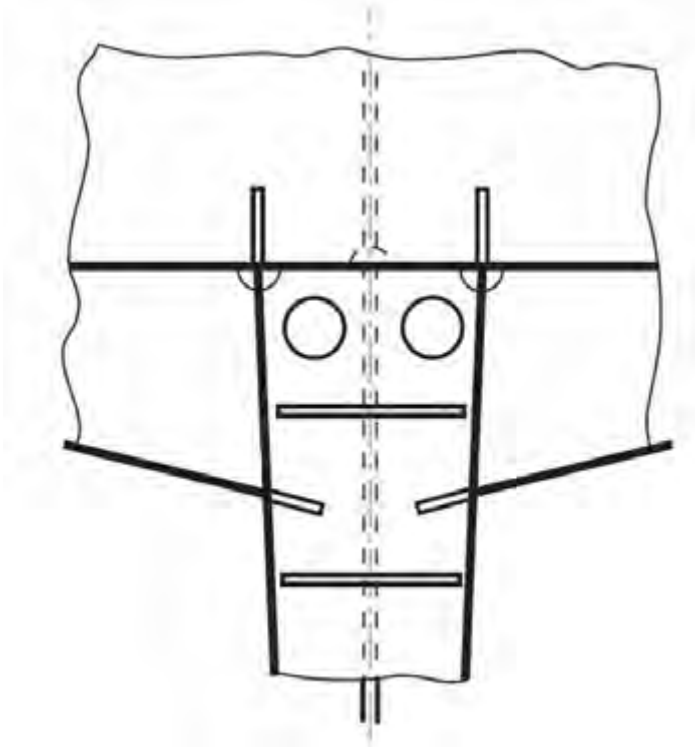

Fig.7.2.3 : Connection of Rudder Horn to aft Ship Structure

.3 Transverse webs of the rudder horn are to be led into the hull up to the next deck in a sufficient number.

.4 Strengthened plate floors are to be fitted in line with the transverse webs in order to achieve a sufficient connection with the hull.

.5 The centre line bulkhead (wash-bulkhead) in the after peak is to be connected to the rudder horn.

.6 Scallops are to be avoided in way of the connection between transverse webs and shell plating.

.7 The weld at the connection between the rudder horn plating and the side shell is to be full penetration. The welding radius is to be as large as practicable and may be obtained by grinding.

7.3 Rudder trunk

The requirements in this sub-section apply to trunk configurations which are extended below stern frame and arranged in such a way that the trunk is stressed by forces due to rudder action.

7.3.1 Materials, welding and connection to hull

The steel used for the rudder trunk is to be of weldable quality, with a carbon content not exceeding 0.23% on ladle analysis or a carbon equivalent C_{EQ} not exceeding 0.41%.
Plating materials for rudder trunks are in general not to be of lower grades than corresponding to Class II as defined in Part 2 of the Rules.

The weld at the connection between the rudder trunk and the shell or the bottom of the skeg is to be full penetration.

For rudder trunks extending below shell or skeg,the fillet shoulder radius r, [mm] (see Figure 7.2.4) is to be as large as practicable and to comply with the following formulae:

$r = 0.1d_c/k$

without being less than

$r = 60$ [mm] when $\sigma \geq 40/k$ [N/mm^2]

$r = 30$ [mm] when $\sigma < 40/k$ [N/mm^2]

where:

d_c = rudder stock diameter axis defined in 5.1.

σ = bending stress in the rudder trunk, [N/mm^2].

k = material factor for the rudder trunk as given in 1.2.3

The radius may be obtained by grinding. If disk grinding is carried out, score marks are to be avoided in the direction of the weld. The radius is to be checked with a template for accuracy. Four profiles at least are to be checked. A report is to be submitted to the attending Surveyor.

Rudder trunks comprising of materials other than steel would be specially considered.

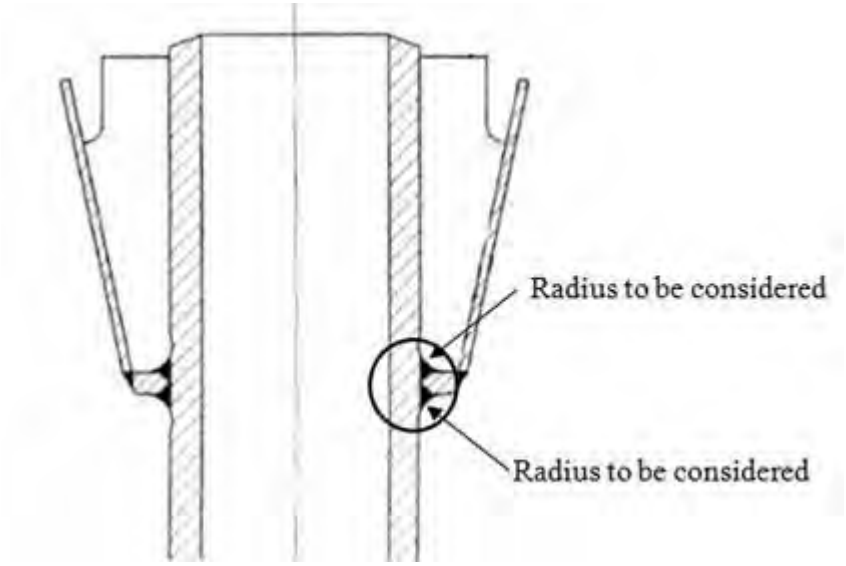

Fig.7.2.4 : Fillet Shoulder Radius

7.3.2 Scantlings

The scantlings of the trunk are to be such that:

- the equivalent stress due to bending and shear does not exceed 0.35 R_{eH},
- the bending stress on welded rudder trunk is to be in compliance with the following formula: $\sigma \leq 80/k$ [N/mm^2]

with:

σ = bending stress in the rudder trunk, as defined in 7.3.1.

k = material factor for the rudder trunk as given in 1.2.3, not to be taken less than 0.7

R_{eH} = specified minimum yield stress [N/mm^2] of the material used.

For calculation of bending stress, the span to be considered is the distance between the mid-height of the lower rudder stock bearing and the point where the trunk is clamped into the shell or the bottom of the skeg.

Section 8

Guidelines for Evaluation of Bending Moment and Shear Force Distribution

8.1 The evaluation of bending moments, shear forces and support forces for the system rudder – rudder stock may be carried out for some basic rudder types as outlined in the succeeding paragraphs:

8.2 Spade rudder

8.2.1 Data for the analysis

ℓ_{10} - ℓ_{30} = Lengths of the individual girders of the system, [m]

I_{10} – I_{30} = Moments of inertia of these girders, [cm^4]

Load of rudder body:

$$P_R = F_r / (\ell_{10}\, 10^3) \quad [kN/m]$$

8.2.2 The moments and forces may be determined by the following formulae:

$$M_b = F_r (\ell_{20} + (\ell_{10} (2\, c_1 + c_2) / 3 (c_1 + c_2))) \quad [Nm]$$

$$B_3 = M_b / \ell_{30} \quad [N]$$

$$B_2 = F_r + B_3 \quad [N].$$

The maximum moment, M_C, in top of the cone coupling as shown in Fig 8.2.2 is applicable for the connection between the rudder and the rudder stock.

8.3 Spade rudder with trunk

8.3.1 Data for the analysis

ℓ_{10} - ℓ_{30} = Lengths of the individual girders of the system, [m]

I_{10} – I_{30} = Moments of inertia of these girders, [cm^4]

Load of rudder body:

$$P_R = Fr / ((\ell_{10} + \ell_{20})10^3) \quad [kN/m]$$

Moments and forces

For a spade rudder with trunk extending inside the rudder, the strength is to be checked against the following two cases:

a) pressure applied on the entire rudder area

b) pressure applied only on rudder area below the middle of neck bearing.

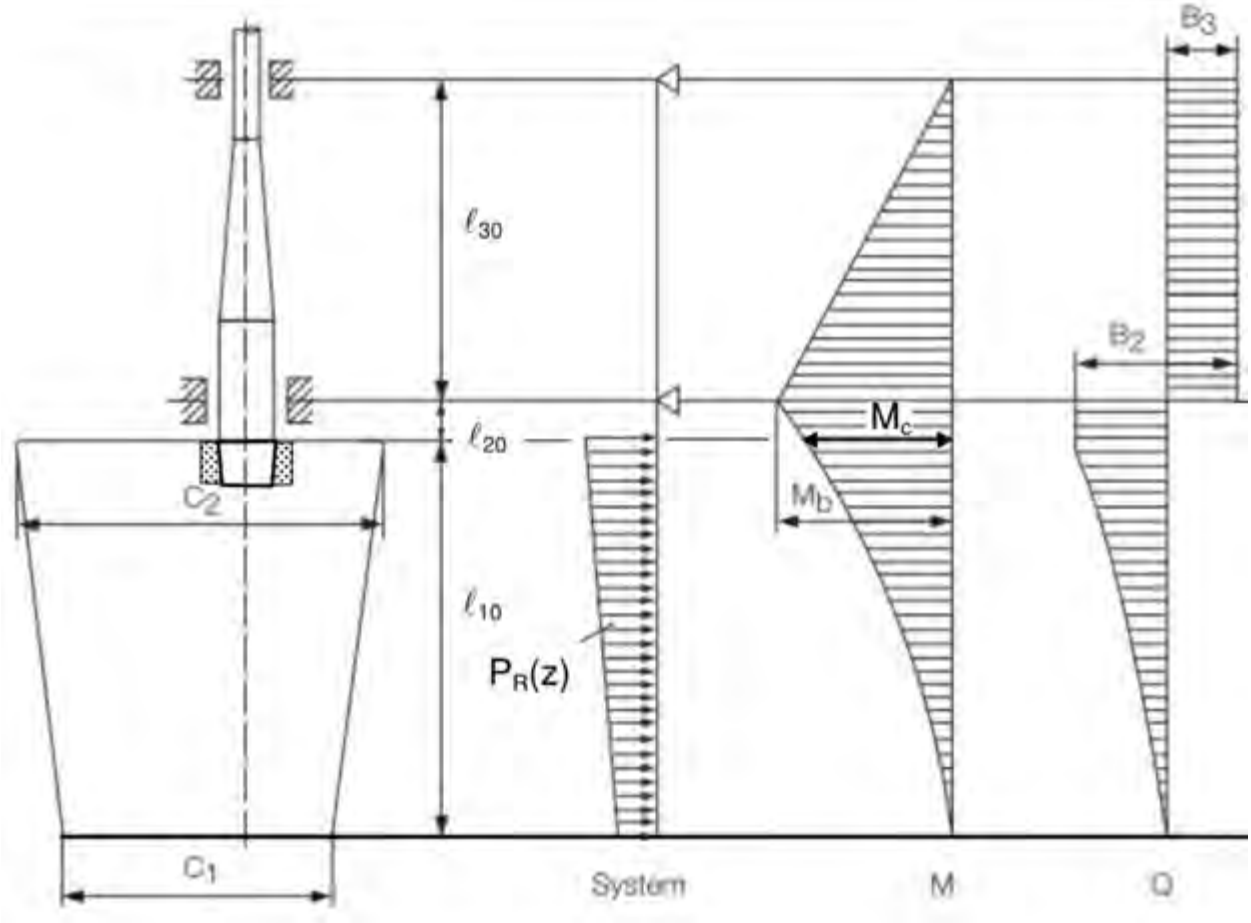

Fig.8.2.2 : Strength Calculations – Spade Rudder

8.3.2 The moments and forces for the two cases defined above may be determined according to Fig 8.3.2 a) and b) respectively.

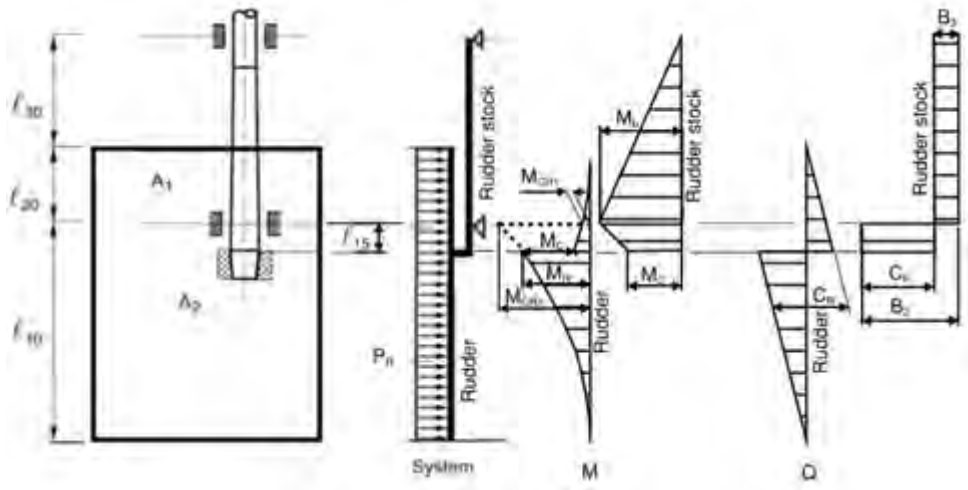

Fig. 8.3.2 a) Full rudder force *CR* = *CR1*+*CR2* and total rudder torque *QR* = *QR1* + *QR2* with rudders stock bending moment *Mb* = *MCR2* - *MCR1*

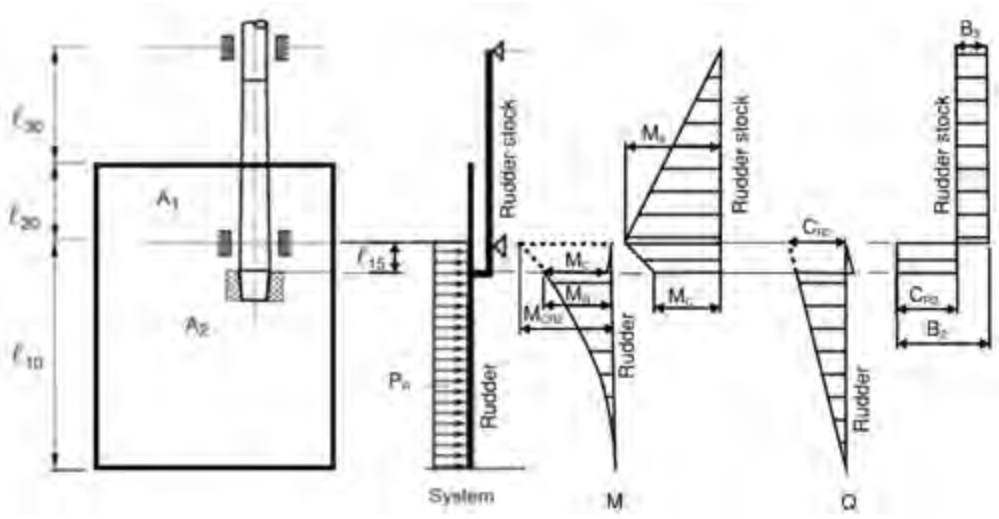

Fig. 8.3.2 b) Rudder force *CR2* corresponding to rudder torque *QR2* acting at rudder blade area *A2* with rudders stock bending moment *Mb = MCR2*

$M_{Fr2} = F_{r2} (\ell_{10} - CG_{2Z})$

$M_{Fr1} = F_{r1} (CG_{1Z} - \ell_{10})$

where:

F_{r1} : Rudder force over the rudder blade area A_1

F_{r2} : Rudder force over the rudder blade area A_2

CG_{1Z} : Vertical position of the centre of gravity of the rudder blade area A_1

CG_{2Z} : Vertical position of the centre of gravity of the rudder blade area A_2

$F_r = F_{r1} + F_{r2}$

$B_3 = (M_{Fr2} - M_{Fr1}) / (\ell_{20} + \ell_{30})$

$B_2 = F_r + B_3$

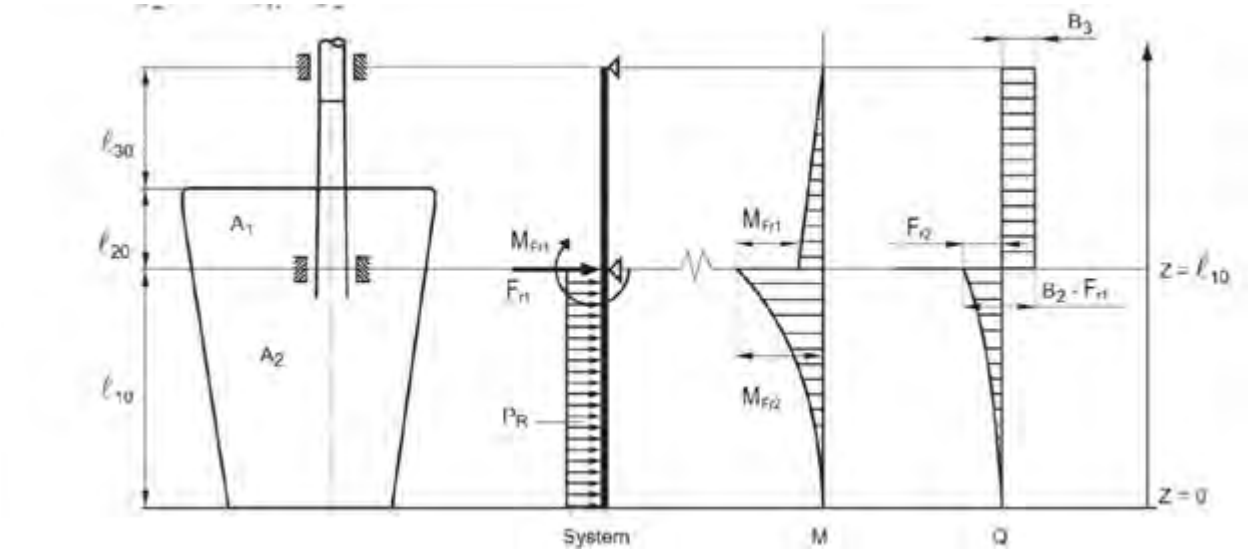

Fig.8.3.2 : Strength Calculations – Spade Rudder with Trunk

8.4 Rudder supported by sole piece

8.4.1 Data for the Analysis

ℓ_{10} - ℓ_{50} = Lengths of the individual girders of the system, [m]

I_{10} – I_{50} = Moments of inertia of these girders, [cm^4]

For rudders supported by a sole piece the length ℓ_{20} is the distance between lower edge of rudder body and centre of sole piece and I_{20} the moment of inertia of the pintle in the sole piece.

I_{50} = moment of inertia of sole piece around the z-axis, [cm^4];

ℓ_{50} = effective length of sole piece, [m];

Load of rudder body:

P_R = F_r / (ℓ_{10} 10^3) [kN/m]

Z = spring constant of support in the sole piece

Z = 6.18 x I_{50} / ℓ_{50}^3 [kN/m]

8.4.2 The moments and shear forces are indicated in Figure 8.4.2.

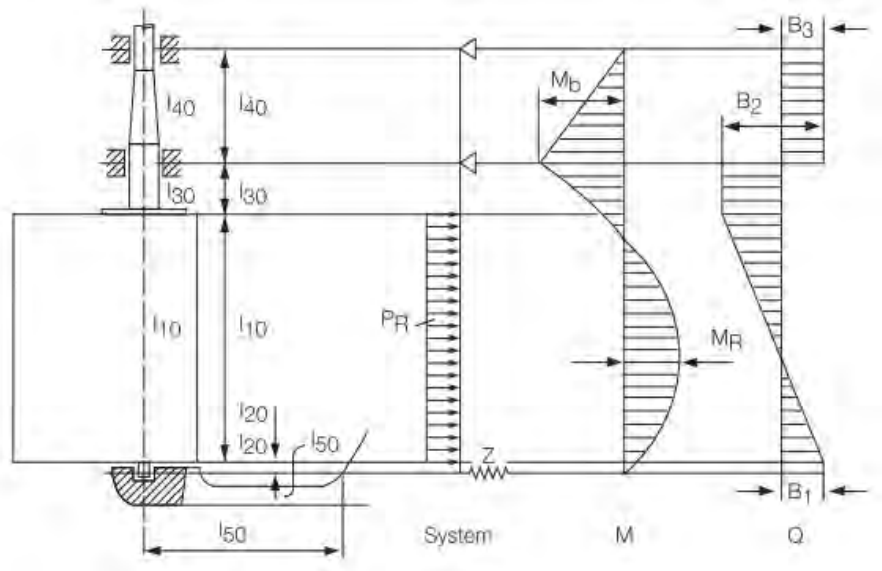

Fig.8.4.2 : Strength Calculations – Rudder supported by Sole Piece

8.5 Semi-spade rudder with one elastic support

8.5.1 Data for the analysis

ℓ_{10} - ℓ_{50} = Lengths of the individual girders of the system, [m];

I_{10} – I_{50} = Moments of inertia of these girders, [cm^4];

Z = spring constant of support in the rudder horn;

Z = 1 / (f_b + f_t) [kN/m] for the support in the rudder horn (Figure 8.5.2);

f_b = unit displacement of rudder horn in [m] due to a unit force of 1 kN acting in the centre of support;

f_b = 1.3 d^3 / (6.18 I_n) [m/kN] (guidance value);

I_n = moment of inertia of rudder horn around the x-axis, [cm^4] (see also Figure 8.5.2);

f_t = unit displacement due to torsion;

$f_t = d\, e^2 \sum {u_i}/{t_i} / [3.14 \times 10^8 F_T^2]$ [m/KN];

F_T = mean sectional area of rudder horn, [m^2];

u_i = breadth, [mm] of the individual plates forming the mean horn sectional area;

t_i = thickness within the individual breadth u_i, [mm];

d = Height of the rudder horn, [m], defined in Figure 8.5.2. This value is measured downwards from the upper rudder horn end, at the point of curvature transition, to the mid-line of the lower rudder horn pintle;

e = distance as defined in Figure 8.5.3

Load of rudder body:

P_{R10} = F_{r2} / (ℓ_{10} x 10^3) [kN/m];

P_{R20} = F_{r1} / (ℓ_{20} x 10^3) [kN/m];

for F_r, F_{r1}, F_{r2}, method indicated in 3.2.2 for estimation may be followed.

8.5.2 Moments and shear forces are indicated in Figure 8.5.2

8.5.3 Rudder horn

The loads on the rudder horn are as follows:

M_b = bending moment = B_1 z [Nm],

M_{bmax} = B_1 d [Nm]

q = shear force = B_1 [N]

$M_T(z)$ = torsional moment = B_1 e (z) [Nm]

An estimate for B_1 is:

B_1 = F_r b / (ℓ_{20} + ℓ_{30}) [N]

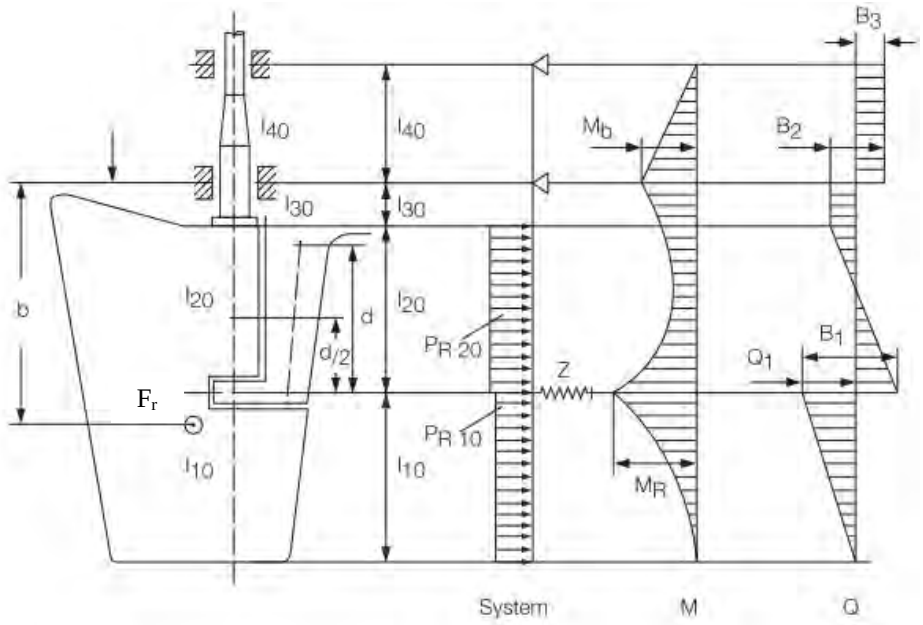

Fig.8.5.2 : Strength Calculations – Semi Spade Rudder with one Elastic Support

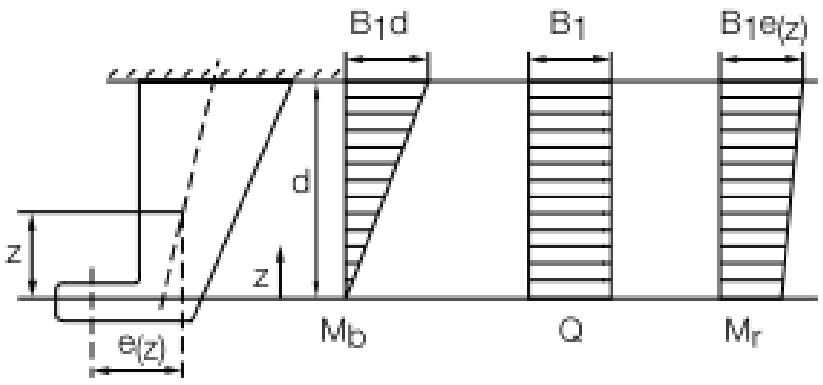

Fig 8.5.3

8.6 Semi-spade rudder with 2-conjugate elastic support

8.6.1 Data for the Analysis

K_{11}, K_{12}, K_{22} : Rudder horn compliance constants calculated for rudder horn with 2-conjugate elastic supports (Figure 8.6.2).The 2-conjugate elastic supports are defined in terms of horizontal displacements, y_i, by the following equations:

at the lower rudder horn bearing:

$$y_1 = - K_{12} B_2 - K_{22} B_1$$

at the upper rudder horn bearing:

$$y_2 = - K_{11} B_2 - K_{12} B_1$$

where:

y_1, y_2 : Horizontal displacements,[m], at the lower and upper rudder horn bearings, respectively.

B_1, B_2 : Horizontal support forces,[kN], at the lower and upper rudder horn bearings, respectively.

K_{11}, K_{12}, K_{22} : Obtained, [m/kN], from the following formulae:

$$K_{11} = 1.3\frac{\lambda^3}{3EJ_{1h}} + \frac{e^2\lambda}{GJ_{th}}$$

$$K_{12} = 1.3\left[\frac{\lambda^3}{3EJ_{1h}} + \frac{\lambda^2(d-\lambda)}{2EJ_{1h}}\right] + \frac{e^2\lambda}{GJ_{th}}$$

$$K_{22} = 1.3\left[\frac{\lambda^3}{3EJ_{1h}} + \frac{\lambda^2(d-\lambda)}{EJ_{1h}} + \frac{\lambda(d-\lambda)^2}{EJ_{1h}} + \frac{(d-\lambda)^3}{3EJ_{2h}}\right] + \frac{e^2 d}{GJ_{th}}$$

d : Height of the rudder horn, [m], defined in Figure 8.6.2. This value is measured downwards from the upper rudder horn end, at the point of curvature transition, to the mid-line of the lower rudder horn pintle.

λ : Length, [m], as defined in Figure 8.6.2. This length is measured downwards from the upper rudder horn end, at the point of curvature transition, to the mid-line of the upper rudder horn bearing. For λ = 0, the above formulae converge to those of spring constant Z for a rudder horn with 1-elastic support, and assuming a hollow cross section for this part.

e : Rudder-horn torsion lever, [m], as defined in Figure 8.6.2 (value taken at z = d/2).

J_{1h} : Moment of inertia of rudder horn about the x axis,[m^4], for the region above the upper rudder horn bearing. Note that J_{1h} is an average value over the length λ (see Figure 8.6.2).

J_{2h} : Moment of inertia of rudder horn about the x axis,[m^4], for the region between the upper and lower rudder horn bearings. Note that J_{2h} is an average value over the length d - λ (see Figure 8.6.2).

J_{th} : Torsional stiffness factor of the rudder horn, [m^4].

For any thin wall closed section:

$$J_{th} = \frac{4F_T^2}{\sum_i \frac{u_i}{t_i}}$$

F_T : Mean of areas enclosed by outer and inner boundaries of the thin walled section of rudder horn, [m^2].

u_i : Length,[mm], of the individual plates forming the mean horn sectional area.

t_i : Thickness,[mm], of the individual plates mentioned above.

The J_{th} value is taken as an average value, valid over the rudder horn height.

Load of rudder body:

$$P_{R10} = F_{r2} / (\ell_{10} \times 10^3) \text{ [kN/m]};$$

$$P_{R20} = F_{r1} / (\ell_{20} \times 10^3) \text{ [kN/m]};$$

for F_r, F_{r1}, F_{r2}, see 3.2.2

8.6.2 The moments and shear forces are indicated in Fig.8.6.2.

8.6.3 Rudder horn bending moment

The bending moment acting on the generic section of the rudder horn is to be obtained, [Nm], from the following formulae:

- between the lower and upper supports provided by the rudder horn:

$M_H = F_{A1}\, z$

- above the rudder horn upper-support:

$M_H = F_{A1}\, z + F_{A2}\, (z - d_{lu})$

where:

F_{A1} : Support force at the rudder horn lower-support, [N], to be obtained according to Figure 8.6.2, and taken equal to B_1.

F_{A2} : Support force at the rudder horn upper-support, [N], to be obtained according to Figure 8.6.2, and taken equal to B_2.

z : Distance, [m], defined in Figure 8.6.3, to be taken less than the distance d, in [m], defined in the same figure.

d_{lu} : Distance, [m], between the rudder-horn lower and upper bearings (according to Figure 8.6.2, $d_{lu} = d - \lambda$).

8.6.4 Rudder horn shear force

The shear force Q_H, [N], acting on the generic section of the rudder horn is to be obtained, from the following formulae:

- between the lower and upper rudder horn bearings:

$Q_H = F_{A1}$

- above the rudder horn upper-bearing:
$Q_H = F_{A1} + F_{A2}$

where:

F_{A1}, F_{A2} : Support forces, in [N].

8.6.5 The torque, [Nm], acting on the generic section of the rudder horn is to be obtained from the following formulae:

- between the lower and upper rudder horn bearings:

$M_T = F_{A1}\, e_{(z)}$

- above the rudder horn upper-bearing:

$M_T = F_{A1}\, e_{(z)} + F_{A2}\, e_{(z)}$

where:

F_{A1}, F_{A2} : Support forces, in [N]

$e_{(z)}$: Torsion lever, [m], defined in Fig.8.6.3.

8.6.6 Rudder horn shear stress calculation

For a generic section of the rudder horn, located between its lower and upper bearings, the following stresses are to be calculated:

T_S: Shear stress, [N/mm^2], to be obtained from the following formula:

$$\tau_S = \frac{F_{A1}}{A_H}$$

T_T : Torsional stress, [N/mm^2], to be obtained for hollow rudder horn from the following formula:

$$T_T = \frac{M_T 10^{-3}}{2F_T t_H}$$

For solid rudder horn, T_T is to be specially considered.

For a generic section of the rudder horn, located in the region above its upper bearing, the following stresses are to be calculated:

T_S: Shear stress, [N/mm^2], to be obtained from the following formula:

$$\tau_S = \frac{F_{A1} + F_{A2}}{A_H}$$

T_T : Torsional stress, [N/mm^2], to be obtained for hollow rudder horn from the following formula:

$$T_T = \frac{M_T 10^{-3}}{2F_T t_H}$$

For solid rudder horn, T_T is to be specially considered, where:

F_{A1}, F_{A2} : Support forces, [N];

A_H : Effective shear sectional area of the rudder horn, [mm^2], in y-direction;

M_T : Torque, [Nm];

F_T : Mean of areas enclosed by outer and inner boundaries of the thin walled section of rudder horn, [m^2];

t_H : Plate thickness of rudder horn,[mm]. For a given cross section of the rudder horn, the maximum value of T_T is obtained at the minimum value of t_H.

8.6.7 Rudder horn bending stress calculation

For the generic section of the rudder horn within the length *d*, the following stresses are to be calculated:

σ_B : Bending stress, [N/mm^2], to be obtained from the following formula:

$$\sigma_B = \frac{M_H}{W_X}$$

where:

M_H : Bending moment, [Nm] at the section considered.

W_X : Section modulus, [cm^3], around the X-axis (see Fig.8.6.3).

Section 1

General

1.1 Introduction

1.1.1 To entitle a vessel to the letter 'L' in her character of classification, anchoring and mooring equipment is to be provided in accordance with the requirements of this Chapter.

1.1.2 Except in case of supply vessels engaged in towing operations and tugs, towlines are not subject of classification and the details given in the equipment table are for guidance purpose only. Requirements for towlines for supply vessels engaged in towing operations and tugs are given in 3.2.4. However, for tugs intended to be classed for operations in harbours only, requirement of towline may be waived with written concurrence from the owner.

1.1.3 Attention is drawn to any relevant requirements of the National Authorities of the country in which the ship is to be registered.

1.2 Design of the anchoring equipment

1.2.1 The anchoring equipment required herewith is intended for temporary mooring of a ship within a harbour or sheltered area when the ship is awaiting berth, tide, etc.

1.2.2 Anchoring equipment requirements for ships, designed for anchoring in deep and unsheltered waters, and assigned additional class notation ‘DWA,’ are indicated in Section 8.

1.2.3 The equipment is therefore not designed to hold a ship off fully exposed coasts in rough weather or to stop a ship which is moving or drifting. In this condition the loads on the anchoring equipment increase to such a degree that its components may be damaged or lost owing to the high energy forces generated, particularly in large ships.

1.2.4 The anchoring equipment required herewith is designed to hold a ship in good holding ground in conditions such as to avoid dragging of the anchor. In poor holding ground the holding power of the anchors is significantly reduced.

1.2.5 The Equipment Number (EN) formula for anchoring equipment required here under is based on an assumed current speed of 2.5 [m/s], maximum wind speed of 25 [m/s] and a minimum scope of chain cable of 6, the scope being the ratio between length of chain paid out and water depth. For ships with equipment

length, greater than 135 [m], alternatively the required anchoring equipment can be considered applicable to a maximum current speed of 1.54 [m/s], a maximum wind speed of 11 [m/s] and waves with maximum significant wave height of 2[m].

1.2.6 It is assumed that under normal circumstances a ship uses only one bow anchor and chain cable at a time.

1.2.7 In addition to planned anchoring for normal operations, anchoring equipment is also important for ship safety in emergency situations such as loss of manoeuvrability, unscheduled repairs and other unexpected situations.

1.2.8 The requirements of anchoring equipment in this Chapter are applicable to all self-propelled vessels over 100GT.

1.3 Documentation

1.3.1 The arrangements of anchoring and mooring and Equipment Number calculations are to be submitted for approval.

For vessels of 500 GT and above, towing arrangement plan is to be submitted for approval.

1.3.2 Following details of the proposed equipment are to be submitted for approval:-

1) Number, weight, type and design of anchors.

2) Length, diameter, grade and type of chain cables.

3) Type and breaking load of steel and fibre ropes.

1.4 Symbols and Definitions

1.4.1 L,B,T,C_b and k as defined in Ch.1, Sec.2.

1.4.2 The equipment length of the ship is the length between perpendiculars but is not to be less than 96% nor greater than 97% of the extreme length on the Summer Load waterline (measured from the forward end of the waterline).

Section 2

Structural Arrangement for Anchoring Equipment

2.1 General

2.1.1 The anchors are normally to be housed in hawse pipes and anchor pockets of adequate size, scantlings and suitable form to prevent movement of anchor and chain due to wave action. To hold the anchor tight in against the hull or the anchor pocket, respectively, it is recommended to fit anchor lashings. Anchor lashings are to be designed to resist a load at least corresponding to twice the anchor mass plus 10 [m] of cable without exceeding 40% of the yield strength of the material.

The arrangements are to provide an easy lead of chain cable from windlass to the anchors. Upon release of the brake, the anchors are to immediately start falling by their own weight. Substantial chafing lips are to be provided at shell and deck. These are to have sufficiently large, radiused faces to minimise the probability of cable links being subjected to large bending stresses. Alternatively, roller fairleads of suitable design may be fitted.

Alternative arrangements for housing of anchors will be specially considered.

2.1.2 The shell plating and framing in way of the hawse pipes are to be reinforced as necessary.

2.1.3 On ships provided with a bulbous bow, and where it is not possible to obtain ample clearance between shell plating and anchors during anchor handling, adequate local reinforcements on bulbous bow are to be provided.

2.1.4 The chain locker is to have adequate capacity and depth to provide an easy direct lead for the cable into the spurling pipes, when the cable is fully stowed. The spurling pipes are to be of suitable size and provided with chafing lips. The port and starboard cables are to have separate spaces.

The chain lockers boundaries and spurling pipes are to be watertight upto the weather deck. Bulkheads which form common boundary of chain lockers need not be watertight.

Where means of access to spurling pipes or cable lockers is provided, it is to be closed by a substantial cover and secured by closely spaced bolts.

Where a means of access to spurling pipes or cable lockers is located below the weather deck, the access cover and its securing arrangements are to be in accordance with recognized standards (such as ISO 5894:2018, IS 15876-2009, etc.) or equivalent for watertight manhole covers. Butterfly nuts and/or hinged bolts are not acceptable as the securing mechanism for the access cover.

Provisions are to be made to minimize the ingress of water to the chain locker in bad weather. The spurling pipes are to be provided with permanently attached closing appliances such as steel plates with cutouts for chain links or canvas hoods with lashing arrangements that maintains the cover in the secured position. For requirements regarding drainage of chain lockers, See Pt.4.

Provisions are to be made for securing the inboard ends of the chains to the structure. The strength of this attachment should be between 15 per cent to 30 per cent of the breaking strength of the chain cable. It is recommended that suitable arrangements be provided so that in an emergency the inboard end of the chain (bitter end) can be readily made to slip from an accessible position outside the chain locker.

2.1.5 The windlass and chain stoppers are to be efficiently bedded and secured to deck. The thickness of deck plating is to be increased in way of the windlass and chain stoppers and adequate stiffening underneath is to be provided.

Section 3

Equipment Specification

3.1 Equipment number

3.1.1 The equipment number, EN, on which the requirements of equipment are based is to be calculated as follows :-

$$EN = K.ENc$$

where,

$ENc = \Delta^{2/3} + 2(BH + S_{fun}) + 0.1A$

Δ = moulded displacement, [t], to the summer load water line

B = moulded breadth, [m]

H = effective height, [m], from the summer load waterline to the top of the uppermost deckhouse, to be measured as follows:

$H = a + \Sigma h_i$

a = vertical distance at hull side [m], from summer load waterline amidships to the upper deck

h_i = height [m] on the centreline of each tier of houses having a breadth greater than B/4. For the lowest tier, h_1 is to be measured at centre line from upper deck, or from a notional deck line where there is a local discontinuity in the upper deck. See Fig.3.1.1(a).

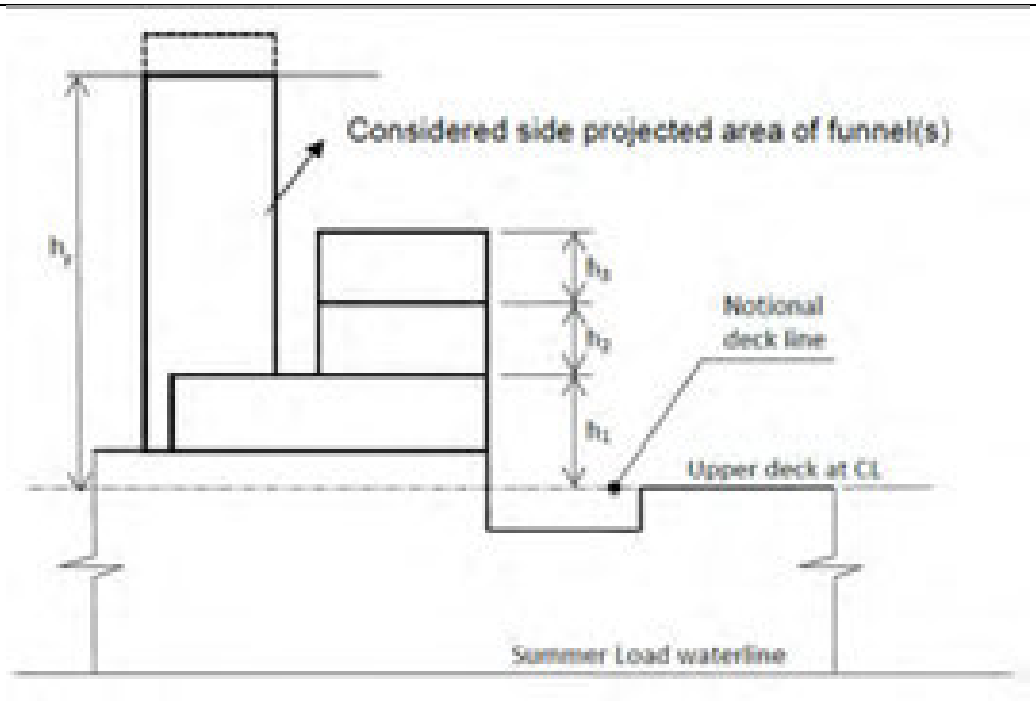

Fig. 3.1.1 (a)

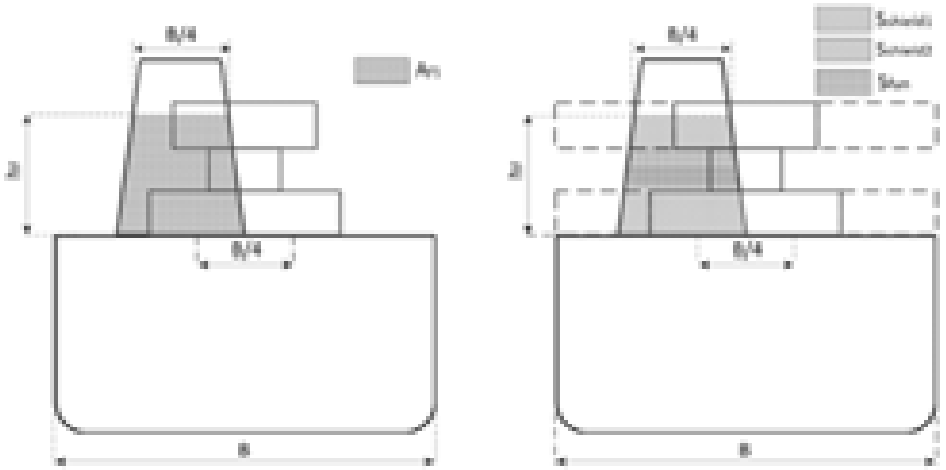

Fig. 3.1.1 (b)

S_{fun} = effective front projected area [m^2] of the funnel, defined as:

$$S_{fun} = A_{FS} - S_{shield}$$

A_{FS} = front projected area of the funnel, [m^2], calculated between the upper deck at centreline, or notional deck line where there is local discontinuity in the upper deck, and the effective height h_F. A_{FS} is taken equal to zero if the funnel breadth is less than or equal to B/4 at all elevations along the funnel height.

h_F = effective height of the funnel, [m], measured from the upper deck at centreline, or notional deck line where there is local discontinuity in the upper deck, and the top of the funnel. The top of the funnel may be taken at the level where the funnel breadth reaches B/4.

S_{shield} = the section of front projected area A_{FS}, [m^2], which is shielded by all deck houses having breadth greater than B/4 . If there are more than one shielded section, the individual shielded sections i.e $S_{shield1}$, $S_{shield2}$ etc as shown in Fig.3.1.1(b) are to be added together. To determine S_{shield}, the deckhouse breadth is assumed as B for all deck houses having breadth greater than B/4 as shown for $S_{shield1}$, $S_{shield2}$ in Fig.3.1.1(b).

A = side projected area [m^2] of the hull, superstructures and houses and funnels above the summer load waterline, which is within the equipment length of the ship and also have a breadth greater than B/4. The side projected area of the funnel is considered in A when A_{FS} is greater than zero. In this case, the side projected area of the funnel should be calculated between the upper deck, or notional deck line where there is local discontinuity in the upper deck, and the effective height h_F.
In the calculation of H , sheer and trim are to be ignored. i.e. H is the sum of freeboard amidships plus the height (at centreline) of each tier of houses having a breadth greater than B/4.

If a deckhouse having a breadth greater than B/4 is above a deckhouse with a breadth of B/4 or less, then the wide deckhouse is to be included but the narrow deckhouse ignored.

Windscreens or bulwarks which are more than 1.5[m] in height are to be regarded as parts of deckhouses when determining H and A. The height of the hatch coamings and that of any deck cargo, such as containers, may be disregarded when determining H and A. With regard to determining A, when a bulwark is more than 1.5 [m] high, the area shown in Fig.3.1.1(c) as A_2 is to be included in A.

When several funnels are fitted on the ship, the above parameters are taken as follows:

H_F: effective height of the funnel, [m], measured from the upper deck, or notional deck line where there is local discontinuity in the upper deck, and the top of the highest funnel. The top of the highest funnel may be taken at the level where the sum of each funnel breadth reaches B/4.

A_{FS}: sum of the front projected area of each funnel, [m^2], calculated between the upper deck, or notional deck line where there is local discontinuity in the upper deck, and the effective height H_F. A_{FS} is to be taken equal to zero if the sum of each funnel breadth is less than or equal to B/4 at all elevations along the funnels height.

A: Side projected area, [m^2], of the hull, superstructures, houses and funnels above the Summer Load waterline which are within the equipment length of the ship. The total side projected area of the funnels is to be considered in the side projected area of the ship, A, when A_{FS} is greater than zero. The shielding effect of funnels in transverse direction may be considered in the total side projected area, i.e., when the side projected areas of two or more funnels fully or partially overlap, the overlapped area needs only to be counted once.

'K' is a factor depending upon the type of vessel and service notation as given below:

For fishing vessels,

K = 1.00

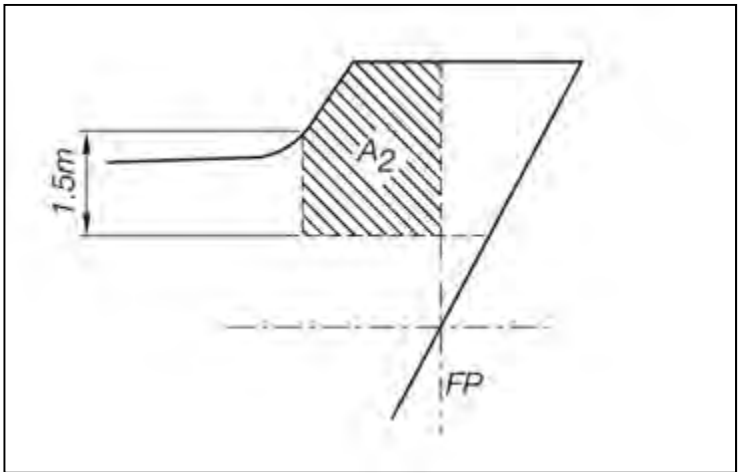

Fig. 3.1.1 (c)

For other vessels,

K = 1.00 for vessels of Unrestricted Service.
K = 0.85 for vessels of Coastal Service
K = 0.775 for vessels of Restricted Water Service.
K = 0.50 for vessels of Sheltered Water Service.

3.1.2 For a barge rigidly connected to a push tug the equipment number is to be calculated for the combination regarded as one unit.

3.1.3 For tugs, while determining the equipment number EN, the term '2BH' in Sec.3.1.1 may be substituted by $2(aB + \Sigma h_i b_i)$ where b_i is the breadth, [m], of the widest superstructure or deckhouse of each tier having a breadth greater than B/4. For tugs under 45 [m] in length intended for towing service only, one anchor may be used onboard provided that the second anchor and its relevant chain cable holds readily available to be installed. In case of loss of anchor, the tug is to remain in port until replace anchor equipment is installed onboard.

3.1.4 Dredgers with unusual design of the underwater part of the hull are not covered by alternative methodology using direct force calculation for anchoring equipment described in 3.3.

3.2 Equipment

3.2.1 For fishing vessels the equipment is to be in accordance with the requirements given in Table 3.2.1 using EN as calculated in 3.1.

3.2.2 For other vessels the equipment is to be in accordance with the requirements given in Table 3.2.2 using EN as calculated in 3.1.

3.2.3 The two bower anchors in Table 3.2.1 and Table 3.2.2 are to be connected to their cables and positioned onboard ready for use. The total length of chain is to be divided in approximately equal parts between the two bower anchors.

3.2.4 For tugs the particulars of towlines are to be based upon the maximum bollard pull and the intended duty of the vessel. However, in no case the breaking strength of the towline is to be less than twice the maximum bollard pull.

3.2.5 For unmanned barges and pontoons of length "L" less than 30 [m] no anchor need be provided.

Where length "L" is greater than or equal to 30 [m] only one anchor of the tabular weight need be provided. The attached chain cable is to be of the tabular diameter and 2 L [m] in length.

Two mooring lines of tabular breaking strength are to be provided where the length 'L' is less than 65 [m], otherwise three mooring lines are to be provided. The length of each mooring line is not be less than the greater of 2L [m] or 80 [m].

For unmanned barges and pontoons where the letter 'L' is not intended to be included in the character of classification only mooring lines of adequate length and strength need be provided.

3.2.6 For Fishing Vessels:

3.2.6.1 For fishing vessels below 40 m in length the anchor chain may be replaced with wire ropes of equal strength of the tabular anchor cables of Grade CC1. Wire ropes of trawl winches complying with this sub-section may be used as anchor chain cables.

3.2.6.2 When wire ropes are substituted for anchor chain cables then:

(i) the length of the ropes is to be equal to 1.5 times the corresponding tabular length of chain cable (Table 3.2.1),

(ii) a short length of chain cable is to be fitted between the wire rope and anchor having a length of 12.5 [m] or the distance between anchor in stowed position and winch, whichever is less,

(iii) all surfaces being in contact with the wire are to be rounded with a radius of not less than 10 times the wire rope diameter (including stem).

(iv) Steel wire is to be selected to fit for purpose based on the manufacturer recommendation and is to be provided with guidance for maintenance and inspection.

3.2.6.3 High holding power anchors of approved design may be used as bower anchors. The mass of each such anchor may be 75% of the tabular mass for ordinary stockless bower anchors.

3.2.6.4 The tabular anchor equipment may be increased for ships fishing and intended for anchoring in very rough waters.

3.2.7 Vessels other than fishing vessels:

3.2.7.1 Wire rope may be used in place of chain cable on ships:

(a) with less than 90 m in length and which will need an anchor for emergency purposes, i.e., not intended to use their anchor in normal temporary anchoring operation, or

(b) with the anchoring equipment used for positioning with a minimum of 4 points anchoring, e.g., for cable or pipe laying.

3.2.7.2 When wire ropes are substituted for anchor chains the following are to be complied with :-

i) The length of rope is to be at least 1.5 times the corresponding tabular length of chain cable and their strength is to be equal to that of chain cable of Grade CC 1.

ii) The anchor weight is to be increased by 25 % compared to anchor associated with chain cable.

iii) A short length of chain is to be fitted between the anchor and the wire rope. The length of the cable need be the smaller of 12.5 [m] and the distance between the anchor in stowed position and the winch.

iv) All surfaces being in contact with the wire need to be rounded with a radius of not less than 10 times the wire rope diameter (including stem).

v) Steel wire is to be selected to fit for purpose based on the manufacturer recommendation and is to be provided with guidance for maintenance and inspection.

3.2.8 For ships of length less than 90m, alternative methodology using direct force calculation for anchoring equipment described in 3.3 may be used.

3.3 Direct force calculation for anchoring equipment

3.3.1 General

3.3.1.1 As an alternative to the prescriptive approach described above, direct force calculation may be performed to determine the necessary anchoring equipment for monohull ships with length less than 90 m.

3.3.2 Total force F_{EN}

3.3.2.1 The total force (static + dynamic) F_{EN} , in [kN], induced by wind and current acting on monohull in anchoring condition as defined in 1.2 may be calculated as follows:

$$F_{EN} = 2\,(F_{SLPH} + F_{SH} + F_{SS})$$

where:

F_{SLPH}: Static force on wetted part of the hull due to current, as defined in 3.3.2.2

F_{SH}: Static force on hull due to wind, as defined in 3.3.2.3

F_{SS}: Static force on superstructures due to wind, as defined 3.3.2.4.

3.3.2.2 Static force on wetted part of hull F_{SLPH}

The theoretical static force induced by current applied on the wetted part of the hull, in [kN], is defined according to the following formula:

$$F_{SLPH} = \frac{1}{2}\rho C_f S_m V_c^2 10^{-3}$$

where:

ρ : Water density, equal to 1025 [kg/m^3]

C_f : Coefficient equal to:

$$C_f = (1+k)\frac{0.075}{(\log R_e - 2)^2}$$

With R_e, Reynolds number:

$$R_e = \frac{(V_c L_{WL})}{1.054 \cdot 10^{-6}}$$

k : Coefficient equal to:

$$k = 0.017 + 20\frac{C_{bWL}}{L_{WL}^2 T^{-0.5} B_{WL}^{-1.5}}$$

With C_{bWL}, block coefficient at waterline:

$$C_{bWL} = \frac{\Delta}{1.025 L_{WL} B_{WL} T}$$

Δ :Moulded displacement at waterline, in [m^3]

S_m :Total wetted surface of the part of the hull below waterline, in [m^2]
The value of S_m is to be given by the designer. When this value is not available, S_m may be taken equal to $6.\Delta^{2/3}$

V_C :Speed of the current, in [m/s], as defined in 1.2.

3.3.2.3 Static force on hull F_{SH}

The theoretical static force induced by wind applied on the upper part of the hull, in [kN], is defined according to the following formula:

$$F_{SH} = \frac{1}{2}\rho\left(C_{hfr}S_{hfr} + 0.02S_{hlat}\right)V_W^2 10^{-3}$$

where:

ρ : Air density, equal to 122 [kg/m^3]

V_W : Speed of the wind, in [m/s], as defined in 1.2

S_{hfr} : Front surface of hull and bulwark if any, in [m^2], projected on a vertical plane of the ship situated aft of the aft end of the ship and perpendicular to the longitudinal axis of the ship

S_{hlat} : Partial lateral surface of one single side of the hull and bulwark if any, in [m^2], through the overall length of the ship, projected on a vertical plane parallel to the longitudinal axis of the ship and delimited according to Figure 3.3.2.2

C_{hfr} :0.8 $\sin\alpha$, with α defined in Figure 3.3.2.2.

In Figure 3.3.2.2, B is the breadth of the hull, in [m].

The upper part of the hull is the part extending from side to side to the uppermost continuous deck extending over the ship length.

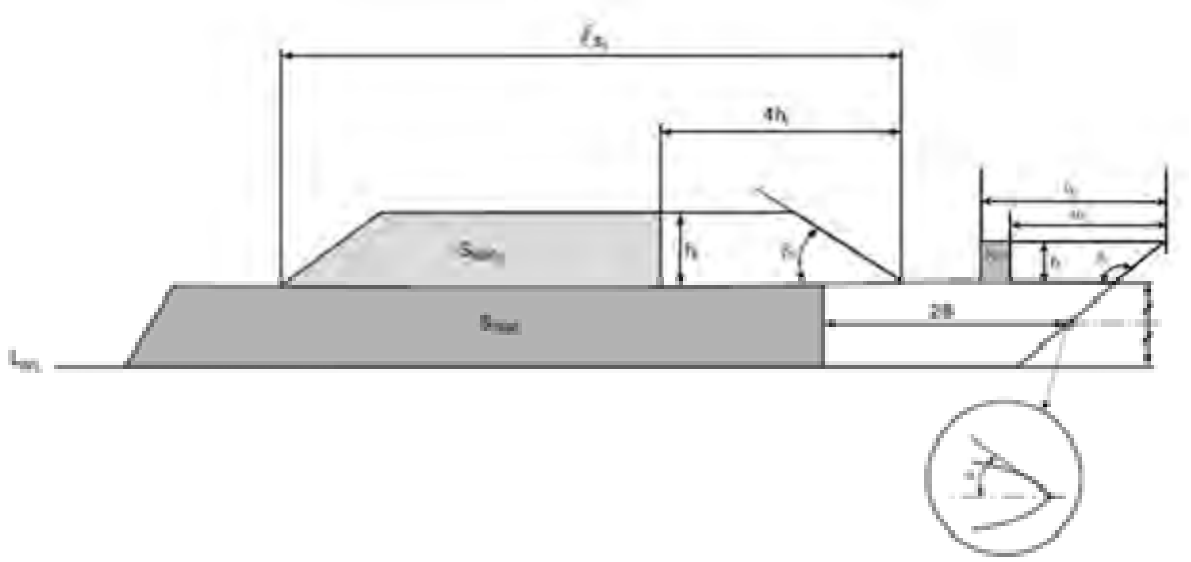

Figure 3.3.2.2

3.3.2.4 Static forces F_{SS} on superstructures and deckhouses

3.3.2.4.1 General case

The theoretical static force induced by wind applied on the superstructures and deckhouses, in [kN], is defined as the sum of the forces applied to each superstructure and deckhouse tier according to the following formula:

$$F_{SS} = \frac{1}{2}\rho\sum\left(C_{sfr_i}S_{sfr_i} + 0.08S_{slat_i}\right)V_W^2\ 10^{-3}$$

where:

ρ :Air density, equal to 1.22 [kg/m^3]

V_W :Speed of the wind, in [m/s], as defined in 3.3.2.3.

S_{sfri}: Front surface of tier i (superstructure or deckhouse, including bulwark if any), in [m^2], projected on a vertical plane of the ship situated aft of the aft end of the ship and perpendicular to the longitudinal axis of the ship

S_{slati} :Partial lateral surface of one single side of tier I (superstructure or deckhouse, including bulwark if any), in [m^2], projected on a vertical plane parallel to the longitudinal axis of the ship and delimited according to Figure 3.3.2.2

When $4h_i \geq l_{si}$, S_{lati} is to be taken equal to 0

C_{sfri} :0.8 sin β_i, with β_i defined in Figure 3.3.2.2 without being greater than 90°

3.3.2.4.2 Superstructures in the forward part of the ship

When superstructures are located in the front of the hull with front and side walls of superstructures in the continuity of the side shell, the static force induced by wind applied on these superstructures, in [kN], is defined as the sum of the forces applied to each superstructure tier according to the following formula:

$$F_{SS} = \frac{1}{2}\rho \sum \left(C_{hfr_i} S_{hfr_i} + 0.08 S_{slat_i}\right) V_W^2 \, 10^{-3}$$

where:

S_{hfri} : Front surface of tier i of the superstructure, in [m^2], projected on a vertical plane of the ship situated aft of the aft end of the ship and perpendicular to the longitudinal axis of the ship

C_{hfri} : $C_{hfri} = 0.8 \sin \alpha_s$, with α_s as defined for α in Figure 3.3.2.2 and measured at mid height of the superstructure tier located in the front of the hull.

ρ, V_W, S_{slati}: As defined in 3.3.2.4.1.

The static force is to be added to the static force calculated for the other superstructures and deckhouses according to 3.3.2.4.1.

3.3.3 Anchor weight

3.3.3.1 The individual mass of anchor, in kg, is to be at least equal to:

for ordinary anchor : $P = (F_{EN} / 7) * 10^2$

for high holding power anchor: $P = (F_{EN} / 10) * 10^2$

for very high holding power: $P = (F_{EN} / 15) * 10^2$

3.3.4 Chain cable

3.3.4.1 Stud link chain cable scantling

Chain cable diameters are to be selected from Pt.2, Ch.10, Table 1.4.1, based on the minimum breaking load BL and proof load PL of steel grades, in [kN], calculated according to the following formulae:

- for steel Grade CC 1:
  BL = 6 F_{EN}
  PL = 0.7 BL
- for steel Grade CC 2:
  BL = 6.8 F_{EN}
  PL = 0.7 BL
- for steel Grade CC 3:
  BL = 7.5 F_{EN}
  PL = 0.7 BL

The chain cable scantling is to be consistent with the mass of the associated anchor. In case the anchor on board is heavier by more than 7% from the mass calculated in 3.3.3, the value of F_{EN} to take into account for the calculation of BL and PL is to be deduced from the actual mass of the anchor according to the formulae in 3.3.3.

3.3.4.2 Length of individual chain cable

The length of chain cable L_{cc}, in [m], linked to each anchor is to be at least equal to:

- When P<180
  L_{cc} = 30 ln(P) - 42
- When P≥180
  L_{cc} to be selected according to Table 3.2.2

where:

P : Anchor weight, in [kg], defined in 3.3.3 for an ordinary anchor according to the considered case.

> 14600 & ≤ 16000	O*	2	46000	770			162					

1) For individual mooring lines with required breaking force above 490 [kN] according to the table, the required strength may be reduced by the corresponding increase of the number of mooring lines and vice versa, provided that the total of all mooring lines on board is not less than the Rule value. However, the number of mooring lines is not to be less than 6, and no line is to have a breaking force less than 490 [kN]

2) The minimum recommended breaking strength and number of mooring lines for ships with an Equipment Number **EN ≤ 2000** are given in the Table.

3) Value is applicable for ships with equipment number 1930 < EN ≤ 2000.

4) For ships with EN > 2000, ship design minimum breaking load and number of mooring lines is to be provided in accordance with the requirements in Section 6, Cl. 6.3.3.

Section 4

Anchors

4.1 General

4.1.1 Anchors are to be of an approved design.

4.1.2 The mass of each bower anchor as required in Sec.3 is for anchors of equal mass. The masses of individual anchors may vary by ±7 per cent of the tabular masses, provided that the total mass of the anchors is not less than that required for anchors of equal mass.

4.1.3 The mass of the head, including pins and fittings, of an ordinary stockless anchor is not to be less than 60 per cent of the total mass of the anchor.

4.1.4 Stocked bower anchors may be used for ships having 50 ≤ EN < 205. The mass of stocked bower anchors, when used or stream anchors, excluding the stock should be 80 per cent of the tabular mass of ordinary stockless bower anchors. The mass of the stock should be 20 per cent of the total mass of the anchor including the shackle etc. but excluding the stock.

4.1.5 When anchors of a design approved for the designation 'High Holding Power' or 'Super High Holding Power' are used as bower anchors, the mass of each such anchor may be 75 percent or 50 percent respectively of the tabular mass of ordinary stockless bower anchors.

4.1.6 Anchor shackles are to be of a design and material suitable to the service for which the anchor is intended.

4.2 High Holding Power (HHP) anchors

4.2.1 A ‘High Holding Power’ (HHP) anchor is an anchor with a holding power of at least twice that of an ordinary stockless anchor of the same mass. Designs of H.H.P. anchors are to be approved for the designation.

H.H.P. anchors are to be designed for effective hold of the sea bed irrespective of the angle or position at which they first settle on the sea bottom after dropping from a normal type of hawse pipe. In case of doubt a demonstration of these abilities may be required. The designs are to be tested on sea bottom at full scale to show that they have a holding down power per unit of mass at least twice that of approved ordinary stockless anchor.

4.2.2 If approval is sought for a range of anchor sizes, at least two sizes are to be tested. The mass of the larger anchor to be tested is not to be less than one-tenth of that of the largest anchor of which approval is sought. The mass of the maximum size approved is not to be more than 10 times the mass of the largest size tested.

Each test is to comprise of a comparison between the H.H.P. anchor and at least one approved ordinary stockless anchor of nearly equal mass. Where an ordinary stockless anchor is not available, for testing of HHP anchors; a previously approved HHP anchor may be used in place of an ordinary stockless anchor.

Anchors are to be tested in association with the size of chain cable appropriate to this mass.

4.2.3 Full scale tests are to be conducted on various types of bottom, which should normally be soft mud or silt, sand or gravel, and hard clay or similarly compacted material. Three tests are to be taken for each anchor and each type of bottom. The stability of the anchor and ease of breaking out are to be noted where possible.

The tests should normally be carried out from a tug, but alternatively shore tests may be accepted. The pull is to be measured by dynamometer or alternatively derived from recently verified curves of tug rev/min against bollard pull.

The length of the cable with each anchor is to be such that the pull on the shank remains horizontal. For this purpose, a scope of 10 is considered normal but a scope of not less than 6 may be accepted.

4.2.4 The holding power test load is not to exceed the proof load of the anchor.

4.3 Super High Holding Power (SHHP) anchors

4.3.1 A super high holding power anchor is an anchor with a holding power of at least four times that of an ordinary stockless anchor of the same mass. The use of SHHP anchors is to be limited to ships with service restrictions given in Pt.1, Ch.1, Sec. 2.7.3. These anchors are not to require prior adjustment or special placement on the sea bottom.

The SHHP anchor mass is generally not to exceed 1500 [kg].

4.3.2 For approval and/or acceptance as a SHHP anchor satisfactory full scale tests are to be made confirming that the anchor has a holding power of at least four times that of an ordinary stockless anchor or at least two times that of a previously approved HHP anchor, of the same mass. The tests are also to verify that the anchor withstands the test without permanent deformation.

4.3.3 The full scale tests are to be carried out at sea as specified in 4.2.3 for HHP anchors, on various types of bottom. The tests are to be applied to anchors of mass which are as far as possible representative of the full range of sizes proposed.

For a definite group within the range, the two anchors selected for testing (ordinary stockless and SHHP anchors) should be approximately the same mass and should be tested in association with the size of chain required for the anchor mass and anchor type. Where an ordinary stockless anchor is not available, a previously approved HHP anchor may be used in its place.

Tests in comparison with a previously approved SHHP anchor may be also accepted as a basis for approval.

If approval is sought for a range of anchor sizes then at least three anchor sizes are to be tested, indicative of the bottom middle and top of the mass range.

4.3.4 The holding power test load is not to exceed the proof load of the anchor.

4.4 Manufacture and testing

4.4.1 Anchors and anchor shackles are to be manufactured and tested in accordance with the requirements of Pt.2, Ch.10.

Section 5

Anchor Chain Cables

5.1 General

5.1.1 Anchor chain cables and steel wire ropes (where proposed in lieu of chain cables) are to be as required by Sec.3.

5.1.2 Grade CC3 chain cable is to be used only when diameter is 20.5 [mm] or more.

5.1.3 Grade CC1 chain cable having material tensile strength of less than 400 [N/mm^2] is not to be used in association with high holding power or super high holding power anchors.

5.1.4 When the vessel may anchor where the current exceeds 2.5 m/s, a length of heavier chain cable locally between the anchor and the rest of the chain to enhance anchor bedding is recommended.

5.2 Manufacture and testing

5.2.1 Chain cables, steel wire ropes and shackles are to be manufactured and tested in accordance with the requirements of Pt.2, Ch.10.

Section 6

Towlines, Mooring Lines and associated Shipboard Fittings

6.1 General

6.1.1 For the purpose of this Section, the following is defined:

- *Conventional ships* means new displacement-type ships of 500 GT and above, excluding high speed craft, special purpose ships (as defined in MSC. 266(84)), and offshore units of all types.

- *Shipboard fittings* mean those components limited to the following: Bollards and bitts, fairleads, stand rollers, chocks used for normal mooring of the ship and the similar components used for normal or other towing of the ship. Other components such as capstans, winches, etc. are not covered by this Section. Any weld or bolt or equivalent device connecting the shipboard fitting to the supporting structure is part of the shipboard fitting and if selected from an industry standard subject to that standard.

- *Supporting hull structures* means that part of the ship structure on/in which the shipboard fitting is placed and which is directly submitted to the forces exerted on the shipboard fitting. The supporting hull structure of capstans, winches, etc. used for normal or other towing and mooring operations mentioned above is also subject to the requirements of this Section.

- *Industry standard* means international standards (ISO, etc.) or standards issued by national association such as DIN or JMSA, etc. which are recognized in the country where the ship is built.

- *The nominal capacity condition* is defined as the theoretical condition where the maximum possible deck cargoes are included in the ship arrangement in their respective positions. For container ships the nominal capacity condition represents the theoretical condition where the maximum possible number of containers is included in the ship arrangement in their respective positions.

- *Ship Design Minimum Breaking Load* (MBL_{SD}) means the minimum breaking load of new, dry mooring lines or tow line for which shipboard fittings and supporting hull structures are designed in order to meet mooring restraint requirements or the towing requirements of other towing service.

- *Line Design Break Force* (LDBF) means the minimum force that a new, dry, spliced, mooring line will break at. This is for all synthetic cordage materials.

6.1.2 Conventional ships are to be provided with arrangements, equipment and fittings of sufficient safe working load to enable the safe conduct of all towing and mooring operations associated with the normal operations of the ship.

6.1.3 The requirements of this Section are intended to apply to design and construction of shipboard fittings and supporting structures used for normal towing and mooring operations. Normal towing means towing operations necessary for maneuvering in ports and sheltered waters associated with normal operations of the ship.

6.1.4 For ships, not subject to SOLAS Regulation II-1/3-4 Para 1, but intended to be fitted with equipment for towing by another ship or a tug, e.g. such as to assist the ship in case of emergency as given in SOLAS Regulation II-1/3-4 Para 2, the requirements designated as 'other towing' in this Section are to be applied to design and construction of those shipboard fittings and supporting hull structures.

6.1.5 This Section is not applicable to design and construction of shipboard fittings and supporting hull structures used for special towing services defined as:

— *Canal transit towing*: Towing service for ships transiting canals, e.g. the Panama Canal. Local canal transit requirements are to be referred.

— *Emergency towing for tankers*: Towing service to assist tankers in case of emergency. For emergency towing arrangements, ships subject to SOLAS regulation II-1/3-4 Para 1 are to comply with that regulation and resolution MSC.35 (63) as may be amended.

— *Escort towing*: Towing service, in particular, for laden oil tankers or LNG carriers, required in specific estuaries. Local escort requirements and guidance given by organizations such as the Oil Companies International Marine Forum (OCIMF), may be referred.

6.2 Manufacture and Testing

6.2.1 Towlines and mooring lines may be of steel wire, natural fibre or synthetic fibre and are to be made by an approved manufacturer. For synthetic fibre ropes, it is recommended to use lines with reduced risk of recoil (snap-back) to mitigate the risk of injuries or fatalities in the case of breaking mooring lines.

6.2.2 Steel wire ropes are to be manufactured and tested in accordance with the requirements of Pt.2, Ch.10.

6.2.3 Fibre ropes will be specially considered in each case.

6.2.4 The number, length and breaking strength of towlines and mooring lines are to be as required by Table 3.2.2. Also see 1.1.2 and 6.3.

6.3 Mooring Lines

6.3.1 Requirements for mooring lines for ships with EN ≤ 2000 are given in Table 3.2.2. For other ships the mooring line requirements are given in 6.3.3. Deck cargoes at the ship nominal capacity condition is to be included for the determination of the side projected area A. The nominal capacity condition is defined in 6.1.1. Minimum number and minimum strength of mooring lines is specified in 6.3.2 and 6.3.3. As an alternative to 6.3.2 and 6.3.3, the minimum requirements for mooring lines may be determined by direct mooring analysis in line with the procedure given in 6.15. The designer should consider verifying the adequacy of mooring lines based on assessments carried out for the individual mooring arrangement, expected shore-side mooring facilities and design environmental conditions for the berth. The definition of line design break force (LDBF) is given in 6.1.1. This value is declared by the manufacturer on each mooring line certificate and is stated on a manufacturer's line data sheet. LDBF of a line is to be 100%-105% of the ship design minimum breaking load defined in 6.3.3.5. The LDBF for nylon mooring lines is to be specified as break tested wet, because nylon lines change strength characteristics once exposed to water and generally do not fully dry to their original construction state.

6.3.2 Mooring lines for ships with EN ≤ 2000

6.3.2.1 The minimum recommended mooring lines for ships having an EN ≤ 2000 are given in Table 3.2.2.

For ships having the ratio A/EN > 0.9, the following number of lines are to be added to the number of mooring lines as given by Table 3.2.2:

One line where $0.9 < \frac{A}{EN} \leq 1.1,$

Two lines where $1.1 < \frac{A}{EN} \leq 1.2,$

Three lines where $1.2 < \frac{A}{EN}$

6.3.3 Mooring lines for ships with EN > 2000

6.3.3.1 The minimum recommended strength and number of mooring lines for ships with an EN > 2000 are given in 6.3.3.5 and 6.3.3.6 respectively. The length of mooring lines is given by 6.3.4.

6.3.3.2 The strength of mooring lines and the number of head, stern, and breast lines (see Note) for ships with an Equipment Number EN > 2000 are based on the side-projected area A_1. Side projected area A_1 is to be calculated similar to the side-projected area A according to Sec. 3, Cl. 3.1 but considering the following conditions:

- The ballast draft is to be considered for the calculation of the side-projected area A_1. For ship types having small variation in the draft, like e.g. passenger and RO/RO vessels, the side projected area A_1 may be calculated using the summer load waterline.

- Wind shielding of the pier can be considered for the calculation of the side-projected area A_1 unless the ship is intended to be regularly moored to jetty type piers. A height of the pier surface of 3 m over waterline may be assumed, i.e. the lower part of the side-projected area with a height of 3 m above the waterline for the considered loading condition may be disregarded for the calculation of the side-projected area A_1.

- Deck cargoes at the ship nominal capacity condition is to be included for the determination of side-projected area A_1. For the condition with cargo on deck, the summer load waterline may be considered. Deck cargoes may not need to be considered if ballast draft condition generates a larger side-projected area A_1 than the full load condition with cargoes on deck. The larger of both side-projected areas is to be chosen as side-projected area A_1. The nominal capacity condition is defined in 6.1.1.

6.3.3.3 The mooring lines as given here under are based on a maximum current speed of 1.0 [m/s] and the following maximum wind speed v_w, in [m/s]:

V_w = 25.0 – 0.002 (A_1 – 2000) for passenger ships, ferries and car carriers with 2000 [m^2] < A_1 ≤ 4000 [m^2]

= 21.0 for passenger ships, and car carriers with A_1 > 4000 [m^2]

= 25.0 for other ships.

The wind speed is considered representative of a 30 second mean speed from any direction and at a height of 10 [m] above the ground. The current speed is considered representative of the maximum current speed acting on bow or stern (±10°) and at a depth of one-half of the mean draft. Furthermore, it is considered that ships are moored to solid piers that provide shielding against cross current.

Special consideration is to be given to additional loads caused by e.g., higher wind or current speeds, cross currents, additional wave loads, or reduced shielding from non-solid piers for designing the mooring arrangements. It may be noted that unbeneficial mooring layouts can considerably increase the loads on single mooring lines.

6.3.3.4 The following is defined with respect to the purpose of mooring lines (Fig. 6.3.3.4):

.1 *Breast Line*: A mooring line that is deployed perpendicular to the ship, restraining the ship in the off-berth direction.

.2 *Spring line*: A mooring line that is deployed almost parallel to the ship, restraining the ship in fore or aft direction.

.3 *Head/Stern line*: A mooring line that is oriented between longitudinal and transverse direction, restraining the ship in the off-berth and in fore or aft direction. The amount of restraint in fore or aft and off-berth direction depends on the line angle relative to these directions.

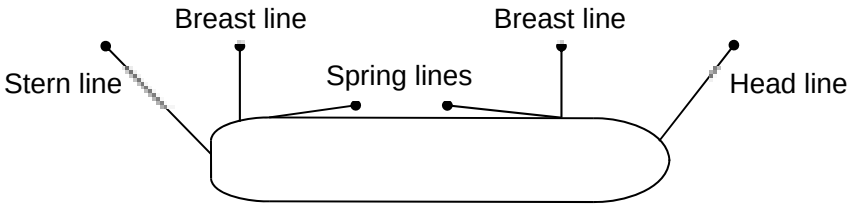

Fig 6.3.3.4 : Mooring Lines

6.3.3.5 Ship design minimum breaking load

.1 The ship design minimum breaking load(MBL_{SD}), in kN, of the mooring lines is to be taken as:

$$MBL_{SD} = 0.1 * A1 + 350$$

The ship design minimum breaking load may be limited to 1275 [kN]. However, in this case the moorings are to be considered as not sufficient for environmental conditions given by 6.3.3. For these ships, the acceptable wind speed vw* [m/s], can be estimated as follows:

$$v_w^* = v_w \cdot \sqrt{MBL_{SD}^* / MBL_{SD}}$$

where v_w is the wind speed as per 6.3.3.3, MBL_{SD}* the ship design minimum breaking load of the mooring lines intended to be supplied and MBL_{SD} the ship design minimum breaking load as recommended according to the above formula.
However, the ship design minimum breaking load is not to be taken less than corresponding to an acceptable wind speed of 21 [m/s]:

$$MBL_{SD}^* \geq \left(\frac{21}{v_w}\right)^2 . \ MBL_{SD}$$

If lines are intended to be supplied for an acceptable wind speed v_w* higher than v_w as per 6.3.3.3, the ship design minimum breaking load is to be taken as:

$$MBL_{SD}^* = \left(\frac{v_w^*}{v_w}\right)^2 . \ MBL_{SD}$$

6.3.3.6 Number of Mooring Lines

.1 The total number of head, stern and breast lines is to be taken as:

$$n = 8.3 * 10^{-4} * A_1 + 6$$

.2 For oil tankers, chemical tankers, bulk carriers, and ore carriers the total number of head, stern and breast lines is to be taken as:

$$n = 8.3 * 10^{-4} * A_1 + 4$$

The total number of head, stern and breast lines is to be rounded to the nearest whole number.

.3 The number of head, stern and breast lines may be increased or decreased in conjunction with an adjustment to the ship design minimum breaking load of the lines. The adjusted ship design minimum breaking load, MBL_{SD}**, is to be taken as:

- for increased number of lines

$$MBL_{SD}^{**} = 1.2 \, MBL_{SD} \times {}^{n}/_{n^{**}} \leq MBL_{SD}$$

- for reduced number of lines

$$MBL_{SD}^{**} = MBL_{SD} \times {}^{n}/_{n^{**}}$$

where MBL_{SD} is MBL_{SD} or MBL_{SD}* specified in 6.3.3.5.1, as appropriate, n** is the increased or decreased total number of head, stern and breast lines and n the number of lines for the considered ship type as calculated by the above formulas without rounding.

Vice versa, the ship design minimum breaking load of head, stern and breast lines may be increased or decreased in conjunction with an adjustment to the number of lines.

.4 The total number of spring lines is to be taken not less than:

Two lines where EN < 5000,

Four lines where EN ≥ 5000.

The ship design minimum breaking load of spring lines is to be the same as that of the head, stern and breast lines. If the number of head, stern and breast lines is increased in conjunction with an adjustment to the ship design minimum breaking load of the lines, the number of spring lines is also to be taken as follows, but rounded up to the nearest even number.

$n_s^* = MBL_{SD}/MBL_{SD}^{**} \; n_s$

where MBL_{SD} is MBL_{SD} or MBL_{SD}^* specified in 6.3.3.5.1, as appropriate, n_s is the number of spring lines as given above and n_s^* the increased number of spring lines.

6.3.4 Length of mooring Lines

6.3.4.1 The length of mooring lines for ships with EN ≤ 2000 may be taken from Table 3.2.2. For ships with EN > 2000 the length of mooring lines may be taken as 200 [m].

6.3.4.2 The lengths of individual mooring lines may be reduced by up to 7% of the above given lengths, but the total length of mooring lines should not be less than would have resulted had all lines been of equal length.

6.4 Mooring and Towing Arrangements

6.4.1 Mooring Arrangements

6.4.1.1 Mooring lines in the same service (e.g. breast lines, as defined in 6.3.3.4) are to be of the same characteristic in terms of strength and elasticity.

6.4.1.2 As far as possible, sufficient number of mooring winches are to be fitted to allow for all mooring lines to be belayed on winches. This allows for an efficient distribution of the load to all mooring lines in the same service and for the mooring lines to shed load before they break. If the mooring arrangement is designed such that mooring lines are partly to be belayed on bitts or bollards, it is to be considered that these lines may not be as effective as the mooring lines belayed on winches.

6.4.1.3 Mooring lines are to have as straight a lead as is practicable from the mooring drum to the fairlead. At points of change in direction sufficiently large radii of the contact surface of a rope on a fitting are to be provided to minimize the wear experienced by mooring lines and as recommended by the rope manufacturer for the rope type intended to be used.

6.4.2 Mooring Winches

6.4.2.1 Each mooring winch is to be fitted with brakes, the holding capacity of which is sufficient to prevent unreeling of the mooring line when the rope tension is equal to 80 % of the ship design minimum breaking load of the rope as fitted on the first layer on the winch drum. The winch is to be fitted with brakes that will allow for the reliable setting of the brake rendering load.

6.4.2.2 For powered winches the maximum hauling tension which can be applied to the mooring line (the reeled first layer) is not to be less than 1/4.5 times, nor be more than 1/3 times the rope's ship design minimum breaking load. For automatic winches these figures apply when the winch is set to the maximum power with automatic control.

6.4.2.3 For powered winches on automatic control, the rendering tension which the winch can exert on the mooring line (the reeled first layer) is not to exceed 1.5 times, nor be less than 1.05 times the hauling tension for that particular power setting of the winch. The winch is to be marked with the range of rope strength for which it is designed.

6.4.3 Towing Arrangements

6.4.3.1 Towing lines are to be led through a closed chock. The use of open fairleads with rollers or closed roller fairleads is to be avoided.

6.4.3.2 For the purpose of towing, bitts or bollards serving a chock are to be located slightly offset and in a distance of at least 2 [m] away from the chock, see Fig. 6.4.3.2:

6.4.3.3 Warping drums are to preferably be positioned not more than 20 [m] away from the chock, measured along the path of the line.

6.4.3.4 Attention is to be given to the arrangement of the equipment for towing and mooring operations in order to prevent interference of mooring and towing lines as far as practicable. It is beneficial to provide dedicated towing arrangements separate from the mooring equipment.

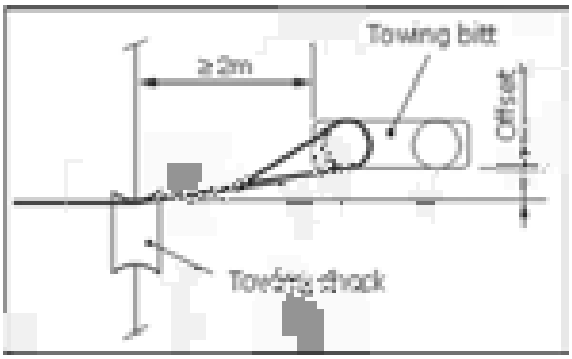

Fig 6.4.3.2

6.5 Shipboard fittings

6.5.1 Means are to be provided to enable towing lines and mooring lines to be adequately secured on board a ship. Bollards and bitts, fairleads, chocks, cleats, etc. are to be so designed and installed as to protect ropes against excessive wear.

6.5.2 The shipboard fittings associated with towing and/or mooring, may be selected from an accepted industry standard, such as. ISO 13795 Ships and Marine Technology – Ship's mooring and towing fittings – welded steel bollards for sea-going vessels and at least based on the following loads:

(a) For normal towing operations, the intended towing load (e.g. static bollard pull) as indicated on the towing and mooring arrangements plan,

(b) For other towing service, the ship design minimum breaking load of the tow line according to Table 3.2.2. Also see 6.7.1 b) and note to 6.7.1.

(c) For fittings intended to be used for, both, normal and other towing operations, the greater of the loads according to (a) and (b).

(d) For mooring operations, the ship design minimum breaking load of the mooring line according to 6.3.2 and 6.3.3, as applicable.

6.5.3 Towing bitts (double bollards) may be chosen for the towing line attached with eye splice if the industry standard distinguishes between different methods to attach the line, i.e. figure-of-eight or eye splice attachment.

6.5.4 Mooring bitts (double bollards) are to be chosen for the mooring line attached in figure-of-eight fashion, if the industry standard distinguishes between different methods to attach the line, i.e. figure-of-eight or eye splice attachment.

6.5.5 When the shipboard fitting is not selected from an accepted industry standard, the strength of the fitting and of its attachment to the ship is to be in accordance with 6.7 and 6.8. Towing bitts (double bollards) are required to resist the loads caused by the towing line attached with eye splice. Mooring bitts (double bollards) are required to resist the loads caused by the mooring line attached in figure--eight fashion, see Note.

Note: With the line attached to a mooring bitt in the usual way (figure-of-eight fashion), either of the two posts of the mooring bitt can be subjected to a force twice as large as that acting on the mooring line. Disregarding this effect, depending on the applied industry standard and fitting size, overload may occur.

6.5.6 For strength assessment beam theory or finite element analysis using net scantlings is to be applied, as appropriate. Corrosion additions are to be as defined in 6.11. A wear down allowance is to be included as defined in 6.12.

6.6 Supporting Hull Structures

6.6.1 Shipboard fittings, winches and capstans are to be suitably located on stiffeners and/or girders, which are part of the deck construction so as to facilitate efficient distribution of the towing and/ or mooring loads. Other

arrangements for mooring such as chocks in bulwarks, may be accepted provided the strength is confirmed adequate for the service.

6.6.2 The supporting structure of capstans and winches used for normal or other towing and mooring operations are also to meet the strength requirements.

6.6.3 The net scantlings of the underdeck supporting structure are to be adequate to meet the design loads specified in 6.7, considering the possible locations for transfer of the load and any horizontal or vertical variation in direction of the applied load. Proper alignment of fittings and supporting hull structure is to be ensured (see sample arrangement in Fig. 6.6.3).

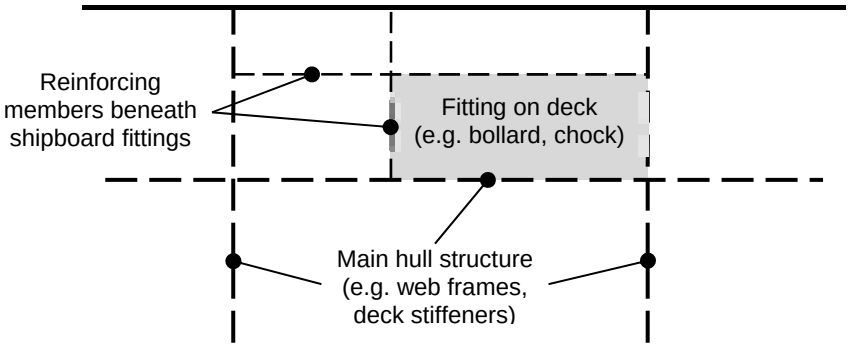

Fig. 6.6.3 : Sample Arrangement

6.6.4 The acting point of the force on the shipboard fittings is to be taken at the attachment point of the towing/mooring line or at a change in its direction. For bollards and bitts the attachment point of the towing/ mooring line is to be taken not less than 4/5 of the tube height above the base, see Fig. 6.6.4(a) and Fig. 6.6.4(b) (i) for towing and mooring respectively. However, if fins are attached to the bollard tubes to keep the mooring lines as low as possible, the attachment point of the mooring line may be taken at the location of the fins, see Fig. 6.6.4 (b) (ii).

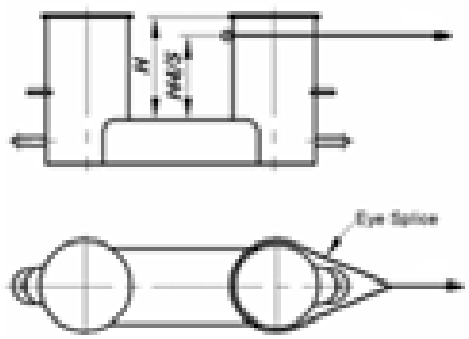

Fig. 6.6.4(a) : Attachment point of the towing line

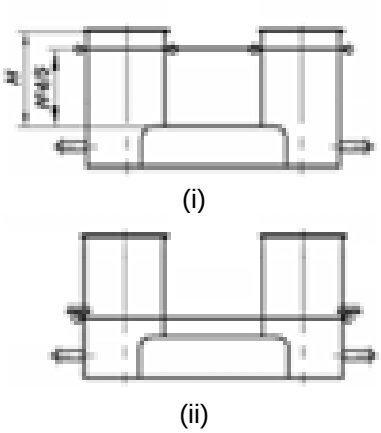

(i)

(ii)

Fig. 6.6.4(b) : Attachment point of the mooring line

6.6.5 The arrangement of the ship's structure in way of the shipboard fittings and their seats and in way of capstans is to be such that abrupt changes of shape or section are to be avoided in order to minimize stress concentrations. Sharp corners and notches are to be avoided, especially in highly stressed areas.

6.7 Design Loads

6.7.1 Unless the designer specifies a greater safe working load (SWL) or safe towing load (TOW) for the shipboard fitting, the minimum design load is to be as follows:

a) For normal towing operations, 1.25 times the intended maximum towing load (e.g. static bollard pull) as indicated on the towing and mooring arrangement plan.

b) For other towing operations, the ship design minimum breaking load as required in Table 3.2.2 corresponding to the equipment number of the vessel as per 3.1.1. Side projected area including that of deck cargoes as given by the ship nominal capacity condition is to be taken into account for selection of the towing lines and the loads applied to shipboard fittings and supporting hull structure.

c) For fittings intended to be used for both normal and other towing operations, the greater of the design loads according to a) and b).

d) For mooring operations, the minimum design load is to be 1.15 times the ship design minimum breaking load according to 6.3.2 and 6.3.3, as applicable. Side projected area including that of deck cargoes as given by the ship nominal capacity condition is to be taken into account for selection of the towing lines and the loads applied to shipboard fittings and supporting hull structure.

Note: The increase of the line design break force for synthetic ropes according to 6.2.6 need not be taken into account for the loads applied to shipboard fittings and supporting hull structures.

6.7.2 The minimum design load applied to supporting hull structures for winches is to be 1.25 times the intended maximum brake holding load, where the maximum brake holding load is to be assumed not less than 80% of the ship design minimum breaking load according to 6.3.2 and 6.3.3. For supporting hull structures of capstans, 1.25 times the maximum hauling-in force is to be taken as the minimum design load.

6.7.3 The design load is to be applied to fittings in all directions that may occur by taking into account the arrangement shown on the towing and mooring arrangements plan. Where the towing line and mooring line takes a turn at a fitting the total design load applied to the fitting is equal to the resultant of the design loads acting on the line, (see Fig. 6.7.3). However, in no case does the design load applied to the fitting need to be greater than twice the design load on the line

6.7.4 When a safe towing load TOW greater than that determined according to 6.9 is requested by the owner/ designer, then the

design load is to be increased in accordance with the appropriate TOW/ design load relationship given by 6.5 and 6.9.

6.7.5 When a safe working load SWL greater than that determined according to 6.9 is requested by the owner/ designer, then the design load is to be increased in accordance with the appropriate SWL/ design load relationship given by 6.5 and 6.9

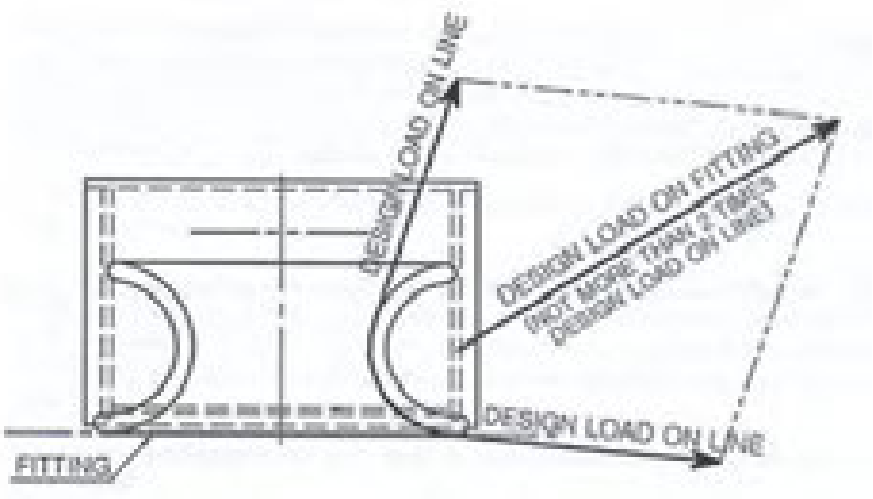

Fig. 6.7.3 : Design Load on Fitting

6.8 Acceptance Criteria

6.8.1 Allowable stresses in the shipboard fittings, supporting structure and welds are not to be exceeded, as given below:

6.8.2 For strength assessment by means of beam theory or grillage analysis:

Normal stress = 1.0 R_{eH}

Shear stress, $\tau = 0.6R_{eH}$

Where R_{eH}= specified minimum yield stress of the material [N/mm^2];

Normal stress is the sum of the bending stress and axial stress. No stress concentration factors being taken into account.

6.8.3 For strength assessment by means of finite element analysis:

Von Mises stress = $1.0R_{eH}$

For strength assessment by means of finite element analysis the mesh is to be fine enough to represent the geometry as realistically as possible. The aspect ratios of elements are not to exceed 3. Girders are to be modelled using shell or plane stress elements. Symmetric girder flanges may be modelled by beam or truss elements. The element height of girder webs must not exceed one-third of the web height. In way of small openings in girder webs the web thickness may be reduced to a mean thickness over the web height. Large openings are to be modelled. Stiffeners may be modelled by using shell, plane stress, or beam elements. The mesh size of stiffeners is to be fine enough to obtain proper bending stress. If flat bars are modeled using shell or plane stress elements, dummy rod elements are to be modelled at the free edge of the flat bars and the stresses of the dummy elements are to be evaluated. Stresses are to be read from the centre of the individual element. For shell elements the stresses are to be evaluated at the mid plane of the element.

6.8.4 Stress concentration factors are not to be taken into account in the above allowable stresses.

6.9 Safe Towing Load (TOW) and Safe Working Load (SWL)

6.9.1 The safe towing load (TOW) is the safe load limit of shipboard fittings used for towing purpose. The following requirements for TOW apply for use with no more than one line. If not otherwise chosen, for towing bitts (double bollards) TOW is the load limit for a towing line attached with eye-splice.

.1 TOW used for normal towing operations is not to exceed 80% of the design load according to 6.7.1 (a)

.2 TOW used for other towing operations is not to exceed 80% of the design load according to 6.7.1 (b)

.3 For fittings used for both normal and other towing operations, the greater of the safe towing loads according to 6.9.1.1. and 6.9.1.2 is to be used

.4 TOW, in [t], of each shipboard fitting is to be marked (by weld bead or equivalent) on the deck fittings used for towing. For fittings intended to be used for, both, towing and mooring, SWL, in [t], according to 6.9.2 is to be marked in addition to TOW.

.5 The towing and mooring arrangements plan as indicated in 6.10 is to define the method of use of towing lines.

6.9.2 The safe working load (SWL) is the safe load limit of shipboard fittings used for mooring purpose. The following requirements for SWL apply for the use with no more than one mooring line:

.1 Unless a greater SWL is requested by the applicant according to 6.7.4, the SWL is not to exceed the ship design minimum breaking load according to 6.3.2 and 6.3.3.

.2 The SWL, in [t], of each shipboard fitting is to be marked (by weld bead or equivalent) on the deck fittings used for mooring. For fittings intended to be used for, both, mooring and towing, TOW, in [t], according to 6.9.1 is to be marked in addition to SWL.

.3 The towing and mooring arrangements plan as indicated in 6.10 is to define the method of use of mooring lines.

6.10 Towing and mooring arrangement plan

.1 The SWL and TOW for the intended use for each shipboard fitting is to be noted in the towing and mooring arrangement plan available on board for the guidance of the Master. It is to be noted that TOW is the load limit for towing purpose and SWL that for mooring purpose. If not otherwise chosen, for towing bitts, it is to be noted that TOW is the load limit for a towing line attached with eye-splice.

.2 Information provided on the plan is to include in respect of each shipboard fitting:

a) location on the ship;
b) fitting type;
c) SWL/ TOW;
d) Purpose (mooring / harbour towing / other towing); and
e) Manner of applying towing or mooring line load including limiting fleet angle i.e. angle of change in direction of an line at the fitting.

Item c) with respect to items d) and e) is subject to approval by IRS.

The following information is also to be clearly indicated on the plan:

a) the arrangement of mooring lines showing number of lines (N), together with

b) the ship design minimum breaking load (MBL_{SD}).

c) the acceptable environmental conditions as given in 6.3.3.3 and 6.3.3.5 for the recommended ship design minimum breaking load for ships with EN > 2000:

• 30 second mean wind speed from any direction. (v_w or v_w^* according to 6.3.3.3 and 6.3.3.5)

• Maximum current speed acting on bow or stern (±10°).

.3 The information as given in 6.10.2 is to be incorporated into the pilot card in order to provide the pilot proper information on harbor and other towing operations.

6.11 Corrosion Addition

6.11.1 The total corrosion addition, t_c, is not to be less than the following values:

- For the supporting hull structure, according to the rules for the surrounding structure (e.g. deck structures, bulwark structures)

- For pedestals and foundations on deck which are not part of a fitting according to an accepted industry standard, 2.0 [mm]

- For shipboard fittings not selected from an accepted industry standard, 2.0 [mm].

6.12 Wear Allowance

6.12.1 In addition to the corrosion allowance specified in 6.11, a wear allowance, t_w, not less than 1.0 [mm] is to be added to surfaces which are intended to regularly contact the line.

6.13 Surveys after construction

6.13.1 The condition of deck fittings, their pedestals or foundations and the hull structures in the vicinity of the fittings are to be surveyed in accordance with the requirements of Pt.1, Ch.2.

6.14 Emergency towing procedure

6.14.1 A ship specific emergency towing procedure is to be provided according to SOLAS Ch.II-1/Reg.3-4 on ships as indicated in the following:

a) all passenger ships, not later than 01 January 2010

b) cargo ships constructed on or after 01 January 2010

c) Cargo ships constructed before 01 January 2010, not later than 01 January 2012.

In the case of oil tankers, chemical carriers and liquefied gas carriers, the requirement for emergency towing arrangements given in Pt.5, Ch.2, Sec.2.8, Pt.5, Ch.3, IR2.8 and Pt.5, Ch.4, IR3.9 respectively are also to be complied with.

6.14.2 The emergency towing procedure is to be based on existing arrangements and equipment available on board the ship

6.14.3 The emergency towing procedure is to include:

a) drawings of fore and aft deck showing possible emergency towing arrangements;

b) inventory of equipment on board that can be used for emergency towing;

c) means and methods of communication; and

d) sample procedures to facilitate the preparation for and conducting of emergency towing operations.

(Refer to the IMO guidelines for owners / operators on preparing emergency towing procedures (MSC.1/Circ.1255)).

6.15 Direct Mooring Analyses

6.15.1 General

6.15.1.1 As an alternative to the prescriptive approach, direct mooring analysis may be performed to determine the necessary mooring restraint, i.e. number and strength of mooring lines. Direct analyses allow to optimize mooring equipment and arrangement for the individual ship and the port mooring facilities typical for the considered ship type and size.

6.15.2 Documentation

6.15.2.1 The calculations are to be documented in a report. The report is to include all assumptions made in calculations for the finally chosen mooring equipment, including lines, and its arrangement, reflected in the mooring arrangement plan as required in this section.

6.15.3 Analysis methodology

6.15.3.1 Three dimensional quasi-static calculations are to be performed to determine the acting mooring line forces. As a minimum, loads from wind and current are to be accounted for in the analysis. Geometrical and material nonlinearities of mooring lines and fenders or breasting dolphins are to be considered. An iterative calculation procedure is to be applied to arrive at a converged solution with forces acting on mooring lines and on fenders or breasting dolphins being in equilibrium with forces and moments applied to the ship.

6.15.4 Environmental conditions

6.15.4.1 Mooring line forces are to be calculated for environmental conditions given in 6.3.3. Additional loads, e.g. wave loads or cross currents, or increased wind and current loads may be considered for certain ship types or for specific ports intended to be regularly called.

6.15.5 Steps to be taken in a direct mooring analysis

6.15.5.1 Direct assessment of mooring forces and determination of the necessary number and strength of mooring lines comprise the following steps:

a) Determine port mooring facilities representative for the considered ship type and size
b) Determine shipboard mooring equipment and arrangement
c) Determine mooring line type(s) to be used
d) Determine mooring layout(s) to be assessed
e) Determine ship loading condition(s) to be assessed
f) Select or determine wind and current drag coefficients
g) Determine wind and current forces and moments
h) Compute forces acting on all mooring line
i) Determine necessary strength of mooring lines
j) If strength of mooring lines should be altered, modify steps b), c) and/or d) with or without changing the number of mooring lines and repeat steps h) and i)

6.15.5.2 Port mooring facilities

.1 Characteristics of port mooring facilities have strong influence on the resulting mooring line forces. Mooring analysis is to be performed for port mooring facilities representative for the considered ship type and size, i.e. type of berth, type and arrangement of hooks/bollards, type and arrangement of fenders or breasting dolphins and height of pier above waterline.

.2 Fenders or breasting dolphins in many cases may not affect the critical mooring line loads. Hence, initially, generic fender or dolphin arrangements and infinitely stiff load-deformation characteristics may be considered. If no fender or dolphin loads occur for load cases yielding the critical mooring line loads, more specific fender or dolphin arrangements and characteristics may be omitted.

.3 If there are substantially different port mooring facilities typically encountered by the considered ship type, additional calculations are to be performed to consider these variations.

6.15.5.3 Shipboard mooring equipment and arrangement

.1 The mooring equipment and arrangement need to be chosen for the mooring analysis, i.e. location of mooring decks and location of mooring winches and fairleads. As a starting point, mooring equipment for the number of lines as determined by the prescriptive approach may be chosen, see 6.3.3.6.

6.15.5.4 Mooring lines

.1 The mooring analysis is to apply the mooring line type(s) intended to be supplied with the vessel. The geometrical and material nonlinearities of the mooring lines are to be considered by the mooring analysis. Load-deflection characteristics of mooring lines can be taken from data sheets of rope manufacturers. If given, characteristics of the broken-in ropes are to be applied.

.2 To achieve a good distribution of mooring line forces, mooring line type and characteristics are to be at least same for lines in the same service, e.g. for head and stern lines, breast lines and spring lines. For very stiff mooring lines, e.g. made of steel or high modulus synthetic fibers, the use of elastic tails is to be considered to enhance the elasticity in the mooring system and taken into account for the mooring analysis.

6.15.5.5 Mooring layout

.1 For the assessment of forces acting on mooring lines, a realistic mooring layout needs to be assumed, i.e. for each mooring line it needs to be determined from which bollard or winch, along which path, through which fairlead it is led and to which shoreside hook or bollard it is connected. Inboard parts of the mooring lines (between fairlead and shipboard fixation point) contribute to the elongation behavior of the line and should be included in the analysis.

.2 The maximum number of lines connected to one shore mooring point needs to be limited to not load the shore side mooring points unrealistically high. For multi-purpose piers the number of lines per shore bollard should be limited to three. For other types of berths, the number mooring lines per shore mooring point is also limited, e.g., by the available number of hooks. Reasonable assumptions are to be made based on typical berth types encountered by the considered ship type.

.3 Alternative mooring layouts are also to be assessed, considering possible and reasonable options to moor the ship to the assumed port mooring facilities. Also, a different position of the ship relative to the shoreside mooring bollards/hooks is to be assessed to find the critical mooring line loads for the normal operation of the ship. Exemptions may be given to e.g. tankers, LNG carriers or ferries if typically moored in the same position relative to the shoreside mooring facilities.

6.15.5.6 Loading conditions

.1 Mooring line forces are to be calculated for loading conditions given in 6.3.3.

6.15.5.7 Wind and current drag coefficients

.1 To calculate the wind and current forces and moments acting on the ship, wind and current drag coefficients are needed for the considered ship type, size and loading condition. Drag coefficients are to be as specific as possible for the considered ship and loading conditions.

.2 There are different sources for drag coefficients. Some Industry Guidelines provide drag coefficients for tankers and LNG carriers which can be applied. Due to the similarity of hull forms and superstructures, these coefficients may also be used for bulk carriers and ore carriers. For other ship types drag coefficients may be taken from the literature, if available, or can be determined by CFD calculations or model tests. CFD calculations are to be justified with suitable validation and sensitivity studies.

.3 There are some effects that can influence the drag coefficients, i.e. blockage (limited under keel clearance, solid quay walls), ship draft and wind shielding by solid quays and buildings or cargo stored on quays (e.g. container stacks). Effects from blockage and ship draft can only be accounted for by appropriate coefficients. Drag coefficient is to be chosen or determined for realistic water depth to draft ratios and for the considered ship draft(s). Some Industry Guidelines provide current drag coefficients for ballast and loaded draft conditions and for different water depth to draft ratios. Wind shielding effects are typically not considered by the wind drag coefficients. The effect of wind shielding of solid quays may be considered by an equivalent reduction of the lateral wind area of the ship. Shielding by buildings or cargo stored on quays should not be considered as their presence is imponderable.

6.15.5.8 Calculation of wind and current forces and moments

.1 Wind and current forces and moments can be calculated for the given environmental conditions with the geometrical particulars of the considered ship and the selected drag coefficients. Usually, the forces in longitudinal and transversal directions as well as the moment about the vertical ship axis (yaw) are calculated.

.2 Wind forces and moments are to be calculated for all directions in intervals of preferably 15°, but not more than 30°. Current forces and moments are to be calculated for selected directions as per 6.3.3. For ships regularly moored to non-solid piers or jetties, cross current may need to be considered in addition.

6.15.5.9 Calculation of mooring line forces

.1 For all considered scenarios and all combinations of applied environmental conditions, the maximum mooring line force is to be determined for groups of lines in the same service.

.2 In case of all lines are intended to be attached to winches, brake rendering can be considered to better distribute line loads among all lines in a group of lines in the same service. Then, the average mooring line force of a group of lines may be determined and taken as mooring line force used to determine the necessary strength of the mooring lines according to 6.15.5.10.

6.15.5.10 Strength of mooring lines

.1 The necessary strength of mooring lines, i.e., the Ship Design Minimum Breaking Load (MBL_{SD}), results from the calculated maximum mooring line force ($F_{L, max}$) divided by the Work Load Limit (WLL) factor of mooring lines. The WLL factor and the resulting MBL_{SD} for different mooring line materials are shown in the below table.

Mooring line material	**WLL factor**	**MBL_{SD}**
Steel wire	0.55	1.82 * $F_{L, max}$
Synthetic fibers	0.5	2.0 * $F_{L, max}$

Preferably, all lines supplied to the ship are to have the same characteristics and strength to avoid confusion of lines. However, for significantly different maximum calculated line loads, lines in different service may also have different strength and characteristics, e.g. for head and stern lines other than for spring lines.

Section 7

Windlass and Chain Stoppers

7.1 General

7.1.1 Windlass of sufficient power and suitable for the size of chain cable is to be fitted. Where wire ropes are proposed and approved in lieu of chain cables, suitable winches capable of controlling wire rope at all times are to be fitted.

7.1.2 Windlass is to have one cable lifter for each anchor required to be kept ready for use. The cable lifter is normally to be connected to the driving shaft by release coupling and provided with brake.

7.1.3 For each chain cable, a chain stopper is normally to be arranged between the windlass and hawse pipe. The chain cables are to reach the hawse pipe through the cable lifter only.

7.1.4 Electrically driven windlasses are to have a torque limiting device. Electric motors are to comply with the requirements of Pt.4, Ch.8.

7.2 Compliance Standards

7.2.1 The design, construction and testing of windlasses are to conform to an acceptable standard such as the following:

- *SNAME T&R Bulletin 3-15:2018 – Guide to the Design and Testing of Anchor Windlasses for Merchant Ships*
- *ISO 7825:2017 – Deck Machinery General Requirements*
- *ISO 4568:2006 – Shipbuilding – Sea going Vessels – Windlasses and Anchor Capstans*
- *JIS F6714:1995 – Windlasses*

7.3 Plans and Documentation

7.3.1 The following plans indicating the design specifications, compliance standards, engineering analyses and construction details; as applicable, are to be submitted:

- Windlass design specifications, anchor and chain cable particulars, anchorage depth, performance criteria, compliance standards
- Windlass arrangement plan showing all of the components of the anchoring/ mooring system such as the prime mover shafting, cable lifter, chain stopper (if fitted), anchors and chain cables; mooring winches, wires and fairleads, if they form part of the windlass machinery, brakes, controls, etc.
- Dimensions, materials, welding details, as applicable, of all torque-transmitting (shafts, gears, clutches, couplings, coupling bolts, etc.) and all load bearing (shaft bearings, cable lifter, sheaves, drums, bed-frames, etc.) components of the windlass and of the winch, where applicable, including brakes, chain stopper (if fitted) and foundation.
- Hydraulic system to include:
  - Piping diagram along with system design pressure
  - Safety valve arrangement and settings
  - Material specifications for pipes and equipment
  - Typical pipe joints, as applicable
  - Technical data and details for hydraulic motors
- Electric one-line diagram along with cable specification and size, motor controller, protective device rating or setting; as applicable
- Control, monitoring and instrumentation arrangements
- Engineering analyses for torque-transmitting and load-bearing components demonstrating their compliance with recognized standards
- Gear analyses in accordance with a recognized standard
- Plans and data for windlass electric motors including associated gears rated 100 [kw] and over

- Calculations demonstrating that the windlass prime mover is capable of attaining the hoisting speed, the required continuous duty pull, and the overload capacity are to be submitted; if the 'load testing' including 'overload capacity' of the entire windlass unit is not carried out at the shop (See 7.6.3)

- Operation and maintenance procedures for the anchor windlass are to be incorporated in the vessel operations manual.

7.4 Materials and Fabrication

7.4.1 Materials used in the construction of torque-transmitting and load-bearing parts of windlasses are to comply with the requirements of Pt. 2 of the Rules. The proposed materials are to be indicated in the construction plans and are to be approved in connection with the design. All such materials are to be certified by the material manufacturers and are to be traceable to the manufacturers' certificates.

7.4.2 Weld joint designs are to be shown in the construction plans and are to be approved in association with the approval of the windlass design. Welding procedures and welders are to be qualified in accordance with the requirements of IRS. Welding consumables are to be approved by IRS in accordance with the requirements of Pt. 2, Ch. 11, as applicable. In case the type and grade of the welding consumables fall outside the scope of Pt. 2, Ch. 11, then the consumables are to comply with suitable national or international standards. The degree of non-destructive examination of welds and post-weld heat treatment, if any, are to be specified and submitted for consideration.

7.5 Design

7.5.1 Notwithstanding the requirements of the chosen standard of compliance, the following requirements are also to be complied with. In lieu of conducting engineering analyses and submitting them for review, approval of the windlass mechanical design may be based on a type test, in which case the testing procedure is to be submitted for consideration.

7.5.2 Mechanical Design

7.5.2.1 Design Loads

(a) Holding Loads

Calculations are to be made to show that, in the holding condition (single anchor, brake fully applied and chain cable lifter declutched), and under a load equal to 80% of the specified minimum breaking strength of the chain cable, the maximum stress in each load bearing component will not exceed yield strength (or 0.2% proof stress) of the material. For installations fitted with a chain cable stopper, 45% of the specified minimum breaking strength of the chain cable may instead be used for the calculation.

(b) Inertia Loads

The design of the drive train, including prime mover, reduction gears, bearings, clutches, shafts, cable lifter and bolting is to consider the dynamic effects of sudden stopping and starting of the prime mover or chain cable so as to limit inertial load.

7.5.2.2 Continuous Duty Pull

The windlass prime mover is to be capable of exerting, for a period of 30 minutes, + a continuous duty pull (e.g. 30-minute short time rating corresponding to S2-30 min. of IEC 60034-1), Z_{cont1}, corresponding to the grade of chain cable, as follows :-

Table 7.5.2.2

Grade of Chain	Z_{cont1}	
	N	Kgf
CC1	37.5 d^2	3.82 d^2
CC2	42.5 d^2	4.33 d^2
CC3	47.5 d^2	4.84 d^2

Where d is the chain diameter [mm]

The values in Table 7.5.2.2 are applicable when using ordinary stockless anchors for anchorage depth down to 82.5 [m].

For anchorage depth deeper than 82.5 [m], a continuous duty pull Z_{cont2} is as follows:

$$Z_{cont2} = Z_{cont1} + (D - 82.5) * 0.27\ d^2$$

Where Z_{cont1} and Z_{cont2} are in [N]

Or

$$Z_{cont2} = Z_{cont1} + (D - 82.5) * 0.0275\ d^2$$

Where Z_{cont1} and Z_{cont2} are in [kgf]

D is the anchor depth in [m]

The anchor masses are assumed to be the masses as given in Pt. 2, Ch. 10. Also, the value of Z_{cont} is based on the hoisting of one anchor at a time, and that the effects of buoyancy and hawse pipe efficiency (assumed to be 70%) have been accounted for. In general, stresses in each torque-transmitting component are not to exceed 40% of yield strength (or 0.2% proof stress) of the material under these loading conditions.

7.5.2.3 Overload Capability

The windlass prime mover is to be able to provide the necessary temporary overload capacity for breaking out the anchor. This temporary overload capacity or "short term pull" is to be at least 1.5 times the continuous duty pull applied for at least 2 minutes. The speed in this period may be lower than normal.

The above criteria do not require both anchors to be raised or lowered simultaneously on windlass fitted with two cable lifters.

7.5.2.4 Hoisting Speed

The mean speed of the chain cable during hoisting of the anchor and cable is to be at least 0.15 [m/sec]. For testing purposes, the speed is to be measured over two shots of chain cable and initially with at least three shots of chain (82.5 [m] or 45 fathoms in length) and the anchor submerged and hanging free.

7.5.2.5 Brake Capacity

.1 The capacity of the windlass brake is to be sufficient for safe stopping of anchor and chain cable when paying out.

.2 The windlass with brakes engaged and release coupling disengaged is to be able to withstand static pull of 45 per cent of the tabular breaking strength of the chain without any permanent deformation of the stressed parts and without brake slip.

.3 If a chain stopper is not fitted, the windlass is to be able to withstand a static pull of 80 per cent of the tabular breaking strength of the chain without any permanent deformation of the stressed parts and without brake slip.

.4 The chain stoppers and their attachments are to withstand a pull of 80 per cent of the tabular breaking strength of the chain without any permanent deformation of the stressed parts. The chain stoppers are to be so designed that additional bending of the individual link does not occur and the links are evenly supported.

.5 Attention is to be paid to stress concentrations in keyways and other stress raisers and also to dynamic effects due to sudden starting or stopping of the prime mover or anchor chain.

7.5.2.6 Hull Supporting Structures of Anchor Windlass and Chain Stopper

The hull supporting structure of anchor windlass and chain stopper is to be sufficient to accommodate the design and sea loads.

7.5.2.6.1 Design Loads

.1 The design loads are to be taken not less than

- for chain stoppers, 80% of the chain cable breaking load
- for windlasses, where no chain stopper is fitted or the chain stopper is attached to the windlass, 80% of the chain cable breaking load
- for windlasses, where chain stoppers are fitted but not attached to the windlass, 45% of the chain cable breaking load

.2 The design loads are to be taken in the direction of the chain cable.

7.5.2.6.2 Sea Loads

.1 In case of ships of length > 80 [m] the windlasses and mooring winches integral with the windlasses fitted on exposed decks in the forward 0.25L are to be adequately secured against the green sea loads given in 7.5.2.6.2.1, if the height of the exposed decks in way of the windlasses is less than 0.1L or 22 [m] above summer LWL. The strength criteria given in 7.5.2.6.2.1 is to be complied with.

.2 Design loads

The following green sea pressures are to be considered:

- Pressure 'p_x' equal to 200 [kN/m^2], normal to the shaft axis as shown in Fig.7.5.2.6.2.1 and acting over the projected area in this direction.

- Pressure 'p_y' equal to 150 [kN/m^2], parallel to the shaft axis as shown in Fig.7.5.2.6.2.1 acting both inboard and outboard separately, over the multiple of 'f' times the projected area in this direction.

where 'f' is defined as:

f = 1+B/H, but need not be taken greater than 2.5

where,

B = width of windlass measured parallel to the shaft axis.

H = overall height of windlass.

.3 For calculation of forces in the bolts securing the windlass to the deck, the bolts may be considered to be divided into 'N' bolt groups each containing one or more bolts. (See Fig.7.5.2.6.2.1).

The axial force R_i in bolt group (or bolt) i, positive in tensile, may be calculated from:

$$R_{xi} = P_x\, hx_i\, A_i / I_x$$
$$R_yi = P_y\, hy_i\, A_i / I_y$$

and $R_i = R_{xi} + R_{yi} – R_{si}$

where,

P_x = force [kN] acting normal to the shaft axis

P_y = force [kN] acting parallel to the shaft axis, either inboard or outboard whichever gives the greater force in bolt group 'i'

h = shaft height above the windlass mounting [cm]

x_i, y_i = x and y coordinates of bolt group 'i' from the centroid of all N bolt groups, positive in the direction opposite to that of the applied force [cm]

A_i = cross sectional area of all bolts in group 'i' [cm^2]

$I_x = \Sigma\, A_i\, x_i^2$ for N bolt groups
$I_y = \Sigma\, A_i\, y_i^2$ for N bolts groups

R_{si} = static reaction at bolt group 'i', due to weight of windlass.

Shear forces F_{xi}, F_{yi} applied to the bolt group 'i', and the resultant combined force F_i may be calculated from:

$$F_{xi} = (P_x - \alpha gM) / N$$
$$F_{yi} = (P_y - \alpha gM) / N$$

and

$$F_i = (F_{xi}^2 + F_{yi}^2)^{0.5}$$

where,

α = coefficient of friction = 0.5
M = mass of windlass (tonnes)
g = gravity acceleration = 9.81 m/sec^2
N = number of bolt groups.

Axial tensile and compressive forces and lateral forces are also to be considered in the design of the supporting structure.

.4 Strength criteria for windlass mounts

Tensile axial stresses in the individual bolts in each bolt group 'i' are to calculated. The horizontal forces F_{xi} and F_{yi} are normally to be reacted by shear chocks. Where "fitted" bolts are designed to support these shear forces in one or both directions, the von Mises equivalent stresses in the individual bolts are to be calculated and compared to the stress under proof load. Where pourable resins are incorporated in the holding down arrangements, due account is to be taken in the calculations.

The safety factor against bolt proof strength is to be not less than 2.0.

.5 Permissible stresses for supporting hull structures of anchor windlass and chain stopper

The permissible stresses acting on the hull structures of windlass and chain stopper, based on net thickness obtained by deducting corrosion addition tc, are not to be greater that the following permissible values:

a) For strength assessment by means of beam theory or grillage analysis:

Normal stress = 1.0 R_{eH}

Shear stress, $\tau = 0.6R_{eH}$

Where R_{eH}= specified minimum upper yield stress [N/mm^2];

The normal stress is the sum of bending stress and axial stress. The shear stress to be considered corresponds to the shear stress acting perpendicular to the normal stress. No stress concentration factors are to be taken into account.

b) For strength assessment with finite element analysis:

Von Mises stress = $1.0R_{eH}$

For strength assessment by means of finite element analysis the mesh is to be fine enough to represent the geometry as realistically as possible. The aspect ratios of elements are not to exceed 3. Girders are to be modelled using shell or plane stress elements. Symmetric girder flanges may be modelled by beam or truss elements. The element height of girder webs must not exceed one-third of the web height. In way of small openings in girder webs, the web thickness may be reduced to a mean thickness over the web height. Large openings are to be modelled. Stiffeners may be modelled using shell, plane stress, or beam elements. The mesh size of stiffeners is to be fine enough to obtain proper bending stress. If flat bars are modeled using shell or plane stress elements, dummy rod elements are to be modelled at the free edge of the flat bars and the stresses of the dummy elements are to be evaluated. Stresses are to be read from the centre of the individual element. For shell elements the stresses are to be evaluated at the mid plane of the element.

7.5.3 Hydraulic Systems

Hydraulic systems where employed for driving windlasses are to comply with the provisions of Pt. 4.

7.5.4 Electrical Systems

7.5.4.1 Electric Motors

Electric motors are to meet the requirements of Pt.4, Ch. 8 and those rated 100 [kW] and over are to be certified. Motors exposed to weather are to have enclosures suitable for their location as provided for in Pt. 4, Ch. 8. Where gears are fitted, they are to meet the requirements of Pt. 4, Ch. 4 and those rated 100 [kW] and over are to be certified.

7.5.4.2 Electrical Circuits

Motor branch circuits are to be protected and cable sizing is to in carried out in accordance with the provisions of Pt. 4, Ch. 8. Electrical cables installed in locations subjected to the sea are to be provided with effective mechanical protection.

7.5.5 Protection of Mechanical Components

To protect mechanical parts including component housings, a suitable protection system is to be fitted to limit the speed and torque at the prime mover. Consideration is to be given to a means to contain debris consequent to a severe damage of the prime mover due to over-speed in the event of uncontrolled rendering of the cable, particularly when an axial piston type hydraulic motor forms the prime mover.

7.5.6 Couplings

Windlasses are to be fitted with couplings which are capable of disengaging between the cable lifter and the drive shaft. Hydraulically or electrically operated couplings are to be capable of being disengaged manually.

7.6 Shop Inspection and Testing

7.6.1 Windlasses are to be inspected during fabrication at the manufacturers' facilities by a Surveyor for conformance with the approved plans. Acceptance tests, as specified in the specified standard of compliance, are to be witnessed by the Surveyor and include the following tests, as a minimum:

.1 *No-load test.* The windlass is to be run without load at nominal speed in each direction for a total of 30 minutes. If the windlass is provided with a gear change, additional run in each direction for 5 minutes at each gear change is required.

.2 *Load test.* The windlass is to be tested to verify that the continuous duty pull, overload capacity and hoisting speed as specified in 7.5.2 can be attained.

Where the manufacturing works does not have adequate facilities, these tests, including the adjustment of the overload protection, can be carried out on board ship. In these cases, functional testing in the manufacturer's works is to be performed under no-load conditions.

.3 *Brake capacity test.* The holding power of the brake is to be verified either through testing or by calculation.

7.7 On-board Testing

7.7.1 Each windlass is to be tested under working conditions, after installation on board, to demonstrate satisfactory working.

7.7.2 Each unit is to be independently tested for braking, clutch functioning, lowering and hoisting of chain cable and anchor, proper riding of the chain over the cable lifter, proper transit of the chain through the hawse pipe and the chain pipe, and effecting proper stowage of the chain and the anchor. It is to be confirmed that anchors properly seat in the stored position and that chain stoppers function as designed if fitted. The mean hoisting speed, as specified in 7.5.2.4, is to be measured and verified. The braking capacity is to be tested by intermittently paying out and holding the chain cable by means of the application of the brake. Where the available water depth is insufficient, the proposed test method will be specially considered.

7.8 Marking

7.8.1 Windlasses are to be permanently marked with the following information:

(a) Nominal size of the windlass (e.g. 100/3/45 is the size designation of a windlass for 100 mm diameter chain cable of Grade CC3, with a holding load of 45% of the breaking load of the chain cable)

(b) Maximum anchorage depth in metres.

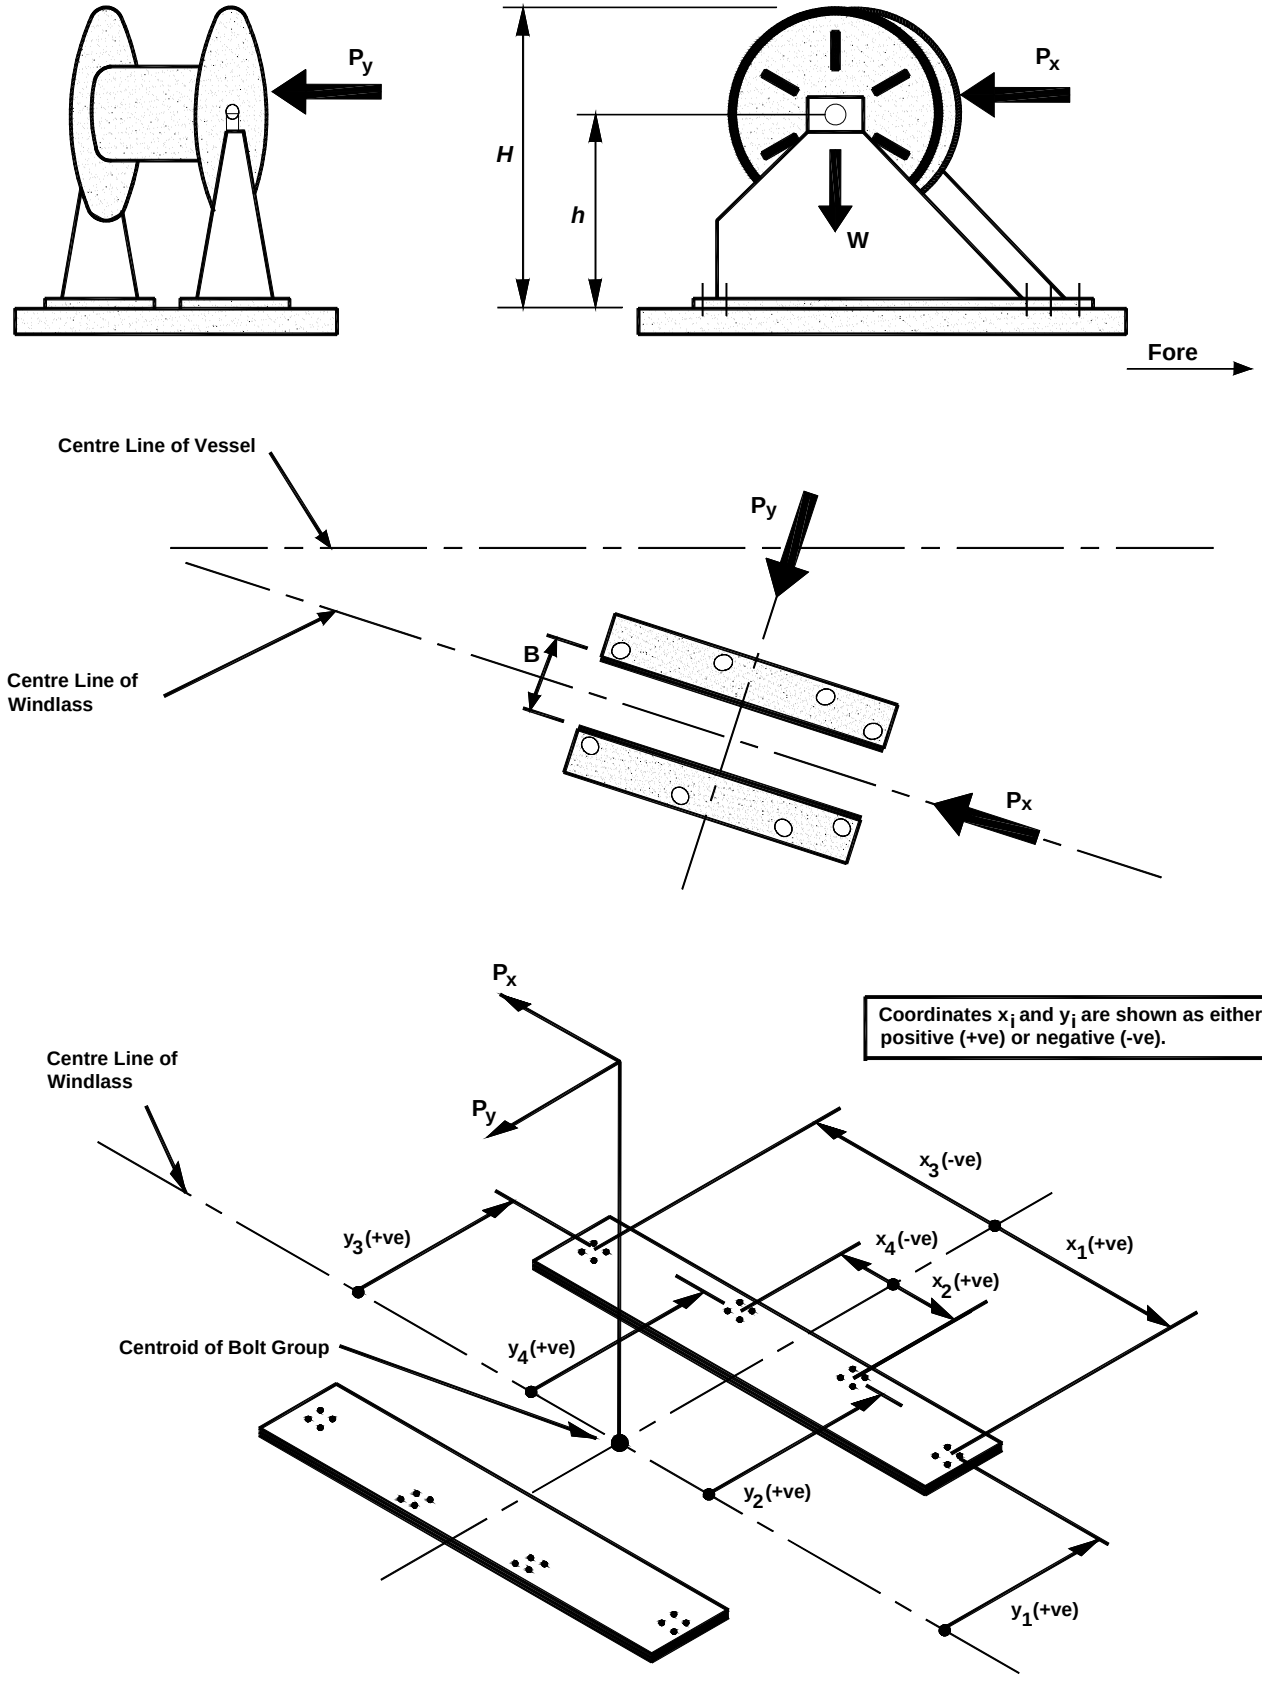

Fig.7.5.2.6.2.1 : Direction of forces and weight

Section 8

Deep Water Anchoring

8.1 General

8.1.1 The requirements in this Section are applicable to ships being assigned additional class notation '**DWA**', These requirements are intended for anchoring equipment of ships anchoring in deep and unsheltered waters.

8.2 Application

8.2.1 The additional class notation, **DWA** indicates that the ship is designed to anchor in deep and unsheltered waters with environmental conditions, as follows:

- Water depth up to 120 [m]
- Current up to 1.54 [m/s]
- Wind speed up to 14 [m/s]
- Waves with significant wave height up to 3[m]

Furthermore, these requirements are applicable to ships with equipment length not less than 135 [m].

8.3 Documentation

8.3.1 The anchoring arrangement plan and Equipment Number calculations are to be submitted for approval.

8.4 Equipment number for deep and unsheltered waters

8.4.1 Anchors and chain cables are to be provided in accordance with the requirements in Table 8.4.1 and based on the Equipment Number, EN_D obtained from the following:

$$EN_D = 0.628 \left[a \left(\frac{EN}{0.628} \right)^{\frac{1}{2.3}} + b((1-a)) \right]^{2.3}$$

Where,

$a = 1.83*10^{-9} * L_E^3 + 2.09 * 10^{-6} * L_E^2 - 6.21 * 10^{-4} * L_E + 0.0866$

$b = 0.156 * L_E + 8.372$

L_E = Equipment Length

EN = Equipment Number as calculated in accordance with Section 3, Cl. 3.1

8.5 Anchors

8.5.1 The bower anchors are to be connected to their chain cables and positioned on board ready for use.

8.5.2 Anchors are to be of the stockless High Holding Power (HHP) type.

8.5.3 The mass of the head of a stockless anchor, including pins and fittings, is not to be less than 60% of the total mass of the anchor. Requirements for HHP anchors are indicated in Section 4.

8.5.4 The mass per anchor, of bower anchors given in Table 8.4.1 is for anchors of equal mass. The mass of individual anchors may vary up to 7% of the tabular mass, but the total mass of anchors is not to be less than that recommended for anchors of equal mass.

8.5.5 Suitable arrangements are to be provided for securing the anchors when stowed, as indicated in Sec. 2.

8.5.6 The manufacture and proof-testing of anchors is to be carried out in accordance with the requirements of Pt. 2, Ch. 10.

Table 8.4.1 Anchoring equipment for ships with DWA notation					
Equipment Number EN_D	High holding power stockless bower anchors		Stud link chain cable for bower anchors

≥ 11500 < 12400	2	31500	770	-	147
≥ 12400 < 13400	2	33200	770	-	152
≥ 13400 < 14600	2	35000	770	-	157
≥ 14600	2	38000	770	-	162

8.6 Chain cables for bower anchors

8.6.1 Bower anchors are to be associated with stud link chain cables of Grade CC2 or Grade CC3 quality. The total length of chain cable, as given in Table 8.4.1 is to be reasonably divided between the two bower anchors. For the proof and breaking loads of stud link chain cables reference is made to Table 2.9.1 (a) and Table 2.9.1 (b) of Pt. 2, Ch. 10.

8.6.2 Manufacture of anchor chain cables is to be carried out in accordance with the requirements of Pt.2, Ch. 10.

8.6.3 Installation of chain cables is to be carried out in accordance with the requirements of Sec.2.

8.7 Anchor windlass and chain stopper

8.7.1 The design and testing of anchor windlass and design of chain stopper is to be carried out in accordance with the requirements of Sec. 7.

8.7.2 In addition to the requirements in Sec. 7, the windlass prime mover is to be able to supply for at least 30 minutes a continuous duty pull Z_{cont} [N] given by:

$$Z_{cont} = 35d^2 + 13.4\, m_A$$

Where:

d = chain diameter [mm] as per Table 8.4.1

m_A = mass of HHP anchor [kg] as per Table 8.4.1

8.7.3 In addition to the requirements of Sec, 7; as far as practicable; for testing purpose the speed of the chain cable during hoisting of the anchor and cable is to be measured over 37.5 [m] of chain cable and initially with at least 120 [m] of chain and the anchor submerged and hanging free. The mean speed of the chain cable during hoisting of the anchor from a depth of 120 [m] to the depth of 82.5 [m] is to be at least 4.5 [m/min].

8.7.4 The hull supporting structure of anchor windlass and chain stopper is to be provided in accordance with the requirements in Sec. 7.

End of Chapter

Chapter 15

Masts and Rigging

Contents

Section

1 *General*

2 *Masts*

3 *Rigging*

Section 1

General

1.1 Application

1.1.1 Masts, derrick posts, crane pedestals etc. and their supporting hull structure are to be in accordance with the requirements of this Chapter. The derricks and the cargo handling gear, are not subject to approval unless required by additional class notations.

1.2 Documentation

1.2.1 The following plans and information are to be submitted:

i) Arrangement plan showing location of mast or derrick post, standing rigging and cargo handling gear alongwith the information about the operation of the derrick booms, their safe working load and working positions.

ii) Plan showing proposed scantlings of mast, derrick post and standing rigging.

iii) Plan showing supporting structures and strengthening of hull in way of mast, post and standing rigging fastenings,

iv) Specification of the steel wire ropes intended to be used for standing rigging, indicating rope construction, scantlings and minimum breaking strength.

1.2.2 Calculations considering the derrick booms at the operating position which results in maximum stresses on the mast, are to be submitted. For masts supporting derricks, angles of heel and trim of the ship in this condition of less than 5° and 2° respectively, may be ignored. Where these angles are exceeded, and in all cases where the mast supports derrick cranes or derricks of special design, the actual angles are to be taken into account in calculating the stresses in the mast. In case of stayed masts, the calculations are to take into account the elongation of the stays under tension.

1.2.3 For masts such as portal, bipod, lattice etc. and those under significant forces other than resulting from cargo gear; detailed stress calculations are to be submitted, taking into account:

i) All horizontal, vertical and torsional forces,
ii) Deflection of the structure,
iii) Variations in the moment of inertia of the parts of the structure,
iv) The effects of outriggers and similar structures,
v) Elasticity and sag in stays, where fitted.

1.3 Materials

1.3.1 Steel for masts, derrick posts, crane pedestals and associated items are to be tested and approved in accordance with the requirements of Pt.2, Ch.3. Material grades of steel are to be as follows:

Thickness [mm]	t ≤ 20	20 ≤ t < 25	25 ≤ t < 40	t > 40
Grade	A/AH	B/AH	D/DH	E/EH

1.3.2 Wire ropes used for stays are to be in accordance with the requirements of Pt.2, Ch.10.

Section 2

Masts

2.1 Scantlings

2.1.1 The outer diameter 'd' of the masts without derricks at the level of upper supporting deck is not to be less than:

d = 37 *l* [mm] for unstayed masts

= 33 *l* [mm] for stayed masts

where,

l = length of the mast [m] measured above upper supporting deck to hounds.

The diameter is to be maintained upto the level of the gooseneck fitting where this is entirely supported by the mast. In case of masts without derricks, the diameter may be reduced to 0.75 d at top.

2.1.2 For masts without derricks, the thickness 't' of the mast plating is not to be less than

t = 0.01d + 2.5 [mm] or 5 [mm] whichever is greater.

2.1.3 The scantlings of masts with derricks are to be based on calculations mentioned in 1.2.2 and 1.2.3. The total stress σ_t at any location, is not to exceed the allowable stress values given below:-

Allowable stresses in masts		
SWL	**Stayed mast**	**Unstayed mast**
SWL ≤ 10t	0.50 σ_y	0.55 σ_y
SWL ≥ 60t	0.625 σ_y	0.675 σ_y
10 < SWL < 60	By linear interpolation	

where,

$$\sigma_t = \sqrt{\left[(\sigma_b + \sigma_c)^2 + 3\tau^2\right]}\ [\mathrm{N/mm^2}]$$

σ_b = bending stress at that location.

σ_c = direct compressive stress at that location due to the vertical components of force. In general, the weight of the mast and cross trees may be ignored in this calculation.

τ = The shear stress due to torque in the mast. The effect of torque need only be considered where cross trees are fitted.

σ_y = Upper yield stress of the material [N/mm^2].

For the above Table, SWL corresponding to the largest derrick operating on the mast is to be taken.

The thickness of the mast plating is to be adequate to prevent buckling and in no case is to be less than 7.5 [mm].

2.2 Construction details

2.2.1 Masts are to be adequately supported by atleast two decks and are to be efficiently scarphed into the main hull structure. The hull structure is to be suitably reinforced. A deckhouse may be considered as a support provided adequate strength is ensured by additional stiffening and increased plate thickness.

2.2.2 In general, mast scantlings are not to be reduced inside the deckhouse and are to be maintained upto the level of the gooseneck fitting where it is entirely supported by the mast.

2.2.3 Cross trees, outriggers, brackets on bridge fronts and similar structures are to be of such design that the stresses on them resulting from the cargo gear and any other significant forces do not exceed the values given in 2.1.3 for unstayed masts. The design is also to be such as to minimize the moments acting on the mast. Attachment to the mast is

to be such as to avoid distortion of the mast under the load.

2.2.4 Special attention is to be paid to structural continuity, and abrupt changes of section are to be avoided. Manholes, lightening holes and other cut outs are to be avoided in way of concentrated loads and areas of high shear. Openings, where unavoidable, are to be well rounded, suitably framed and stiffened.

2.2.5 Care should be taken in the design of masts and fittings to reduce the likelihood of water collecting in inaccessible parts of the structure. Adequate means of drainage should be provided to remove any water which might otherwise accumulate.

2.2.6 Masts are to be strengthened either by addition of doubling plates or equivalent strengthening, or by an increase of the thickness of the plating at the following locations:

i) In way of the fastening of the derrick heels,

ii) In way of the fastening of the derrick spans,

iii) In way of the fastening of all metal fittings.

Suitable arrangements are to be made to avoid notch effects.

2.2.7 Welding and weld details are to comply with Ch.17.

2.2.8 Where a mast supports a derrick with a SWL > 25 [t], all welded joints of the masts below a level 3.0 [m] above the uppermost supporting deck or that of the derrick head, whichever is higher, are to be examined by non-destructive crack or flaw detection method.

2.2.9 Where higher tensile steel is used, preheating or other heat treatments may be required at the Surveyors discretion. Such treatments will normally be required for all ring seams on masts supporting derricks of SWL > 60 [t]. Non-destructive examination may be required in areas of high stresses.

2.2.10 Lightning conductors are to be fitted to masts having wood, aluminium or plastic top masts or where a break in electrical conductivity occurs in other arrangements.

Section 3

Rigging

3.1 General

3.1.1 The positioning of the rigging (shrouds, stays etc.) is to be so designed as to ensure proper working of the cargo gear and that they do not foul with the running rigging or derrick booms under the expected service conditions.

3.1.2 Wire rope stays are to be in one length and are to be set up with an initial tension of 30 [N/mm^2].

3.2 Stay construction

3.2.1 The scantlings of the stay are to be such as to provide the necessary tensile force and elongation for the stayed mast. The breaking load of the stay is to be not less than 3.5 times the maximum calculated force on that stay.

3.2.2 The connection of the stay to a deck, bulwark, house or mast is to be such as to allow rotation at the point of attachment and is to be designed so that the stay cannot become disconnected while the derrick system is in use.

End of Chapter

Chapter 16

Welding

Contents

Section

1 *General*

2 *Welding*

3 *Welded Connections*

Section 1

General

1.1 Scope

1.1.1 Welding in steel hull construction of all types of ships is to comply with the requirements of this Chapter.

Welding in aluminium structures will be specially considered.

1.2 Documentation

1.2.1 Connection details of the welded structural members, including type and size of welds are to be clearly indicated on the plans submitted for approval. An explanation of all symbols or abbreviations used in detailing the weld connections should be included on the plans.

Details of proposed welding procedure is to be submitted indicating preheating temperature and any post-welding heat treatment, if employed. Extent to which automatic welding, including deep penetration welding, is to be employed should also be indicated.

Section 2

Welding

2.1 Welders and supervision

2.1.1 Welders are to be proficient in the type of work on which they are to be engaged. The records of their tests and qualifications are to be kept by the builders and made available to the Surveyors. A sufficient number of skilled supervisors are to be employed to ensure effective control at all stages of assembly and welding operations.

2.2 Welding electrodes

2.2.1 Electrodes and welding consumables approved by IRS in accordance with the requirements of Pt.2, Ch.11 and suitable for the type of joint and grade of steel, are to be used.

2.2.2 For the connection of two different grades of steel of the same tensile strength properties, electrodes suitable for the lower grade will be generally acceptable except at structural discontinuities or other points of stress concentration.

2.2.3 For the connection of steel of different tensile strengths, the electrodes are to be suitable for the tensile strength of the component, on the basis of which the weld fillet size has been determined in Sec.3.

2.3 Preparation for welding

2.3.1 The parts to be welded are to be fitted in accordance with the approved joint detail. The edge preparation is to be accurate and uniform. Means are to be provided for maintaining the parts to be welded, in correct position during the welding operations. Excessive force is not to be employed in aligning the parts before welding and the means employed in maintaining the alignment are to be so arranged as to allow for expansion and contraction during the welding operation. All methods employed in correcting improper alignment are to be to the satisfaction of the Surveyor.

2.3.2 All surfaces to be welded are to be clean, dry and free from rust, scale and grease. The surface and boundaries of each run of deposit are to be thoroughly cleaned and freed from slag before the next run is applied. Before a manual sealing run is applied to the back of a weld, the original root material is to be gouged out to sound metal.

2.3.3 Tack welding is to be kept to a minimum, and where used, should be equal in quality to that of the finished welds. Any defective tack weld is to be cut out before completing the finished welds. Care is to be taken in removing the tack welds to ensure that the structure is not damaged in doing so.

2.4 Welding procedure

2.4.1 Only approved welding procedures are to be used, See 2.5.

2.4.2 Structural arrangements are to be such as to allow adequate access for satisfactory completion of all welding operations. Welded joints are to be so arranged so as to facilitate downhand welding wherever possible.

2.4.3 The sequence of welding is to be so planned that any restraint during welding operations is reduced to a minimum. The ends of the frames and stiffeners should be left unattached to the plating at the subassembly stage until connecting welds are made, in the intersecting systems of plating, framing and stiffeners, at the erection stage.

In general, where a butt meets a seam, the welding of the seam should be interrupted well clear of the junction and not be continued until the butt is completed. Welding of the butt should continue past the open seam and the weld be chipped out for the seam to be welded straight through. Alternative weld sequences may be accepted provided weld distortions are in accordance with recognized fabrication standards such as IACS Recommendation 47 "*Shipbuilding and Repair Quality Standard*".

2.4.4 Adequate precautions are to be taken to ensure that the welding site is protected from the deleterious effects of high moisture, severe wind and extreme cold.

2.5 Approval of procedures

2.5.1 Unless previously approved, welding procedures are to be established by the yard and forwarded to IRS for approval. The welding procedure specifications are to include detailed description of the base material, primer, plate thickness range, joint/groove design, welding consumable, welding position, welding techniques, welding parameters, preheating/ interpass temperature and post heat treatment if any.

The welding for procedure qualification and subsequent testing, are to be witnessed by the IRS Surveyor.

2.6 Inspection of welds

2.6.1 Effective arrangements are to be provided for the inspection of finished welds to ensure that all welding has been satisfactorily completed.

2.6.2 All finished welds are to be visually inspected and are to be sound, uniform and substantially free from slag inclusions, porosity, undercutting or other defects. Welds and adjacent base metal are to be free from injurious arc strikes.

2.6.3 For the examination of important structural welds, visual inspection is to be supplemented by radiography or other acceptable non- destructive crack or flaw detection methods. The extent of such examination is to be to the Surveyors' satisfaction, but particular attention is to be given to the following locations:

a) Junction and crossings of seams and butts in strength deck, sheer strake, side and bottom shell within 0.4L amidships.

b) Butts of keel plating and rounded sheerstrake within 0.4L amidships.

c) Insert plates in way of hatch openings on the strength deck.

d) Butts of longitudinal framing and longitudinal bulkhead stiffeners within 0.4L amidships.

2.6.4 Defective sections of welds as found by visual or non- destructive examination or leakages under hydrostatic tests, are to be gouged out as necessary and carefully rewelded.

Section 3

Welded Connections

3.1 Butt welds

3.1.1 Plates of equal thickness may be manually butt welded as per Fig.3.1.1. For automatic welding procedures and special welding techniques, the welding procedure will be specially considered.

3.1.2 For joints of plates with difference in thickness of more than 4 [mm], the thicker plate is to be tapered. The taper is not to exceed 1:3. Edge preparation after the tapering is to be as indicated in 3.1.1 above.

3.1.3 All manual butt welds are normally to be welded from both sides. Where a back ceiling run is not practicable or in certain cases when the stress level in the members is very low, welding on one side may be permitted provided the welding process is found satisfactory.

3.1.4 Where stiffening members, attached by continuous fillet welds, cross the finished butt or seam welds, these welds are to be made flush in way of the faying surface. Similarly for butt welds in webs of stiffening members, the butt weld is to be first completed and made flush with the stiffening member before the stiffener is connected to the plating by fillet weld. The ends of the flush portion are to run out smoothly without notches or any sudden change of section. Where such conditions can not be complied with, a scallop is to be arranged in the web of the stiffening member. Scallops are to be of such size and in such a position, that a satisfactory weld can be made.

3.2 'T' connections

3.2.1 The throat thickness (See Fig.3.2.1) of the fillet welds is given by:

throat thickness = t_p . weld factor . d/s

where,

t_p = thickness [mm], of the thinner of the two parts being connected.

d = distance [mm], between the successive weld fillets.

s = length [mm], of the correctly proportioned weld fillets, clear of end craters is not to be less than 75 [mm].

The weld factors for various connections are generally to be as given in Table 3.2.1.

Where an approved automatic deep penetration procedure is used, the weld factors may be reduced by 15 per cent.

3.2.2 The throat thickness is not to be less than 3.0 [mm] for t_p upto 8.0 [mm] and 0.21 t_p or 3.25 [mm], whichever is greater, for t_p over 8 [mm]. The throat thickness is also generally not to be greater than 0.44 t_p for double continuous welds and the greater of 0.44 t_p or 4.5 [mm] for intermittent welds.

3.2.3 The leg length is not to be less than $\sqrt{2}$ times the specified throat thickness.

3.2.4 Where the connection is highly stressed, deep penetration or full penetration welding may be required. Where full penetration welding is required, the abutting plate may require to be beveled. (See Fig.3.2.4).

3.2.5 Continuous welding is to be adopted in the following locations and may be used elsewhere if desired.

a) Boundaries of weathertight decks and erections, including hatch coamings, companionways and other openings.

b) Boundaries of tanks and watertight compartments.

c) All structures in the afterpeak and the afterpeak bulkhead stiffeners.

d) All welding inside tanks intended for chemicals or edible liquid cargoes.

e) All lap welds in tanks.

f) Floors and girders to bottom shell in the 0.25L forward.

g) Primary and secondary members to plating in way of end connection and end brackets to plating in the case of lap connection.

h) Where the thickness of the abutting member (i.e. stiffener web) is greater than 15 [mm] and also exceeds the thickness of the table member (e.g. plating).

i) Where loading is mainly of dynamic nature (e.g. bottom and side plating forward subjected to slamming and bow impact).

j) Other connections as given in Table - 3.2.1.

3.2.6 Where intermittent welding is used, the welding is to be made continuous around the ends of brackets, lugs, scallops and at other orthogonal connections with other members. Where intermittent welding is permitted as per Table 3.2.1, only scalloped welding is to be used in tanks for water ballast, cargo oil or freshwater.

Chain or staggered intermittent welding may be used in dry spaces or tanks arranged for fuel oil only.

3.2.7 Where structural members pass through the boundary of a tank, and leakage into the adjacent space could be hazardous or undesirable, full penetration welding is to be adopted for the members for at least 150 [mm] on each side of the boundary. Alternatively, a small scallop of suitable shape may be cut in the member close to the boundary outside the compartment, and carefully welded all round.

3.3 Lap connections

3.3.1 Overlaps are not to be used to connect plates which may be subjected to high strength or compressive loading. However, where they are adopted, the width of overlap is to be adequate to ensure a good weld, the surfaces are to be in close contact and the joints should be closed all round by continuous fillet weld.

3.4 Slot weld

3.4.1 For the connection of plating to internal webs, where access for welding is not practicable, the closing plating is to be attached by continuous full penetration or slot welds to flat bars fitted to the webs. Slots are to be well rounded at ends, to have a minimum length of 75 [mm] and in general, a minimum width of twice the plating thickness. The distance between the slots is not to exceed 150 [mm]. Complete filling of the slots is normally not permitted.

3.5 End connection

3.5.1 In way of the end connections of girders double continuous welding is to be used all around. The weld area is not to be less than the cross-sectional area of the member, and the throat thickness not less than that given by Table 3.2.1 for girder ends.

3.5.2 Where stiffeners have bracketed end connections, bracket arms are to be welded all around and the throat thickness is not to be less than 0.35 times the thickness of bracket.

3.5.3 Where stiffeners are continuous at girder, they are to be connected to the webs, either directly and/or by means of lugs. The weld area is to be such that the shear stress does not exceed 80/k [N/mm^2]. Where the shear forces are high, a double sided connection to the web and/or a web stiffener welded on top of the continuous stiffener may be required.

Masts, derrick posts, crane pedestals, deck machinery and mooring equipment seating - to deck etc.		To be considered in each individual case			

Intermittent welding means chain intermittent, staggered intermittent or scalloped welding with rounded ends.
For permitted use see 3.2.6.

F.P. means Full Penetrant weld

Note 1 For tank boundaries see 3.2.5. Where intermittent fillet welding of internals is proposed, see 3.2.6.

Note 2 Preferably to be deep penetration or full penetration weld depending on the thickness of the engine girders.

Note 3 Generally full penetration, but alternative proposals may be considered depending on t_p.

Note 4 For end connections see Chapter 11, 3.1.4.

Note 5 See Chapter 14, Section 4.1.

Hull Inspection, Workmanship and Testing

Contents

Section	
1	*Hull Inspection*
2	*Workmanship*
3	*Testing of Tanks and Tight Boundaries for SOLAS Ships*
4	*Testing of Tanks and Tight Boundaries for SOLAS Exempt / Equivalent Ships*
5	*Testing of Tanks and Tight Boundaries for Non-SOLAS Ships*
6	*Construction Monitoring*

Section 1

Hull Inspection

1.1 Approval of works

1.1.1 The builders, intending to class vessels to be built at their yard with IRS, are to demonstrate their capability to carry out the fabrication to acceptable quality standards before the commencement of the fabrication. Similar approval procedure shall apply to subcontractor's works also. Previous experience in the building and repair of relevant structures and equipment can be considered favourably in this regard.

1.2 Inspection facilities

1.2.1 Adequate facilities are to be provided to enable the Surveyor to carry out a satisfactory inspection of all components during each stage of prefabrication and construction.

Section 2

Workmanship

2.1 General

2.1.1 All workmanship is to be of good quality and in accordance with good shipbuilding practice. Any defect is to be rectified to the satisfaction of the Surveyor before being covered with paint, cement or other composition.

2.1.2 The assembly sequence and welding sequence are to be agreed prior to construction and are to be to the satisfaction of the Surveyor.

2.2 Plate edges and cut-outs

2.2.1 Openings, holes and other cut-outs in the main structural components are to be rounded off by adequately large radii. The free edges of cut-outs, hatch corners etc. are to be properly prepared and are to be free from notches. All edges should be faired.

2.3 Cold forming

2.3.1 Flanging and bending of plates while cold forming are not to have an average bending radius less than three times the plating thickness. The minimum radius is not to be less than twice the plating thickness.

2.3.2 During joggling of plates and profiles, the depth of joggle is not to be less than four times and the bending radius not less than twice the web thickness.

2.4 Hammering, bending and straightening

2.4.1 Steel being worked on when hot, is not to be overheated, and it is to be hammered and bent in the appropriate heat condition. Steel which is burnt, is not to be used.

2.4.2 Flame heating may be employed to straighten buckled plating when the buckling is not severe.

Section 3

Testing of Tanks and Tight Boundaries for SOLAS Ships

3.1 General

3.1.1 Testing procedures of watertight compartments for SOLAS Ships are to be carried out in accordance with this section, unless the shipyard provides documentary evidence of the shipowner's agreement to a request to the Flag Administration:

a) for an exemption from the application of SOLAS Chapter II-1, Regulation 11, or

b) for agreeing to an equivalency, that the requirements of Section 4 is equivalent to SOLAS Chapter II-1, Regulation 11;

c) and, the above-mentioned exemption/equivalency has been granted by the Flag Administration

3.1.2 These test procedures are to confirm the watertightness of tanks, watertight boundaries and the structural adequacy of tanks which form part of the watertight subdivisions of ships. These procedures may also be applied to verify the weathertightness of structures and shipboard outfitting. The tightness of all tanks and watertight boundaries of ships during new construction and those relevant to major conversions or major repairs (repairs affecting structural integrity) is to be confirmed by these test procedures prior to the delivery of the ship.

Note: "Watertight Subdivision" means the transverse and longitudinal subdivisions of the ship required to satisfy the subdivision requirements of SOLAS Chapter II-1.

3.2 Application

3.2.1 All gravity tanks and other boundaries required to be watertight or weathertight are to be tested in accordance with this section and proven to be tight and structurally adequate as follows:

- Gravity tanks for their tightness and structural adequacy.
- Watertight boundaries other than tank boundaries for their watertightness, and
- Weathertight boundaries for their weathertightness.

Note : Gravity tank means a tank that is subject to vapour pressure not greater than 0.07 [MPa].

"Watertight" means having scantlings and arrangements capable of preventing the passage of water in any direction under the head of water likely to occur in intact and damaged conditions. In the damaged condition, the head of water to be considered in the worst situation at equilibrium, including intermediate stage of flooding.

"Weathertight" means that in any sea conditions, water will not penetrate into the ship. Weathertight Closing appliances for hatches, doorways and other access openings, ventilators, air-pipes etc are to be such as to prevent the passage of water into the ship in all sea conditions.

3.2.2 The testing of the cargo containment systems of liquefied gas carriers is to be in accordance with testing requirements in Pt.5, Ch.4, Sec.4.21 to 4.26 and Table 3.4.2.

3.2.3 The testing of structures not listed in Table 3.4.1 or 3.4.2 is to be specially considered.

3.3 Test Types and Definitions

3.3.1 The following two types of tests are specified in this requirement:

.1) Structural Test : A test to verify the structural adequacy of tank construction. This may be a hydrostatic test or, where the situation warrants, a hydropneumatic test.

.2) Leak Test : A test to verify the tightness of a boundary. Unless a specific test is indicated, this may be a hydrostatic / hydropneumatic test or an air test. A hose test may be considered an acceptable form of leak test for certain boundaries, as indicated by note 3 of Table 3.4.1.

3.3.2 The definition of each test type is as follows:

Hydrostatic Test: (Leak and Structural)	A test wherein a space is filled with a liquid to a specified head
Hydropneumatic Test: (Leak and Structural)	A test combining a hydrostatic test and an air test, wherein a space is partially filled with a liquid and pressurized with air.
Hose Test (Leak)	A test to verify the tightness of a joint by a jet of water with the joint visible from the opposite side.
Air Tests: (Leak)	A test to verify tightness by means of air pressure differential and leak indicating solution. It includes tank air test and joint air tests, such as compressed air fillet weld tests and vacuum box tests.
Compressed Air Fillet Weld Test: (Leak)	An air test of fillet welded tee joints wherein leak indicating solution is applied on fillet welds
Vacuum Box Test: (Leak)	A box over a joint with leak indicating solution applied on the welds. A vacuum is created inside the box to detect any leaks
Ultrasonic Test: (Leak)	A test to verify the tightness of the sealing of closing devices such as hatch covers by means of ultrasonic design techniques.
Penetration Test: (Leak)	A test to verify that no visual dye penetrant indications of potential continuous leakages exist in the boundaries of a compartment by means of low surface tension liquids (i.e. dye penetrant test).

3.3.3 The ‘top of the overflow’ is defined as being the top of any overflow system which is used to prevent overfilling of a tank. Such a system can be an overflow pipe, airpipe or, an intermediate tank. For gravity tanks (i.e. sewage, grey water and similar tanks, not filled by pumps) the top of the overflow is to be taken as the highest point of the filling line.

Note: Gauging devices are not considered equivalent to an overflow system with the exception of fuel oil overflow tanks not intended to hold fuel which have been fitted with a level alarm.

Where a tank is fitted with multiple means of preventing overfilling, the decision on which overflow system is to be used to determine the test head is to be based on the highest point to which the liquid may rise in service.

3.4 Test procedures

3.4.1 General

3.4.1.1 Tests are to be carried out in the presence of a Surveyor at a stage sufficiently close to the completion of work with all hatches, doors, windows, etc., installed and all penetrations including pipe connections fitted and before any ceiling and cement work is applied over the joints. Specific test requirements are given in 3.4.4 and Table 3.4.1. For the timing of the application of coating and the provision of safe access to joints, see 3.4.5, 3.4.6 and Table 3.4.3.

3.4.2 Structural test procedures

3.4.2.1 Type and time of test

Where a structural test is specified in Table 3.4.1 or Table 3.4.2, a hydrostatic test in accordance with 3.4.4.1 will be acceptable. Where practical limitations, (strength of building berth, light density of liquid, etc.) prevent the performance of a hydrostatic test, a hydropneumatic test in accordance with 3.4.4.2 may be accepted instead

A hydrostatic test or hydropneumatic test for the confirmation of structural adequacy may be carried out while the vessel is afloat provided the results of a leak test are confirmed to be satisfactory before the vessel is afloat.

Alternative equivalent tank testing procedures may be considered for tanks which are constructed from composite materials such as glass reinforced plastic (GRP) and fibre reinforced plastic (FRP) based on the recommendations of the composite manufacturer.

3.4.2.2 Testing Schedule for New Construction or Major Structural Conversion

3.4.2.2.1 Tanks which are intended to hold liquids, and which form part of the watertight subdivision of the ship are to be tested for tightness and structural strength as indicated in Table 3.4.1 and 3.4.2.

3.4.2.2.2 The tank boundaries are to be tested from at least one side. The tanks for structural test are to be selected so that all representative structural members are tested for the expected tension and compression.

3.4.2.2.3 The watertight boundaries of spaces other than tanks for structural testing may be exempted, provided that the water-tightness of boundaries of exempted spaces is verified by leak tests and inspections. Structural testing may not be exempted and the requirements for structural testing of tanks in 3.4.2.2.1 to 3.4.2.2.2 are to be applied, for ballast holds, chain lockers and a representative cargo hold if intended for in-port ballasting.

3.4.2.2.4 Tanks which do not form part of the watertight subdivision of the ship may be exempted from structural testing provided that the water-tightness of boundaries of exempted spaces is verified by leak tests and inspections.

3.4.3 Leak test procedures

3.4.3.1 For the leak tests specified in Table 3.4.1, tank air tests, compressed air fillet weld tests, vacuum box tests in accordance with 3.4.4.4 through 3.4.4.6, or their combination, will be acceptable. Hydrostatic or hydropneumatic tests may also be accepted as leak tests provided that 3.4.5, 3.4.6 and 3.4.7 are complied with. Hose tests will also be acceptable for such locations as specified in Table 3.4.1 with Note 3, in accordance with 3.4.4.3. The application of the leak test for each type of welded joint is specified in Table 3.4.3.

3.4.3.2 Air tests of joints may be carried out in the block stage provided that all work on the block that may affect the tightness of a joint is completed before the test. See also 3.4.5.1 for the application of final coatings and 3.4.6 for the safe access to joints and the summary in Table 3.4.3.

3.4.4 Test Methods

3.4.4.1 Hydrostatic Test

3.4.4.1.1 Unless another liquid is approved, hydrostatic tests are to consist of filling the space with fresh water or sea water, whichever is appropriate for testing, to the level specified in Table 3.4.1 or Table 3.4.2. (See also 3.4.7).

3.4.4.1.2 In cases where a tank is designed for cargo densities greater than sea water and testing is with fresh water or sea water, the testing pressure height is to simulate the actual loading for those greater cargo densities as far as practicable, but the test pressure is not to exceed the maximum design internal pressure at the top of tank.

3.4.4.1.3 All external surfaces of the tested space are to be examined for structural distortion, bulging and buckling, other related damage and leaks.

3.4.4.2 Hydropneumatic test

3.4.4.2.1 Hydropneumatic tests, where approved, are to be such that the test condition, in conjunction with the approved liquid level and supplemental air pressure, will simulate the actual loading. The requirements and recommendations for tank air tests in 3.4.4.4 will also apply to hydropneumatic tests. (See also 3.4.7).

3.4.4.2.2 All external surfaces of the tested space are to be examined for structural distortion, bulging and buckling, other related damage and leaks.

3.4.4.3 Hose test

3.4.4.3.1 Hose tests are to be carried out with the pressure in the hose nozzle maintained at least at 0.2 [MPa] i.e. (2 bar) during the test. The nozzle is to have a minimum inside diameter of 12 [mm] and be at a perpendicular

distance from the joint not exceeding 1.5 [m]. The water jet is to impinge directly upon the weld.

3.4.4.3.2 Where a hose test is not practical because of possible damage to machinery, electrical equipment insulation or outfitting items, it may be replaced by a careful visual examination of welded connections, supported where necessary by means such as a dye penetrant test or ultrasonic leak test or the equivalent.

3.4.4.4 Tank air test

3.4.4.4.1 All boundary welds, erection joints and penetrations, including pipe connections, are to be examined in accordance with approved procedure and under a stabilized pressure differential above atmospheric pressure not less than 0.015 [MPa], with a leak indicating solution such as soapy water/detergent or a proprietary brand applied.

3.4.4.4.2 A U-tube with a height sufficient to hold a head of water corresponding to the required test pressure is to be arranged. The cross sectional area of the U-tube is not to be less than that of the pipe supplying air to the tank. Arrangements involving the use of two calibrated pressure gauges to verify the required test pressure may be accepted taking into account the following:

a) Where there is no protection by suitable barriers / screens,

    i. verification and confirmation that the test procedure is followed,
    ii. Verification and confirmation that test equipment is in good condition,
    iii. Verification and confirmation that the isolating valves are tight,
    iv. Verification and confirmation that the test pressure gauges (at least 2 pcs) are calibrated and are of suitable range as per test pressure,
    v. Confirmation that the pressure gauges are not isolated or bypassed, and that releasing mechanisms or safety valves are of adequate size/rating and correctly set.
    vi. Confirmation that the Pipe work, especially flexible piping, is free from damage or leaking joints.
    vii. Confirmation that the Inlet, outlet and release arrangement for the test medium to or from the item being tested are properly fabricated and supported, including their appropriate dimensions (e.g. Smaller diameter for inlets and bigger diameter for outlets, as well as releasing means).

b) If a releasing mechanism is used in lieu of a U-tube,

    i. It is to be evaluated, whether the design of the mechanism is similar to the U-tube principle (i.e. suitable to be lifted by the predetermined excessive pressure, and not subject to any kind of spring or restricting device).
    ii. The safety precautions adopted for the test are to be carefully reviewed and the risks after taking into account necessary precautions are to be evaluated

3.4.4.4.3 A double inspection is to be made of tested welds. The first is to be immediately upon applying the leak indication solution; the second is to be after approximately four or five minutes in order to detect those smaller leaks which may take time to appear.

3.4.4.5 Compressed air fillet weld test

3.4.4.5.1 In this air test, compressed air is injected from one end of a fillet welded joint and the pressure verified at the other end of the joint by a pressure gauge. Pressure gauges are to be arranged so that an air pressure of at least 0.015 [MPa] can be verified at each end of all passages within the portion being tested.

Note : Where a leak test is required for fabrication involving partial penetration welds, a compressed air test is also to be applied in the same manner as to fillet weld where the root face is large, i.e., 6-8 [mm].

3.4.4.6 Vacuum box test

3.4.4.6.1 A box (vacuum testing box) with air connections, gauges and an inspection window is placed over the joint with a leak indicating solution applied to the weld cap vicinity. The air within the box is removed by an ejector to create a vacuum of 0.02 - 0.026 [MPa] inside the box.

3.4.4.7 Ultrasonic test

3.4.4.7.1 An ultrasonic echo transmitter is to be arranged inside of a compartment and a receiver is to be arranged on the outside. The watertight / weathertight boundaries of the compartment are scanned with the receiver in order to detect an ultrasonic leak indication. A location where sound is detectable by the receiver indicates a leakage in the sealing of the compartment.

3.4.4.8 Dye penetration test

3.4.4.8.1 A test of butt welds or other weld joints uses the application of a low surface tension liquid at one side of a compartment boundary or structural arrangement. If no liquid is detected on the opposite sides of the boundaries after the expiration of a defined period of time, this indicates tightness of the boundaries. In certain cases, a developer solution may be painted or sprayed on the other side of the weld to aid leak detection.

3.4.4.9 Other tests

3.4.4.9.1 Other methods of testing may be considered by IRS upon submission of full particulars prior to the commencement of testing.

3.4.5 Application of coating

3.4.5.1 Final coating

3.4.5.1.1 For butt joints welded by an automatic process, the final coating may be applied any time before the completion of a leak test of spaces bounded by the joints, provided that the welds have been carefully inspected visually to the satisfaction of the Surveyor.

3.4.5.1.2 However, the Surveyor reserves the right to require a leak test prior to the application of the final coating over automatic erection butt welds.

3.4.5.1.3 For all other joints, the final coating is to be applied after the completion of the leak test of the joint. See also Table 3.4.3.

3.4.5.2 Temporary coating

3.4.5.2.1 Any temporary coating which may conceal defects or leaks is to be applied at the time as specified for the final coating (See 3.4.5.1). This requirement does not apply to shop primer.

3.4.6 Safe access to joints

3.4.6.1 For leak tests, a safe access to all joints under examination is to be provided. See also Table 3.4.3.

3.4.7 Hydrostatic or hydropneumatic tightness test

3.4.7.1 In cases where the hydrostatic or hydropneumatic tests are applied instead of a specific leak test, examined boundaries must be dew-free, otherwise small leaks are not visible.

Table 3.4.1 : Test requirements for Tanks and Boundaries				
Sr. No.	**Tank or boundary to be tested**	**Test type**	**Test head or pressure**	**Remarks**
1	Double bottom tanks[4]	Leak and structural[1]	The greater of - top of the overflow[12] - to 2.4 [m] above top of tank[2], or - to bulkhead deck	
2	Double bottom voids[5]	Leak	See 3.4.4.4 through 3.4.4.6, as applicable	Including pump room double bottom and bunker tank protection double hull required by MARPOL Annex I
3	Double side tanks	Leak and structural[1]	The greater of - top of the overflow[12], - to 2.4 [m] above top of tank[2,8], or - to bulkhead deck	
4	Double side voids	Leak	See 3.4.4.4 through 3.4.4.6, as applicable	
5	Deep tanks other than those listed elsewhere in this table	Leak and structural[1]	The greater of - top of the overflow[12], - to 2.4 [m] above top of tank[2,8]	
6	Cargo oil tanks	Leak and structural[1]	The greater of - top of the overflow[12], - to 2.4 [m] above top of tank[2,8], or - top of tank[2] plus the design vapour pressure	
7	Ballast hold of bulk carriers	Leak and structural[1]	- Top of cargo hatch coaming	
8	Peak tanks	Leak and structual[1]	The greater of - top of the overflow[12], or - to 2.4 [m] above top of tank[2,8]	After peak to be tested after installation of stern tube
9	a. Fore peak spaces with equipment	Leak	See 3.4.4.3 through 3.4.4.6, as applicable	
	b. Fore peak voids	Leak	See 3.4.4.4 through 3.4.4.6, as applicable	
	c. Aft peak spaces with equipment	Leak	See 3.4.4.3 through 3.4.4.6, as applicable	
	d. Aft peak voids	Leak	See 3.4.4.4 through 3.4.4.6, as applicable	After peak to be tested after installation of stern tube
10	Cofferdams	Leak	See 3.4.4.4 through 3.4.4.6, as applicable	
11	a. Watertight bulkheads	Leak[10]	See 3.4.4.3 through 3.4.4.6, as applicable[7]	
	b. Superstructure end bulkheads	Leak	See 3.4.4.3 through 3.4.4.6, as applicable	
12	Watertight doors below freeboard or bulkhead deck	Leak [6, 7]	See 3.4.4.3 through 3.4.4.6, as applicable	
13	Double plate rudder blades	Leak	See 3.4.4.4 through 3.4.4.6, as applicable	
14	Shaft tunnels clear of deep tanks	Leak[3]	See 3.4.4.3 through 3.4.4.6, as applicable	
15	Shell doors	Leak[3, 9]	See 3.4.4.3 through 3.4.4.6, as applicable	
16	Weathertight hatch covers and closing appliances	Leak[3,7]	See 3.4.4.3 through 3.4.4.6, as applicable	Hatch covers closed by tarpaulins and battens excluded

Table 3.4.1 : (Contd.)

Sr. No.	Tank or boundary to be tested	Test type	Test head or pressure	Remarks
17	Dual purpose tanks / dry cargo hatch covers	Leak[3,7]	See 3.4.4.3 through 3.4.4.6, as applicable	In addition to structural test in item 6 or 7
18	Chain lockers	Leak and structural[1]	Top of chain pipe	
19	L.O. sump tanks and other similar tanks/spaces under main engines	Leak	- See 3.4.4.3 through 3.4.4.6 as applicable	
20	Ballast ducts	Leak and structural[1]	The greater of - Ballast pump maximum pressure, or - Setting of any pressure relief valve	
21	Fuel Oil Tanks	Leak and structural[1]	The greater of - Top of the overflow[12], - To 2.4 [m] above top of tank[2,8] or - To top of tank[2] plus the design vapour pressure, or - To bulkhead deck	
22	Fuel oil overflow tanks not intended to hold fuel	Leak and structural[1]	The greater of - Top of the overflow[12], - To 2.4 [m] above top of tank[2] or - To bulkhead deck	

Notes :

1. Refer to section 3.4.2.2
2. The top of a tank is the deck forming the top of the tank excluding any hatchways.
3. Hose Test may also be considered as a method of the test, see 3.3.2.
4. Including tanks arranged in accordance with the provisions of SOLAS regulation II-1/9.4.
5. Including duct keels and dry compartments arranged in accordance with the provisions of SOLAS regulation II-1/11.2 and II-1/9.4 respectively, and/or oil fuel tank protection and pump room bottom protection arranged in accordance with the provisions of MARPOL Annex I, Chapter 3, Part A regulation 12A and Chapter 4, Part A, regulation 22 respectively.
6. Where water tightness of a watertight door has not been confirmed by prototype test, testing by filling watertight spaces with water is to be carried out. See SOLAS regulation II-1/16.2 and MSC.1/Circ.1572/Rev.1.
7. An alternative to the hose testing, other testing methods listed in 3.4.4.7 through 3.4.4.9 may be applicable subject to adequacy of such testing methods being verified. See SOLAS regulation II-1/11.1. For watertight bulkheads (item 11 a) alternatives to the hose testing may only be used where a hose test is not practicable.
8. For vessels of L < 90 [m], the head of water above highest point of tank may be (0.02L + 0.6) [m], but not less than 1.0 [m]. However, in mechanically propelled cargo ships of 500 GT and above and passenger ships, for tanks forming part of the watertight subdivision (See Pt.3, Ch.10, 4.2.1), head of water above the highest point of tank is to be 2.4 [m].
9. Watertight shell doors are to be prototype tested prior to installation on board.
10. A “Leak and Structural test” (see 3.4.2.2) is to be carried out for a representative cargo hold if intended for in-port ballasting. The filling level requirement for testing cargo holds intended for in-port ballasting is to be the maximum loading that will occur in-port as indicated in the loading manual.
11. Where L.O sump tanks and other similar spaces under main engines intended to hold liquid form part of the watertight subdivision of the ship, they are to be tested as per the requirements of item 5, Deep tanks other than those listed elsewhere in this table.
12. Refer to section 3.3.3

Table 3.4.2 : Additional Test requirements for Listed Types of Ships / Tanks

Sr. No.	Type of Ship / Tank	Structures to be tested	Type of Test	Test Head of Pressure	Remarks
1	Liquefied gas carriers	Integral tanks	Leak and structural	Refer Pt 5, Ch 4, Sec 4	
		Hull structure supporting membrane or semi-membrane tanks	Refer to Pt.5, Ch.4, Sec 4	Refer Pt 5, Ch 4, Sec 4	
		Independent tanks type A	Refer to Pt.5, Ch.4, Sec 4	Refer Pt 5, Ch 4, Sec 4	
		Independent tanks type B	Refer to Pt.5, Ch.4, Sec 4	Refer Pt 5, Ch 4, Sec 4	
		Independent tanks type C	Refer to Pt.5, Ch.4, Sec4	Refer Pt 5, Ch 4, Sec 4	
2	Edible liquid tanks	Independent tanks	Leak and structural[1]	The greater of - top of the overflow[3], or - to 0.9 [m] above top of tank[2]	
3	Chemical carriers	Integral or independent cargo tanks	Leak and structural[1]	The greater of[4] - to 2.4 [m] above top of tank[2], or - to top of tank[2] plus the design vapour pressure	

Note :

1 Refer to section 3.4.2.2

2. Top of tank is deck forming the top of the tank excluding any hatchways

3. Refer to section 3.3.3

4. Where a cargo tank is designed for the carriage of cargoes with specific gravities greater than seawater, refer to section 3.4.4.1.2.

Table 3.4.3 : Application of leak test, coating and provision of safe access for type of welded joints

Type of welded joints		Leak Test	Coating[1]		Safe Access[2]	
			Before leak test	After leak test but before structural test	Leak test	Structural test
Butt	Automatic	Not required	Allowed[3]	N/A	Not required	Not required
	Manual or semi-automatic[4]	Required	Not allowed	Allowed	Required	Not required
Fillet	Boundary including penetrations	Required	Not allowed	Allowed	Required	Not required

Notes :

1. Coating refers to internal (tank / hold coating), where applied and external (shell/deck) painting. It does not refer to shop primer.
2. Temporary means of access for verification of the leak test.
3. The condition applies provided that the welds have been carefully inspected visually to the satisfaction of the Surveyor
4. Flux Core Arc Welding (FCAW) semiautomatic butt welds need not be tested provided that careful visual inspection show continuous uniform weld profile shape, free from repairs, and the results of NDE testing show no significant defects.

Section 4

Testing of Tanks and Tight Boundaries for SOLAS Exempt/ Equivalent Ships

4.1 General

4.1.1 These test procedures are to confirm the watertightness of tanks, watertight boundaries and the structural adequacy of tanks which form part of the watertight subdivisions of ships. These procedures may also be applied to verify the weathertightness of structures and shipboard outfitting. The tightness of all tanks and watertight boundaries of ships during new construction and those relevant to major conversions or major repairs is to be confirmed by these test procedures prior to the delivery of the ship.

Note: *Major repair means a repair affecting structural integrity*

4.1.2 Testing procedures of watertight compartments are to be carried out in accordance with this section for those SOLAS ships for which the shipyard provides documentary evidence of the shipowner's agreement to a request to the Flag Administration:

a) for an exemption from the application of SOLAS Chapter II-1, Regulation 11, or

b) for agreeing to an equivalency, that the requirements of this section is equivalent to SOLAS Chapter II-1, Regulation 11;

c) and, the above-mentioned exemption/equivalency has been granted by the Flag Administration.

4.2 Application

4.2.1 Testing procedures are to be carried out in accordance with the requirements of Section 3 in association with the following alternative procedures for 3.4.2.2 of Section 3 “Testing Schedule for New Construction or Major Structural Conversion”.

4.2.2 The tank boundaries are to be tested from at least one side. The tanks for structural test are to be selected so that all representative structural members are tested for the expected tension and compression.

4.2.3 Structural tests are to be carried out for at least one tank of a group of tanks having structural similarity (i.e. same design conditions, alike structural configurations with only minor localised differences determined to be acceptable by the attending Surveyor) on each vessel provided all other tanks are tested for leaks by an air test. The acceptance of leak testing using an air test instead of a structural test does not apply to cargo space boundaries adjacent to other compartments in tankers and combination carriers or to the boundaries of tanks for segregated cargoes or pollutant cargoes in other types of ships.

4.2.4 Additional tanks may require structural testing if found necessary after the structural testing of the first tank.

4.2.5 For tanks which are less than 2 [m^3] in volume, structural testing may be replaced by leak testing.

4.2.6 Where the structural adequacy of the tanks and spaces of a vessel was verified by the structural testing required by Section 3 or Section 4.2.3, subsequent vessels in the series (i.e. sister ships built from the same plans at the same shipyard) may be exempted from structural testing of tanks, provided that:

1.water-tightness of boundaries of all tanks and spaces are verified by leak tests and thorough inspections are carried out.

2.structural testing is carried out for at least one tank or space of each type among all tanks/ spaces of each sister vessel.

3.additional tanks and spaces may require structural testing if found necessary after the structural testing of the first tank or if deemed necessary by the attending Surveyor.

For cargo space boundaries adjacent to other compartments in tankers and combination carriers or boundaries of tanks for segregated cargoes or pollutant cargoes in other types of ships, structural tests are to be carried out for at least one tank of a group of tanks having structural similarity (i.e. same design conditions, alike structural configurations with only minor localised differences determined to be acceptable by the attending Surveyor) on each vessel provided all other tanks are tested for leaks by an air test.

4.2.7 Sister ships built (i.e. keel laid) two years or more after the delivery of the last ship of the series, may be tested in accordance with 4.2.6 at the discretion of IRS, provided that:

1.general workmanship has been maintained (i.e. there has been no discontinuity of shipbuilding or significant changes in the construction methodology or technology at the yard, shipyard personnel are appropriately qualified and demonstrate an adequate level of workmanship as determined by IRS); and

2. an NDT plan is implemented and evaluated by IRS for the tanks not subject to structural tests. Shipbuilding quality standards for the hull structure during new construction are to be reviewed and agreed during the kick-off meeting. Structural fabrication is to be carried out in accordance with a recognised fabrication standard (such as, IACS Recommendation 47, “Shipbuilding and Repair Quality Standard”) which has been accepted by IRS prior to the commencement of fabrication/construction. The work is to be carried out in accordance with the Rules and under survey of IRS.

Section 5

Testing of Tanks and Tight Boundaries for Non-SOLAS Ships

5.1 General

5.1.1 These test procedures are to confirm the watertightness of tanks, watertight boundaries and the structural adequacy of tanks which form part of the watertight subdivisions of ships. These procedures may also be applied to verify the weathertightness of structures and shipboard outfitting. The tightness of all tanks and watertight boundaries of ships during new construction and those relevant to major conversions or major repairs is to be confirmed by these test procedures prior to the delivery of the ship.

Note:

Watertight subdivision means the main transverse and longitudinal subdivisions of the ship.

Major repair means a repair affecting structural integrity

5.1.2 For the purpose of application of this section, Non-SOLAS Ships are those ships not engaged on international voyages or cargo ships which are less than 500 GT.

5.1.3 Testing procedures of watertight compartments are to be carried out in accordance with this Section, see SOLAS Chapter I, Regulation 1 and Regulation 3.

5.2 Application

5.2.1 Testing procedures are to be carried out in accordance with the requirements of Section 3 in association with the following alternative procedures for 3.4.2.2 of Section 3 “Testing Schedule for New Construction or Major Structural Conversion”.

5.2.2 The tank boundaries are to be tested from at least one side. The tanks for structural test are to be selected so that all representative structural members are tested for the expected tension and compression.

5.2.3 The requirements given in Table 3.4.1 of Section 3 to structurally test tanks to 2.4 metres above the top of the tank do not apply. Instead, the minimum test pressure for structural testing is to be taken as 0.3D + 0.76 metres above the top of the tank where the top of the tank is the deck forming the top of the tank, excluding any hatchways and D is the depth of the ship. The minimum test pressure need not be taken greater than 2.4 metres above the top of the tank.

5.2.4 Structural tests are to be carried out for at least one tank of a group of tanks having structural similarity (i.e. same design conditions, alike structural configurations with only minor localised differences determined to be acceptable by the attending Surveyor) on each vessel provided all other tanks are tested for leaks by an air test. The acceptance of leak testing using an air test instead of a structural test does not apply to cargo space boundaries adjacent to other compartments in tankers and combination carriers or the boundaries of tanks for segregated cargoes or pollutant cargoes in other types of ships.

5.2.5 Additional tanks may require structural testing if found necessary after the structural testing of the first tank.

5.2.6 For tanks which are less than 2 [m^3] in volume, structural testing may be replaced by leak testing.

5.2.7 Where the structural adequacy of the tanks and spaces of a vessel were verified by the structural testing required by either Section 3 or Section 5.2.4, subsequent vessels in the series (i.e. sister ships built from the same plans at the same shipyard) may be exempted from structural testing of tanks, provided that:

1. water-tightness of boundaries of all tanks and spaces are verified by leak tests and thorough inspections are carried out.

2. structural testing is carried out for at least one tank or space among all tanks/spaces of each sister vessel.

3. additional tanks and spaces may require structural testing if found necessary after the structural testing of the first tank or if deemed necessary by the attending Surveyor.

For cargo space boundaries adjacent to other compartments in tankers and combination carriers or boundaries of tanks for segregated cargoes or pollutant cargoes in other types of ships, structural tests are to be carried out for at least one tank of a group of tanks having structural similarity (i.e. same design conditions, alike structural configurations with only minor localised differences determined to be acceptable by the attending Surveyor) on each vessel provided all other tanks are tested for leaks by an air test.

5.2.8 Sister ships built (i.e. keel laid) two years or more after the delivery of the last ship of the series, may be tested in accordance with 5.2.7 at the discretion of IRS, provided that:

1. general workmanship has been maintained (i.e. there has been no discontinuity of shipbuilding or significant changes in the construction methodology or technology at the yard, shipyard personnel are appropriately qualified and demonstrate an adequate level of workmanship as determined by IRS); and

2. an NDT plan is implemented and evaluated by IRS for the tanks not subject to structural tests. Shipbuilding quality standards for the hull structure during new construction are to be reviewed and agreed during the kick-off meeting. Structural fabrication is to be carried out in accordance with a recognised fabrication standard (such as, IACS Recommendation 47, “Shipbuilding and Repair Quality Standard”) which has been accepted by IRS prior to the commencement of fabrication/construction. The work is to be carried out in accordance with the Rules and under survey of IRS.

Section 6

Construction Monitoring

6.1 Scope

6.1.1 This section provides requirements for new construction ships to be assigned **CM** notation, i.e. Construction Monitoring.

6.1.2 The aim of the **CM** notation is to ensure an acceptable quality of construction at critical locations of the ship thereby ensuring better structural integrity of the hull.

6.1.3 Critical locations are defined as those locations which are identified to be important for structural integrity of the hull (identified from finite element analysis, fatigue assessment), those locations where the fabrication is difficult in practice due to complexity of the details or the finesse of the tolerances to be achieved. Those locations which have been previously reported on ships classed with IRS or the global fleet as being particularly susceptible to failure or cracking are also to be included within the list of critical locations.

6.1.4 A construction monitoring plan is to be submitted to IRS for approval. The construction monitoring plan is to identify and consider all the critical locations, as applicable.

6.1.5 The builder’s shipbuilding quality standard and the details of the builder and subcontractors’ (if any) facilities are also to be submitted for IRS review. These standards are not to be less stringent than IACS Recommendation 47. If deemed necessary, IRS may visit the builder’s facilities including those of the sub-contractors (if any) to assess capability of the builder to fabricate and construct the critical locations.

6.1.6 The construction monitoring plan is to provide details of the following, for each critical location:

- Construction tolerances to be achieved. These may be in terms of dimensional tolerances, maximum values for gaps, misalignments, etc.
- Fabrication procedures/ construction procedures including sequences of welding
- Non-destructive testing plan and acceptance criteria in accordance with IRS Classification Note: *Requirements for Non-Destructive Testing*
- Defect rectification plan.

6.1.7 All critical locations are to be inspected by the Surveyor to ascertain and record the actual construction tolerances achieved.

6.1.8 Records of non-destructive testing for the critical locations are to be made available to the Surveyor.

Chapter 1 : General Requirements for the Design and Construction of Machinery

Section 1 : General

1.1 Scope

1.2 Machinery to be constructed under survey

1.3 Extent of survey

1.4 Departures from the rules

1.5 Plans and particulars

1.6 Availability of machinery for operation

1.7 Environmental conditions

1.8 Power ratings

1.9 Units

1.10 Astern power

1.11 Fuel

1.12 Materials

1.13 Alternative design and arrangements

Section 2 : Machinery Room Arrangements

2.1 General

2.2 Accessibility

2.3 Fire protection

2.4 Ventilation

2.5 Communications

2.6 Machinery controls

Section 3 : Trials

3.1 General

3.2 Sea Trials

Section 4 : Certification of Machinery and Components Based on Alternative Certification Scheme

4.1 General

4.2 Certification of diesel engines

Chapter 2 : Piping Design Requirements

Section 1 : General

1.1 Scope

1.2 Classes of pipes

1.3 Design pressure

1.4 Design temperature

1.5 Design symbols

1.6 Heat treatment

1.7 Minimum thickness of pipes and bends

1.8 Flanges

1.9 Materials

Section 2 : Carbon and Low Alloy Steel Pipes and Fittings

2.1 Materials

2.2 Minimum thickness of steel pipes and bends

2.3 Types of connection

2.4 Flange connections

2.5 Threaded sleeve joints

2.6 Welding, non-destructive examination and post-weld heat treatment of welded pipes

2.7 Mechanical joints

Section 3 : Copper and Copper Alloy Pipes and Fittings

3.1 Materials

3.2 Minimum thickness of pipes

3.3 Heat treatment

Section 4 : Cast Iron Pipes and Fittings

4.1 Spheroidal or nodular graphite cast iron

4.2 Grey cast iron

Section 5 : Plastic Pipes and Fittings

5.1 General

5.2 Terms and definitions

5.3 Strength

5.4 Axial strength

5.5 Impact resistance

5.6 Temperature

5.7 Requirements for pipes/piping systems depending on service and/or locations

5.8 Material approval and quality control during manufacture

5.9 Installation

5.10 Test specification for plastic pipes

Section 6 : Flexible Hoses

6.1 Definition

6.2 Scope

6.3 Design and construction

6.4 Installation

6.5 Tests

6.6 Marking

Section 7 : Hydraulic Tests on Pipes and Fittings

7.1 Hydraulic tests before installation on board

7.2 Testing after assembly on board

Chapter 3 : Pumping and Piping

Section 1 : General

1.1 Scope

1.2 Plans

1.3 Materials

1.4 Valves and cocks

1.5 Shipside fittings (other than sanitary discharges and scuppers)

1.6 Piping installation

Section 2 : Bilge and Ballast Piping Systems

2.1 General

2.2 Drainage of cargo holds

2.3 Drainage from refrigerated cargo spaces

2.4 Drainage from fore and aft peaks

2.5 Drainage from tanks, cofferdams and void spaces

2.6 Drainage from spaces above fore and after peaks, chain lockers and above machinery spaces

2.7 Drainage from machinery spaces

2.8 Drainage from tunnel

2.9 Sizes of bilge suctions

2.10 Bilge pumps and ejectors

2.11 Pump types

2.12 Bilge piping arrangements and fittings

2.13 Additional requirements for passenger ships

2.14 Drainage arrangements on vessels not fitted with propelling machinery

2.15 Ballast system

Section 3 : Vents, Sounding, Overflow and Scuppers and Discharges Piping Systems

3.1 General

3.2 Vent pipes

3.3 Overflow pipes

3.4 Sounding arrangements

3.5 Scuppers and discharges

3.6 Water level detectors on single hold cargo ships other than bulk carriers

3.7 Water level detectors on multiple hold cargo ships other than bulk carriers and tankers

Section 4 : Fuel Oil Systems

4.1 General

4.2 Oil fuel tanks

4.3 Oil fuel piping

4.4 Arrangement of valves, cocks, pumps and fittings

4.5 Heating arrangements

4.6 Temperature indication

4.7 Filling arrangements

4.8 Alternate carriage of oil fuel and water ballast

4.9 Deep tanks for the alternative carriage of oil, water ballast or dry cargo

4.10 Oil fuel burning arrangements

4.11 Remote stop of oil fuel pumps and fans

4.12 Fuel oil treatment system

Section 5 : Steam Piping and Condensate Piping Systems

5.1 Expansion and drainage

5.2 Steam pipes in way of holds, shaft and pipe tunnels

5.3 Relief valves

5.4 Steam supply to auxiliaries

5.5 Steam for fire extinguishing in cargo holds

5.6 Condensate pumps

Section 6 : Boiler Feed Piping Systems

6.1 Feed water piping

6.2 Feed pumps

6.3 Valves, cocks and fittings

6.4 Fresh-water connections

6.5 Feed water tanks

6.6 Evaporators

Section 7 : Engine Cooling Water Systems

7.1 General

7.2 Cooling water main supply

7.3 Cooling water standby supply

7.4 Relief valves on cooling water pumps

7.5 Sea inlets for cooling water pumps

Section 8 : Lubricating Oil Piping Systems

8.1 General

8.2 Pumps

8.3 Control of pumps and alarms

8.4 Emergency supply for propulsion turbines and propulsion turbogenerators

8.5 Filters

8.6 Valves and cocks on lubricating oil tanks

Chapter 4 : Prime Movers and Propulsion Shafting Systems

Section 1 : General

1.1 Scope

1.2 Materials

1.3 Turning gear

1.4 Power ratings

1.5 Overload capacity

1.6 Certification of machinery

1.7 Type approval program

Section 2 : Steam Turbines

2.1 Scope

2.2 Plan and particulars

2.3 Materials

2.4 Design and construction

2.5 Vibration

2.6 External influences

2.7 Steam supply and water system

2.8 Turning gear

2.9 Safety arrangement

2.10 Bled steam connections

2.11 Steam strainers

2.12 Emergency arrangements

2.13 Tests and equipment

2.14 Balancing

2.15 Hydraulic tests

2.16 Indicators for movement

2.17 Weardown gauges

Section 3 : Gas Turbines

3.1 Scope

3.2 Plans and particulars

3.3 Materials

3.4 Design and construction

3.5 Welded components

3.6 Vibration

3.7 Containment

3.8 Inlet and exhaust systems

3.9 Fuel and salt deposits

3.10 Indication of temperature

3.11 External influences

3.12 Overhaul life

3.13 Safety arrangements

3.14 Starting arrangements

3.15 Tests

3.16 Shop trials

3.17 Electric starting

3.18 Type testing of gas turbine

Section 4 : Internal Combustion Engines

4.1 Scope

4.2 Materials and material testing

4.3 Crankshaft design

4.4 Design and construction

4.5 Crankcase ventilation

4.6 Safety devices

4.7 Governing

4.8 Oil fuel, lubricating oil, cooling water and exhaust gas systems

4.9 Engine starting arrangements

4.10 Type testing of oil engines

4.11 Factory acceptance test

4.12 Shipboard trials

4.13 Reciprocating Internal combustion engines fuelled by natural gas

4.14 Storage and use of selective catalytic reduction (SCR) reductants

4.15 Safety Measures for chemical treatment fluids used in Exhaust Gas Cleaning Systems and the Residues which have Hazardous Properties

4.16 AC generating sets

4.17 Capacity and availability of compressed air for essential services onboard ships other than the supply of compressed air for engine starting

Section 5 : Gearing

5.1 Scope

5.2 Plans and particulars

5.3 Materials

5.4 Design and construction

5.5 Accuracy of gear cutting and alignment

5.6 Balancing of gear pinions and wheels

5.7 Gearcases

5.8 Type tests and sea trials

5.9 Alignment and weardown gauges

5.10 Trials

Section 6 : Main Propulsion Shafting

6.1 Scope

6.2 Alternative calculation methods

6.3 Plans and particulars

6.4 Materials for shafting

6.5 Intermediate and thrust shafts

6.6 Tailshafts and stern tube shafts

6.7 Hollow shafts

6.8 Integral couplings

6.9 Demountable couplings

6.10 Tooth couplings

6.11 Flexible couplings

6.12 Interference fit assemblies

6.13 Coupling bolts

6.14 Tailshaft liners

6.15 Keys and keyways for propeller connections

6.16 Stern tube and bearings

6.17 Roller element bearings

6.18 Shaft bearing materials

6.19 Glass Reinforced Plastic coating

6.20 Special approval of alloy steel used for intermediate shaft material

Section 7 : Propellers

7.1 Scope

7.2 Plans and particulars

7.3 Materials

7.4 Design

7.5 Fitting of propellers

7.6 Keyless fittings of propellers without ice strengthening

Section 8 : Vibrations and Alignment

8.1 Scope

8.2 Basic system requirements

8.3 Resilient mountings

8.4 Torsional vibration

8.5 Axial vibrations

8.6 Lateral vibrations

8.7 Shaft alignment

Section 9 : Thrusters

9.1 Scope

9.2 Plans and particulars

9.3 Materials

9.4 Design and construction

9.5 Piping systems

9.6 Control and monitoring

9.7 Electrical systems

9.8 Tests

Chapter 5 : Boilers and Pressure Vessels

Section 1 : General

1.1 Scope

1.2 Design pressure

1.3 Metal temperature

1.4 Plans and particulars

1.5 Classification of pressure vessels

1.6 Definition of symbols

1.7 Materials

1.8 Allowable stress

1.9 Joint factors

1.10 Pressure parts of irregular shape

1.11 Adverse working conditions

1.12 Minimum shell thickness

1.13 Heat treatment, non-destructive examination and routine tests

Section 2 : Design Requirements

2.1 Cylindrical shells and drums subject to internal pressure

2.2 Spherical shells subject to pressure on the concave side

2.3 Dished ends subject to pressure on concave side

2.4 Conical ends subject to internal pressure

2.5 Unstayed flat end plates

2.6 Standpipe and branches

2.7 Particular design requirements for boilers, superheaters, economizers, steam receivers and similar vessels

2.8 Access arrangements

2.9 Shell type exhaust gas heated economizers that may be isolated from the steam plant system

Section 3 : Fittings and Mountings

3.1 General

3.2 Safety valves

3.3 Stop valves

3.4 Water level indicators

3.5 Low water level fuel shut-off and alarm

3.6 Feed check valves

3.7 Pressure gauges

3.8 Blow-down and scum valves

3.9 Salinometer valve or cock

Section 4 : Hydraulic Tests

4.1 Boilers (fired and exhaust gas heated), economizers, superheaters, reheaters, steam receivers, steam heated generators and similar vessels

4.2 Other pressure vessels

Chapter 6 : Steering Gear

Section 1 : General

1.1 Scope

1.2 Definitions

1.3 Installation

1.4 Steering gear compartment

1.5 Plans

1.6 Materials

1.7 Rudder, rudder stock, vanes, tiller and quadrant

1.8 Mechanical steering gear

Section 2 : Performance

2.1 Requirements for traditional type of steering gears

2.2 Requirements for non-traditional (azimuthing propellers, waterjets, etc.) type of steering gears

2.3 Other requirements

Section 3 : Construction and Design

3.1 General

3.2 Components

3.3 Valve and relief valve arrangement

3.4 Flexible hoses

Section 4 : Steering Control Systems

4.1 General
IR4.2 Mechanical, hydraulic and electrical independency and failure detection and response of steering control systems

Section 5 : Electric Power Circuits, Electric Control Circuits, Monitoring and Alarms

5.1 Electric power circuits

5.2 Electric control circuits

5.3 Monitoring and alarms

Section 6 : Emergency Power

6.1 General

Section 7 : Testing and Trials

7.1 Testing

7.2 Trials

Section 8 : Additional Requirements

8.1 For tankers, chemical tankers or gas carriers of 10,000 tons gross and upwards and every ship of 70,000 tons gross and upwards

8.2 For tankers, chemical tankers or gas carriers of 10,000 tons gross and upwards

8.3 For tankers, chemical tankers or gas carriers of 10,000 tons gross and upwards but of less than 100,000 tonnes deadweight

Section 9 : Guidelines for the Acceptance of Non-duplicated Rudder Actuators for Tanker, Chemical Tankers or Gas Carriers of 10,000 tons gross and upwards but of less than 100,000 tonnes Deadweight

9.1 Materials

9.2 Design

9.3 Construction details

9.4 Non-destructive testing

9.5 Testing

Chapter 7 : Control Engineering

Section 1 : General

1.1 Scope

1.2 Remote control systems capability

1.3 Plans and particulars

1.4 Operational guidance manual

1.5 Location of controls

1.6 Main control location

1.7 Secondary control locations

1.8 Control console construction

1.9 Instrumentation

1.10 Displays, indications and alarms

1.11 Safety systems

Section 2 : Control - System Characteristics

2.1 Power supply

2.2 Electrical and electronic devices

2.3 Hydraulic controls

2.4 Pneumatic controls

2.5 Ship motion effects

2.6 Bridge control for main propulsion machinery

2.7 Valve control system

Section 3 : Requirements for various Machinery Installations

3	*Trials*
4	*Certification of Machinery and Components Based on Alternative Certification Scheme*

Section 1

General

1.1 Scope

1.1.1 The Chapters of this Part cover the construction and installation of main propulsion and auxiliary machinery systems, together with their associated equipment, boilers, pressure vessels and pumping and piping arrangements fitted in vessels classed or intended to be classed with IRS.

1.2 Machinery to be constructed under survey

1.2.1 In ships intended to be built under Special Survey, all important units of equipment are to be surveyed at the manufacturer's works. The workmanship is to be to the Surveyor's satisfaction and the Surveyor is to be satisfied that the components are suitable for the intended purpose and duty. Examples of such units are:

- Main propulsion engines, including their associated gearing, flexible couplings, scavenge blowers and superchargers;

- Boilers supplying steam for propulsion or for services essential for the safety or the operation of the ship at sea, including superheaters, economisers, desuper-heaters, steam receivers. All other boilers having working pressures exceeding 0.34 [N/mm^2], and having heating surfaces greater than 4.65 [m^2];

- Auxiliary engines which are the source of power for services essential for safety or for the operation of the ship at sea;

- Steering machinery;

- Athwartship thrust units, their prime movers and control mechanisms;

- All pumps necessary for the operation of vessel, main propulsion and essential machinery, e.g. boiler feed, cooling water circulating, condensate extraction, oil fuel, lubricating oil, etc.;

- All heat exchangers necessary for the operation of main propulsion and essential machinery, e.g. air, water and lubricating oil coolers, oil fuel and water heaters, de-aerators and condensers, evaporators and distiller units;

- Air compressors, air receivers and other pressure vessels necessary for the operation of main propulsion and essential machinery. Any other unfired pressure vessels for which plans are required to be submitted for approval in accordance with the requirements of Ch.5;

- Alarm and control equipment as detailed in Ch.7;

- Electrical equipment and electrical propelling machinery as detailed in Ch.8.

- All pumps essential for safety of the ship, e.g. fire, bilge and ballast pumps; and

- Valves and other components detailed in Ch.2.

1.3 Extent of survey

1.3.1 The Surveyors are to examine and test the materials and workmanship from the commencement of work until the final test of the machinery under full power working conditions. Any defects, etc., are to be indicated as early as possible.

1.3.2 Where items of machinery are manufactured as individual or series produced units, IRS would be prepared to give consideration to the adoption of a survey procedure based upon quality assurance concepts as detailed in Sec.4.

1.4 Departures from the rules

1.4.1 Where it is proposed to depart from the requirements of the Rules, IRS will be prepared to give due consideration to the circumstances of any special case.

1.4.2 Any novelty in the construction of the machinery, boilers or pressure vessels is to be reported to IRS.

1.5 Plans and particulars

1.5.1 Before the work is commenced, plans in triplicate of all machinery items, as detailed in relevant Chapters of this Part giving the requirements for individual systems, are to be submitted for approval. The particulars of the machinery, including power ratings and design calculations, where applicable, necessary to verify the design, are also to be submitted. Any subsequent modifications are subject to approval before being put in to operation.

1.5.2 The strength requirements for rotating parts of the machinery, as specified in relevant Chapters of this Part, are based upon strength consideration only and their application does not relieve the manufacturer from the responsibility for the presence of dangerous vibrations in the installation at speeds within the operating range.

1.6 Availability of machinery for operation

1.6.1 Ship's machinery is to be so arranged that it can be brought in to operation from the "dead ship" condition using only the facilities available on board. "Dead ship" condition is understood to mean a condition under which the main propulsion plant, boilers and auxiliaries are not in operation and in restoring the propulsion, no stored energy for starting and operating the propulsion plant, the main source of electrical power and other essential auxiliaries is assumed to be available. In order to restore operation from the "dead ship" condition, an emergency generator complying with the requirements of Pt.4, Ch.8, Cl.2.8 may be used provided that the emergency power supply from it is available at all times. It is assumed that means are available to start the emergency generator at all times.

1.6.2 "Blackout" is a sudden loss of electric power in the main distribution system. All means of starting by stored energy are available.

1.7 Environmental conditions

1.7.1 All components and systems covered by the Rules are to be designed to operate under the following environmental conditions if not otherwise specified in the detailed requirements for the component or system:

- ambient air temperature in the machinery space between 0°C and 55°C;

- relative humidity of air in the machinery space up to 96 per cent;

- sea water temperature up to 32°C; and

- list, rolling, trim and pitch in accordance with Table 1.7.1.

- ship accelerations and motions in accordance with 1.7.5.

1.7.2 Where the Rules have requirements for capacity or effect of machinery, these are to be based on a total barometric pressure of 1 bar, an engine room ambient temperature or suction air temperature of 45°C, a relative humidity of 60 per cent and a sea water temperature or where applicable the temperature of the charge air coolant at inlet of

32°C. The engine manufacturer is not expected to provide simulated ambient reference conditions at test bed.

1.7.3 In the case of ships to be classed for restricted service, the rating is to be suitable for the temperature conditions associated with the geographical limits of the restricted service.

1.7.4 Where electrical equipment is installed within environmentally controlled spaces the ambient temperature for which the equipment is suitable may be reduced from 45°C to a value not less than 35°C provided:

- The equipment is not for use for emergency services.

Table 1.7.1 : Machinery inclinations

Installations/Components	Angle of inclination [1]			
	Athwartships		Fore and aft	
	Static	Dynamic	Static	Dynamic
Main and auxiliary machinery	15°	22.5°	5°[4]	7.5°
Safety equipment e.g. emergency power installations, emergency fire pumps and their devices Switch gear, electric and electronic appliances[2] and remote control systems	22.5°[3]	22.5°[3]	10°	10°

Notes

1 Athwartships and fore and aft inclinations occur simultaneously.

2 Switches and controls are to remain in their last set position. No undesired switching operations or operational changes are to occur.

3 In ships for the carriage of liquefied gases and of chemicals the emergency power supply must also remain operable with the ship flooded to a final athwartships inclination upto maximum of 30°.

4 For ships where Rule length (L) exceeds 100 [m], the fore and aft static angle of inclination can be taken as 500/L degrees.

5 Any deviations from these angles of inclination taking into consideration the size and service conditions of the ship will be specially considered.

- Temperature control is achieved by at least two cooling units so arranged that in the event of loss of one cooling unit, for any reason, the remaining unit(s) is capable of satisfactorily maintaining the design temperature.

- The equipment is able to be initially set to work safely within a 45°C ambient temperature until such a time that the lesser ambient temperature may be achieved. The cooling equipment is to be rated for a 45°C ambient temperature.

- Audible and visual alarms are provided, at a continually manned control station, to indicate any malfunction of the cooling units.

- It is to be ensured that electrical cables for their entire length are adequately rated for the maximum ambient temperature to which they are exposed along their length.

- The equipment used for cooling and maintaining the lesser ambient temperature is to be classified as a secondary essential service, as defined in Ch.8, sec.1.

1.7.5 Shipboard accelerations

1.7.5.1 General

.1 Main propulsion and steering machinery and auxiliary machinery that is essential to the propulsion and steering, and the safety of the

ship is to be capable of operation under the effects of accelerations and motions.

.2 The requirements in 1.7.5.2 to 1.7.5.4 apply where documented evidence of equipment suitability is specifically required by the Rules.

1.7.5.2 Documentation

.1 The ship builders are to identify and document the ship accelerations and motions periods to which machinery and equipment might be subjected to. The expected accelerations and ship motions periods are to be within machinery and equipment manufacturers requirements. The estimations are to consider vessel type, machinery or equipment location and expected service conditions.

1.7.5.3 Evaluation of equipment suitability

.1 Machinery and equipment manufacturers are to submit evidence of their machinery or equipment, that can operate under the required static and dynamic conditions stated in Table 1.7.1 and at least at the levels of shipboard accelerations as stated in 1.7.5.2 and/or specified in the Rules. Documentation of satisfactory performance is to take the form of:

- Report of testing under representative conditions; or
- Report of theoretical verification using recognized computational techniques accompanied by detailed and relevant validation data: or
- Historical data which provides relevant demonstration of satisfactory experience in service.

1.7.5.4 Installation and operation

.1 Machinery and equipment manufacturers are to submit details of the requirements /recommendations for installation of the machinery and equipment onboard to ensure satisfactory operation in service under the required static and dynamic conditions as described in Table 1.7.1 and at least at the levels of shipboard accelerations as stated in 1.7.5.2 and/or specified in the Rules.

Note: Consideration should be given for positioning machinery in order to minimize the dynamic load on bearings due to ship motion.

.2 Shipbuilders are to submit details demonstrating that the installation of the machinery and equipment onboard is in accordance with manufacturer's requirements /recommendations.

1.8 Power ratings

1.8.1 In the following Chapters, where the dimensions of any particular component are determined from shaft power, P in kW, and revolutions per minute, R, the values to be used are to be derived from the following:

- For main propulsion machinery, the maximum shaft power and corresponding revolutions per minute giving the maximum torque for which the machinery is to be classed; and
- For auxiliary machinery, the maximum continuous shaft power and corresponding revolutions per minute which will be used in service.

1.9 Units

1.9.1 Units and formulae included in the Rules are shown in SI units.

1.9.2 Where the metric version of shaft power, i.e. (shp), appears in the Rules, 1 shp is equivalent to 75 [kgf] [m/sec] or 0.735 [kW].

1.9.3 Pressure gauges may be calibrated in bar

where,

1 bar = 0.1 [N/mm^2] = 1.02 [kgf/cm^2].

1.10 Astern power

1.10.1 In order to maintain sufficient maneuverability and secure control of the ship in all normal conditions, the main propulsion machinery is to be capable of reversing the direction of thrust so as to bring the ship to rest from the maximum service speed. The main propulsion machinery is to be capable of maintaining in free route astern at least 70% of the ahead revolutions.

1.10.2 Where steam turbines are used for main propulsion, they are to be capable of maintaining in free route astern at least 70% of the ahead revolutions for a period of at least 15 minutes. The astern trial is to be limited to 30 minutes or in accordance with

manufacturer's recommendation to avoid overheating of the turbine due to the effects of "windage" and friction.

1.10.3 For main propulsion systems with reversing gears, controllable pitch propeller or electric propeller drive, running astern is not to lead to overload of the propulsion machinery.

1.10.4 Main propulsion systems are to undergo tests to demonstrate the astern response characteristics. The tests are to be carried out at least over the maneuvering range of the propulsion system and from all control positions. A test plan is to be provided by the yard and accepted by the surveyor. If specific operational characteristics have been defined by the manufacturer, these are to be included in the test plan.

1.10.5 The ahead revolutions as mentioned above are understood as those corresponding to the maximum continuous ahead power for which the vessel is classed.

1.10.6 The reversing characteristics of the propulsion plant, including the blade pitch control system of controllable pitch propellers, are to be demonstrated, tested and recorded as specified in Sec.3, 3.2.8 during trials.

1.11 Fuel

1.11.1 The flash point (closed cup test) of oil fuel for use in ships classed for unrestricted service, in general, is not to be less than 60°C.

1.11.2 For emergency generator engines, fuel having a flash point (closed cup test) of not less than 43°C may be used.

1.11.3 Fuels with flash points lower than 60°C, but not less than 43°C unless specially approved, may be used in ships intended for service restricted to geographical limits where it can be ensured that the temperature of the machinery and boiler spaces will always be 10°C below the flash point of fuel. In such cases, safety precautions and the arrangements for storage and pumping will be specially considered. (Also refer Pt.6, Ch.2, 1.2.1).

1.11.4 The use of fuels having a lower flash point than specified in 1.11.1 to 1.11.3 as applicable may be permitted provided that such fuel is not stored in any machinery space and arrangements for the complete installation are specially approved.

1.11.5 For engines operating on "boil-off" vapours from the cargo, the arrangements will be specially considered.

1.12 Materials

1.12.1 The materials used in the construction are to be manufactured and tested in accordance with the requirements of Pt.2 of the Rules. Materials for which provision is not made therein may be accepted, provided that they comply with an approved specification and such tests as may be considered necessary.

1.12.2 Installation of material which contain asbestos is prohibited.

1.13 Alternative design and arrangements

1.13.1 The Rules generally cover the requirements of SOLAS Ch.II-1, Parts C, D and E. Design and arrangements alternative to these requirements may be accepted based on SOLAS Reg. II-1/55 and MSC.1/Circ. 1212, Rev.1.

Section 2

Machinery Room Arrangements

2.1 General

2.1.1 The machinery is to be so designed, installed and protected that risks of fire, explosions, accidental pollution, leakages and accidents thereof, and accidents to personnel working in machinery spaces will be minimised.

2.1.2 The design and arrangement of machinery foundations, shaft connections, piping and ducting is to take into account the effects of thermal expansion, vibrations, mis-alignment and hull interaction to ensure operation within safe limits.

Bolts and nuts exposed to dynamic forces and vibrations are to be properly secured.

2.2 Accessibility

2.2.1 Accessibility, for attendance and maintenance purposes, is to be provided for machinery plants.

2.3 Fire protection

2.3.1 All surfaces of machinery where the surface temperature may exceed 220°C, e.g., steam and exhaust gas lines, silencers, boilers, exhaust gas boilers, turbo blowers, etc. are to be effectively shielded to prevent ignition of combustible materials coming in to contact with them. Where insulation covering these surfaces is oil absorbing or may permit penetration of oil, the insulation is to be encased in steel or its equivalent.

2.3.2 The insulation is to be of a type and so supported that it will not crack or deteriorate when subjected to vibration.

2.3.3 Oil spillages coming into contact with hot surfaces, electrical installations or other sources of ignition.

a) Precautions (e.g. shielding) are to be taken to prevent oil that may escape under pressure from any pump, filter or heater or piping from coming into contact with sources of ignition.

b) Oil tanks, pipes, filters, heaters, etc. are not to be located immediately above or near units of high temperature including boilers, steam pipe lines, exhaust manifolds, silencers or other equipment required to be insulated and electrical equipment, as far as practicable. In particular, oil fuel filters under pressure for diesel engines are to be located such that in the event of leakage, oil cannot be sprayed on to the exhaust manifold.

c) Oil filters fitted in parallel for the purpose of enabling cleaning without disturbing oil supply to engines (e.g. duplex filters) are to be provided with arrangements that will minimise the possibility of a filter under pressure being opened by mistake. Filter/filter chambers are to be provided with suitable means for :

   - venting when put in to operation; and
   - depressurizing before being opened.

   Valves or cocks with drain pipes led to a safe location are to be used for this purpose.

d) Hydraulic units with working pressure above 15 bar are preferably to be placed in separate spaces. If it is impracticable to locate such units in separate space, adequate shielding is to be provided.

2.3.4 Flammable or oil absorbing materials are not to be used in floors, gratings, etc. in boiler and engine rooms, shaft tunnels or in compartments where settling tanks are installed.

2.3.5 Segregation of oil fuel purifiers

a) Oil fuel purifiers for heated oil are to be in separate room enclosed by steel bulkheads extending from deck to deck and provided with self-closing steel doors.

b) The room is to be provided with :

   - independent mechanical ventilation or a ventilation arrangement which can

be isolated from the machinery space ventilation;

- fire detecting system; and

- fixed fire extinguishing installation.

The extinguishing installation is to be capable of being activated from outside the room. Closing of ventilation openings is to be effected from a position close to where the extinguishing system is activated. The extinguishing system is to be separate for the room, but may be part of the main fire extinguishing system for the machinery spaces.

c) If it is impracticable to locate the oil fuel purifiers in a separate space, IRS will give special consideration with regard to location, containment of possible leakages, shielding and ventilation. A local fixed fire extinguishing system is to be provided which is to be capable of being activated manually from the machinery control position or from other suitable location. If automatic release is provided, additional manual release is to be arranged.

2.4 Ventilation

2.4.1 All spaces, including engine and cargo pump spaces, where flammable or toxic gases or vapours may accumulate, are to be provided with adequate ventilation under all conditions.

2.4.2 Machinery spaces of Category A are be adequately ventilated so that a sufficient supply of air is maintained to the spaces for the safety and comfort of personnel and for operation of the machinery, when machinery or boilers are operating at full power in all weather conditions including heavy weather. Any other machinery space is to be adequately ventilated appropriate for the purpose of that machinery space.

IR2.4.2 The openings on deck through which the air is supplied to machinery space should be suitably protected (taking into account the requirements of Pt.3, Ch.13, Sec.2.2 and Sec.2.3).

The machinery spaces of Category A and other machinery spaces are as defined in Pt.6, Ch.1, Clauses 3.31 and 3.30 respectively.

2.5 Communications

2.5.1 At least two independent means of communication are to be provided between the bridge and engine room control station from which the engines are normally controlled.

One of these means is to visually indicate the order and response, both at the engine room control station and on the bridge.

2.5.2 At least one means of communication is to be provided between the bridge and any other control position(s) from which the propulsion machinery may be controlled.

2.5.3 Propulsion machinery orders from the navigation bridge are to be indicated in the main machinery control room and at the manoeuvring platform.

2.6 Machinery controls

2.6.1 Main and auxiliary machinery essential for the propulsion, control and safety of ship are to be provided with effective means for its operation and control. All control systems essential for the propulsion, control and safety of the ship are to be independent or designed such that failure of one system will not affect the performance of the other system.

2.6.2 Where remote control of propulsion machinery from the navigating bridge is provided, the control is to be performed by a single control device for each independent propeller, with automatic control of all associated services, including, where necessary, means of preventing overload of the propulsion machinery.

Section 3

Trials

3.1 General

3.1.1 Tests of components and trials of machinery, as detailed in the Chapters giving the requirements for individual systems are to be carried out to the satisfaction of the Surveyors.

3.2 Sea trials

3.2.1 For all types of installations, the sea trials are to be of sufficient duration, and carried out under normal maneuvering conditions, to prove the machinery under rated power. The trials are also to demonstrate that any vibration which may occur within the operating speed range is acceptable.

3.2.2 The trials are to include demonstrations of the following :

- The adequacy of the starting arrangements to provide the required number of starts of the main engines;

- The ability of the machinery to reverse the direction of thrust of the propeller/propulsion device in sufficient time, under normal maneuvering conditions, and so bring the ship to rest from maximum ahead rated speed; and

- In turbine installations, the ability to permit astern running at 70 per cent of the full power ahead revolutions without adverse effects. The astern trial need not be of more than 30 minutes duration.

3.2.3 Where controllable pitch propellers are fitted, the free route astern trial is to be carried out with the propeller blades set in full pitch astern position. Where emergency manual pitch setting facilities are provided, their operation is to be demonstrated to the satisfaction of the Surveyors.

3.2.4 In geared installations, prior to full power sea trials, the gear teeth are to be suitably coated to demonstrate the contact markings, and on conclusion of sea trials all gears are to be opened up sufficiently to permit the Surveyors to make an inspection of the teeth. The marking is to indicate freedom from hard bearing, particularly towards the end of the teeth, including both ends of each helix where applicable.

3.2.5 The stopping times, ship headings and distances recorded on trials, together with the results of trials to determine the ability of ships having multiple propellers or propulsion/steering arrangements to navigate and maneuver with one or more such devices inoperative, are to be available on board for the use of the master or designated personnel.

3.2.6 Where the ship is provided with supplementary means for maneuvering or stopping, the effectiveness of such means is to be demonstrated and recorded as referred to in 3.2.5.

3.2.7 All trials are to be to Surveyor's satisfaction.

3.2.8 Testing of the control system of controllable pitch propellers

3.2.8.1 General

.1 The purpose of the tests is to ascertain that the pitch control system of controllable pitch propellers for main propulsion is working correctly.

3.2.8.2 Application

.1 The requirements in this sub-section apply to all new buildings and to all replacements, modifications, repairs, or re-adjustments that may affect the pitch control or response characteristics for main propulsion.

3.2.8.3 Scope of the tests

3.2.8.3.1 Pitch response test

.1 A full range of tests is to be carried out to get the pitch response and verify that it coincides with the combinator curve of the propeller (refer Note1). The tests are to be carried out for at least three positions of the control lever in ahead and astern directions (e.g., dead slow ahead / astern, half ahead / astern, full ahead / astern).

.2 The tests are to be carried out in normal and emergency operating conditions.

.3 Tests that are not affected by the control position may be carried out from one control position only.

Note1: The combinator curve is the relationship between the propeller pitch setting and the propeller speed.

3.2.8.3.2 Test of the fail-to-safe characteristics

.1 A test of the fail-to-safe characteristics of the propeller pitch control system is to be carried out to demonstrate that failures in the pitch command and control or feedback signals are alarmed and do not cause any change of thrust. Such failures are to be clearly identified and included in the test procedure.

3.2.8.3.3 Test procedure

.1 Test procedure is to be prepared and proposed by the pitch control system manufacturer or integrator and agreed with IRS.

3.2.8.4 Parameters to be recorded

.1 The list of the parameters to be recorded during the pitch response test is to be established by the pitch control system manufacturer or integrator and agreed with IRS. This is to at least include the following parameters:

- Position of the control handle,
- Actual pitch indication (local indication, remote indications),
- Rotational speed of the propeller,
- Response time between the pitch change order (modification of the lever position) and the instant when the pitch and propeller speed have reached their final position,
- Propelling thrust variation during the transfer of the control from one location to another one.

3.2.8.5 Tests results

.1 Tests are to demonstrate:

- that the propelling thrust is not significantly altered when transferring control from one location to another and in case of failures in the pitch command and control or feedback signals.
- that the pitch response times measured during the test do not exceed the maximum value to be defined by the pitch control system manufacturer or integrator.

Section 4

Certification of Machinery and Components Based on Alternative Certification Scheme

4.1 General

4.1.1 Machinery and components may be certified by Alternative Certification Scheme (ACS) for products including machinery and components as described in Part 1, Chapter 1, Section 4 of the Rules.

4.2 Certification of diesel engines

4.2.1 Certification of diesel engines based on Alternative Certification Scheme described in Part1, Chapter 1, Section 4 of the Rules can be considered only for diesel engines which have been type approved in accordance with IRS type approval scheme.

4.2.2 Certification of individual components of diesel engines is to be undertaken in accordance with the *Classification Note: "Approval of I.C Engines".*

4	*Cast Iron Pipes and Fittings*
5	*Plastic Pipes and Fittings*
6	*Flexible Hoses*
7	*Hydraulic Tests on Pipes and Fittings*

Section 1

General

1.1 Scope

1.1.1 The requirements of this Chapter apply to the design and construction of piping systems, including pipe fittings and valves forming parts of such systems for the following services:

Air, vapour, gas (excluding liquefied gas cargo and process piping), water, lubricating oil, fuel oil, hydraulic fluid systems for steering gear, toxic gas and liquids, cargo oil and tank cleaning piping and open ended lines such as drains, overflows, vents and boiler escape pipes.

1.1.2 The requirements of this Chapter do not cover the following:

Exhaust pipes from internal combustion engines and gas turbines, and pipes forming integral part of a boiler.

1.1.3 Hydraulic fluid systems other than those for steering gear will be specially considered.

1.1.4 For requirements pertaining to piping systems for liquefied gases (cargo and process) and cargo piping systems of ships carrying chemicals in bulk reference should be made to applicable Chapters of Pt.5 of the Rules.

1.2 Classes of pipes

1.2.1 For the purpose of testing, type of joints to be adopted, heat treatment and welding procedure, piping systems are divided into three classes, as given in Table 1.2.1.

1.3 Design pressure

1.3.1 The design pressure, P, is the maximum permissible working pressure and is to be not less than the highest set pressure of the safety valve or relief valve. For oil fuel pipes the design pressure is to be taken in accordance with Table 1.3.1. For gaseous fuel, the design pressure will be specially considered.

1.3.2 In water tube boiler installations, the design pressure for steam piping between the boiler and integral superheater outlet is to be taken as the design pressure of the boiler, i.e. not less than the highest set pressure of any safety valve on the boiler drum. For piping leading from the superheater outlet, the design pressure is to be taken as the highest set pressure of the superheater safety valves.

1.3.3 The design pressure of feed piping and other piping on the discharge from pumps is to be taken as the pump pressure at full rated speed against a shut valve. Where a safety valve or other protective device is fitted to restrict the pressure to a lower value than the shut valve load, the design pressure is to be the highest set pressure of the protective device.

Table 1.2.1 : Classes of piping systems [3,4]

Piping system	Class I	Class II	Class III
Toxic or corrosive media	Without special safeguards	Not to be used	Not to be used
a) Flammable media heated above flash point[2] b) Flammable media having flash point below 60°C[2] c) Liquefied gas	Without special safeguards	With special safeguards[1]	Not to be used
Steam	P > 16 or T > 300	16 ≥ P > 7 and 300 ≥ T > 170	P ≤ 7 and T ≤ 170
Thermal Oil	P > 16 or T > 300	16 ≥ P > 7 and 300 ≥ T > 150	P ≤ 7 and T ≤ 150
Fuel oil + Lubricating oil + Flammable hydraulic oil	P > 16 or T > 150	16 ≥ P > 7 and 150 ≥ T > 60	P ≤ 7 and T ≤ 60
Other media[5] including water, air, gases, non-flammable hydraulic oil	P > 40 or T > 300	40 ≥ P > 16 and 300 ≥ T > 200	P ≤ 16 and T ≤ 200

Notes:

1 Safeguards for reducing leakage possibility and limiting its consequences will be specially considered e.g. leading pipes in positions where leakage of internal fluids will not cause a potential hazard or damage to surrounding areas or by the usage of pipe ducts, shielding, screening etc.
2 Cargo oil pipes belong to Class III piping systems.
3 P = Design pressure in bar as defined in 1.3
4 T = Design temperature in °C as defined in 1.4.
5 For open ended pipes (drains, overflow, vents, exhaust gas lines, boiler escape lines, etc.) irrespective of the temperature, Class III pipes may be used.

Table 1.3.1 : Definition of the design pressure for fuel oil systems

Working temperature / **Working Pressure (WP)**	**T ≤ 60°C**	**T > 60°C**
WP ≤ **7 bar**	3 bar or max. working pressure, whichever is greater	3 bar or max. working pressure, whichever is greater
WP > 7 bar	Max. working pressure	14 bar or max. working pressure, whichever is greater

1.4 Design temperature

1.4.1 The design temperature is to be taken as the maximum temperature of the internal fluid, but in no case is it to be less than 50°C. For special cases the design temperature will be specially considered.

1.4.2 In the case of pipes for superheated steam, the temperature is to be taken as the designed operating steam temperature for the pipeline, provided that the temperature at the superheater outlet is closely controlled. Where temperature fluctuations exceeding 15°C above the designed temperature are to be expected in normal service, the steam temperature to be used for determining the allowable stress is to be increased by the amount of this excess.

1.5 Design symbols

1.5.1 The symbols used in this Chapter are defined as follows:

a = percentage negative manufacturing tolerance on thickness;

b = bending allowance [mm];

c = corrosion allowance [mm];

D = outside diameter of pipe [mm] (see 1.5.2);

d = inside diameter of pipe [mm] (see 1.5.3);

e = weld efficiency factor (see 1.5.4);

P = design pressure, in bar;

P_t = hydraulic test pressure, in bar;

R = radius of curvature of a pipe bend at the centreline of the pipe [mm];

T = design temperature, in °C;

t = the minimum thickness of a straight pipe [mm], including corrosion allowance and negative tolerance, where applicable;

t_b = the minimum thickness of a straight pipe to be used for a pipe bend [mm]; including bending allowance, corrosion allowance and negative tolerance, where applicable;

K = maximum permissible design stress [N/mm^2].

1.5.2 The outside diameter, D, is subject to manufacturing tolerance, but these are not to be used in the evaluation of formulae.

1.5.3 The inside diameter, d, is not to be confused with nominal size, which is an accepted designation associated with outside diameters of standard rolling sizes.

1.5.4 The weld efficiency factor, e, is to be taken as 1.0 for seamless and electric resistance and induction welded steel pipes delivered by manufacturers approved for making welded pipes which are considered to be equivalent to seamless pipes. Where other methods of pipe manufacture are proposed, the value of e will be specially considered.

1.6 Heat treatment

1.6.1 Method of heat treatment and means of temperature control and recording are to be to the satisfaction of Surveyors.

1.7 Minimum thickness of pipes and bends

1.7.1 The minimum thickness, t, of straight pipes is to be determined by the following formula when ratio of outside-diameter to inside-diameter does not exceed the value 1.7:-

$$t = \left(\frac{PD}{20Ke + P} + c \right) \frac{100}{100 - a} \text{ [mm]}$$

where,

P, D, e and a are defined in 1.5.1.

The maximum permissible design stress, K, is to be taken as the lowest of the following values:-

$$K = \frac{E_t}{1.6} \text{ or } \frac{R_{20}}{2.7} \text{ or } \frac{S_R}{1.6} \text{ or } \sigma_{1/100,000} / 1$$

where,

$\sigma_{1/100,000}/1$ = average stress [N/mm^2] to produce 1% creep in 100,000 hrs at the design temperature.

E_t = specified minimum lower yield or 0.2 per cent proof stress at the design temperature

R_{20} = specified minimum tensile strength at ambient temperature

S_R = average stress to produce rupture in 100,000 hours at the design temperature.

Value of K may be obtained from Sec.2, Table 2.1.1 and Table 2.1.2 for carbon and low alloy steel pipes and fittings or from Sec.3, Table 3.2.1 for copper and copper alloys pipes and fittings.
c is obtained from Sec.2, Table 2.2.1 for carbon and low alloy steel pipes and fittings or from Sec.3, Table 3.2.3 for copper and copper alloys pipes and fittings.

1.7.2 Where it is proposed to use, for high temperature service, alloy steels other than those detailed in Sec.2, particulars of the tube sizes, design conditions and appropriate national or proprietary material specifications are to be submitted for consideration.

1.7.3 The minimum thickness, t_b, of a straight steel pipe to be used for a pipe bend is to be determined by the following formula, except where it can be demonstrated that the use of a thickness less than t_b would not reduce the thickness below 't' at any point after bending:-

$$t_b = \left(\frac{PD}{20Ke + P} + b + c \right) \frac{100}{100 - a} \text{ [mm]}$$

where,

P, D, R, e, b and a are defined in 1.5.1;

K and c are defined in 1.7.1;

$$b = \frac{D}{2.5R} \left(\frac{PD}{20Ke + P} \right) \text{ [mm]}$$

In general, R, is to be not less than 3D.

1.7.4 Notwithstanding the requirements of 1.7.1 and 1.7.3, the minimum thickness of pipes is not to be less than that indicated in Sec.2 or 3, as applicable. For threaded pipes, where permitted, the minimum thickness is to be measured at the bottom of the thread.

1.8 Flanges

1.8.1 The dimensions of flanges and related bolts, gaskets are to be chosen in accordance with recognised national/international standards. For special applications, the dimensions of the flanges and related bolts, will be specially considered.

1.8.2 Gaskets are to be suitable for the medium being conveyed under design pressure and temperature conditions and their dimensions and configurations are to be in accordance with a recognized standard and for the intended service.

1.9 Materials

1.9.1 Materials for ferrous castings and forgings of Class I and Class II piping systems are to be produced at Works approved by IRS and are in general to be tested in accordance with the requirements of Pt.2 of the Rules.

1.9.2 The manufacturer's test certificate for materials of valves and fittings will be accepted in lieu of the IRS certificate provided the maximum conditions are less than given in Table 1.9.1.

1.9.3 Pipes and bodies of valves, intended to be fitted on ship's side and bottom or on collision bulkhead, are to comply with the requirements of Class II piping systems.

1.9.4 Materials for Class III piping systems may be manufactured and tested in accordance with the requirements of an acceptable national/ international standard.

1.9.5 Stainless steel grades 304, 304L, 316 and 316L are generally not considered suitable for use in seawater piping systems due to their limited corrosion resistance in contact with sea water.

Table 1.9.1 : Maximum conditions for valves and fittings for which manufacturer's test certificate is acceptable

Material	Working temp.°C	DN = Nominal Diameter [mm] P_w = Working Pressure in bar
Carbon and low alloy steel Spheroidal or nodular cast iron	< 300	DN < 50 or P_w x DN < 250
Copper alloy	< 200	DN < 50 or P_w x DN < 150

Section 2

Carbon and Low Alloy Steel Pipes and Fittings

2.1 Materials

2.1.1 Pipes having forge butt welded longitudinal seams are not to be used for oil fuel systems, for heating coils in oil tanks, or for pressures exceeding 4.0 bar.

2.1.2 Steel pipes, valves and fittings may be used within the temperature limits indicated in Table 2.1.1 and Table 2.1.2. Where rimming steel is used for pipes manufactured by electric resistance or induction welding processes, the design temperature is limited to 400°C.

2.2 Minimum thickness of steel pipes and bends

2.2.1 The minimum thickness of steel pipes and bends is to be higher of that calculated by Sec.1, Cl.1.7 and that indicated in Table 2.2.2, Table 2.2.3 or Table 2.2.4 as applicable.

2.2.2 The value of 'c' to be used in Sec.1, Cl.1.7 is to be in accordance with Table 2.2.1.

Table 2.1.1 : Carbon and carbon-manganese steel pipes

Specified min. tensile strength [N/mm^2]	Maximum permissible stress [N/mm^2]												
	Maximum design temperature °C												
	50	100	150	200	250	300	350	400	410	420	430	440	450
320	107	105	99	92	78	62	57	55	55	54	54	54	49
360	120	117	110	103	91	76	69	68	68	68	64	56	49
410	136	131	124	117	106	93	86	84	79	71	64	56	49
460	151	146	139	132	122	111	101	99	98	85	73	62	53
490	160	156	148	141	131	121	111	109	98	85	73	62	53

Table 2.1.2 : Alloy steel pipes

Type of steel	Specified min. tensile strength [N/mm^2]	Minimum permissible stress [N/mm^2]									
		Maximum design temperature °C									
		50	**100**	**200**	**300**	**350**	**400**	**440**	**450**	**460**	**470**

2 1/4 Cr 1 Mo normalised and tempered (Note 1)	490	106	96	86	76	67	58	49	43	37	32
2 1/4 Cr 1 Mo normalised and tempered (Note 2)	490	96	88	79	72	64	56	49	43	37	32
1/2 Cr 1/2 Mo 1/4 V	460	101	99	97	94	82	72	62	53	45	37

Notes:

1 Maximum permissible stress values applicable when the tempering temperature does not exceed 750°C.

2 Maximum permissible stress values applicable when the tempering temperature exceeds 750°C.

Table 2.2.1 : Values of 'c' for steel pipes

Piping service	**c [mm] (See Notes 1,2, 3)**
Superheated steam systems	0.3
Saturated steam systems	0.8
Steam coil systems in cargo tanks	2.0
Feed water for boilers in open circuit systems	1.5
Feed water for boilers in closed circuit systems	0.5
Blow down (for boilers) systems	1.5
Compressed air systems	1.0
Hydraulic/lubricating oil systems	0.3
Fuel oil systems	1.0
Cargo oil systems	2.0
Refrigerating plants	0.3
Fresh water systems	0.8
Sea water systems, in general	3.0

Table 2.2.1 (Contd.)

Notes:

1 For pipes passing through tanks an additional corrosion allowance is to be considered according to the figures given in Table and depending upon the external medium in order to account for the external corrosion.
2 The corrosion allowance may be reduced where pipes and any integral pipe joints are protected against corrosion by means of coating, lining etc., however, the reduction is not to be more than 50 percent in any case.
3 In the case of use of special alloy steel with sufficient corrosion resistance, the corrosion allowance may be reduced to zero.

Table 2.2.2 : Minimum wall thickness for steel pipes [11] [All dimension in mm]

Nominal size	External diameter D	Pipes in general [3, 4, 6, 8, 9, 10]	Venting overflow and sounding pipes for structural tanks [1-4, 6, 8]	Bilge ballast and general sea water pipes [1, 3-8]	Bilge, air, overflow and sounding pipes passing through ballast and fuel tanks, ballast lines through fuel tanks and fuel lines through ballast tanks [1-8]
6	10.2	1.6

200	219.1	4.5	5.9	5.9	8.8
225	244.5	5	6.3	6.3	8.8

Table 2.2.2 (Contd.)

Nominal size	External diameter D	Pipes in general [3, 4, 6, 8, 9, 10]	Venting overflow and sounding pipes for structural tanks [1-4, 6, 8]	Bilge ballast and general sea water pipes [1, 3-8]	Bilge, air, overflow and sounding pipes passing through ballast and fuel tanks, ballast lines through fuel tanks and fuel lines through ballast tanks [1-8]
250	273	5	6.3	6.3	8.8
	298.5	5.6	6.3	6.3	8.8
300	323.9	5.6	6.3	6.3	8.8
350	355.6	5.6	6.3	6.3	8.8
	368	5.6	6.3	6.3	8.8
400	406.4	6.3	6.3	6.3	8.8
450	457.2	6.3	6.3	6.3	8.8

Notes:

1 IRS may accept reduction in thickness of pipes by an amount not exceeding 1 mm for pipes efficiently protected against corrosion.

2 For sounding pipes, except for those for cargo tanks with cargo having a flash point less than 60°C, the minimum wall thickness is to apply to the part outside the tank.

3 For threaded pipes, where permitted, the minimum wall thickness is to measured at the bottom of the thread.

4 The external diameters and thicknesses have been selected from ISO 4200 for welded and seamless steel pipes. For pipes covered by other standards, slightly less thicknesses may be accepted.

5 The minimum wall thickness for bilge lines and ballast lines through deep tanks will be specially considered. See Pt.5 for thickness of ballast lines passing through oil cargo tanks.

6 The minimum wall thickness for pipes larger than 450 [mm] nominal size is to be in accordance with a national or international standard and in any case not less than the minimum wall thickness indicated for 450 [mm] pipe size.

7 The minimum internal diameter for bilge, sounding, air and overflow pipes shall be 50 [mm], 32 [mm] and 50 [mm] respectively.

8 In general the minimum thickness given in this table is the nominal wall thickness and no allowance need be made for negative tolerance and reduction in thickness due to bending.

9 Minimum wall thickness of exhaust gas pipes will be specially considered.

10 Minimum wall thickness for cargo oil lines will be specially considered.

11 This table is not applicable to air pipes above weather deck, scuppers and discharges which are covered by loadline convention and also to pipes covered by Table 2.2.3.

Table 2.2.3 : Minimum wall thickness for steel pipes for CO_2 fire extinguishing

External diameter D [mm]	From bottles to distribution station	From distribution station to nozzles
21.3 - 26.9	3.2	2.6
30 - 48.3	4	3.2
51 - 60.3	4.5	3.6
63.5 - 76.1	5	3.6
82.5 - 88.9	5.6	4
101.6	6.3	4
108 - 114.3	7.1	4.5
127	8	4.5
133 - 139.7	8	5
152.4 - 168.3	8.8	5.6

Table 2.2.3 (Contd.)

Notes:

1 Pipes are to be galvanised at least internally, except those fitted in the engine room where galvanising may be dispensed with.
2 For threaded pipes, where allowed, the minimum wall thickness is to be measured at the bottom of the thread.
3 The external diameters and thicknesses have been selected from ISO recommendations R 336 for smooth welded and seamless steel pipes. For pipes covered by other standards, slightly less thickness may be accepted.
4 For larger diameters, the minimum wall thickness will be specially considered.
5 In general, the minimum thickness is the nominal wall thickness and no allowance need be made for negative tolerance and reduction in wall thickness due to bending.

Table 2.2.4 : Minimum wall thickness for austenitic stainless steel pipes

External diameter D [mm]	Minimum wall thickness [mm]	External diameter D [mm]	Minimum wall thickness [mm]
10.2 to 17.2	1.0	219.1	2.6
21.3 to 48.3	1.6	273.0	2.9
60.3 to 88.9	2.0	323.9 to 406.4	3.6
114.3 to 168.3	2.3	Over 406.4	4.0

Note : Diameters and thicknesses according to national or international standard may be accepted.

2.3 Types of connection

2.3.1 Pipe lengths may be joined by

- screwed-on or welded on bolted flanges
- Butt welds between pipes or between pipes and valve chests or other fittings
- Socket weld joints
- Threaded sleeve joints
- Mechanical joints.

and are to be to a recognized standard or of a design proven to be suitable for the intended purpose.

2.4 Flange connections

2.4.1 Flange attachments are to be in accordance with recognized national or international standards applicable to piping system keeping in view the boundary fluids, design pressure and temperature conditions, external or cyclic loading and location.

2.4.2 Flanges may be cut from plates or may be forged or cast. The material is to be suitable for the design temperature. Flanges may be attached to the branches by screwing and expanding or by welding. Alternative methods of flange attachment may be accepted provided details are submitted for consideration.

2.4.3 Examples of accepted flanged connections and their uses are given in Fig.2.4.1 and Table 2.4.1 respectively.

2.4.4 Where flanges are secured by screwing, as indicated in Fig.2.4.1, the pipe and flange are to be screwed with a vanishing thread and the diameter of the screwed position of pipe over the thread is not to be appreciably less than the outside diameters of the unscrewed pipe. After the flange has been screwed hard home, the pipe is to be expanded into the flange.

The vanishing thread on a pipe is to be not less than three pitches in length, and the diameter at the root of the thread is to increase uniformly from the standard root diameter to the diameter at the top of the thread. This may be produced by suitably grinding the dies, and the flange should be tapered out to the same formation.

Table 2.4.1 : Type of flange connections

Class of piping	t°C	Steam	Lub. and fuel oil	Other media
		Typical flange application	Typical flange application	Typical flange application
I [1)]	> 400	A	A - B	A
	≤ 400	A - B[2]		A - B
II	> 250	A - B - C	A - B - C	A - B - C
	≤ 250	A - B - C - D - E		A - B - C - D - E
III		A - B - C - D - E	A - B -C - E	A - B - C - D - E

1 For Class I only one condition is sufficient.

2 Type B for outer diameter < 150 [mm] only.

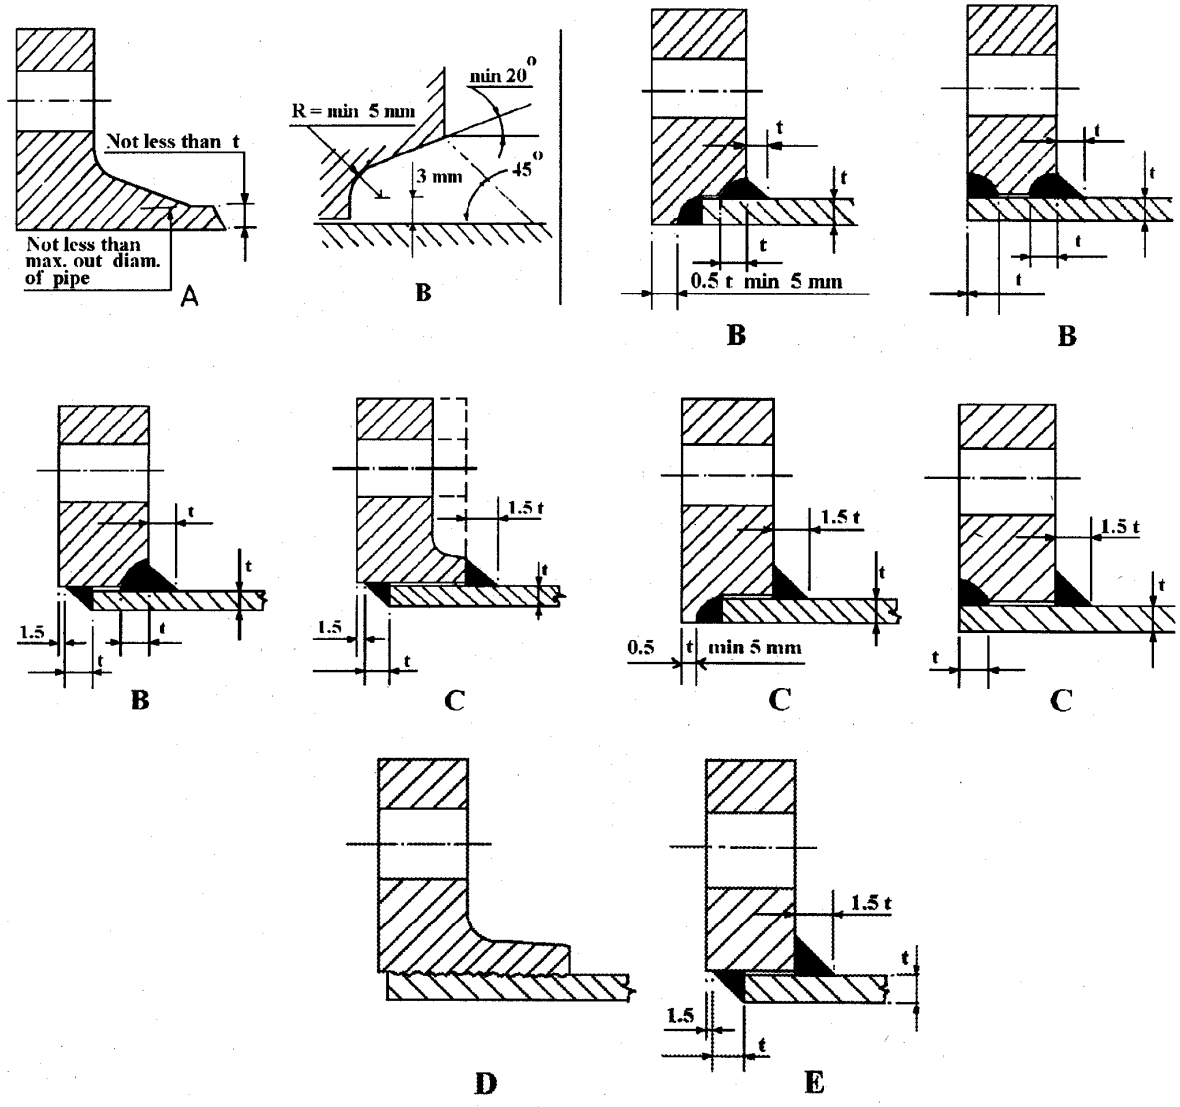

Fig. 2.4.1 : Types of flange connections

2.5 Threaded sleeve joints

2.5.1 Threaded sleeve joints requiring pressure-tight joints, having parallel or tapered threads in accordance with national or other established standards, may be used with carbon steel pipes within the limits given in Table 2.5.1 and for services other than pipe systems conveying combustible or toxic fluids or services where fatigue, severe erosion or crevice corrosion is expected to occur.

Threaded joints in CO_2 systems shall be allowed only inside protected spaces and in CO_2 cylinder rooms.

Threaded joints for direct connections of pipe lengths with tapered threads are to be allowed for

a) Class I piping having outside diameter not more than 33.7 [mm].

b) Class II and Class III piping having outside diameter not more than 60.3 [mm].

Threaded joints with parallel threads are to be allowed for Class III piping having outside diameter not more than 60.3 [mm].

In particular cases, sizes in excess of those mentioned above may be accepted by IRS if in compliance with a recognized national and/or international standard.

Table 2.5.1 : Limiting design conditions for threaded sleeve joints

Nominal bore [mm]	Maximum pressure in bar	Maximum temp.°C
≤ 25	12	260
$> 25 \leq 40$	10	260
$> 40 \leq 80$	8.5	260
$> 80 \leq 100$	7	260

2.6 Welding, non-destructive examination and post-weld heat treatment of welded pipes

2.6.1 Requirements regarding welding procedures, non-destructive examination of welds and post-weld heat treatment are given in Ch.10.

2.7 Mechanical joints

2.7.1 Mechanical joints means devices intended for direct connection of pipe lengths other than by flanges, threaded joints or welding as described in 2.4, 2.5 and 2.6.

2.7.2 The requirements given here are applicable to pipe unions, compression couplings, slip-on joints as shown in Fig.2.7. Similar joints complying with these requirements may be acceptable.

2.7.3 Mechanical joints including pipe unions, compression couplings, slip-on joints and similar joints are to be of approved type for the pressure ratings, service conditions and the intended application. The construction and type are to conform to the examples shown in Fig.2.7. Application of mechanical joints and their acceptable use for each service is indicated in Table 2.7.1. The relevant requirements of the flag Administration are also to be complied with. In case exposure time (t_T) for fire endurance test is greater than 30 minutes, the dry-wet test conditions are 8 minutes dry and, accordingly, the wet period t_T-8 minutes. Application of mechanical joints depending upon the class of piping and pipe dimensions is indicated in Table 2.7.2. (For approval refer Classification Notes “Type Approval of Mechanical Joints used in Piping”).

2.7.4 Where the application of mechanical joints results in reduction in pipe wall thickness due to the use of bite type rings or other structural elements, this is to be taken into account in determining the minimum wall thickness of the pipe to withstand the design pressure.

The materials used in construction of mechanical joints is to be compatible with the piping material and internal and external media. Where appropriate, the mechanical joints are to be of fire resistant type as required by Table 2.7.1.

2.7.5 Mechanical joints, which in the event of damage could cause fire or flooding, are not to

be used in piping sections directly connected to the ship's side below the bulkhead deck of passenger ships and freeboard deck of cargo ships or tanks containing flammable fluids.

2.7.6 The number of mechanical joints in flammable fluid systems is to be kept to a minimum. In general, flanged joints conforming to recognised standards are to be used.

2.7.7 Piping in which a mechanical joint is fitted is to be adequately adjusted, aligned and supported Supports or hangers are not to be used to force alignment of piping at the point of connection.

2.7.8 Slip-on joints are normally not to be used in pipelines in cargo holds, tanks and other spaces which are not easily accessible (refer to MSC/ Circ. 734), except that these joints may be permitted in tanks that contain the same media.

2.7.9 Usage of slip type slip-on joints as the main means of pipe connection is not permitted except for cases where compensation of axial pipe deformation is necessary.

2.7.10 In particular cases, sizes in excess of those mentioned in Table 2.7.2 may be accepted if in compliance with a recognised national and/or international standard.

2.7.11 Mechanical joints are to be subjected to the following tests:

.1 leakage test
.2 vacuum test
.3 vibration (fatigue) test
.4 fire endurance test
.5 burst pressure test at 4 times the design pressure (for design pressures above 200 bar, the burst pressure will be specially considered by IRS)
.6 pressure pulsation test
.7 assembly test
.8 pull out test.

NOTE : For details of tests refer classification notes, "Type Approval of Mechanical Joints used in Piping".

2.7.12 The installation of mechanical joints is to be in accordance with the manufacturer's assembly instructions and using special tools and gauges as required.

Table 2.7.1 : Application of mechanical joints

Systems		Kind of connections			Classification of pipe system	Fire endurance test condition[7]
		Pipe unions	Compression couplings	Slip-on joints		
Flammable Fluids (Flash point ≤ 60°C)

Abbreviations

\+ Application is allowed
\- Application is not allowed
***** Fire endurance test as specified in IRS Classification Note: *Type Approval of Mechanical Joints used in Piping.*

Footnotes: - Fire resistance capability

If mechanical joints include any components which readily deteriorate in case of fire, the following footnotes are to be observed:

1) Fire endurance test is to be applied when mechanical joints are installed in pump rooms and open decks.
2) Slip-on joints are not acceptable inside machinery spaces of category A or accommodation spaces. May be accepted in other machinery spaces provided the joints are located in easily visible and accessible positions (Refer to MSC/Circ. 734).
3) Approved fire-resistant types except in cases where such mechanical joints are installed on open decks, as defined in Pt. 6, Ch. 3, Cl. 3.2.3.3.2.2(10) and not used for fuel lines.
4) Fire endurance test is to be applied when mechanical joints are installed inside machinery spaces of category A.

Footnotes – General (Table 2.7.1)

5) Only above bulkhead deck of passenger ships and freeboard deck of cargo ships.
6) Slip type slip-on joints as shown in Fig. 2.7 may be used for pipes on deck with a design pressure of 10 bar or less.
7) If a connection has passed the "30 min dry" test, it is considered suitable also for applications for which the "8 min dry+22 min wet" and/or "30 min wet " tests are required. If a connection has passed the "8 min dry+22 min wet" test, it is considered suitable also for applications for which the "30 min wet" test is required.

Table 2.7.2 : Application of mechanical joints depending upon the class of piping

Types of joints	Classes of piping systems		
	Class I	**Class II**	**Class III**
Pipe Unions			
Welded and brazed type	+ (OD ≤ 60.3 mm)	+ (OD ≤ 60.3 mm)	+
Compression Couplings			
Swage type	+	+	+
Bite type	+ (OD ≤ 60.3 mm)	+ (OD ≤ 60.3 mm)	+
Typical compression type	+ (OD ≤ 60.3 mm)	+ (OD ≤ 60.3 mm)	+

Section 3

Copper and Copper Alloy Pipes and Fittings

3.1 Materials

3.1.1 Pipes are to be seamless and branches are to be provided by cast or stamped fittings, pipe pressings or other approved fabrications. Copper pipes for class I and II are to be seamless.

3.1.2 Brazing and welding materials are to be suitable for the operating temperature and for the medium being carried. All brazing and welding are to be carried out to the satisfaction of the Surveyors.

3.1.3 In general, the maximum permissible service temperature of copper and copper alloy pipes, valves and fittings is not to exceed 200°C for copper and aluminium brass, and 300°C for copper nickel. Cast bronze valves and fittings complying with the requirements of Pt.2 Ch.8 may be accepted up to 260°C.

3.2 Minimum thickness of pipes

3.2.1 The minimum thickness of copper and copper alloy pipes and bends is to be higher of that calculated by Sec.1, Cl.1.7 and that indicated in Table 3.2.2.

3.2.2 The value of 'c' to be used in Sec.1, Cl.1.7 is to be in accordance with Table 3.2.3.

3.3 Heat treatment

3.3.1 Pipes which have been hardened by cold bending are to be suitably heat treated on completion of fabrication and prior to being tested by hydraulic pressure. Copper pipes are to be annealed and copper alloy pipes are to be either annealed or stress relief heat treated.

Table 3.2.1 : Copper and copper alloy pipes

Pipe material	Condition of supply	Specified min. tensile strength [N/mm^2]	Permissible stress [N/mm^2]					
			Maximum design temperature °C					
			50	75	100	125	150	175
Copper	Annealed	220	41.2	41.2	40.2	40.2	34.3	27.5
Aluminium brass	Annealed	320	78.5	78.5	78.5	78.5	78.5	78.5
95/5 90/10 copper nickel-iron	Annealed	270	68.6	68.6	67.7	65.7	63.7	61.8
70/30 copper nickel	Annealed	360	81.4	79.4	77.5	75.5	73.5	71.6
			Maximum design temperature °C					
			200	225	250	275	300	
Copper	Annealed	220	18.6	-	-	-	-	
Aluminium brass	Annealed	320	24.5	-	-	-	-	
95/5 90/10 copper nickel-iron	Annealed	270	58.8	55.9	52.0	48.1	44.1	
70/30 copper nickel	Annealed	360	69.6	67.7	65.7	63.7	61.8	

Notes :

1. Intermediate values may be determined by linear interpolation.
2. For materials not included in the Table, the permissible stress shall be specially considered by IRS.

Table 3.2.2 : Minimum thickness for copper and copper alloy pipes

Standard pipe sizes (outside diameter[mm])	Minimum overriding nominal thickness [mm]	
	Copper	Copper alloy
8 to 10	1.0	0.8
12 to 20	1.2	1.0
25 to 44.5	1.5	1.2
50 to 76.1	2.0	1.5
88.9 to 108	2.5	2.0
133 to 159	3.0	2.5
193.7 to 267	3.5	3.0
273 to 457.2	4.0	3.5
508	4.5	4.0

Table 3.2.3 : Corrosion allowance 'c' for copper and copper alloy pipes	
Piping Material	**c [mm]**
Copper, brass and similar alloys, copper-tin alloys except those with lead contents	0.8
Copper-nickel alloys (with Ni ≥ 10%)	0.5
Note: For media without corrosive action in respect of the material employed and in case of special alloys with sufficient corrosion resistance, the corrosion allowance may be reduced to zero.	

Section 4

Cast Iron Pipes and Fittings

4.1 Spheroidal or nodular graphite cast iron

4.1.1 Spheroidal or nodular graphite iron castings for pipes, valves and fittings in Class II and III piping systems are to be made in a grade having a specified minimum elongation not less than 12 per cent on gauge length of $5.65\sqrt{S_o}$, where S_o is the actual cross-sectional area of the test piece.

4.1.2 Proposals for the use of this material in Class I piping systems will be specially considered, but in no case is the material to be used in systems where the design temperature exceeds 350°C.

4.1.3 Where the elongation is less than the minimum required by 4.1.1, the material is, in general, to be subject to the same limitations as grey cast iron.

4.2 Grey cast iron

4.2.1 Grey cast iron pipes, valves and fittings will, in general, be accepted in Class III piping systems except as stated in 4.2.2. Grey cast iron valves and fittings may be accepted in the Class II steam systems, but the design pressure or temperature is not to exceed 13 bar or 220°C respectively.

4.2.2 Grey cast iron is not to be used for the following:

a) Pipes for steam systems and fire extinguishing systems;

b) Pipes, valves and fittings for boiler blow down systems and other piping systems subject to shock or vibration;

c) Ship-side valves and fittings;

d) Valves fitted on collision bulkhead;

e) Clean ballast lines through cargo oil tanks to forward ballast tanks;

f) Bilge lines in tanks;

g) Outlet valves of fuel and lubricating oil tanks with static head.

Section 5

Plastic Pipes and Fittings

5.1 General

5.1.1 Proposals to use plastics material in shipboard piping systems will be considered in relation to the properties of the materials, the operating conditions of temperature and pressure, and the intended service. Any proposed service for plastics pipes not mentioned in these Rules is to be submitted for special consideration.

5.1.2 Attention is also drawn to the Guidelines for the Application of Plastic Pipes on Ships contained in IMO Resolution A.753(18), (as amended by Res MSC.313(88) and 399(95)).

5.1.3 Plastic pipes and fittings will, in general, be accepted in Class III piping systems. Proposals for the use of plastics in Class I and Class II piping systems will be specially considered.

5.1.4 These requirements are applicable to piping systems on ships including pipe joints and fittings, made predominantly of material other than metal. The use of mechanical joints approved for the use in metallic piping systems only are not permitted.

5.1.5 Piping systems intended for non-essential services are to meet only the requirements of recognized standards and that of 5.3.3 (b), 5.7.1.2, 5.8.2 to 5.8.7 and 5.9 of this Section. However, the safety aspects due to fire will require to be considered.

5.1.6 The use of plastics may be restricted by statutory requirements of the National Authority of the country in which the ship is to be registered.

5.1.7 The specification of piping is to be in accordance with a recognized national or international standard acceptable to IRS. In addition, requirements given in 5.3 to 5.6 are to be complied with.

5.2 Terms and definitions

5.2.1 "Plastic(s)" means both thermoplastic and thermosetting plastic materials with or without reinforcement, such as PVC and fibre reinforced plastics - FRP. Plastic includes synthetic rubber and materials of similar thermo/ mechanical properties.

5.2.2 "Pipes/piping systems" means those made of plastic(s) and include the pipes, fittings, system joints, method of joining and any internal or external liners, coverings and coatings required to comply with the performance criteria.

5.2.3 "Joint" means the location at which two pieces of pipe or a pipe and a fitting are connected together. The joint may be made by adhesive bonding, laminating, welding, flanges and mechanical joints according to Fig 2.7.

5.2.4 "Fittings" means bends, elbows, fabricated branch pieces etc. of plastic materials.

5.2.5 "Nominal pressure" means the maximum permissible working pressure which should be determined in accordance with the requirements in 5.3.3.

5.2.6 "Fire endurance" means the capability of piping to maintain its strength and integrity (i.e. capable of performing its intended function) for some predetermined period of time while exposed to fire.

5.2.7 “Essential to the safety of ship” means all piping systems that in event of failure will pose a threat to personnel and the ship (Examples for piping systems essential to the safety are provided by Table 5.7.1).

5.2.8 “Essential services” are those services essential for propulsion and steering and safety of the ship as specified in Pt.4, Ch.8, 1.5.

5.3 Strength

5.3.1 The strength of the pipes is to be determined by hydrostatic test failure pressure of a pipe specimen under the standard conditions: atmospheric pressure equal to 100 kPa, relative humidity 30%, environmental and carried fluid temperature 298 K (25°C).

5.3.2 The strength of fittings and joints is to be not less than that of the pipes.

5.3.3 The nominal pressure is to be determined from the following conditions :

a) Internal Pressure

For an internal pressure the nominal pressure, Pn, is to be lesser of the following :

$$\text{Pn Int} \leq \frac{\text{Psth}}{4}$$

or

$$\text{Pn Int} \leq \frac{\text{Plth}}{2.5}$$

where,

Psth = short-term hydrostatic test pipe failure pressure;

Plth = long-term hydrostatic test pipe failure pressure (> 100,000 h)

b) External pressure (for any installation which may be subject to vacuum conditions inside the pipe or a head of liquid acting on the outside of the pipe; and for any pipe installation required to remain operational in case of flooding damage, as per SOLAS II-1/8-1 or for any pipes that would allow progressive flooding to other compartments through damaged piping or through open ended pipes in the compartments).

For an external pressure the nominal pressure, Pn, is to be as under :

$$\text{Pn ext} \leq \frac{\text{Pcol}}{3}$$

where,

Pcol = pipe collapse pressure.

In no case is the pipe collapse pressure to be less than 3 bar.

The maximum working external pressure is a sum of the vacuum inside the pipe and a head of liquid acting on the outside of the pipe.

5.3.4 Notwithstanding the requirements of 5.3.3 (a) or (b) above as applicable, the pipe or pipe layer minimum wall thickness is to follow recognized standards. In the absence of standards for pipes not subject to external pressure, the requirements of 5.3.3 (b) above are to be met.

5.3.5 The maximum permissible working pressure is to be specified with due regard for maximum possible working temperatures in accordance with Manufacturer's recommendations.

5.4 Axial strength

5.4.1 The sum of the longitudinal stresses due to pressure, weight and other loads is not to exceed the allowable stress in the longitudinal direction.

5.4.2 In the case of fibre reinforced plastic pipes, the sum of the longitudinal stresses is not to exceed half of the nominal circumferential stress derived from the nominal internal pressure condition (See 5.3).

5.5 Impact resistance

5.5.1 Plastic pipes and joints are to have a minimum resistance to impact in accordance with recognised national or international standards such as ASTM D.2444-21 or equivalent.

5.5.2 After the test the specimen is to be subjected to hydrostatic pressure equal to 2.5 times the design pressure for at least 1 hour.

5.6 Temperature

5.6.1 The permissible working temperature depending on the working pressure is to be in accordance with Manufacturer's recommendations, but in each case it is to be at least 20°C lower than the minimum heat distortion/ deflection temperature of the pipe material, determined according to ISO 75-2:2013 method A, or equivalent, such as ASTM D648-18.

5.6.2 The minimum heat distortion/deflection temperature is to be not less than 80°C.

5.7 Requirements for pipes/piping systems depending on service and/or locations

5.7.1 Fire endurance

5.7.1.1 Pipes and their associated joints and fittings whose integrity is essential to the safety of ships including plastic piping required by SOLAS II-2/21.4(safe return to port) to remain operational after a fire casualty, are required to meet the minimum fire endurance requirements of Appendix 1 or 2, as

applicable, of IMO Resolution A.753(18), (as amended by Resolutions MSC.313(88) and MSC. 399(95)).

5.7.1.2 Unless instructed otherwise by the Flag Administration, fire endurance tests are to be carried out with specimen representative for pipes, joints and fittings Note 1:

(i) Pipes:

- for sizes with outer diameter < 200 mm the minimum outer diameter and wall thickness Note 2

- for sizes with outer diameter ≥ 200 mm one test specimen for each category of t/d (D = outer diameter, t = structural wall thickness). A scattering of ±10% for t/D is regarded as the same group. Minimum size approved is equal to the diameter of specimen successfully tested.

(ii) Joints

- Each type of joint applicable for applied fire endurance level tested on pipe to pipe specimen

Notes:

1 A test specimen incorporating several components of a piping system may be tested in a single test.

2 Test conditions are most demanding for minimum wall thickness and thus larger wall thickness is covered. A key factor determining the fire performance of a pipe component variant is the thickness-to-diameter (t/D) ratio and whether it is larger or smaller than that of the variant which has been fire-tested. If fire-protective coatings or layers are included in the variant used in the fire test, only variants with the same or greater thickness of protection, regardless of the (t/D) ratio, is to be qualified by the fire test.

5.7.1.3 Means are to be provided to ensure a constant media pressure inside the test specimen during the fire test as specified in Appendix 1 or 2 of the IMO Res.A.753(18), as amended by IMO Resolutions MSC.313(88) and MSC.399(95). During the test it is not permitted to replace media drained by fresh water or nitrogen.

5.7.1.4 Depending on the capability of a piping system to maintain its strength and integrity, there exist three different levels of fire endurance for piping systems.

a) Level 1. Piping having passed the fire endurance test specified in Appendix 1 of IMO Resolution A.753(18) (as amended by IMO Resolutions MSC.313(88) and MSC. 399(95)) for a duration of a minimum of one hour without loss of integrity in the dry condition is considered to meet level 1 fire endurance standard (L1). Level 1W – Piping systems similar to Level 1 systems except these systems do not carry flammable fluid or any gas and a maximum 5% flow loss in the system after exposure is acceptable (L1W).

b) Level 2. Piping having passed the fire endurance test specified in Appendix 1 of IMO Resolution A.753(18) (as amended by IMO Resolutions MSC.313(88) and MSC. 399(95)) for a duration of a minimum of 30 minutes in the dry condition is considered to meet level 2 fire endurance standard (L2). Level 2W – Piping systems similar to Level 2 systems except a maximum 5% flow loss in the system after exposure is acceptable (L2W).

c) Level 3. Piping having passed the fire endurance test specified in Appendix 2 of IMO Resolution A.753(18) (as amended by IMO Resolutions MSC.313(88) and MSC. 399(95)) for a duration of a minimum of 30 minutes in the wet condition is considered to meet level 3 fire endurance standard (L3).

5.7.1.5 Permitted use of piping depending on fire endurance, location and piping system is given in Table 5.7.1 "Fire Endurance Requirements Matrix".

5.7.1.6 For Safe Return to Port purposes (SOLAS II-2/21.4), plastic piping can be considered to remain operational after a fire casualty if the plastic pipes and fittings have been tested to L1 standard.

5.7.2 Flame spread

5.7.2.1 All pipes, except those fitted on open decks and within tanks, cofferdams, pipe tunnels and ducts separated from accommodation, permanent manned areas and escape ways by means of an A class bulkhead, are to have low surface flame spread characteristics not exceeding average values listed in Appendix 3 of IMO Resolution

A. 753(18), as amended by IMO Resolutions MSC. 313(88) and MSC. 399(95).

5.7.2.2 Surface flame spread characteristics are to be determined using the procedure given in the 2010 FTP Code, Annex 1, Part 5 with regard to the modifications due to the curvilinear pipe surfaces as also listed in Appendix 3 of IMO Resolution A.753(18) (as amended by IMO Resolutions MSC.313(88) and MSC.399(95)).

5.7.2.3 Surface flame spread characteristics may also be determined using the test procedures given in ASTM D635-18, or in other equivalent standards. Under the procedure of ASTM D635-18 a maximum burning rate of 60 mm/min applies.

5.7.3 Fire protection coatings

5.7.3.1 Where a fire protective coating of pipes and fittings is necessary for achieving the fire endurance level required, it is to meet the following requirements:

a) The pipes are generally to be delivered from the manufacturer with the protective coating on.

b) The fire protection properties of the coating are not to be diminished when exposed to salt water, oil or bilge slops. It is to be demonstrated that the coating is resistant to products likely to come into contact with the piping.

c) In considering fire protection coatings, such characteristics as thermal expansion, resistance against vibrations and elasticity are to be taken into account.

d) The fire protection coatings are to have sufficient resistance to impact to retain their integrity.

5.7.4 Electrical conductivity

Where electrical conductivity is to be ensured, the resistance of the pipes and fittings is not to exceed 1×10^5 Ohm/m.

Abbreviations:

L1: Fire endurance test (appendix 1 of IMO Resolution A.753(18), as amended by IMO Resolutions MSC. 313(88) and MSC. 399(95)) in dry conditions, 60 min
L1W Fire endurance test (Cl. 5.7.1.2)
L2: Fire endurance test (appendix 1 of IMO Resolution A.753(18), as amended by IMO Resolutions MSC. 313(88) and MSC. 399(95)) in dry conditions, 30 min
L2W Fire endurance test (Cl. 5.7.1.2)
L3: Fire endurance test (appendix 2 of IMO Resolution A.753(18), as amended by IMO Resolutions MSC. 313(88) and MSC. 399(95)) in wet conditions, 30 min
O : No fire endurance test required
NA : Not applicable
X : Plastic piping is not allowed. Metallic materials having a melting point greater than 925°C are permitted.

Footnotes:

1 Where plastic piping is used, remotely controlled valves to be provided at ship's side (valve is to be controlled from outside space).

2 Remote closing valves to be provided at the cargo tanks.

3 When cargo tanks contain flammable liquids with f.p. > 60°C, "O" may replace "NA" or "X".

4 For drains serving only the space concerned, "O" may replace "L1W".

5 When controlling functions are not required by statutory requirements or guidelines, "O" may replace "L1".

6 For pipe between machinery space and deck water seal, "O" may replace "L1".

7 For passenger vessels, "X" is to replace "L1".

8 Scuppers serving open decks in positions 1 and 2, as defined in Regulation 13 of Protocol of 1988 relating to the International Convention on Load Lines, 1966 should be "X" throughout unless fitted at the upper end with the means of closing capable of being operated from a position above the freeboard deck in order to prevent downflooding.

9 For essential services, such as fuel oil tank heating and ship's whistle, "X" is to replace "O".

10 For tankers where compliance with paragraph 6 of Regulation 19 of MARPOL Annex 1, as amended by IMO Resolutions up to MEPC. 314(74) is required, "NA" is to replace "0".

11 L3 in service spaces, NA in accommodation and control spaces.

12 Type Approved plastic piping without fire endurance test (0) is acceptable downstream of the tank valve, provided this valve is metal seated and arranged as fail-to-closed or with quick closing from a safe position outside the space in the event of fire.

13 For Passenger Ships subject to SOLAS II-2/21.4 (Safe return to Port), plastic pipes for services required to remain operative in the part of the ship not affected by the casualty thresholds, such as systems intended to support safe areas, are to be considered essential services. In accordance with MSC.1/Circ.1369, Interpretation 12, for Safe Return to Port purposes, plastic piping can be considered to remain operational after a fire casualty if the plastic pipes and fittings have been tested to L1 standard.

Location Definitions:

A	Machinery spaces of Category A	Machinery spaces of Category A as defined in SOLAS II-2/3.31*.
B	Other machinery spaces and pump rooms	Spaces, other than Category A machinery spaces and cargo pump rooms, containing propulsion machinery, boilers, fuel oil units, steam and internal combustion engines, generators and major electrical machinery, pumps, oil filling stations, refrigerating, stabilising, ventilation and air-conditioning machinery and similar spaces and trunks to such spaces.
C	Cargo pump rooms	Spaces containing cargo pumps and entrances and trunks to such spaces.
D	Ro-ro cargo holds	Ro-ro cargo holds are ro-ro cargo spaces and special category spaces as defined in SOLAS II-2/3.46*.
E	Other dry cargo holds	All spaces other than ro-ro cargo holds used for non-liquid cargo and trunks to such spaces.

F	Cargo tanks	All spaces used for liquid cargo and trunks to such spaces.
G	Fuel oil tanks	All spaces used for fuel oil (excluding cargo tanks) and trunks to such spaces.
H	Ballast water tanks	All spaces used for ballast water and trunks to such spaces.
I	Cofferdams, voids, etc.	Cofferdams and voids are those empty spaces between two bulkheads separating two adjacent compartments.
J	Accommodation, service	Accommodation spaces, service spaces and control stations as defined in SOLAS Chapter II-2/3.1, SOLAS *.
K	Open decks	Open deck spaces as defined in SOLAS II-2/9.2.2.3.2(5)*.
*	SOLAS Chapter II-2	

5.8 Material approval and quality control during manufacture

5.8.1 Except as required in 5.1.5, prototypes of pipes and fittings are to be tested to determine short-term and long-term design strength, fire endurance and low surface flame spread characteristics, electrical resistance (for electrically conductive pipes), impact resistance in accordance with this Section.

5.8.2 For prototype testing representative samples of pipes and fittings are to be selected to the satisfaction of the Classification Society.

5.8.3 The Manufacturer is to have quality system that meets ISO 9000 series standards or equivalent. The quality system is to consist of elements necessary to ensure that pipes and fittings are produced with consistent and uniform mechanical and physical properties.

5.8.4 Each pipe and fitting made by hand lay up technique, is to be tested by the Manufacturer at a hydrostatic pressure not less than 1.5 times the nominal pressure. For other pipes and fittings, manufactured in accordance with the recognized standards by machined processes (e.g. ‘Continuous extruding’, ‘Filament wound and centrifugally cast’) the hydrostatic pressure test may be carried out in accordance with requirements stipulated in the relevant standard to which the pipe or fittings are manufactured, provided that there is an effective quality system in place at manufacturer’s works.

5.8.5 Piping and fittings are to be permanently marked with identification. Identification is to include pressure ratings, the design standards that the pipe or fitting is manufactured in accordance with and the material of which the pipe or fitting is made.

5.8.6 In case the Manufacturer does not have an approved quality system complying with ISO 9000 series or equivalent, pipes and fittings are to be tested in accordance with this Section to the satisfaction of the attending surveyors for every batch of pipes.

5.8.7 Depending upon the intended application, IRS may require, pressure testing of each pipe and/or fitting.

5.9 Installation

5.9.1 Supports

5.9.1.1 Selection and spacing of pipe supports in shipboard systems are to be determined as a function of allowable stresses and maximum deflection criteria. Support spacing is not to be greater than the pipe Manufacturer's recommen-ded spacing. The selection and spacing of pipe supports are to take into account pipe dimensions, length of the piping, mechanical and physical properties of the pipe material, mass of pipe and contained fluid, external pressure, operating temperature, thermal expansion effects, loads due to external forces, thrust forces, water hammer, vibrations, maximum accelerations to which the system may be subjected. Combination of loads is to be considered.

5.9.1.2 Each support is to evenly distribute the load of the pipe and its contents over the full width of the support. Measures are to be taken to minimise wear of the pipes where they contact the supports.

5.9.1.3 Heavy components in the piping system such as valves and expansion joints are to be independently supported.

5.9.2 Expansion

5.9.2.1 Suitable provision is to be made in each pipeline to allow for relative movement between pipes made of plastic and the steel structure, having due regard to:

i) the difference in the coefficients of thermal expansion;
ii) deformations of the ship's hull and its structure.

5.9.2.2 When calculating the thermal expansions, account is to be taken of the system working temperature and the temperature at which assembly is performed.

5.9.3 External loads

5.9.3.1 When installing the piping, allowance is to be made for temporary point loads, where applicable. Such allowances are to include at least the force exerted by a load (person) of 100 kg at mid-span on any pipe of more than 100 mm nominal outside diameter.

5.9.3.2 Besides for providing adequate robustness for all piping including open-ended piping a minimum wall thickness, complying with 5.3.7 may require to be increased taking into account the conditions encountered during service on board ships.

5.9.3.3 Pipes are to be protected from mechanical damage where necessary.

5.9.4 Strength of connections

5.9.4.1 The strength of connections is to be not less than that of the piping system in which they are installed.

5.9.4.2 Pipes may be assembled using adhesive-bonded, welded, flanged or other joints.

5.9.4.3 Adhesive, when used for joint assembly, are to be suitable for providing a permanent seal between the pipes and fittings throughout the temperature and pressure range of the intended application.

5.9.4.4 Tightening of joints is to be performed in accordance with Manufacturers' instructions.

5.9.5 Installation of conductive pipes

5.9.5.1 In piping systems for fluids with conductivity less than 1000 pico siemens per metre (pS/m) such as refined products and distillates use is to be made of conductive pipes.

5.9.5.2 Regardless of the fluid being conveyed, plastic piping is to be electrically conductive if the piping passes through a hazardous area. The resistance to earth from any point in the piping system is not to exceed 1×10^6 Ohm. It is preferred that pipes and fittings be homogeneously conductive. Pipes and fittings having conductive layers are to be protected against a possibility of spark damage to the pipe wall. Satisfactory earthing is to be provided.

5.9.5.3 After completion of the installation, the resistance to earth is to be verified. Earthing wires are to be accessible for inspection.

5.9.6 Application of fire protection coatings

5.9.6.1 Fire protection coatings are to be applied on the joints, where necessary for meeting the required fire endurance for 5.7.3, after performing hydrostatic pressure tests of the piping system.

5.9.6.2 The fire protection coatings are to be applied in accordance with Manufacturer's recommendations, using a procedure approved in each particular case.

5.9.7 Penetration of divisions

5.9.7.1 Where plastic pipes pass through "A" or "B" class divisions, arrangements are to be made to ensure that the fire endurance is not impaired. These arrangements are to be tested in accordance with Recommendations for fire test procedures for "A", "B" and "F" bulkheads specified in Part 3 of Annex 1 to the 2010 FTP Code .

5.9.7.2 When plastic pipes pass through watertight bulkheads or decks, the watertight integrity of the bulkhead or deck is to be maintained. For pipes not able to satisfy the requirements in 5.3.3 (b), a metallic shut-off valve operable from above the freeboard deck is to be fitted at the bulkhead or deck.

5.9.7.3 If the bulkhead or deck is also a fire division and destruction by fire of plastic pipes may cause the inflow of liquid from tanks, a metallic shut-off valve operable from above the freeboard deck should be fitted at the bulkhead or deck.

5.9.8 Control during installation

5.9.8.1 Installation is to be in accordance with the Manufacturer's guidelines.

5.9.8.2 Prior to commencing the work, joining techniques are to be approved by the Classification Society.

5.9.8.3 The tests and examinations specified in this Section are to be completed before shipboard piping installation commences.

5.9.8.4 The personnel performing this work are to be properly qualified and certified to the satisfaction of the Classification Society.

5.9.8.5 The procedure of making bonds is to include:

i) materials used,
ii) tools and fixtures,
iii) joint preparation requirements,
iv) cure temperature,
v) dimensional requirements and tolerances, and
vi) tests acceptance criteria upon completion of the assembly.

5.9.8.6 Any change in the bonding procedure which will affect the physical and mechanical properties of the joint is to require the procedure to be requalified.

5.9.9 Bonding procedure quality testing

5.9.9.1 A test assembly is to be fabricated in accordance with the procedure to be qualified and it is to consist of at least one pipe-to-pipe joint and one pipe-to-fitting joint.

5.9.9.2 When the test assembly has been cured, it is to be subjected to a hydrostatic test pressure at a safety factor 2.5 times the design pressure of the test assembly, for not less than one hour. No leakage or separation of joints is allowed. The test is to be conducted so that the joint is loaded in both longitudinal and circumferential directions.

5.9.9.3 Selection of the pipes used for test assembly, is to be in accordance with the following:

a) When the largest size to be joined is 200 mm nominal outside diameter, or smaller, the test assembly is to be the largest piping size to be joined.

b) When the largest size to be joined is greater than 200 mm nominal outside diameter, the size of the test assembly is to be either 200 mm or 25% of the largest piping size to be joined, whichever is greater.

5.9.9.4 When conducting performance qualifications, each bonder and each bonding operator are to make up test assemblies, the size and number of which are to be as required above.

5.9.10 Testing after installation on board

5.9.10.1 Piping systems for essential services are to be subjected to a test pressure not less than 1.5 times the design pressure or 4 bar whichever is greater. Notwithstanding the requirement above, the requirement in 5.9.10.2 for checking leakage under operational conditions may be applied to open ended pipes (drains, effluent, etc.).

5.9.10.2 Piping systems for non-essential services are to be checked for leakage under operational conditions.

5.9.10.3 For piping required to be electrically conductive, earthing is to be checked and random resistance testing is to be conducted.

5.10 Test specification for plastic pipes

5.10.1 Scope

Section 5.10 contains requirements for the Type Approval of plastic pipes. It is applicable to piping systems, including pipe joints and fittings, made predominantly of other material than metal.

5.10.2 Documentation

The following information for the plastic pipes, fittings and joints is to be submitted for consideration and approval:

I. General information

1) Pipe and fitting dimensions
2) Maximum internal and external working pressure
3) Working temperature range
4) Intended services and installation locations
5) The level of fire endurance
6) If electrically conductive

7) Fluids Intended to be carried
8) Limits on flow rates
9) Serviceable life
10) Installation instructions
11) Details of marking.

II. Drawings and supporting documentation:

1) Certificates and reports for relevant tests previously carried out.
2) Details of relevant standards.
3) All relevant design drawings, catalogues, data sheets, calculations and functional descriptions.
4) Fully detailed section assembly drawings showing pipe, fittings and pipe connections.

III. Materials (as applicable)

1) The resin used for the construction of plastic pipes and fittings.
2) Catalyst and accelerator types and concentration employed in the case of reinforced polyester resin pipes or hardeners where epoxide resins are employed.
3) A statement of all reinforcements employed where the reference number does not identify the mass per unit area or the text number of a roving used in a filament winding process, these are to be detailed.
4) Full information regarding the type of gel-coat or thermoplastic liner employed during construction, as appropriate.
5) Cure/post-cure conditions. The cure and post-cure temperatures and time required and resin/reinforcement ratio.
6) Winding angle and orientation.
7) Joint bonding procedures and qualification results, see Cl. 5.9.8.5.

5.10.3 Testing

Testing is to demonstrate that pipes, fittings and joints for which Type Approval is sought comply with requirements of Section 5.

The standards to be used for testing of pipes, joints and fittings are given in Table 5.10.1 and Table 5.10.2.

Table 5.10.1 : Typical standards for general requirements for all systems			
	Test	**Rule clause no. / Typical Standard**	**Remarks**
1	Internal pressure (1)	5.3.3a) ASTM D 1599 ASTM D 2992 ISO 15493 or equivalent	Top, Middle, Bottom (of range) Tests are to be carried out on pipe spools made of different pipe sizes, fittings and pipe connections
2	External pressure (1)	5.3.3b) ISO 15493 or equivalent	As above, for straight pipes only
3	Axial strength	5.4	As above
4	Load deformation	ASTM D2412 or equivalent	Top, Middle Bottom (of each pressure range)
5	Temperature limitations	ISO 75 Method A GRP piping system: HDT test on each type of resin acc. To ISO 75 method A Thermoplastic piping systems: ISO 75 Method A; ISO 306 Plastics – Thermoplastic materials – Determination of Vicat softening temperature (VST) VICAT test according to ISO 2507 Polyesters with an HDT below 80°C should not be used.	Each type of resin
6	Impact resistance	ISO 9854, ISO 9653 ISO 15493 ASTM D2444 or equivalent	Representative sample of each type of construction
7	Ageing	Manufacturer's standard ISO 9142	Each type of construction
8	Fatigue	Manufacturer's standard or service experience	Each type of construction
9	Fluid absorption	ISO 8361	
10	Material compatibility (2)	ASTM C581 Manufacturer's standard	

Notes:
(1) Test to be witnessed by IRS Surveyor.
(2) If applicable.

Table 5.10.2 : Typical standards for additional requirements depending on service and/or locations of piping

	Test	Rule clause no. / Typical Standard	Remarks
1	Fire endurance (1) (2)	IMO Res. A.753(18) (as amended), Appendix 1,2	Representative samples of each type of construction and type of pipe connection
2	Flame spread (1) (2)	IMO Res. A.753(18) (as amended), Appendix 3	Representative samples of each type of construction
3	Smoke generation (2)	IMO Res. A.753(18) (as amended), Appendix 3	Representative samples of each type of construction
4	Toxicity (2)	IMO Res. A.753(18) (as amended), Appendix 3	Representative samples of each type of construction
5	Electrical conductivity (1) (2)	ASTM F1173-95 or ASTM D257, NS6126 para 11.2 or equivalent	Representative samples of each type of construction

Notes:
(1) Test to be witnessed by IRS Surveyor.
(2) If applicable.

Tests of above table are optional. However, if not carried out, the range of approved applications for the pipes will be limited accordingly (See 5.7).

Section 6

Flexible Hoses

6.1 Definition

6.1.1 Flexible hose assembly is defined as short length of integral metallic or non-metallic hose with prefabricated end fittings ready for installation.

Note: Flexible hose assemblies for essential services or containing either flammable or toxic media are not to exceed 1.5 [m] in length.

6.2 Scope

6.2.1 The requirements of 6.3 to 6.6 apply to flexible hoses of metallic or non-metallic material intended for a permanent connection between a fixed piping system and items of machinery where necessary to accommodate relative movement between the machinery and the fixed piping system. The requirements may also be applied to temporarily connected flexible hoses or hoses of portable equipment.

6.2.2 Flexible hose assemblies as defined in 6.1.1 may be accepted for use in oil fuel, lubricating, hydraulic and thermal oil systems, fresh water and sea water cooling systems, compressed air systems, bilge and ballast systems and Class III steam systems where they comply with 6.3 to 6.6. Flexible hoses are not accepted in high pressure fuel oil injection systems.

6.2.3 These requirements for flexible hose assemblies are not applicable to hoses intended to be used in fixed fire extinguishing systems.

6.3 Design and construction

6.3.1 Flexible hoses are to be designed and constructed in accordance with recognized National or International Standards. Flexible hoses constructed of rubber or plastics materials and intended for use in bilge, ballast, compressed air, oil fuel, lubricating, hydraulic

and thermal oil systems are to incorporate a single double or more closely woven integral wire braid or other suitable material for reinforcement.

Flexible hoses of plastics materials such as Teflon or Nylon, (which are used for the purposes mentioned above), where reinforcement is not possible by incorporating closely woven integral wire braid are to have suitable reinforcing material as far as practicable.

Where rubber or plastic material hoses are to be used in oil supply lines to burners, the hoses are to have external wire braid protection in addition to the reinforcement mentioned above which is provided during manufacturing. Flexible hoses for use in steam systems are to be of metallic construction.

6.3.2 Flexible hoses are to be complete with approved end fittings in accordance with manufacturer's specification. The end connections that do not have a flange are to comply with 2.7 as applicable and each type of hose/fitting combination is to be subject to prototype testing to the same standard as that required by the hose with particular reference to pressure and impulse tests. Refer Pt.4, Ch.4, 4.6.5.2.

6.3.3 The use of hose clamps and similar types of end attachments is not acceptable for flexible hoses in piping systems for steam, flammable media, starting air systems or for sea water systems where failure may result in flooding. In other piping systems, the use of hose clamps may be accepted where the working pressure is less than 5 bar and provided there are double clamps at each end connection.

6.3.4 Flexible hose assemblies intended for installation in piping systems where pressure pulses and/or high levels of vibration are expected to occur in service, are to be designed for the maximum expected impulse peak pressure and forces due to vibration. The tests required by 6.5 are to take into consideration the maximum anticipated in-service pressures, vibration frequencies and forces due to installation.

6.3.5 Flexible hose assemblies constructed of non-metallic materials intended for installation in piping systems for flammable media and sea water systems where failure may result in flooding, are to be of fire-resistant type except in cases where such hoses are installed on open decks, as defined in Pt. 6, Ch. 3, 3.2.3.3.2.2(10) and not used for fuel lines. Fire resistance is to be demonstrated by testing to ISO 15540:2016 and ISO 15541:2016.

6.3.6 Flexible hose assemblies are to be selected for the intended location and application taking into consideration ambient conditions, compatibility with fluids under working pressure and temperature conditions consistent with the manufacturer's instructions and any requirements given elsewhere in the Rules. (Refer Pt.4, Ch.3, 4.3.5; Pt.4, Ch.6, 3.4; Pt.5, Ch.26, 3.2.4.10; Pt.5, Ch.29, 2.1.2).

6.4 Installation

6.4.1 In general, flexible hoses are to be limited to a length necessary to provide for relative movement between fixed and flexibly mounted items of machinery / equipment or systems.

6.4.2 Flexible hose assemblies are not to be installed where they may be subjected to torsional deformation (twisting) under normal operating conditions.

6.4.3 The number of flexible hoses, in piping systems mentioned in 6.2.2 is to be kept to minimum and to be limited for the purpose stated in 6.2.1.

6.4.4 Where flexible hoses are intended to be used in piping systems conveying flammable fluids that are in close proximity of heated surfaces the risk of ignition due to failure of the hose assembly and subsequent release of fluids is to be mitigated as far as practicable by the use of screens or other similar protection to the satisfaction of the Surveyor.

6.4.5 Flexible hoses are to be installed in clearly visible and readily accessible locations.

6.4.6 The installation of flexible hose assemblies is to be in accordance with the manufacturer's instructions and use limitations with particular attention to the following, if any:

- Orientation
- End connection support (where necessary)
- Avoidance of hose contact that could cause rubbing and abrasion
- Minimum bend radii.

6.5 Tests

6.5.1 Acceptance of flexible hose assemblies is subject to satisfactory prototype testing. Prototype test programmes for flexible hose assemblies are to be submitted to IRS by the manufacturer and are to be sufficiently detailed to demonstrate performance in accordance with the specified standards given in 6.5.2 and 6.5.3.

6.5.2 The tests are, as applicable, to be carried out on different nominal diameters of hose type complete with end fittings for pressure, burst, impulse resistance and fire resistance in accordance with the requirements of the relevant standard. The following standards are to be used as applicable:

- ISO 6802:2018 – Rubber and plastics hoses and hose assemblies with wire reinforcements– Hydraulic impulse test with flexing.

- ISO 6803:2017 – Rubber or plastics hoses and hose assemblies – Hydraulic-pressure impulse test without flexing.

- ISO 15540:2016 – Ships and marine technology – Fire resistance of hose assemblies – Test methods.

- ISO 15541:2016 – Ships and marine technology – Fire resistance of hose assemblies – Requirements for test bench.

- ISO 10380:2012 – Pipe work – Corrugated metal hoses and hose assemblies. Other standards may be accepted where agreed by IRS.

Note:

Prototype tests are to be carried out for each size of hose assembly. However, for ranges with more than 3 different diameters, the prototype tests are to be carried out for at least:

  - the smallest diameter,

  - the largest diameter,

  - Intermediate diameters selected based on the principle that prototype tests carried out for a hose assembly with a diameter D are considered valid only for the diameters ranging between 0.5 D and 2 D.

- For fire resistance tests the specimens are to be selected in accordance with ISO 15540:2016.

6.5.3 All flexible hose assemblies are to be satisfactorily prototype burst tested to an international standard***** to demonstrate they are able to withstand a pressure not less than four times its design pressure without indication of failure or leakage.

Note : ***** The international standards, e.g. EN or SAE for burst testing of non-metallic hoses, require the pressure to be increased until burst without any holding period at 4 x MWP.

6.6 Marking

6.6.1 Flexible hoses are to be permanently marked by the manufacturer with the following details:

- Hose manufacturer’s name or trademark.
- Date of manufacture (month/year).
- Designation type reference.
- Nominal diameter.
- Pressure rating.
- Temperature rating.

Where a flexible hose assembly is made up of items from different manufacturers, the components are to be clearly identified and traceable to evidence of prototype testing.

Section 7

Hydraulic Tests on Pipes and Fittings

7.1 Hydraulic tests before installation on board

7.1.1 All Class I and II pipes and their associated fittings are to be tested by hydraulic pressure to the Surveyor's satisfaction. Further, all steam, feed, compressed air and fuel oil pipes, together with their fittings, are to be similarly tested where the design pressure is greater than 3.5 bar. The test is to be carried out after completion of manufacture and before installation on board and, where applicable, before insulating and coating.

7.1.2 Where the design temperature does not exceed 300°C, the test pressure is to be 1.5 times the design pressure.

7.1.3 For steel pipes and integral fittings for use in systems where the design temperature exceeds 300°C, the test pressure is to be as follows but need not exceed twice the design pressure:

$$P_t = 1.5P\frac{K_{100}}{K_t}\text{bar}$$

where,

P_t and P are defined in Sec.1, Cl.1.5.1

K_{100} = allowable stress for 100°C [N/mm^2]

K_t = allowable stress for the design temperature [N/mm^2].

7.1.4 In no case is the membrane stress to exceed 90 per cent of the yield stress at the testing temperature.

7.1.5 All valves and fittings are to be tested in accordance with recognized standards, but not less than 1.5 times the nominal pressure rating at ambient temperature. Valves, cocks and distance pieces intended to be fitted on the ship side below the load waterline are to be hydraulically tested to a pressure not less than 5 bar.

7.1.6 When, for technical reasons, it is not possible to carry out complete hydrotesting before assembly on board for all sections of piping, proposals for testing the remaining/ closing lengths of piping, particularly in respect of the closing seams, are to be submitted for approval.

7.1.7 Pressure testing of small bore pipes (less than 15 mm) may be waived at the discretion of IRS depending on the application.

7.2 Testing after assembly on board

7.2.1 Heating coils in tanks and liquid or gas fuel oil piping are to be tested by hydraulic pressure, after installation on board, to 1.5 times the design pressure but in no case to less than 4 bar.

7.2.2 Where pipes specified in 7.1.1 are butt welded together during assembly on board, they are to be tested by hydraulic pressure in accordance with the requirements of 7.1 after welding. The pipe lengths may be insulated, except in way of the joints made during installation and before hydraulic test is carried out.

7.2.3 The hydraulic test required by 7.2.2 may be omitted provided non- destructive tests by ultrasonic or radiographic methods are carried out on the entire circumference of all butt welds with satisfactory results. Where ultrasonic test has been carried out, the manufacturer is to provide the Surveyor with a signed statement confirming that ultrasonic examination has been carried out by an approved operator and that there were no indications of defects which could be expected to have prejudicial effect on the service performance of the piping.

7.2.4 Where bilge pipes are accepted in way of double bottom tanks or deep tanks, the pipes after fitting are to be tested by hydraulic pressure to the same pressure as the tanks through which they pass.

Section 1

General

1.1 Scope

1.1.1 The requirements of this Chapter are applicable to all ships but may be modified for ships classed for restricted services or for special services.

1.1.2 Whilst these requirements are considered to satisfy the relevant requirements of the International Convention for the Safety of Life at Sea, 1974, and applicable amendments, attention should be given to any relevant statutory requirements of the National Authority of the country in which the ship is to be registered.

1.1.3 Consideration will be given to special cases or to arrangements which are considered equivalent to those required by Rules.

1.2 Plans

1.2.1 The following plans in diagrammatic form are to be submitted for consideration before proceeding with the work:

a) General arrangement of pumps and piping systems;

b) Oil-fuel filling, transfer and service piping systems;

c) Boiler feed piping systems;

d) Steam piping and condensate piping systems;

e) Bilge and ballast piping systems;

f) Lubricating-oil piping systems;

g) Liquid cargo pumping systems;

h) Hydraulic power piping systems for essential services;

i) Compressed air piping systems;

j) Steering gear piping systems;

k) Sea water and fresh water service piping systems;

l) Vents, sounding and overflow piping systems;

m) Sanitary piping systems;

n) Fire main and fire extinguishing piping systems.

1.2.2 The plans are to include the information like size, wall thickness, maximum working pressure, temperature and material of all pipes, and type, size and material of the valves and fittings.

1.3 Materials

1.3.1 The materials to be used in piping systems are to be suitable for the service intended. In general, except where otherwise stated, pipes, valves and fittings are to be made of steel, cast iron, copper, copper alloy or other approved material. See Ch.2 also.

Materials for pipes carrying corrosive fluids are to be compatible with the fluids being handled and are to be specially considered. See Ch.2, 1.9.5.

1.3.2 Materials sensitive to heat such as aluminium, lead or plastics, are not to be used in systems essential to the safe operation of the ship.

1.4 Valves and cocks

1.4.1 All the valves and cocks are to be so designed and constructed so that the valve covers or glands will not slacken up when the valves are operated.

1.4.2 All the valves are to be designed to close with right hand (clockwise when facing the end of the stem) motion of the wheel of the valve.

1.4.3 All the valves and cocks are to be fitted in places where they are easily accessible at all times and are to be fitted with legible nameplates indicating their function in the system and their installation is to be such that it can be readily observed that they are open or closed.

1.4.4 All the valves and cocks fitted with remote control are to be provided with local manual control independent of the remote operating mechanism. The operation of the local control is not to render the remote control system inoperable.

1.4.5 The valves, cocks and other fittings which are attached directly to plating, which is required to be of watertight construction, are to be secured to the plating by means of studs screwed into the plating and not by bolts passing through clearance holes. Alternatively the studs may be welded to the plating.

1.5 Shipside fittings (other than sanitary discharges and scuppers)

1.5.1 All sea inlet and overboard discharge valves are to be fitted in either of the following ways :

a) directly on the shell plating;

b) to the plating of fabricated steel water boxes of rigid construction integral with the ship's plating;

c) to short, rigid distance pieces welded to the shell plating.

1.5.2 Valves for ship-side applications are to be installed such that the section of piping immediately inboard of the valve can be removed without affecting the watertight integrity of the hull.

1.5.3 All valves and cocks fitted directly to the shell plating are to have spigots extending through the plating. These spigot on valves may however be omitted, if valves are fitted on pads which themselves form spigots in way of plating.

1.5.4 Boiler blow-down valves or cocks are to have a protection ring fitted on the outside of the shell plating. The spigot of the valve or the cock is to be flush with the outer surface of the protection ring.

1.5.5 Valves and cocks are to be attached to the shell plating by bolts tapped into the plating and fitted with countersunk heads, or by studs screwed into heavy steel pads fitted to the plating. The stud holes are not to penetrate the pad plating.

1.5.6 Ship side valves and fittings, if made of steel or material with low corrosion resistance, are to be suitably protected against wastage.

1.5.7 Gratings are to be fitted at all openings in ship's side for inlet of seawater. The net area through the gratings is to be at least twice the area of the valves connected to the opening. Provision is to be made to clear the gratings by low pressure steam or compressed air.

1.5.8 The scantlings of valves and valve stools fitted with steam, or compressed air clearing connections are to be suitable for the

maximum pressure to which the valves and stools may be subjected.

1.6 Piping installation

1.6.1 Heavy pipes and valves are to be so supported that their weight is not taken up by connected pumps and fittings.

1.6.2 Support of the pipes is to be such that detrimental vibrations do not arise in the system.

1.6.3 Where pipes are carried through watertight bulkheads or tank tops, means are to be made to ensure the integrity of the watertightness of the compartment.

1.6.4 As far as possible, installation of pipes for water, oil, exhaust gases from oil engines or steam, is to be avoided near electric switchboards. If this is impracticable, all the joints in pipe line and valves are to be at a safe distance from the switchboards and shielded to prevent damage to switchboard.

1.6.5 Provision is to be made to take care of expansion or contraction stresses in pipes due to temperature stresses or working of the hull.

1.6.6 Expansion pieces of approved type, made of oil resistant re-inforced rubber or other approved material may be used in circulating water systems in machinery spaces.

1.6.7 All piping systems, where a pressure greater than the designed pressure could be developed, are to be protected by suitable relief valves.

1.6.8 Seawater pipes in cargo holds for dry cargoes, including cargo spaces of container ships and ro-ro ships, are to be protected from impact of cargo where they are liable to be damaged.

1.6.9 All pipes which pass through chambers intended for the carriage or storage of refrigerated cargo are to be well insulated. In case the temperature of the chamber is below 0°C the pipes are to be insulated from the ship's structure also, except at positions where the temperature of the ship's structure is always above 0°C and is controlled by outside temperature.

Air refreshing pipes leading to and from refrigerated chambers need not be insulated from the ship's structure.

1.6.10 Deck wash pipes and discharge pipes from the pumps to domestic water tanks are not to pass through cargo holds.

Section 2

Bilge and Ballast Piping Systems

2.1 General

2.1.1 All ships are to be provided with necessary pumps, suction and discharge piping and means of drainage so arranged that any compartment can be pumped out effectively, when the ship is on an even keel and/or designed trim and is either upright or has a list of not more than 5 degrees, through at least one suction, except for machinery spaces where at least two suctions are required, one of which is to be a branch bilge suction and the other is to be a direct bilge suction. Wing suctions will, generally, be necessary for this purpose, except for short narrow compartments, where a single suction may be sufficient.

2.1.2 All passenger ships are to be provided with an efficient bilge pumping plant capable of pumping from and draining any watertight compartment which is neither a permanent oil compartment nor a permanent water compartment under all practicable conditions, after a casualty, whether the ship is upright or listed.

2.2 Drainage of cargo holds

2.2.1 In ships without a double bottom one bilge suction is normally to be provided on each side of the cargo hold, at the after ends. However, if the rise of floor exceeds 5 degrees, one bilge suction at the after end situated as near the centerline as practicable may be accepted.

In ships where the bilge water cannot be entirely drained by suctions as provided above due to the fitting of watertight floors or keelsons, additional suctions may be required. Recesses and cementing/composition are to be so arranged that water in any part of the hold may find its way to the suction pipes easily.

2.2.2 In the holds of ships with double bottom, bilge suctions are to be provided on each side at the after end of the holds. Where the tanktop extends to the shipside, bilge suctions are to be led from bilge wells of at least 0.15 [m^3] capacity each, situated at the after end at each side of the hold. Where the tanktop has inverse camber, an additional bilge suction from a well situated near the centerline is also to be provided. Bilge wells of smaller size may be considered depending on the size of the vessel and the size of the compartment.

If the tanktop is of a design having discontinuities or depressions, the number and position of bilge suctions will be given special consideration.

2.2.3 Ships with one cargo hold, are to have suctions in the fore and after ends of the hold. In ships having two or more holds, bilge suctions are to be fitted in suitable positions in the fore and after ends of holds over 30 [m] in length.

2.3 Drainage from refrigerated cargo spaces

2.3.1 Provision is to be made for the continuous drainage of the inside of all insulated chambers and cooler trays.

2.3.2 Drains which are led from lower holds and cooler trays situated on the tank top are to be fitted with liquid sealed traps and non-return bilge valves.

2.3.3 Drains from 'tween deck chambers and from cooler trays which are situated well above the tank top are to be fitted with liquid sealed traps.

2.3.4 Where drains from separate chambers join a common main, the branch pipes are each to be provided with a liquid sealed trap.

2.3.5 The liquid sealed traps are to be of adequate depth and are to have a pressure head of at least 100 [mm] when connected to air ducts and 50 [mm] otherwise and arrangements are to be made for ready access to the traps for cleaning and refilling with brine.

2.3.6 Sluices, scuppers or drain pipes, which would permit drainage from compartments outside the insulated chambers into the bilges of the latter, are not to be fitted.

2.3.7 Screwed plugs or other means for blanking off scuppers draining insulating chambers and cooler trays are not to be fitted. If, however, it is especially desired to provide means for temporarily closing these scuppers, they may be fitted with shutoff valves controlled from readily accessible positions on a deck above the load waterline. An indicator is to be provided to indicate whether the valve is open or shut.

2.4 Drainage from fore and aft peaks

2.4.1 Where the peaks are used as tanks, a power pump suction is to be led to each tank, except in case of small tanks (generally not exceeding 2 [m^3] used for the carriage of domestic fresh water where hand pumps may be used.

2.4.2 The peaks may be drained by hand pumps provided the peaks are not used as tanks and they are not connected to bilge main. The suction lift is to be well within the capacity of the hand pumps and is not to exceed 7.3 [m].

In case of vessels of length 24 [m] or less and fishing vessels, after peak may be drained by means of a self closing cock situated in a well lighted and accessible position, and draining into engine room or tunnel.

2.4.3 Except as provided in 2.4.5 below, the collision bulkhead may be pierced below the bulkhead deck of passenger ships and the freeboard deck of cargo ships by not more than one pipe for dealing with fluid in the forepeak tank, provided that the pipe is fitted with a screwdown valve capable of being operated from above the bulkhead deck of passenger ships and the freeboard deck of cargo ships, the valve being located inside the forepeak at the collision bulkhead. The Administration may, however, authorize the fitting of this valve on the after side of the collision bulkhead provided that the valve is readily accessible under all service conditions and the space in which it is located is not a cargo space. Alternatively, for cargo ships, the pipe may be fitted with a butterfly valve suitably supported by a seat or flanges and

capable of being operated from above the freeboard deck. All valves are to be of steel, bronze or other approved ductile material. Valves of ordinary cast iron or similar material are not acceptable.

2.4.4 For ships constructed on or after 1 January 2024, except as provided in paragraph 2.4.5, the collision bulkhead may be pierced below the bulkhead deck of passenger ships and the freeboard deck of cargo ships by not more than one pipe for dealing with fluid in the forepeak tank, provided that the pipe is fitted with a remotely controlled valve capable of being operated from above the bulkhead deck of passenger ships and the freeboard deck of cargo ships. The valve is to be normally closed. If the remote control system should fail during operation of the valve, the valve is to close automatically or be capable of being closed manually from a position above the bulkhead deck of passenger ships and the freeboard deck of cargo ships. The valve is to be located at the collision bulkhead on either the forward or aft side, provided the space on the aft side is not a cargo space. The valve is to be of steel, bronze or other approved ductile material. Valves of ordinary cast iron or similar material are not acceptable.

2.4.5 If the forepeak is divided to hold two different kinds of liquids the Administration may allow the collision bulkhead to be pierced below the bulkhead deck of passenger ships and the freeboard deck of cargo ships by two pipes, each of which is fitted as required by 2.4.3, provided the Administration is satisfied that there is no practical alternative to the fitting of such a second pipe and that, having regard to the additional subdivision provided in the forepeak, the safety of the ship is maintained.

2.5 Drainage from tanks, cofferdams and void spaces

2.5.1 All the tanks except self-draining tanks, whether for water ballast, oil fuel, liquid cargoes etc. are to be provided with suction pipes led to suitable power pumps. The pumping plant is to be so arranged that any water or liquid within any compartment of the ship can be pumped out through atleast one suction, when the ship is on an even keel and/or designed trim and is either upright or has a list of not more than 5 degrees.

2.5.2 Where the length of the ballast tank exceeds 30 [m], an additional suction is to be provided at the forward end of the tank. Where the width of the tank is unusually large, suctions near the centerline in addition to wing suctions may be required.

2.5.3 Suction pipes from the cofferdams and void spaces are to be led to the main bilge line.

2.5.4 In ships where deep tanks may be used for either water ballast or dry cargo, provision is to be made for blanking the water ballast suction and filling when the tank is being used for carrying cargo and for blanking the bilge line when the tank is being used for carriage of water ballast.

2.6 Drainage from spaces above fore and after peaks, chain lockers and above machinery spaces

2.6.1 Provision is to be made for the drainage of chain locker and watertight compartments above the fore peak tank by hand or power pump suctions.

2.6.2 Steering gear compartments or other small enclosed spaces situated above the after peak tank are to be provided with suitable means of drainage, either by hand or power bilge suctions.

2.6.3 If the compartments referred to in 2.6.2 are adequately isolated from the adjacent 'tween decks, they may be drained by scuppers of not less than 38 [mm] bore, discharging into the tunnel (or machinery spaces in case of ships with machinery aft) and fitted with self-closing cocks situated in well lighted and visible positions. These arrangements are not applicable to passenger ships unless they are specially approved in relation to subdivision considerations.

2.7 Drainage from machinery spaces

2.7.1 Machinery spaces with double bottom:

a) Where the inner bottom extends the full length of the engine room forming bilges at the wings, one branch bilge suction and one direct bilge suction will be required at each side. Where the inner bottom extends the full length and breadth of machinery space, one branch and one direct bilge suctions are to be led to each of the two bilge wells, situated one at each side;

b) The capacity of the bilge wells is to be at least 0.15 [m^3];

c) If the inner bottom has inverse camber or discontinuity or depressions formed due to crankpins or other recesses, additional suctions are to be provided.

2.7.2 Machinery spaces without double bottom:

In ships without inner bottom, where the rise of floor is 5 degrees or more, one branch and one direct bilge suctions are to be led to positions as near the center-line as possible. Bilge suctions at wings will be required in all ships having rise of floor less than 5 degrees.

2.7.3 General requirements for machinery spaces:

a) In ships where machinery is situated at the after end, it will generally be necessary to provide suctions at the forward wings in addition to the suctions at the after end of the machinery space;

b) Special means are to be provided to prevent accumulation of bilge water under main propulsion generators and motors;

c) Where the machinery space is divided into watertight compartments, the drainage system for all compartments except for main engine room is to be same as for cargo holds except that one direct bilge suction from each watertight compartment would also be required;

d) The direct bilge suctions in machinery space(s) are to be led to independent power pump(s), and the arrangements are to be such that these direct suctions can be used independently of the main bilge line suctions.

2.7.4 Emergency bilge suction :

a) An emergency bilge suction is to be fitted to the largest independent power pump, the capacity of which is at least equal to the bilge pump. The suction is to be led to a suitable low position in the machinery space fitted with a screw-down non-return valve having the spindle so extended that the hand wheel is at least 450 [mm] above the engine room floor plates. The valve name plate is to be clearly marked - 'EMERGENCY BILGE SUCTION';

b) In motorships, the emergency bilge suction is to be led to the main cooling water pump. The suction is to be the same size as that of the cooling water pump;

c) In steamships, the main sea water circulating pump is to be fitted with an emergency bilge suction. This suction is to have diameter of at least two third of the pump suction;

d) If two or more cooling water pumps are provided for main engine(s), each capable of supplying sufficient cooling water for normal power, only one pump need be fitted with an emergency bilge suction;

e) Where the main circulating pump is not suitable for emergency bilge suction, the emergency bilge suction is to be led to the largest available independent power pump, which is not fitted with a direct bilge suction and is situated in the same compartment;

f) If the pump to which emergency bilge is connected is of self priming type, then the direct bilge suction on the same side as the emergency bilge suction may be omitted except in passenger ships.

2.8 Drainage from tunnel

2.8.1 A bilge suction, connected to the main bilge line is to be provided for draining the tunnel well. This tunnel well may extend to the outer bottom. If the shaft tunnel slopes from aft to forward end, an additional bilge suction at forward end is to be provided.

2.8.2 Internal diameter of the tunnel bilge suction pipe is not to be less than 65 [mm] except for vessels of length less than 60 [m], where tunnel bilge suction pipes of 50 [mm] bore are acceptable.

2.8.3 Where the length of the tunnel is more than 30 [m], bilge suctions are to be provided at both the forward and aft ends.

2.9 Sizes of bilge suctions

2.9.1 The internal diameter of the bilge pipes is not to be less than that found by the following formula to the nearest 5 [mm] commercial size available:

$$dm = 1.68\sqrt{L\,(B + D)} + 25\ [mm]$$

$$db = 2.15\sqrt{C\,(B + D)} + 25\ [mm]$$

where,

dm = internal diameter of bilge main [mm];

db = internal diameter of branch bilge [mm];

L = Rule length of ship [m];

B = Moulded breadth of ship [m];

C = Length of the compartment [m];

D = Moulded depth to bulkhead deck [m].

2.9.2 In any case, bilge main suction line and branch bilge suction line diameters are not to be less than 50 [mm] and the diameter of the main bilge line is not be less than that of the branch bilge line.

2.9.3 The internal diameter of the direct bilge suction is not to be less than the main bilge line.

2.9.4 In oil tankers and similar ships, where the engine room pumps do not deal with bilge drainage outside the machinery spaces, the rule diameter of the bilge main may be reduced provided the proposed cross-sectional area of the bilge main is not less than twice that required for the branch bilge suction in machinery spaces.

2.9.5 The area of each branch pipe connecting the bilge main to a distribution chest is to be not less than the sum of the areas required by the rules for the two largest branch bilge suction pipes connected to that chest, but need not be greater than that required for the main bilge line.

2.10 Bilge pumps and ejectors

2.10.1 All ships, other than passenger ships, are to be provided with at least two independent power bilge pumps. For ships of length 91.5 [m] and below, one of these pumps may be main engine driven. See 2.13 for requirements regarding passenger ships.

2.10.2 The capacity of each bilge pump is to be sufficient enough to give the water a speed of at least 122 [metres/minute] through the rule size of the main bilge line under normal working conditions.

The capacity of the bilge pump may be found by the following formula :

$Q = 5.75 \times 10^{-3} \times d^2$ [m^3/hour]

where,

Q = Capacity of pump [m^3/hour];

d = rule diameter of bilge main [mm].

2.10.3 In ships, other than passenger ships, where one bilge pump is of slightly less than rule capacity, the deficiency may be made good by an excess capacity of the other pump. In general this deficiency is to be limited to 30 per cent.

2.10.4 An ejector in conjunction with a sea water pump may be accepted as a substitute for independent power bilge pump. This, however, is not acceptable on passenger ships.

2.10.5 Pumps required for essential services are not to be connected to a common suction or discharge chest or pipe unless the arrangements are such that the working of any pumps so connected is unaffected by the other pumps being in operation at the same time.

2.10.6 General service pumps and ballast pumps may be accepted as independent power bilge pumps, provided :

a) Their capacity is adequate and in accordance with 2.10.2.

b) These pumps, together with the pipelines to which they are connected, are fitted with necessary devices to ensure that there is no risk of entry of water or oil fuel in the holds or machinery spaces.

c) The arrangements are such that at least one of these pumps is immediately available for bilge duty, when required, even when the remaining pumps are in use for other essential duties such as fire fighting.

2.10.7 For bilge pump capacity for ships having closed vehicle and ro-ro spaces and special category spaces, refer Pt.6, Ch.7, Cl. 3.6.1.4 and 3.6.1.5.

2.11 Pump types

2.11.1 The bilge pumps required by the rules are to be of self-priming type, unless an approved priming system is provided for these ships.

2.12 Bilge piping arrangements and fittings

2.12.1 Bilge pipes are not, as far as possible, to pass through double bottom tanks. If unavoidable, such bilge pipes are to be provided with welded joints or heavy flanged joints and are to be tested after fitting to the same pressure as the tanks through which they pass.

2.12.2 The parts of bilge pipes passing through deep tanks, intended to carry water ballast, fresh water, liquid cargo or fuel oil are normally to be contained in a pipe tunnel, but where this is not done, the pipes are to be of heavy gauge with welded or heavy flanged joints. The open ends of such pipes are to be fitted with non-return valves. The pipes are to be tested, after fitting, to a pressure of not less than the maximum head to which the tanks may be subjected.

2.12.3 Expansion bends, not glands, are to be fitted to pipes passing through double bottom tanks or deep tanks.

2.12.4 The intactness of the machinery spaces, bulkheads and of tunnel plating is not to be impaired by fitting of scuppers discharging into machinery spaces or tunnel from adjacent compartments which are situated below the bulkhead deck. These scuppers may, however, be led into a strongly built scupper drain tank situated in the machinery space or tunnel but closed to these spaces and drained by means of a suction of appropriate size led from the main bilge line through a screw-down non-return valve.

a) The scupper tank air pipe is to be led above the bulkhead deck and provision is to be made for ascertaining the level of the water in the tank;

b) Where one tank is used for the drainage of several watertight compartments, the scupper pipes are to be provided with screw-down non- return valves.

2.12.5 No drain valve or cock is to be fitted to the collision bulkhead. Drain valves or cocks are not to be fitted to other watertight bulkheads if alternative means of drainage are practicable. These arrangements are not permissible in passenger ships.

2.12.6 Where drain valves or cocks are fitted to bulkheads other than collision bulkhead, as permitted by 2.12.5, the drain valves or cocks are to be at all times readily accessible and are to be capable of being shut off from positions above the bulkhead deck. Indicators are to be provided to show whether the drains are open or shut.

2.12.7 Bilge pipes which are required for draining cargo or machinery spaces are to be entirely distinct from sea inlet pipes or from pipes which may be used for filling or emptying spaces where water or oil is carried. This does not, however, exclude a bilge ejection connection, a connecting pipe from a pump to its suction valve chest, or a deep tank suction pipe suitably connected through a change-over device to bilge, ballast or oil line.

2.12.8 The arrangement of pumps, valves and piping is to be such that any pump could be opened up for overhaul and repairs without affecting the operation of the other pumps.

2.12.9 The arrangement of valves, pumps, cocks and their pipe connections is to be such as to prevent the possibility of placing one watertight compartment in communication with another, or of cargo spaces, machinery spaces or other dry spaces coming in communication with the sea or the tanks. For this purpose the bilge suction pipe of any pump also having sea suction is to be fitted with a non-return valve which cannot permit communication between the bilges and the sea or the compartments in use as tanks.

2.12.10 Screw-down non-return valves are to be provided in the following fittings :

a) Bilge distribution chest valves;

b) Direct bilge suction and bilge pump connection to main line;

c) Bilge suction hose connections on the pumps or on the main line;

d) Emergency bilge suctions.

2.12.11 Bilge suction pipes from machinery spaces and shaft tunnel, except emergency bilge suction, are to be led from easily accessible mud boxes fitted with straight tail pipes to the bilges. The open ends of the tail pipes are not to be fitted with strum boxes. The mud boxes are to be provided with covers which can be easily opened and closed for cleaning purposes.

2.12.12 Strum boxes are to be fitted to the open ends of bilge suction pipes from the cargo holds. The diameter of holes from these

strum boxes is not to be more than 10 [mm] and the total area of the holes is not to be less than twice the area of the pipes.

2.12.13 Where access manholes to bilge wells are necessary, they are to be fitted as near to the suction strums as practicable.

2.12.14 Adequate distance is to be provided between the open ends of suction pipes and bilge well bottom to permit adequate and easy flow of water and to facilitate cleaning.

2.12.15 All the valves, cocks and mud boxes are to be located in easily accessible positions above or at the same level as the floor plates. Where this is unavoidable, they may be fitted immediately below the floor plates provided the floor plates are capable of being opened and closed easily and suitable name plates are fitted indicating the fittings below.

2.12.16 Where relief valves are fitted to pumps having sea connections, these valves are to be fitted in readily visible positions above the platform. The arrangement is to be such that any discharge from the relief valves will also be readily visible.

2.12.17 Where non-return valves are fitted to the open ends of bilge suction pipes in cargo holds in order to decrease the risk of flooding, they are to be of an approved type which does not offer undue obstruction to the flow of water.

2.13 Additional requirements for passenger ships

2.13.1 All passenger ships are to have at least three power bilge pumps connected to the bilge main, one of which may be attached to the propelling unit. Where the bilge pump numeral is 30 or more, one additional independent power pump is to be provided. Sanitary, ballast and general service pumps may be accepted as independent power bilge pumps if fitted with necessary connections to the bilge pumping system.

The bilge pump numeral is to be calculated as follows:

When P_1 is greater than P : bilge pump numeral

$$= 72\left[\frac{M + 2P_1}{V + P_1 - P}\right]$$

in other cases: bilge pump numeral

$$= 72\left[\frac{M + 2P}{V}\right]$$

where,

L_L = the load line length of the ship (metres), as defined in Pt.3, Ch.1, Cl.2.1.9;

M = the volume of the machinery space (cubic metres), as defined in Pt.6, Ch.1, Sec.3 that is below the bulkhead deck; with the addition thereto of the volume of any permanent oil fuel bunkers which may be situated above the inner bottom and forward of, or abaft, the machinery space;

P = the whole volume of the passenger and crew spaces below the bulkhead deck (cubic metres) which are provided for the accommodation and use of passengers and crew, excluding baggage, store, and provision rooms;

V = the whole volume of the ship below the bulkhead deck (cubic metres);

P_1 = KN,

where,

N = the number of passengers for which the ship is to be certified, and

$K = 0.056L_L$

However, where the value of KN is greater than the sum of P and the whole volume of the actual passenger spaces above the bulkhead deck, P_1 is to be taken as the above sum (i.e. the sum of P and the whole volume of the actual passenger spaces above the bulkhead deck) or two-thirds KN, whichever is the greater.

2.13.2 Where practicable, the power bilge pumps are to be placed in watertight compartments so arranged or situated that these compartments will not readily be flooded by the same damage. If the engines and boilers are in two or more watertight compartments, the pumps available for bilge service are to be distributed throughout these compartments as far as is possible.

2.13.3 On ships 91.5 [m] or more in length or having a bilge pump numeral of 30 or more, the arrangements are to be such that at least

one power pump is available for use in all ordinary circumstances in which a ship may be flooded at sea and for ships, subject to the provisions of SOLAS Regulation II-1/1.1.1.1, (i.e. for which the building contract is placed on or after 01 January 2020) in all flooding conditions derived from the consideration of minor damages as specified in SOLAS Regulation II-1/8. These requirements will be satisfied if:

a) One of the required pumps is an emergency pump of reliable submersible type having a source of power situated above the bulkhead deck; or

b) The pumps and their sources of power are so disposed throughout the length of the ship that under any condition of flooding which the ship is required to withstand, at least one pump in undamaged compartment will be available.

2.13.4 In passenger ships, independent power bilge pumps situated in machinery spaces are to have direct suctions from these spaces, except that not more than two such suctions are required in any one space, where two or more such suctions are provided there is to be at least one on the port side and one on the starboard side.

2.13.5 Provision is to be made to prevent the compartment served by any bilge suction pipe being flooded in the event of the pipe being severed, or otherwise damaged by collision or grounding in any other compartment. For this purpose where the pipe is at any part situated nearer the side of the ship than one-fifth the breadth of the ship (measured at right angles to the centerline at the level of the deepest subdivision loadline), or in a duct keel, a non-return valve is to be fitted to the pipe in the compartment containing the open end. For ships subject to the provisions of SOLAS Regulation II-1/1.1.1.1, (i.e. for which the building contract is placed on or after 01 January 2020) the deepest subdivision load line is to be taken as the deepest subdivision draught.

For the purpose of 2.13.5 and 2.13.6, 'breadth' means the maximum moulded breadth of the ship at or below the deepest sub-division loadline.

2.13.6 All the distribution boxes, cocks and valves in connection with the bilge pumping arrangements are to be in positions which are accessible at all times under ordinary circumstances. They are to be so arranged that, in the event of flooding, one of the bilge pumps may be operative on any compartment, in addition, damage to a pump or its pipe connecting to the bilge main outboard of a line drawn at one-fifth of the breadth of the ship (measured as per 2.13.5) is not to put the bilge system out of action. If there is only one system of pipes common to all the pumps, the necessary cocks or valves for controlling the bilge suctions must be capable of being operated from above the bulkhead deck. Where in addition to the main bilge pumping system an emergency bilge pumping system is provided, it is to be independent of the main system and so arranged that a pump is capable of operating on any compartment under flooding conditions, in that case only the cocks and valves necessary for the operation of the emergency system need be capable of being operated from above the bulkhead deck.

2.13.7 All valves and cocks mentioned in 2.13.6 which can be operated from above the bulkhead deck shall have their controls at their place of operation clearly marked and provided with means to indicate whether they are open or closed.

2.13.8 Where it is necessary to correct large angles of heel, in case of damage, the means adopted, are where practicable, to be self acting, but in any case where controls to cross flooding fittings are provided, they are to be operable from above the bulkhead deck.

2.13.9 Bilge wells constructed in the double bottom in connection with drainage arrangements of holds, etc. are not to extend downwards more than necessary. The depth of the well is in no case to be more than the depth less 457 [mm] (18 inches) of the double bottom at the center line nor is the well to extend below the horizontal plane passing through the point of intersection with the frame line amidships of a transverse diagonal line inclined at 25 degrees to the base line and cutting it at a point one half the ship's moulded breadth from the middle line. A well extending to the outer bottom is, however, permitted at the after end of the shaft tunnel.

2.14 Drainage arrangements on vessels not fitted with propelling machinery

2.14.1 Vessels not fitted with propelling machinery are to be provided effective hand pumps which can be operated from above the bulkhead deck or the highest convenient level which is always available. There is to be one

pump for each compartment or two pumps connected to a bilge main having at least one branch to each compartment.

2.15 Ballast system

2.15.1 Provision is to be made for ballasting and deballasting all the ballast tanks by pipe lines which are entirely separate and distinct from pipe lines used for bilging.

2.15.2 Where the length of the ballast tanks exceeds 30 [m], an additional suction is to be provided at the forward end of the tanks. Where the width of the tank is unusually large, suction near the centerline in addition to wing suctions may be required.

Section 3

Vents, Sounding, Overflow and Scuppers and Discharges Piping Systems

3.1 General

3.1.1 Reference to oil in this Section is to be taken to mean oil which has a flash point of 60°C or above (closed cup test).

3.1.2 The portions of vent, overflow and sounding pipes fitted above the weather deck are to be of steel.

3.1.3 Name plates are to be affixed to the upper ends of all vent and sounding pipes.

3.1.4 For vent pipes and sounding pipes passing through refrigerated spaces, see Pt.5.

3.1.5 For design and test heads of tanks see Pt.3.

3.2 Vent pipes

3.2.1 Vent pipes are to be fitted to all tanks, cofferdams, tunnels, sea chests and other compartments which are not fitted with alternative ventilation arrangements.

3.2.2 The vent pipes are to be fitted at the opposite end of the tank to which the filling pipes are placed and/or at the highest part of the tank. Where the tank top is of unusual or irregular profile, special consideration will be given to the number and positions of the vent pipes.

3.2.3 Tanks provided with anodes for cathodic protection, are to be provided with vent pipes at forward and aft ends.

3.2.4 Vent pipes to double bottom tanks, deep tanks extending to the shell plating or tanks which can be run up from the sea and sea chests are to be led above the bulkhead deck.

3.2.5 Air pipes for sea chests are to be fitted with shut off valve directly on sea chest.

3.2.6 Vent pipes to oil fuel and cargo oil tanks, cofferdams, all tanks which can be pumped up, shaft tunnels and pipe tunnels are to be led above the bulkhead deck and to open air.

3.2.7 Vent pipes from lubricating oil storage tanks may terminate in the machinery spaces, provided that the open ends are so situated that issuing oil cannot come into contact with electrical equipment or heated surfaces.

3.2.8 The open ends of vent pipes to oil fuel and cargo oil tanks are to be situated where no danger will be incurred from issuing oil or vapour when the tank is being filled.

3.2.9 For details regarding height and closing devices for vent pipes see Pt.3.

3.2.10 The open ends of vent pipes to oil fuel, cargo oil and ballast tanks fitted with anodes for cathodic protection, are to be fitted with a wire gauze diaphragm of incorrodible material which can be readily removed for cleaning. The clear area through the wire gauze is to be at least equal to the area of the vent pipe. Location and arrangement of vent pipes for fuel oil service, settling and lubricating oil tanks is to be such that a broken vent pipe will not directly lead to the risk of ingress of seawater splashes or rainwater.

3.2.11 In the case of all tanks which can be pumped up either by ship's pumps or by shore

pumps through a filling main, the total cross-sectional area of the vent pipes to each tank, or of the overflow pipes where an overflow system is provided, is to be not less than 25 per cent greater than the effective area of the respective filling pipes.

3.2.12 Where tanks are fitted with cross flooding connections, the vent pipes are to be of adequate area for these connections.

3.2.13 Vent pipes are not to be less than 50 [mm] bore.

3.2.14 Shaft tunnels and pipe tunnels are to be fitted with vent pipes with an internal diameter of not less than 75 [mm].

3.2.15 Vent pipes are to be self-draining under normal conditions of trim.

3.2.16 The thickness of the exposed portion of the vent pipes are to be as required in Pt.3, Ch.13, 3.2.5.

3.3 Overflow pipes

3.3.1 All tanks which can be pumped up are to be fitted with overflow pipes when the pressure head corresponding to the height of vent pipe is greater than that for which the tanks are suitable or when the sectional area of the vent pipes is less than that required by 3.2.11.

3.3.2 Oil fuel and lubricating oil tanks which can be pumped up and which have openings for fittings, for example - for a float sounding system, are to be fitted with overflow pipes. The tank openings, for such fittings, are to be situated above the highest point of the overflow piping.

3.3.3 In the case of oil fuel and lubricating oil tanks, the overflow pipe is to be led to an overflow tank of adequate capacity or to a storage tank having space reserved for overflow purposes and be in readily visible position. A sight glass is to be provided in the overflow pipe to indicate when the tanks are overflowing. Such sight glasses are to be placed only in the vertical portion of the pipes and be located in a readily visible position. Alternatively, an alarm device is to be provided to give warning either when the tanks are overflowing or when the oil reaches a predetermined level in the tanks.

3.3.4 Overflow pipes from tanks, other than oil fuel, cargo oil and lubricating oil tanks, are to be led to the open or to suitable overflow tanks arranged as in 3.3.3.

3.3.5 Where overflow from tanks, which are used for the alternative carriage of oil and water ballast, are connected to an overflow system, arrangements are to be made to prevent water ballast overflowing in to tanks containing oil.

3.3.6 The arrangement of the vent and/or overflow system is to be such that in the event of any one of the tanks being bilged, tanks situated in other watertight compartments of the ship cannot be flooded through combined vent pipes or the overflow main. In the case of vessels of 24 [m] length and less, fishing vessels and trawlers the arrangement is to be such that in the event of any one of the tanks being bilged, the other tanks cannot be flooded from the sea through combined vent pipes or the overflow main.

3.3.7 Overflow pipes are to be self-draining under normal conditions of trim.

3.3.8 For size of overflow pipes, see 3.2.11.

3.4 Sounding arrangements (Also refer Pt.6, Ch.2, 1.2.for F.O., L.O. and other flammable oils)

3.4.1 All tanks, cofferdams and pipe tunnels are to be provided with sounding pipes or other approved means for ascertaining the level of liquid in the tanks. Means of ascertaining the level of liquid in oil fuel tanks is to be of safe type. Level switches may be used provided they are contained in steel enclosure or other enclosures not destroyed by fire. Bilges of compartments which are not, at all times, readily accessible are to be provided with sounding pipes. The soundings are to be taken as near the suction pipes as practicable.

3.4.2 Oil level gauges may be used for tanks containing lubricating oil, oil fuel or other flammable liquid in place of sounding pipes, subject to the following conditions:

- In passenger ships such gauges should not require penetration below the top of the tank and their failure or overfilling of the tanks will not allow release of their contents; and

- In cargo ships, the failure of level gauges or overfilling of the tank will not allow release of their contents into the space.

The use of cylindrical gauge glasses is not acceptable. Flat type glasses may be accepted provided they are of heat resisting quality, adequately supported, protected from mechanical damage and fitted with self closing valves between the gauges and the tanks.

3.4.3 Except as permitted by 3.4.4 sounding pipes are to be led to positions above the bulkhead deck which are at all times accessible. In the case of oil fuel tanks, cargo oil tanks and lubricating oil tanks, the sounding pipes are to be led to safe positions on the open deck. The sounding pipes should not terminate in any space where the risk of ignition from spillage from sounding pipe exists. Sounding pipes are not to terminate in passenger or crew spaces.

3.4.4 Where it is impracticable to comply with 3.4.3 above, short sounding pipes may be fitted in readily accessible positions as indicated in the following:

a) Passenger ships:

- Only to double bottom tanks and cofferdams in machinery spaces.
- All short sounding pipes are to be provided with self-closing cocks as described in Pt.6, Ch.2, 1.2.2.3.5.1.

b) Cargo ships:

- Only to tanks and cofferdams in machinery spaces and shaft tunnels.
- Short sounding pipes to oil fuel, lubricating oil and other flammable oil tanks are to be provided as per Pt.6, Ch.2, 1.2.2.3.51 and 1.2.3.1(a) and (b). Short sounding pipes to other types of tanks and cofferdams may be fitted with screw caps attached by chain to the pipe or with shut-off cocks.

3.4.5 Elbow sounding pipes are not to be used for deep tanks unless the elbows and pipes are situated within closed cofferdams or within tanks containing similar liquids. They may, however, be fitted to other tanks and may be used for sounding bilges, provided that it is not practicable to lead them direct to the tanks or compartments.

a) The elbows are to be of heavy construction and adequately supported;
b) In passenger ships, elbow sounding pipes are not permissible.

3.4.6 Striking plates of adequate thickness and size are to be fitted under open ended sounding pipes. Where slotted pipes having closed ends are employed, the closing plugs are to be of substantial construction.

3.4.7 All sounding pipes are to be not less than 32 [mm] bore. All sounding pipes, whether for compartments or tanks, which pass through refrigerated spaces or the insulation thereof, in which the temperatures contemplated are 0°C or below, are to be not less than 65 [mm] bore.

3.4.8 The upper ends of all sounding pipes are to be provided with efficient closing devices. The sounding pipes are to be arranged as straight as practicable, and if curved, the curvature is to be large enough to permit easy passage of sounding rod/chain.

3.5 Scuppers and discharges (Also refer Pt.3, Ch.13)

3.5.1 Scupper and discharge pipes which are not required to be of substantial thickness in accordance with Pt.3 are to be at least 4.5 [mm] thick for pipes of 155 [mm] external diameter and less; and 6.0 [mm] for pipes of external diameter of 230 [mm] and more, intermediate sizes are to be determined by linear interpolation.

3.5.2 Scupper and discharge pipes which are required to be of substantial thickness in accordance with Pt.3 are to be at least of following thickness:

- 7 [mm] thick for pipes of external diameter of equal to or less than 80 [mm];
- 10 [mm] thick for pipes of external diameter equal to 180 [mm];
- 12.5 [mm] thick for pipes of external diameter equal to or more than 220 [mm];

Intermediate sizes are to be determined by linear interpolation.

3.5.3 Overboard discharges are to be so located as to prevent any discharge of water into the life boats.

3.6 Water level detectors on single hold cargo ships other than bulk carriers

3.6.1 Ships of load line length L_{LL} (see Pt.3, Ch.1 for definition of L_{LL}) less than 80 [m] and having a single cargo hold below the freeboard deck or cargo holds below the freeboard deck

which are not separated by at least one full watertight bulkhead, are to be fitted with water level detectors in such cargo hold/s, unless exempted by 3.6.3.

3.6.2 The water level detectors are to:

i) give an audible and visual alarm at the navigation bridge when the water level above the inner bottom in the cargo hold reaches a height of not less than 0.3 [m] and another when such level reaches not more than 15% of the mean depth of the cargo hold; and

ii) be fitted at the aft end of the hold, or above its lowest part where the inner bottom is not parallel to the design waterline. Where webs or partial watertight bulkheads are fitted above the inner bottom, fitting of additional detectors may be required.

3.6.3 The water level detectors required in 3.6.1 need not be fitted in ships having watertight side compartments each side of the cargo hold length extending vertically at least from inner bottom to freeboard deck.

Note : The water level detectors are to be of approved type. For further details regarding performance tests, sensor locations, installation and other testing requirements refer classification notes: “Type approval, installation and testing of water level detectors on ships subject to SOLAS Reg. II-1/25, II-1/25-1 and XII/12”.

3.7 Water level detectors on multiple hold cargo ships other than bulk carriers and tankers

3.7.1 Multiple hold cargo ships other than bulk carriers and tankers constructed on or after 1 January 2024 (Refer MSC.1/Circ.1673) are to be fitted with water level detectors (Refer MSC.188(79)/Rev.1) in each cargo hold intended for dry cargoes. Water level detectors are not required for cargo holds located entirely above the freeboard deck.

3.7.2 The water level detectors required by 3.7.1 are to:

.1 give audible and visual alarms at the navigation bridge, one when the water level above the bottom of the cargo hold reaches a height of not less than 0.3 m, and another at a height not less than 15% of the depth of the cargo hold but not more than 2 m; and

.2 be fitted at the aft end of the cargo holds. For cargo holds which are occasionally used for water ballast, an alarm overriding device may be installed. The audible and visual alarms are to clearly discriminate between the two different water levels detected in each hold.

3.7.3 As an alternative to the water level detector at a height of not less than 0.3 m as per 3.7.2.1, a bilge level sensor (Refer MSC.188(79)/Rev.1) serving the bilge pumping arrangements required by SOLAS Regulation 35-1 (Refer Pt.3, Ch.13, Sec 4) and installed in the cargo hold bilge wells or other suitable location is considered acceptable, subject to:

.1 the fitting of the bilge level sensor at a height of not less than 0.3 m at the aft end of the cargo hold; and
.2 the bilge level sensor giving audible and visual alarm at the navigation bridge which is clearly distinctive from the alarm given by the other water level detector fitted in the cargo hold.

Note: The water level detectors are to be of approved type. For further details regarding performance tests, sensor locations, installation and other testing requirements refer classification notes: “Type approval, installation and testing of water level detectors on ships subject to SOLAS Reg. II-1/25, II-1/25-1 and XII/12”.

Section 4

Fuel Oil Systems

4.1 General

4.1.1 Reference to oil in this Section is to be taken to mean oil which has a flash point of 60°C (closed cup test) or above.

4.2 Oil fuel tanks

4.2.1 Oil fuel tanks are to be separated from fresh water and lubricating oil tanks by means of cofferdams. For requirements in respect of protective location of fuel oil tanks, see Pt.3, Ch.1, Sec.1.6.

4.2.2 The clearance spaces between the boilers and tops of the double bottom tanks, and between the boilers and the sides of the storage tanks in which oil fuel and cargo oil is carried, are to be adequate for the free circulation of the air necessary to keep the temperature of the stored oil sufficiently below it's flash point except in the case of tanks complying with arrangement in 4.5.3 Where water tube boilers are installed, there is to be a space of at least 760 [mm] between the tanktop and the underside of the pans forming the bottom of the combustion spaces. The boilers are to be adequately lagged.

4.2.3 Oil fuel tanks are not to be located directly above the boilers or other highly heated surfaces.

4.2.4 Minimum two fuel oil service tanks for each type of fuel used on board necessary for propulsion and vital systems or equivalent arrangements (See Fig. 4.2.4 for equivalent arrangement) are to be provided with a capacity of at least 8 hours at maximum continuous rating of the propulsion plant and normal operating load of the generating plant.

Fig.4.2.4 : 'Equivalent arrangement' for F.O. service tanks (Refer Clause 4.2.4)

A) Main and auxiliary engines and boilers operating on heavy fuel (one fuel ship)

Rule requirements

HFO Serv Tank Capacity for at least 8.h each Main Eng + Aux. Eng + Aux Boiler	HFO Serv Tank Capacity for at least 8.h each Main Eng + Aux. Eng + Aux Boiler	MDO Tank For initial cold starting or repair work of engines/Boiler

Equivalent arrangements (Any fuel oil which requires post service tank heating to achieve the required injection viscosity is not regarded in this context as MDO).

HFO Serv Tank Capacity for at least 8.h each Main Eng + Aux. Eng + Aux Boiler	MDO Serv Tank Capacity for at least 8.h each Main Eng + Aux. Eng + Aux Boiler

The above arrangement only applies where main and auxiliary engines can operate with heavy fuel oil under all load conditions and, in the case of main engines, during manoeuvring.

For pilot burners of auxiliary boilers if provided, an additional MDO tank for 8 h operation may be necessary.

B) Main engines and boilers on HFO and aux. Engines on MDO (two fuel ship)

Rule requirement

HFO Serv Tank Capacity for at least 8.h each Main Eng + Aux Boiler	HFO Serv Tank Capacity for at least 8.h each Main Eng + Aux Boiler	MDO Serv Tank Capacity for at least 8.h each Aux. Eng	MDO Serv Tank Capacity for at least 8.h each Aux. Eng

Equivalent arrangement (Any fuel oil which requires post service tank heating to achieve the required injection viscosity is not regarded in this context as MDO).

HFO Serv Tank Capacity for at least 8.h each Main Eng + Aux Boiler	MDO Serv Tank Capacity for at least the highest of : 8h each Aux. Eng + Aux. Boiler or 4h each Main Eng + Aux. Eng + Aux Boiler	MDO Serv Tank Capacity for at least the highest of : 8h each Aux. Eng + Aux Boiler or 4h each Main Eng + Aux. Eng + Aux Boiler

Fig.4.2.4 : (Contd.)

Notes:

1. The arrangements in A) and B) above apply, provided the propulsion and vital systems which use two types of fuel, support rapid fuel change over and are capable of operating in all normal operating conditions at sea with both types of fuel (MDO and HFO)

2. Service tank is a fuel oil tank which contains only fuel of a quality ready for use, i.e. fuel of a grade and quality that meets the specification required by the equipment manufacturer. A service tank is to be declared as such and not to be used for any other purpose.

3. Use of a settling tank with or without purifiers alone and one service tank is not acceptable as an “equivalent arrangement” to two service tanks.

4. The equivalent arrangements described above are the interpretations followed by IRS, unless the flag administration has provided a different interpretation.

4.3 Oil fuel piping

4.3.1 Oil fuel pressure pipes are to be led, where practicable, remote from heated surfaces and electrical appliances, but where this is impracticable the pipes are to have a minimum number of joints and are to be led in well lighted and readily visible positions.

4.3.2 Pipes conveying oil heated above 60°C are to be of seamless steel or other approved material having flanged or welded joints.

4.3.3 The flanges are to be machined, and the jointing material, which is to be impervious to oil heated to 150°C, is to be the thinnest possible, so that the flanges are practically metal to metal. The scantlings of the pipes and their flanges are to be suitable for a pressure of at least 14 bar or for the design pressure, whichever is the greater.

4.3.4 The short joining lengths of pipes to the burners from the control valves at the boiler may have cone unions, provided these are of specially robust construction.

4.3.5 Flexible hoses of approved material and design may be used for the burner pipes, provided that spare length complete with couplings, are carried on board.

4.3.6 Transfer, suction and other low pressure oil pipes and all pipes passing through oil storage tanks are to be made of cast iron or steel, having flanged joints suitable for a working pressure of not less than 7 bar. The flanges are to be machined and the jointing material is to be impervious to oil. Where the pipes are of 25 [mm] bore or less, they may be seamless copper or copper alloy, except those which pass through storage tanks.

4.3.7 Pipes for tanks storing fresh water are to be separate and distinct from any pipes which may be used for oil or oily water, and are not to be led through tanks which contain oil, nor are oil pipes to be led through fresh water tanks.

4.3.8 Pipes conveying vegetable oils or similar cargo oils are not to be led through oil fuel tanks, nor are oil fuel pipes to be led through tanks containing such cargoes.

4.3.9 In passenger ships, provision is to be made for the transfer of oil fuel from any oil fuel storage or settling tank to any other oil fuel storage tank.

4.3.10 Where IRS may permit the conveying of oil and combustible liquids through accommodation and service spaces, the pipes conveying oil or combustible liquids are to be of a material approved by IRS having regard to the risk of fire.

4.3.11 Fuel Oil Sampling

.1 Requirements for sampling points are applicable to all ships of 400 GT or above, and, at the flag Administration's discretion, to ships of less than 400 GT.

.2 Sampling points are to be provided within the fuel oil system for measurement of sulphur content in fuel. The design and location of sampling points is to be such as to enable fuel oil samples to be taken easily, when the machinery is running and in a safe manner.

.3 The position of a sampling point is to be such that sample of the fuel oil is representative of the fuel oil quality passing that location within the system, by ensuring steady state flow past the sampling point.

.4 Sampling points are to be

- downstream of the fuel oil service tank, and
- before fuel enters the oil fueled machinery

.5 The sampling points are to be located in positions as far removed as possible from any heated surface or electrical equipment so as to preclude impingement of fuel oil onto such surfaces on equipment under all operating conditions.

.6 Sampling points are to comply with the requirements of MEPC.1/Circ. 864/ Rev.1 *'Guidelines for on-board sampling and verification of the sulphur content of the fuel oil used onboard ships'*.

4.4 Arrangement of valves, cocks, pumps and fittings

4.4.1 The oil fuel pumping arrangements are to be distinct from other pumping systems as far as practicable and the means provided for preventing dangerous interconnection in service are to be thoroughly effective.

4.4.2 All valves and cocks forming part of the oil fuel installation are to be capable of being controlled from readily accessible positions which, in the engine room and boiler spaces are to be above the working platform.

4.4.3 Every oil fuel suction pipe from a double bottom tank is to be fitted with a valve or a cock.

4.4.4 For oil fuel tanks which are situated above the double bottom tanks, the inlet and outlet, pipes which are connected to the tank at a point lower than the outlet of the overflow pipe or below the top of the tanks without an overflow pipe, are to be fitted with shut off valves located on the tank itself.

4.4.5 In the engine and boiler spaces, valves, mentioned in 4.4.4, are to be capable of being closed locally and from positions outside these spaces which will always be accessible in the event of fire occurring in these spaces. Instructions for closing the valves are to be indicated at the valves and at the remote control positions. The controls for remote operation of the quick closing valve for the emergency generator fuel tank are to be in a separate location from other quick closing valves for tanks in the engine room.

4.4.6 Every oil fuel suction pipe which is led into the engine and boiler spaces, from a tank situated above the double bottom, outside these spaces (including shaft tunnel, pipe

tunnel or similar spaces), is to be fitted in the machinery space with a valve controlled as in 4.4.5, except where the valve on the tank is already capable of being closed from an accessible position above the bulkhead deck.

4.4.7 Settling tanks are to be provided with means for draining water from the bottom of the tanks. If the settling tanks are not provided, the oil fuel bunkers or daily service tanks are to be fitted with water drains.

Open drains for removing water from oil tanks are to be fitted with valves or cocks of self-closing type, and suitable provision is to be made for collecting the oily discharge.

4.4.8 Where a power driven pump is necessary for transferring oil fuel, a stand by pump is to be provided and connected ready for use, or, alternatively, emergency connections may be made to another suitable power driven pump.

4.4.9 All pumps which are capable of developing a pressure exceeding the design pressure of the system are to be provided with relief valves. Each relief valve is to be in close circuit, i.e. arranged to discharge back to the suction side of the pump and to effectively limit the pump discharge pressure to the design pressure of the system. Pressure relief valves need not be fitted when the system is secured only by centrifugal pumps so designed that the pressure delivered cannot exceed that for which the piping is designed.

4.4.10 Valves or cocks are to be interposed between the pumps on the suction and discharge pipes in order that any pump may be shut off for opening up and overhaul.

4.4.11 Relief valves are to be fitted on the oil side of the heaters and are to be adjusted to operate at a pressure of 3.5 bar above that of the supply pump relief valves. The discharge from the relief valves is to be led to a safe position.

4.4.12 Drip trays are to be fitted at location where frequent leakage is expected, oil burners at furnace mouths, drain and valves under daily service tanks, filter and all other oil fuel appliances which are required to be opened up frequently for cleaning or adjustment. Where drain pipes are provided from collected leakages, they shall be led to a suitable oil drain tank not forming part of an overflow system.

4.4.13 Where MARPOL Regulation I/12A for protective location of fuel oil tanks applies (see Pt.3, Ch.1, Sec.1.6), the fuel oil lines, suction wells and valves are to satisfy the requirements of paragraph 9 and 10 of the above MARPOL Regulation.
Valves for such fuel oil tanks are to be located above the bottom at distances not less than that required for suction wells` in paragraph 10 of MARPOL Regulation I/12A. Plan showing the location of tanks, suction wells and valves, indicating the distances are to be submitted for approval.

The requirements for locations of oil fuel lines do not apply to fuel oil air escapes and overflow pipes.

4.5 Heating arrangements

4.5.1 Steam heating installation

4.5.1.1 Where steam is used for heating oil fuel, cargo oil or lubricating oil, in bunkers, tanks, heaters or separators, the exhaust drains are to discharge the condensate into an observation tank in a well lighted and accessible position where it can be readily seen whether or not it is free from oil.

4.5.2 Thermal oil installations

4.5.2.1 The inlet and outlet valves of oil-fired thermal oil heaters and exhaust-fired thermal oil heaters is to be controllable from outside the compartment where they are situated. Alternatively an arrangement for quick gravity drainage of the thermal oil contained in the system into a collecting tank is acceptable.

4.5.2.2 Heating of liquid cargoes with flash points below 60°C shall be arranged by means of a separate secondary system, located completely within the cargo area.

A single circuit system is acceptable on the following conditions:

- system is so arranged that a positive pressure in the coil shall be at least 3 [m] water column above the static head of the cargo when circulating pump is not in operation,

- the thermal oil system expansion tank shall be fitted with high and low level alarms,

- means to be provided in the thermal oil system expansion tank for detection of

flammable cargo vapours. Portable equipment is accepted,

- valves for the individual heating coils is to be provided with locking arrangement to ensure that the coils are under static pressure at all times.

4.5.2.3 The thermal oil circulating pumps is to be arranged for emergency stopping from a position outside the space where they are situated.

4.5.2.4 Vents from expansion tanks and thermal oil storage tanks of thermal oil heating plants is to be led to open deck.

4.5.2.5 Exhaust-fired thermal oil heaters

- The heater is to be so designed and installed that all tubes are easily and readily be inspected for signs of corrosion and leakage.

- Visual inspection and tightness testing of the heater tubes is to be not less than the working pressure and is to be carried out annually. Hydraulic testing is to be carried out bi-annually.

- The heater is to be fitted with temperature sensor(s) and an alarm for fire detection.

- A fixed fire extinguishing and cooling system is to be fitted. A drenching system providing copious amounts of water is acceptable. The exhaust ducting below the exhaust boiler is to be arranged for adequate collection and drainage, to prevent water flowing into the diesel engine. The drain is to be led to a suitable location.

4.5.3 Oil fuel in storage tanks is not to be heated to a temperature within 10°C below the flash point of the oil. Where oil fuel in service tanks, settling tanks and any other tanks in the supply system is heated following arrangements are to be provided:

- The length of the vent pipes from such tanks and/or a cooling device is sufficient for cooling the vapours to below 60°C; otherwise the outlet of the vent pipes is to be located at least 3 m away from a source of ignition;

- There are no openings from the vapour space of the fuel tanks in to machinery spaces (bolted manholes are acceptable);

- Any enclosed spaces are not to be located directly above such oil fuel tanks, except for vented cofferdams; and

- Electrical equipment is not to be fitted in the vapour space of the tanks, unless they are certified intrinsically safe.

4.6 Temperature indication

4.6.1 Tanks and heaters in which oil is heated are to be provided with suitable means for ascertaining the temperature of the oil.

4.7 Filling arrangements

4.7.1 The bunkering of the ship is to be carried out through a permanently fitted pipeline, provided with the required fittings and ensuring fuel delivery to all storage tanks. The open end of the filling pipe is to be led to the tank bottom.

In passenger ships fuel bunkering stations are to be isolated from other spaces and are to be efficiently drained and ventilated.

4.7.2 Provision is to be made against over-pressure in the filling pipes, served by pumps on board, and any relief valve fitted for this purpose is to discharge into an overflow tank or other safe position.

4.8 Alternate carriage of oil fuel and water ballast

4.8.1 Where it is intended to carry oil fuel and water ballast in the same tanks alternatively, the valves or cocks connecting the suction pipes of these tanks with the ballast pump and those connecting them with the oil fuel transfer pump are to be so arranged that the oil may be pumped from one tank by the oil fuel pump at the same time as the ballast pump is being used on any other tank.

Where settling or service tanks are fitted, each having a capacity sufficient to permit 12 hour normal service without replenishment, the above requirement may be dispensed with.

4.8.2 Attention is drawn to the statutory requirements issued by the National Authorities in connection with *International Convention for the Prevention of Pollution of the Sea by Oil, 1973/78.*

4.9 Deep tanks for the alternative carriage of oil, water ballast or dry cargo

4.9.1 In the case of deep tanks which can be used for the carriage of oil fuel, cargo oil, water ballast or dry cargo, provision is to be made for blank flanging the oil and water ballast filling and suction pipes, also the steam coils if retained in place, when the tank is used for dry cargo, and for blank flanging the bilge suction pipes when the tanks are used for oil or water ballast.

4.9.2 If the deep tanks are connected to an overflow system, the arrangements are to be such that liquid or vapour from other tanks cannot enter the deep tanks when dry cargo is carried in them.

4.10 Oil fuel burning arrangements

4.10.1 For boilers

4.10.1.1 Where steam is required for the main propelling engines, for auxiliary machinery for essential services, or for heating of heavy fuel oil and is generated by burning oil fuel under pressure, there are to be not less than two oil burning units, each unit comprising a pressure pump, suction and discharge filters and a heater. For auxiliary boilers, a single oil burning unit may be accepted, provided that alternative means, such as an exhaust gas boiler or composite boiler, are available for supplying steam for essential services.

4.10.1.2 In two unit installations, each unit is to be capable of supplying fuel for generating all the steam required for essential services. In installations of three or more units, the capacities and arrangements of the units are to be such that all the steam required for essential services can be maintained with any one unit out of action.

4.10.1.3 In systems where oil is fed to the burners by gravity, duplex filters are to be fitted in the supply pipeline to the burners and so arranged that one filter can be opened up when the other is in use.

4.10.1.4 Where steam is required to bring the boiler plant into operation, starting up oil fuel unit, including an auxiliary heater and hand pump, or other suitable starting up device, which does not require power from shore, is to be provided.

4.10.1.5 Where burners are provided with steam purging and/or atomizing connections, the arrangements are to be such that oil fuel cannot find its way into steam system in the event of valve leakage.

4.10.1.6 The burner arrangements are to be such that a burner cannot be withdrawn unless the oil fuel supply to that burner is shut off and that oil cannot be turned on unless the burner has been correctly coupled to the supply line.

4.10.1.7 A quick-closing master valve is to be fitted to the oil supply to each boiler manifold, suitably located so that the valve can be readily operated in an emergency, either directly or by means of remote control, having regard to the machinery arrangements and location of controls.

4.10.1.8 In the case of top-fired boilers, means are to be provided so that, in the event of flame failure, oil fuel supply to the burners is shut off automatically, and audible and visual warnings are given.

4.10.1.9 Provision is to be made, by suitable non-return arrangements, to prevent oil from spill systems being returned to the burners when oil supply to these burners has been shut off.

4.10.1.10 For alternatively fired furnaces of the boilers using exhaust gases and oil fuel, the exhaust gas inlet pipe is to be provided with an isolating device and interlocking arrangements whereby oil fuel can only be supplied to the burners when the isolating device is closed to the boiler.

4.10.2 For internal combustion engines

4.10.2.1 Filters are to be fitted in the supply lines to the main and auxiliary machinery. For non-redundant units for essential services, it must be possible to clean the filters without stopping the unit or reducing the supply of filtered oil to the unit.

For auxiliary engines one single oil fuel filter for each engine may be accepted.

4.10.2.2 Where an oil fuel booster pump is fitted, which is essential to the operation of the main engine(s), a standby pump is to be provided. The standby pump is to be

connected ready for immediate use but where two or more main engines are fitted, each with its own pump, a complete spare pump may be accepted provided that it is readily accessible and can be easily installed.

4.10.2.3 Where pumps are provided for fuel valve cooling, the arrangements are to be as in 4.10.2.2.

4.10.2.4 In multi-engine installations which are supplied from the same fuel source, means of isolating the fuel supply and spill piping to individual engines, shall be provided. The means of isolation shall not affect the operation of the other engines and shall be operable from a position not rendered inaccessible by a fire on any of the engines.

4.10.3 Oil fired galleys

4.10.3.1 The fuel supply to the burners is to be controlled from a position which will always be accessible in the event of a fire occurring in the galley.

4.10.3.2 The galley is to be well ventilated.

4.10.4 Special requirements for low sulphur Oil fuel burning arrangements:

For ships intending to use Heavy Fuel Oil (HFO) or Marine Diesel Oil (MDO) in non-restricted areas and marine fuels with a sulphur content not exceeding 0,1 % m/m and minimum viscosity of 2 cSt in emission control areas, the oil fuel burning arrangements essential for the normal operation of propulsion machinery are to comply with the following:

4.10.4.1 In non-restricted areas, ships are provided with two (2) fuel oil pumps that can each supply the fuel primarily used by the ship (i.e. HFO or MDO) in the required capacity for normal operation of the propulsion machinery.

4.10.4.2 In emission control areas one of the following configurations are to be provided:

a) Fuel oil pumps as in 4.10.4.1, provided these are each suitable for marine fuels with a sulphur content not exceeding 0.1 % m/m and minimum viscosity of 2 cSt operation at the required capacity for normal operation of propulsion machinery, or,

b) When the fuel oil pumps in 4.10.4.1 are suitable to operate on marine fuels with a sulphur content not exceeding 0.1 % m/m and minimum viscosity of 2 cSt but one pump alone is not capable of delivering marine fuels with a sulphur content not exceeding 0.1 % m/m and minimum viscosity of 2 cSt at the required capacity, then both pumps may operate in parallel to achieve the required capacity for normal operation of propulsion machinery. In this case, one additional fuel oil pump is to be provided. The additional pump is to, when operating in parallel with one of the pumps in 4.10.4.1, be suitable for and capable of delivering marine fuels with a sulphur content not exceeding 0,1 % m/m and minimum viscosity of 2 cSt at the required capacity for normal operation of the propulsion machinery, or,

c) In addition to 4.10.4.1, two separate fuel oil pumps are provided, each capable of and suitable for supplying marine fuels with a sulphur content not exceeding 0,1 % m/m and minimum viscosity of 2 cSt at the required capacity for normal operation of propulsion machinery.
Notes:

1. If a marine distillate grade fuel with a different maximum sulphur content is specified by regulation for the area of operation of the ship (e.g., ECA, specific ports or local areas, etc.) then that maximum is to be applied.

2. In the case of vessels with class notation SYJ, requirement in Pt. 5, Ch. 22 for activating of alarm when pumps are automatically started is applicable regardless of the pump arrangement.

3. Where electrical power is required for the operation of propulsion machinery, the requirements are also applicable for machinery for power generation when such machinery is supplied by common fuel supply pumps.

4. The minimum viscosity of 2cSt specified above is the value corresponding to the standard reference temperature.

4.11 Remote stop of oil fuel pumps and fans

4.11.1 Emergency stop of power supply to the following pumps and fans is to be arranged from a central place outside the engine and boiler room (Also refer Ch.8, Cl. 2.15.2) and Pt.6, Ch.2, Sec.2:

- oil fuel transfer pump;

- oil fuel booster pump;
- nozzle cooling pumps when oil fuel is used as coolant;
- oil fuel purifiers;
- pumps for oil-burning installations;
- fans for forced draught to boilers;
- fans for ventilation of engine and boiler rooms.

4.12 Fuel oil treatment system

4.12.1 Vessel fitted with a fuel oil treatment system complying with the requirements of IRS Classification Note "*Fuel Oil Treatment Systems*" will be assigned additional class notation **FT**.

Section 5

Steam Piping and Condensate Piping Systems

5.1 Expansion and drainage

5.1.1 In all steam piping systems, ample provision is to be made for expansion and contraction to take place without unduly straining the pipes.

5.1.2 The slope of the pipes and the number and position of the drain valves or cocks are to be such that water can be efficiently drained from any portion of the steam piping system, when the ship is on even keel and/or designed trim and is either upright or has a list of not more than 5 degrees.

5.1.3 Drain valves or cocks are to be readily accessible.

5.2 Steam pipes in way of holds, shaft and pipe tunnels

5.2.1 In general, steam pipes are not to be led through spaces which may be used for carrying cargo. But where it is impracticable to avoid steam pipes passing through cargo spaces, the pipes are to be efficiently insulated, secured and protected against mechanical damage. Plans for such arrangements are to be submitted for consideration.

5.2.2 Where the steam pipes pass through shaft tunnels and pipe tunnels, these are to be efficiently secured and insulated in such a way that the lagging surface temperature does not exceed 60°C.

5.3 Relief valves

5.3.1 Auxiliary steam lines not designed to withstand boiler pressure are to be fitted with relief valves, installed on the low pressure side, immediately after pressure reducing valve, having sufficient discharge capacity to protect the piping against excessive pressure.

5.4 Steam supply to auxiliaries

5.4.1 The steam supply to steering gear and essential auxiliaries is to be so arranged that it is not affected in the event of main steam supply to propulsion machinery or cargo oil pumps being shut off.

5.5 Steam for fire extinguishing in cargo holds

5.5.1 Where steam is used for fire extinguishing in cargo holds, provision is to be made to prevent damage to cargo by leakage of steam or drip. Details of proposed precautionary measu-res are to be submitted for approval.

5.6 Condensate pumps

5.6.1 Two or more extraction pumps are to be provided for dealing with the condensate from the main and auxiliary condensers, at least one of which is to be independently driven. Where one of the independent feed pumps is fitted with direct suctions from the condensers and a discharge to the feed tank, it may be accepted as an independently driven extraction pump.

5.6.2 Condensate pumps are to be provided with valves or cocks, interposed between the pumps and the suctions and the discharge pipes, so that any pump may be opened up for overhaul while the others continue in operation.

Section 6

Boiler Feed Piping Systems

6.1 Feed water piping

6.1.1 Two separate means of feed are to be provided for all main and auxiliary boilers, which are required for essential services, with the exception of boilers in which steam is generated exclusively by exhaust gases or steam, where one means of feed will be accepted provided an alternative steam supply is available.
IR6.1.1 Where a steam generating system consists of two or more adequately sized boilers, one independent feed water supply pipe to each boiler from two feed pumps is considered acceptable.

6.2 Feed pumps

6.2.1 Two or more feed pumps are to be provided of sufficient capacity to supply the boilers under full load conditions with any one pump out of action. At least one of these pumps is to be independently driven.

6.2.2 In multiple screw ships in which there is only one independently driven feed pump, each main engine is to be provided with a feed pump.

6.2.3 Where only one independent feed pump has been provided, a harbour feed pump or an injector is to be fitted to provide second means of feed to the boilers which are in use when the main engines are not working.

6.2.4 The harbour feed pump, as required by 6.2.3, may be used as general service pump, provided that it is not connected to tanks containing oil, or to tanks, cofferdams and bilges which may contain oily water.

6.3 Valves, cocks and fittings

6.3.1 Independent feed pumps, required for feeding the main boilers, are to be fitted with automatic regulators for controlling their output.

6.3.2 The valves on the suction pipes from hotwell or condenser and the feed drain tanks or filter are to be of the non-return type.

6.3.3 Feed pumps are to be provided with valves or cocks, interposed between the pumps and the suction and the discharge pipes, so that any pump may be opened up for overhaul while the others continue in operation.

6.4 Fresh-water connections

6.4.1 Feed pumps for water-tube boilers are to have fresh-water connections only.

6.5 Feed water tanks

6.5.1 All ships fitted with boilers are to be provided with storage space for reserve feed water. Capacity of these tanks is to be at least twice the hourly evaporation rate of the boilers.

6.5.2 Feed water tanks are to be separated from oil tanks by cofferdam.

6.6 Evaporators

6.6.1 For main boilers, one or more evaporators, of adequate capacity, are to be provided.

Section 7

Engine Cooling Water Systems

7.1 General

7.1.1 Centrifugal cooling water pumps are to be installed as low as possible in the ship.

7.2 Cooling water main supply

7.2.1 Provision is to be made for an adequate supply of cooling water to the main propelling machinery and essential auxiliary engines, also to lubricating oil and fresh water coolers and air coolers for electric propelling machinery, where these coolers are fitted. The cooling water pump(s) may be worked from the engines or be driven independently.

7.3 Cooling water standby supply

7.3.1 Provision is also to be made for a separate supply of cooling water from a suitable independent pump of adequate capacity.

7.3.2 The following arrangements are acceptable, depending on the purpose for which the cooling water is intended:

a) Where only one main engine is fitted, the standby pump is to be connected ready for immediate use;

b) Where more than one main engine is fitted, each with its own pump, a complete spare pump of each type may be accepted;

c) Where a sea inlet scoop arrangement is fitted, and there is only one independent condenser circulating pump, a further pump, or a connection to the largest available pump suitable for circulation duties, is to be fitted to provide the second means of circulation when the ship is maneuvering. The pump is to be connected ready for immediate use;

d) Where fresh water cooling is employed for main/or auxiliary engines, a standby means of cooling need not be fitted if there are suitable emergency connections from a salt water system;

e) Where each auxiliary is fitted with a cooling water pump, standby means of cooling need not be provided for auxiliaries. Where, however a group of auxiliaries is supplied with cooling water from a common system, a standby cooling water pump is to be provided for this system. This pump is to be connected ready for immediate use and may be a suitable general service pump.

7.3.3 When selecting a pump for standby purposes, consideration is to be given to the maximum pressure which it can develop if the overboard discharge valve is partly or fully closed and, when necessary, condenser doors, water boxes, etc. are to be protected by an approved device against inadvertent over pressure.

7.4 Relief valves on cooling water pumps

7.4.1 Where cooling water pumps can develop a pressure head greater than the design pressure of the system, they are to be provided with relief valves on the pump discharge to effectively limit the pump discharge pressure to the design pressure of the system.

7.5 Sea inlets for cooling water pumps

7.5.1 Sea-water cooling systems for main and auxiliary machinery are to be connected to at least two cooling water inlets, preferably on opposite sides of the ship.

7.5.2 Where sea water is used for the direct cooling of main engines and auxiliaries, the sea water suction pipes are to be provided with strainers which can be cleaned without interrupting the cooling water supply.

Section 8

Lubricating Oil Piping Systems

8.1 General

8.1.1 The lubricating systems are to be so arranged that they will remain efficient with the ship inclined from the normal to any angle up to 15° transversely and when pitching 10° longitudinally and when rolling up to 22.5° from the vertical.

8.1.2 Lubricating oil systems are to be entirely separated from other systems. This requirement, however, does not apply to hydraulic governing and maneuvering systems for main and auxiliary engines.

8.1.3 Lubricating oil tanks are to be separated from other tanks containing water, fuel oil or cargo oil, by means of cofferdams.

8.1.4 For fire protection requirements also refer Pt.6, Ch.2, 1.2.3.

8.2 Pumps

8.2.1 Where lubricating oil for the main engine(s) is circulated under pressure, a standby lubricating oil pump is to be provided where the following conditions apply:

a) The lubricating oil pump is independently driven and the total output of the main engine(s) exceeds 370 [kW];

b) One main engine with its own pump is fitted and the output of the engine exceeds 370 [kW];

c) More than one main engine each with its own lubricating oil pump is fitted and the output of each engine exceeds 370 [kW].

8.2.2 The standby pump is to be of sufficient capacity to maintain the supply of oil for normal conditions with any one pump out of action. The pump is to be fitted and connected ready for immediate use, except that where the conditions referred to in 8.2.1(c) apply, a complete spare pump may be accepted. In all cases satisfactory lubrication of the engines is to be ensured while starting and maneuvering.

8.2.3 Similar provisions to those of 8.2.1 and 8.2.2 are to be made where separate lubricating oil systems are employed for piston cooling, reduction gearing, oil operated couplings and controllable pitch propellers, unless approved alternative arrangements are provided. Where the oil glands for stern tubes are provided with oil circulating pump, and the continuous running of this pump is necessary during normal operation, then a standby pump for this purpose is to be provided.

8.2.4 Independently driven rotary type pumps are to be fitted with non- return valves on the discharge side of the pumps.

8.2.5 A relief valve in close circuit is to be fitted on the pump discharge if the pump is capable of developing a pressure exceeding the design pressure of the system, the relief valve is to effectively limit the pump discharge pressure to the design pressure of the system.

8.3 Control of pumps and alarms

8.3.1 The power supply, to all independently driven lubricating oil service pumps is to be capable of being stopped from a position outside the space which will always be accessible in the event of fire occurring in the compartment in which they are situated, as well as from the compartment itself.

8.3.2 All main and auxiliary engines and turbines intended for essential services are to be provided with means of indicating the lubricating oil pressure supply to them. Alarms for reduction in pressure of the lubricating oil supply are to be actuated from the outlet side of any restrictions such as filters, coolers etc. For main and auxiliary internal combustion engines, above 37 [kW] an alarm device with audible and visual signal for failure of lubricating system is to be provided.

8.4 Emergency supply for propulsion turbines and propulsion turbogenerators

8.4.1 A suitable emergency supply of lubricating oil is to be arranged to come automatically into use in the event of low oil pressure.

The emergency source of supply is to be independent of power from main switchboard.

8.4.2 The emergency supply may be obtained from a gravity tank containing sufficient oil to maintain adequate lubrication for not less than 6 minutes, and, in case of propulsion turbo-generators, until the unloaded turbine comes to rest from its maximum rated running speed.

8.5 Filters

8.5.1 In systems, where lubricating oil is circulated under pressure, provision is to be made for efficient filtration of the oil. For non-redundant units, for essential services, it must be possible to clean the filters without stopping the unit or reducing the supply of filtered oil to the units.

8.5.2 In the case of propulsion turbines and their gears, arrangements are to be made for lubricating oil to pass through magnetic strainers and fine filters.

8.6 Valves and cocks on lubricating oil tanks

8.6.1 The provisions of 4.4.4, 4.4.5 and 4.4.6 are also to apply to lubricating oil tanks except those having a capacity less than 500 litres, storage tanks on which valves are closed during the normal operation mode of the ship, or where it is determined that an unintended operation of a quick closing valve on the oil lubricating tank would endanger the safe operation of the main propulsion and essential auxiliary machinery.

8.6.2 Where an engine lubricating oil drain tank extends to the bottom shell plating in ships that are required to be provided with a double bottom, a shutoff valve is to be fitted in the drain pipe between the engine crank case and the double bottom lubricating oil tank. This valve is to be capable of being closed from an accessible position above the level of the lower platform (floor plates).

Section 1

General

1.1 Scope

1.1.1 The requirements of this Chapter are applicable to all ships but may be modified for ships classed for restricted services or for special services.

1.1.2 Prime movers of less than 100 [kW] capacity may be accepted based upon manufacturer's certificate provided the prime movers are of an approved type.

1.1.3 Attention is drawn to any relevant statutory requirements of the country in which the ship is to be registered.

1.1.4 Prime movers and power transmission systems not specified in this Chapter will be specially considered by IRS.

1.2 Materials

1.2.1 Materials intended for the main parts of the prime movers and power transmission systems are to be manufactured and tested in accordance with the requirements of Pt.2.

1.3 Turning gear

1.3.1 Arrangements are to be provided to turn the prime movers of main propulsion systems, reduction gears and auxiliary drives. Suitable interlocks are to be provided.

1.4 Power ratings

1.4.1 Where requirements to dimensions in this Chapter are based on power and revolutions per minute, the values to be applied are maximum continuous power measured on engine output shaft and corresponding revolutions per minute.

1.4.2 The maximum continuous power for which the engine is to be approved is defined in ISO 3046/I for oil engines and ISO 3977 for gas turbines.

1.4.3 For plants where overload is used frequently, the scantling criteria may have to be based on over load due to accumulated fatigue.

1.5 Overload capacity

1.5.1 Prime movers of electric generators are to be capable of developing 10 per cent overload for a short period of time (15 minutes). The overload power refers to the power of the generator set.

1.6 Certification of machinery

1.6.1 The certification of machinery is to be in accordance with requirements given in Chapter 1, Section 4 of this part.

1.7 Type approval program

1.7.1 Products that can be consistently manufactured to the same design and specification may be type approved in accordance with "IRS certification scheme for type approval of products".

1.7.2 For non mass-produced engines the requirements given in subsection 4.12 of this chapter are applicable for type approval.

1.7.3 For mass-produced machinery, "Type approval certification scheme for machinery manufactured by mass production system" is to be referred to.

Section 2

Steam Turbines

2.1 Scope

2.1.1 The requirements of this Section are applicable to steam turbines for main propulsion and to those for essential auxiliary services.

2.2 Plan and particulars

2.2.1 The following plans are to be submitted for consideration, together with particulars of materials, maximum shaft powers and revolutions per minute. The pressures and temperatures applicable at maximum shaft power and under the emergency conditions are to be stated or indicated on the plans.

- General technical specifications;
- General arrangement;
- Sections showing rotors, bearings and casings;
- Sections showing typical blades and blade fastenings;
- Integrated steam and drain piping;
- Foundation and fastening;
- Block diagram with functional description of control and monitoring system;
- Lubricating oil system;
- Operating instructions manual; and
- Test programmes.

If required, the following information is also to be submitted:

- Vibration calculation of rotors and/or blades;
- Performance characteristics with functional description;
- Specification of reliability and availability; and
- Analysis proving the specified reliability and availability.

2.2.2 Full particulars of the means proposed for emergency propulsion are to be submitted.

2.2.3 Where rotors and castings are of welded construction, details of the welded joints are also to be submitted for consideration.

2.3 Materials

2.3.1 In the selection of materials, consideration is to be given to their creep strength, corrosion resistance and scaling properties at working temperatures to ensure satisfactory performance and long life under service condition.

2.3.2 Grey cast iron is not to be used for temperatures exceeding 260°C.

2.3.3 Turbine rotors and discs are to be of forged steel. For carbon and carbon-manganese steel forgings, the specified minimum tensile strength is to be selected within the limits of 400 and 600 [N/mm^2]. For alloy steel rotor forgings, the specified minimum tensile strength is to be selected within the limits of 500 and 800 [N/mm^2]. For discs and other alloy steel forgings, the specified minimum tensile strength is to be selected within the limits of 500 and 1000 [N/mm^2].

2.3.4 For alloy steels, details of the proposed chemical composition, heat treatment and mechanical properties are to be submitted for approval.

2.3.5 When it is proposed to use material of higher tensile strength, full details are to be submitted for approval.

2.4 Design and construction

2.4.1 In the design and arrangement of turbine machinery, adequate provision is to be made for the relative thermal expansion of the various turbine parts, and special attention is to be given to minimizing casing and rotor distortion under all operating conditions.

2.4.2 Turbine bearings are to be so disposed and supported that lubrication is not adversely affected by heat flow from adjacent hot parts of the turbine. Effective means are to be provided for intercepting oil leakage and preventing oil from reaching high temperature glands and casings and steam pipes pockets are to be sufficiently large to prevent excessive accumulation and leakage of oil.

2.4.3 The design analysis, if required, is to include a full vibration analysis with measurements as necessary, covering vibration of the rotor as well as blade vibrations.

2.4.4 Turbine rotors, cylinders and associated components fabricated by means of welding will be considered for acceptance if constructed by firms whose works are properly equipped to undertake welding to equivalent standards, for rotors and cylinders respectively, to those required by the Rules for Class 1 welded pressure vessels, See Ch.10.

2.4.5 Before work is commenced, manufacturers are to submit for consideration details of proposed welding procedures and their proposals for routine examination of joints by non-destructive means.

2.4.6 Where it is proposed to construct rotors from two or more forged components joined by welding, full details of the chemical composition, mechanical properties and heat treatment of the materials, together with particulars of the welding consumables, an outline of the welding procedure, method of fabrication and heat treatment, are to be submitted for consideration.

2.4.7 Joints in rotors and major joints in cylinders are to be designed as full-strength welds and for complete fusion of the joint.

2.4.8 Adequate preheating is to be employed for mild steel cylinders and components and where the metal thickness exceeds 44 [mm], and for all low alloy steel cylinders and components and for any part where necessitated by joint restraint.

2.4.9 Stress relief heat treatment is to be applied to all cylinders and associated components on completion of the welding of all joints and attached structures. For details of stress relief procedures, temperature and duration, See Ch.10.

2.4.10 Surveyors are to be satisfied that the desired quality of welding is attainable with the proposed welding equipment and procedure, and for this purpose test specimens representative of the welded joints are to be provided for radiographic examination and mechanical tests.

2.4.11 Smooth fillets are to be provided at abrupt changes of section of rotors, spindles, discs, blade roots and tensions. The rivet holes in blade shrouds are to be rounded and radiused on top and bottom surfaces, and tenons are to be radiused at their junction with blade tips. Balancing holes in discs are to be well rounded and polished.

2.4.12 Surveyors are to be satisfied as to the workmanship and riveting of blades to shroud bands, and that the blade tenons are free from cracks, particularly with high strength blade material. Test samples are to be sectioned and examined, and pull-off tests made if considered necessary by Surveyors.

2.4.13 Main turbine rotor discs fitted by shrinking are to be secured with keys, dowels or other approved means.

2.5 Vibration

2.5.1 Care is to be taken in the design and manufacture of turbine rotors, rotor discs and blades to ensure freedom from undue vibration within the operating speed range. Consideration of blade vibration should include the effect of centrifugal force, blade root fixing, metal temperature and disc flexibility where appropriate.

2.6 External influences

2.6.1 Pipes and ducts connected to turbine casings are to be so designed that no excessive thrust loads or moments are applied by them to the turbines. Grating and any fittings in way of sliding feet or flexible-plate supports are to be so arranged that casing expansion is not restricted. Where main turbine seatings incorporate a tank structure, consideration is to be given to the temperature variation of the tanks in service to ensure that turbine alignment will not be adversely affected.

2.7 Steam supply and water system

2.7.1 In the arrangement of the gland sealing system, the pipes are to be made self-draining and every precaution is to be taken against the possibility of condensed steam entering the glands and turbines. The steam supply to the gland sealing system is to be fitted with an effective drain trap. In the air ejector re-circulating water system, the connection to the condenser is to be so located that water cannot impinge on the L.P. rotor or casing.

2.8 Turning gear

2.8.1 The turning gear for all propulsion turbines is to be power-driven and if electric, is to be continuously rated.

2.9 Safety arrangement

2.9.1 Overspeed protective devices

a) An overspeed protective device is to be provided for main and auxiliary turbines to shut off the steam automatically and prevent the maximum designed speed being exceeded by more than 15 per cent.

b) Where two or more turbines of a compound main turbine installation are separately coupled to the same main gear wheel, and one over-speed protective device is provided, this is to be fitted to the L.P. ahead turbine. Hand trip gear for shutting off the steam in an emergency is to be provided at the maneuvering platform.

c) Where exhaust steam from auxiliary systems is led to the main turbine, activation of the over-speed protective device is to cut off this steam supply to the main turbine.

2.9.2 Speed governors

a) Where a turbine installation incorporates a reverse gear, electric transmission or reversible propeller, a speed governor in addition to, or in combination with, the overspeed protective device is to be fitted, and is to be capable of controlling the speed of the unloaded turbine without bringing the overspeed protective device into action.

b) Auxiliary turbines intended for driving electric generators are to be fitted with speed governors which, with fixed setting, are to control the speed within 10 per cent momentary variation and five per cent permanent variation when full load is suddenly taken off or put on. The permanent speed variations of alternating current machines intended for parallel operations are to equal within a tolerance of $\pm$ 0.5 per cent.

2.9.3 Low vacuum and over pressure protective device

a) Sentinel relief valves are to be provided at the exhaust ends of all turbines, to provide a warning to personnel of allowable pressure being exceeded. The valve discharge outlets are to be visible and suitably guarded if necessary to avoid injury to personnel. Where a low vacuum cut-out device is provided, the sentinel relief valve at the L.P. exhaust may be omitted.

b) Sentinel relief valves are to be provided at the exhaust ends of all auxiliary turbines and the valve discharge outlets are to be visible and suitably guarded if necessary. Low vacuum or over pressure cut-out devices, as appropriate, are also to be provided for auxiliary turbines not installed with their own condensers.

c) When for auxiliary turbines, the inlet steam pressure exceeds the pressure for which the exhaust casing and associated piping

up to exhaust valve are designed, means to relieve the pressure are to be provided.

2.10 Bled steam connections

2.10.1 Non-return or other means, which will prevent steam and water returning to the turbines, are to be fitted in bled steam connections.

2.11 Steam strainers

2.11.1 Efficient steam strainers are to be provided close to the inlets to ahead and astern high pressure turbines, or alternatively at the inlets to the maneuvering valves.

2.12 Emergency arrangements

2.12.1 Lubricating oil failure

a) Arrangements are to be made for the steam to the ahead propulsion turbines to be automatically shut off in the event of failure of the lubricating oil pressure; however, steam is to be made available at the astern turbine for braking purposes in such an emergency.

b) Auxiliary turbine arrangements are to be such that steam supply is automatically shut off in the event of failure of the lubricating oil pressure.

c) Main turbines are to be provided with a satisfactory emergency supply of lubricating oil which will come into use automatically in case of lubricating oil pressure falling below a predetermined value. The emergency supply may be obtained from a gravity tank containing sufficient oil to maintain adequate lubrication until the turbine is brought to rest or by equivalent means. If emergency pumps are used these are to be so arranged that their operation is not affected by failure of the power supply. Suitable arrangements for cooling the bearings after stopping may also be required.

2.12.2 Single screw ships

a) In single screw ships fitted with cross compound steam turbine installations in which two or more turbines are separately coupled to the same main gear wheel, the arrangements are to be such as to enable safe navigation, when the steam supply to any one of the turbines is required to be isolated. For this emergency operation purpose, the steam may be led direct to the L.P. turbine and either the H.P. or I.P. turbine can exhaust direct to the condenser. Adequate arrangements and controls are to be provided for these operating conditions to ensure that the pressure and temperature of the steam will not exceed those which the turbines and condenser can safely withstand.

b) The necessary pipes and valves for these arrangements are to be readily available and properly marked. A fit up test of all combinations of pipes and valves is to be performed prior to the first sea trials.

c) The permissible power/speeds when operating without one of the turbines (all combinations) is to be specified and information provided on board.

d) The operation of the turbines under emergency conditions is to be assessed for the potential influence on shaft alignment and gear teeth loading conditions.

2.12.3 Single main boiler

a) Ships intended for unrestricted service, fitted with steam turbines and having a single main boiler, are to be provided with means to ensure emergency propulsion in the event of failure of the main boiler.

2.13 Tests and equipment

2.13.1 Stability testing of turbine rotors

a) All solid forged H.P. turbine rotors intended for main propulsion service where the inlet steam temperature exceeds 400°C are to be subjected to at least one thermal stability test. This requirement is also applicable to rotors constructed from two or more forged components joined by welding. The test may be carried out at the forge or turbine builders' works (a) after heat treatment and rough machining of the forging or (b) after final machining, or (c) after final machining and blading of the rotor. The stabilizing test temperature is to be not less than 28°C above the maximum steam temperature to which the rotor will be exposed and not more than the tempering temperature of the rotor material.

b) Where main turbine rotors are subjected to thermal stability tests at both forge and

turbine builders' works the foregoing requirements are applicable to both tests. It is not required that auxiliary turbine rotors be tested for thermal stability, but if such tests are carried out, the requirements for main turbine rotors will be generally applicable.

2.14 Balancing

2.14.1 All rotors as finished-bladed and complete with half-coupling are to be dynamically balanced to the Surveyor's satisfaction, in a machine of sensitivity appropriate to the size of rotor.

2.15 Hydraulic tests

2.15.1 Maneuvering valves are to be tested to twice the working pressure. The nozzle boxes of impulse turbines are to be tested to 1.5 times the working pressure.

2.15.2 The cylinders of all turbines are to be tested to 1.5 times the working pressure in the casing, or to 2.0 bar whichever is greater.

2.15.3 For test purposes, the cylinders may be subdivided with temporary diaphragms for distribution of test pressures.

2.15.4 Condensers are to be tested in the steam space to 1.0 bar. The water space is to be tested to the maximum pressure which the pump can develop at ship's full draught with the discharge valve closed plus 0.7 bar with a minimum test pressure of 2.0 bar. Where the operating conditions are not known, the test pressure is to be not less than 3.4 bar.

2.16 Indicators for movement

2.16.1 Indicators for determining the axial position of rotors relative to their casings, and for showing the longitudinal expansion of casings at the sliding feet, if fitted, are to be provided for main turbines. The latter indicators should be fitted at both sides and be readily visible.

2.17 Weardown gauges

2.17.1 Main and auxiliary turbines are to be provided with bridge weardown gauges for testing the alignment of the rotors.

Section 3

Gas Turbines

3.1 Scope

3.1.1 The requirements of this Section are applicable to gas turbines for main propulsion and to those for essential auxiliary services. These requirements do not apply to exhaust gas turbo-blowers.

3.1.2 The spare gear for gas turbines has not been indicated in view of the variation in turbine design and service conditions. In the circumstances, a list of proposed spare gear is to be submitted for consideration.

3.2 Plans and particulars

3.2.1 Following data is to be submitted:

- Rated power;
- Rated speed;
- Maximum turbine entry temperature at which rated power can be achieved;
- Mass and velocity of rotating elements;
- Balancing data;
- Type test schedule, measurements and data;
- Manufacturer’s shop test schedule.

3.2.2 The following plans are to be submitted for consideration together with particulars of materials.

- General technical specifications including effect of inlet temperature on power;
- General arrangement;
- Sectional assembly;
- Casings;
- Combustion chambers and heat exchangers;
- Gasifiers;

- Regenerators or recuperators;

- Rotors (turbine and compressor), including discs, blades, bearings couplings, and clutches;

- Sections showing blades, blade fastenings and sealings;

- Oil fuel and lubricating oil systems including controls and safety devices;

- Governor arrangements;

- Enclosure configurations (where applicable);

- Starting arrangements;

- Air intake and exhaust system;

- Control systems, safety systems and devices and associated failure mode and effect analysis;

- Details of proposed automatic safety devices to safeguard against hazardous conditions arising in the event of malfunctions in the gas turbine installation together with failure mode and effect analysis(FMEA);

- Vibration monitoring systems; and

- All other critical systems such as fire fighting arrangements for enclosures, ventilation, lighting, smoke detector etc.

3.2.3 Where applicable, plans are to indicate the most onerous pressures and temperatures to which each component is subject.

3.2.4 Details are to be submitted, where applicable, of high temperature characteristics of the materials, including (at the working temperatures) the associated creep rate and rupture strength for the designed service life, fatigue strength, corrosion resistance and scaling properties. Particulars of heat treatment, including stress relief, where applicable, are to be submitted.

3.3 Materials

3.3.1 Rotors and discs are to be of forged steel. For carbon and carbon- manganese steel forgings, the specified minimum tensile strength is to be selected within the limits of 400 and 600 [N/mm^2]. For alloy steel rotor forgings, the specified minimum tensile strength is to be selected within the limits of 500 and 800 [N/mm^2]. For discs and other alloy steel forgings, the specified minimum tensile strength is to be selected within the limits of 500 to 1000 [N/mm^2].

3.3.2 For alloy steels, specifications giving the proposed chemical composition and heat treatment are to be submitted for approval.

3.3.3 When it is proposed to use a material of higher tensile strength, full details are to be submitted for approval.

3.4 Design and construction

3.4.1 All parts of turbines, compressors, etc., are to have clearances and fits consistent with adequate provision for the relative thermal expansion of the various components. Special attention is to be given to minimizing casing and rotor distortion under all operating conditions.

3.4.2 Turbine bearings are to be so disposed and supported that lubrication is not adversely affected by heat flow from adjacent hot parts. Effective means are to be provided for intercepting oil leakage and preventing oil from reaching high temperature glands and casings.

3.4.3 Design basis

a) Calculations of the steady stresses, including the effect of stress raisers, etc., in the turbine and compressor rotors and blading at the maximum speed and temperature in service, are to be submitted for consideration. Such calculations should indicate the designed service life and be accompanied, where possible, by test results substantiating the limiting criteria.

b) Details of calculations and tests to establish the service life of other stressed parts, including gearing (where applicable), bearings, seals, etc., are to be submitted. All calculations and tests should take account of all relevant environmental factors including particular type of service and fuels intended to be used.

3.5 Welded components

3.5.1 Components fabricated by means of welding will be considered for acceptance if constructed by firms whose works are properly equipped to undertake welding of the standards

appropriate to the components according to the relevant requirements of Ch.10.

3.5.2 Before work is commenced, manufacturers are to submit for consideration details of proposed welding procedures and their proposals for routine examination of joints by non-destructive means.

3.5.3 Major joints are to be designed as full-strength welds and for complete fusion of the joint.

3.5.4 Stress relief treatment is to be applied to all cylinders, rotors and associated components on completion of the welding of all joints and attached structures. For details of stress relief procedure, temperature and duration, See Ch.10.

3.5.5 Surveyors are to be satisfied that the desired quality of welding is attainable with the proposed welding equipment and procedure, and for this purpose test specimens representative of the welded joints are to be provided for radiographic examination and mechanical tests as required for steam turbines.

3.6 Vibration

3.6.1 Care is to be taken in the design and manufacture of turbine and compressor rotors, rotor discs and rotor blades to ensure freedom from undue vibration within the operating speed range. Calculations of the critical speeds giving full details of the basic assumptions are to be submitted for consideration. Where critical speeds are found by calculation to occur within the operating speed range, vibration tests may be requested in order to verify the calculations.

3.7 Containment

3.7.1 Consideration should be given to the need for containment, with a view to minimizing and localizing damage, in the event of rotor blade failure.

3.8 Inlet and exhaust systems

3.8.1 The air-inlet system is to be designed to minimize the entrance of harmful foreign matter.

3.8.2 The arrangement of the turbine exhaust system is to be such as to prevent exhaust gases being drawn into the compressors.

3.9 Fuel and salt deposits

3.9.1 When it is intended to burn non-distillate fuels forming harmful deposits, adequate provision should be made for periodic removal of the deposits.

3.9.2 Means for preventing the accumulation of salt deposits in the compressors and turbines are to be provided.

3.9.3 Flow path cleaning or washing system is to be provided, where required by the gas turbine manufacturer. Provision is to be made for periodical cleaning / washing by inhibiting liquids, steam or any other cleaning medium. The details of the arrangements and the associated system are to be submitted for approval.

3.10 Indication of temperature

3.10.1 Means are to be provided for indicating the temperature of the power turbine exhaust gases.

3.11 External influences

3.11.1 Pipes and ducting connected to casings are to be so designed that no excessive thrust loads or moments are applied by them to the compressors and turbines.

3.11.2 Platform gratings and fittings in way of the supports are to be so arranged that casing expansion is not restricted.

3.11.3 Where main turbine seatings incorporating a tank structure are proposed, consideration is to be given to the temperature variation of the tank in service to ensure that turbine alignment will not be adversely affected.

3.11.4 Where the turbine is provided with an acoustic enclosure, this is to act as shield to prevent contamination of machinery spaces from external hazards and contain the heat emission from the gas generator. The enclosure is to be structurally sound and is to be a self-contained unit with arrangements for ventilation, lighting and noise attenuation. The drainage arrangements in the enclosure are to be provided to prevent build up of liquids. A self contained and independent fire fighting system is to be provided for such enclosure. One or more observation window/s is/are to be provided for visual inspection of critical components such as auxiliary gearbox and burner manifold.

3.12 Overhaul life

3.12.1 The overhaul schedule recommended by the manufacturer is to be submitted for consideration.

3.13 Safety arrangements

3.13.1 Overspeed protective devices

a) An overspeed protective device is to be provided for each shaft of main and auxiliary turbines to shut off the fuel automatically, near the burners, to prevent a dangerous overspeed condition of the shaft, except where it can be established that such a condition cannot arise.

b) The overspeed device should normally be set to operate when the speed of the line exceeds the rated maximum speed by 15 per cent.

3.13.2 Speed governors

a) Where a main propulsion installation incorporates a reverse gear, electric transmission or controllable (reversible) pitch propeller, a speed governor, independent of the overspeed protective device, is to be fitted and is to be capable of controlling the speed of the unloaded power turbine without bringing the overspeed protective device into action.

b) Where an auxiliary turbine is intended for driving an electric generator, a speed governor, independent of the overspeed protective device, is to be fitted which, with fixed setting, is to control the speed within 10 per cent momentary variation and 5 per cent permanent variation when full load is suddenly taken off or put on. The permanent speed variation of a.c. machines intended for parallel operations are to be equal within a tolerance of 0.5 per cent.

3.13.3 The following turbine services are to be provided with automatic temperature controls so as to maintain steady state conditions throughout the normal operating range of the main turbine:

- lubricating oil system;
- oil fuel supply (or automatic control of oil fuel viscosity as an alternative); and
- exhaust gas.

3.13.4 Alarms and automatic shutdown devices are to be provided in accordance with Table 3.13.1. Although in principle alarming devices listed in Table 3.13.1 are to be provided, they can be added or omitted, taking into account the result of FMEA specified in item 3.2.2.

3.13.5 Hand trip gear for shutting off the fuel in an emergency is to be provided locally at the turbine control platform and where applicable, at the centralized control station.

3.13.6 All non-mobile gas turbines are to be provided with independent, self contained suitable foam or CO_2 or water mist fire fighting system with detection ability to give warning automatically at local and remote control positions when activated. This system is to be distinctly separate from the fire fighting arrangements in the machinery space. The arrangements together with calculations showing the capacities of the cylinders is to be submitted for approval.

3.13.7 Inlet and exhaust silencers are to be fitted to limit the sound power level at one meter from the gas turbine system to 110 dB for unmanned machinery spaces or to 90 dB for manned machinery spaces.

3.14 Starting arrangements

3.14.1 Means are to be provided, preferably automatic or interlocked, to clear all parts of the gas turbine of the accumulation of liquid fuel, or for purging gaseous fuel, before ignition commences on starting, or recommences after failure to start.

3.14.2 The starting arrangements can be pneumatic, hydraulic or electric. The starting air pipes system, safety fittings and number of starts are to comply with the requirements for oil engines as given in Section 4.11.

3.14.3 Starting devices are to be so arranged that firing operation is discontinued and main fuel valve is closed within pre-determined time in case of ignition failure.

Table 3.13.1 : List of alarms and shutdown

Monitoring parameter	Alarm	Automatic Shutdown
Turbines speed	High value	Yes
Lubricating oil pressure	Low value*	Yes
Lubricating oil pressure of reduction gear	Low value*	Yes
Differential pressure across lubricating oil filter	High value	
Lubricating oil temperature	High value	
Oil fuel supply pressure	Low value	
Oil fuel temperature	High value	
Cooling medium temperature	High value	
Bearing temperature	High value	
Flame and ignition failure	Activated	Yes
Automatic starting failure	Activated	
Vibration	High value*	Yes
Axial displacement of rotor	High value	Yes
Exhaust gas temperature	High value*	Yes
Vacuum pressure at the compressor inlet	High value*	Yes
Loss of control system	Activated	

Notes:

1. Alarms marked with "*" are to be activated at the suitable setting points prior to arriving the critical condition for the activation of shutdown devices.

3.14.4 Where the gas turbine is arranged for air starting, the total air receiver capacity is to be sufficient to provide, without replenishment, not less than six consecutive starts. At least two air receivers of equal capacity are to be provided. For details of air receivers, see Chapter 5. For multi engine installations three consecutive starts per engine are required.

3.15 Tests

3.15.1 Balancing

a) The rotors as finished-bladed and complete with half-coupling are to be dynamically balanced to the Surveyor's satisfaction, in a machine of sensitivity appropriate to the size of rotor.

3.15.2 Hydraulic tests

a) All casings are to be tested to a hydraulic pressure equal to 1.5 times the highest pressure in the casing during normal operation or 1.5 times the pressure during starting, whichever is the higher. For test purposes if necessary, the casings may be subdivided with temporary diaphragms for distribution of test pressure.

b) Where hydraulic tests cannot be carried out, the manufacturers are to submit, for approval, alternative proposals for determining the soundness of the component.

c) Inter coolers and heat exchangers are to be tested to 1.5 times the maximum working pressure on each side separately.

3.16 Shop trials

3.16.1 Upon completion of fabrication and assembly, each gas turbine is to be subjected to a shop trial in accordance with the manufacturer's test schedule, which is to be submitted for review before the trial. During the trial, the turbine is to be brought up to its over speed limit to enable testing of the overspeed protective device.

3.17 Electric starting

3.17.1 Where main turbines are fitted with electric starters, two batteries are to be fitted. Each battery is to be capable of starting the turbines when cold and the combined capacity is to be sufficient without recharging to provide the number of starts of the main turbines as required by 3.14.4.

3.17.2 Electric starting arrangements for auxiliary turbines are to have two separate batteries or be supplied by separate circuits from the main turbine batteries when such are provided. Where one of the auxiliary turbines only is fitted with an electric starter one battery will be acceptable.

3.17.3 The combined capacity of the batteries for starting the auxiliary turbines is to be sufficient for at least three starts for each turbine.

3.17.4 The requirements for battery installations are given in Pt.4, Ch.8.

3.18 Type testing of gas turbine

3.18.1 Type tests are to be carried out in accordance with the agreed test programme on a representative machine comprising gas generator and power turbine and are to be witnessed by IRS surveyor. It may be carried out at the manufacturer's works or at any establishment having suitable facilities acceptable to IRS.

3.18.2 Where the gas turbine unit can be separated conveniently into a gas generator and a power turbine, the type test is to include an initial test of the gas generator to ascertain that the fuel consumption and gas horse power are within ±2.5% of design maximum conditions at rated speed.

3.18.3 After completion of the initial test of the gas generator, the gas generator and power turbine are to be assembled together and prepared for the gas turbine type test.

3.18.4 On the over speed test, a propulsion gas generator is to be run at not less than 10% in excess of gas generator speed corresponding to specified full power of the gas turbine engine for not less than 10 minutes continuously and the power turbine disconnected from the dynamometer is to be run at not less than 15% in excess of the maximum designed speed for not less than 10 minutes continuously.

3.18.5 Where it is impracticable to overspeed the complete installation, each rotor, completely bladed and with all relevant parts such as half-couplings, shall be overspeed tested individually at the appropriate speed.

3.18.6 During the type tests at specified full power the pressure and temperature of the gas at outlet from the gas generator is to be recorded and the gas mass flow is to be assessed from air flow and fuel flow measurements.

3.18.7 During the type tests the following features are to be demonstrated:

i) Freedom from air and gas leaks.
ii) Operation of starting arrangements.
iii) Effectiveness of interlocks, if fitted.
iv) Satisfactory lubricating oil and fuel oil system characteristics.
v) Wet and dry motoring.
vi Engine start following a failure to start.
vii) Operation of engine cleaning system.
viii) Reliability of operation at minimum idling speed.

3.18.8 Starting tests are to be carried out to determine:

i) Time to light from cold.
ii) Time to reach idling speed from cold.
iii) Time to reach full output from idling speed.
iv) That the required number of starts can be obtained from the specified starting air bottle capacity.
v) The minimum pressure to ensure a cold start is to be established.

- A cold start is defined as a start after 2 hours or more of natural cooling with the engine at rest.

- A warm start is defined as a start within 15 minutes of shutting down after the engine has been running for not less than two hours.

- An intentional failure to start is defined as the performance of a normal starting sequence with the ignition system deliberately rendered inoperative.

Note : i), ii), iii) and iv) are to be average of four readings.

Section 4

Internal Combustion Engines

4.1 Scope

4.1.1 The requirements of this Section apply to conventional type of internal combustion engines used as prime movers for main propulsion and for essential auxiliary machinery.

4.1.2 The approval of IC Engines is covered in detail in the IRS *Classification Note "Approval of I.C Engines"*. The document flow between the engine designer, IRS Plan Approval Centre, engine builder/ licensee and IRS Surveyors is indicated in the Classification Note. The Classification Note also covers the procedure to be followed for certification of engine components. The requirements with regard to design approval, type testing and certification of turbochargers and their matching on engines is also indicated in the Classification Note (Also refer Cl. 4.11.4).

4.1.3 Engines below 100[kW] including gear boxes used for propulsion and for essential auxiliary machinery may be accepted based on certificate from approved manufacturers. Engines of 100 [kW] and over including gear boxes used for propulsion and for essential auxiliary machinery, are to be type approved and undergo unit certification. Unit certification may be exempted for those engines approved in accordance with the Alternative Certification Scheme of IRS (Refer Pt. 1, Ch. 1, Sec. 4).

4.2 Materials and material testing

4.2.1 Materials used for the construction of oil engines are to comply with the requirements of Pt.2 in so far as applicable. Other materials will be specially considered.

4.2.2 The specified minimum tensile strength of castings and forgings for crankshafts is to be selected within the following general limits:

a) Carbon and carbon-manganese steel castings 400 - 550 [N/mm^2];

b) Carbon and carbon manganese steel forgings (normalized and tempered) : 400 - 600 [N/mm^2];

c) Carbon and carbon-manganese steel forgings (quenched and tempered) : not exceeding 700 [N/mm^2];

d) Alloy steel castings : not exceeding 700 [N/mm^2];

e) Alloy steel-forgings : not exceeding 1000 [N/mm^2];

f) Spheroidal or nodular graphite iron castings: 370 - 800 [N/mm^2].

4.2.3 Where it is proposed to use alloy steel castings, forgings or iron castings for crankshafts, details of the chemical composition, heat treatment and mechanical properties are to be submitted for approval.

4.2.4 Documentation required to be submitted for certification of engine components including their materials are indicated in the IRS *Classification Note "Approval of I.C Engines"*.

4.3 Crankshaft design

4.3.1 Detailed analysis to prove the design of the crankshaft is to be submitted for consideration. Classification Notes on design of crankshafts may be followed in this regard. Manufacturers may also be required to submit detailed analysis for special design features, e.g. serrations in connecting rods and bearing caps.

4.4 Design and construction

4.4.1 The design and construction is to be such as to enable the oil engine to meet the general requirements with regard to environmental conditions, functional capability and reliability.

4.4.2 Cylinders, cylinder liners, cylinder covers, pistons and other parts subject to high temperature or pressure are to be of material suitable for the stress and temperature to which they are exposed.

4.4.3 The engine bedplate or crankcase is to be of rigid and oil-tight construction. The bedplate is to be provided with sufficient number of holding down bolts to effectively secure it to the engine seatings.

4.4.4 Transverse girders, cylinder blocks and columns, when of fabricated construction, are normally to be stress-relieved after welding.

4.4.5 Crankcases and their doors are to be of robust construction and the doors are to be securely fastened so that they will not be readily displaced by an explosion taking into account the installation of explosion relief valve as required by 4.6.

4.4.6 Piston rod glands, which are subjected to pressure from scavenging air, are to be of a design ensuring that air will not leak into the crankcase.

4.5 Crankcase ventilation

4.5.1 Ventilation of crankcase and any arrangement which could produce a flow of external air within the crankcase, is in general not permitted except for dual fuel engines where crankcase ventilation is to be provided in accordance with 4.13.1.3. If forced extraction of the gases from crankcase is provided (e.g. for smoke-detection purposes), the vacuum in the crankcase is not to exceed 25 [mm] of water column.

4.5.2 Crankcase ventilation pipes where provided are to be as small as practicable to minimize the in rush of air after crankcase explosion.

4.5.3 To avoid interconnection between crankcases and the possible spread of fire following an explosion, crankcase ventilation pipes and oil drain pipes for each engine are to be independent of each other.

4.6 Safety devices

4.6.1 For crankcase:

4.6.1.1 Crankcases are to be provided with light weight spring-loaded valves or other quick-acting and self closing devices, of an approved type, to relieve the crankcases of pressure in the event of an internal explosion and to prevent any inrush of air thereafter. The valves are to be designed to open at a pressure not greater than 0.2 bar.

4.6.1.2 The valve lids are to be made of ductile material capable of withstanding the shock of contact with stoppers at the full open position. The discharge from the valves is to be shielded by flame guard or flame trap to minimise the possibility of danger and damage arising from the emission of flame.

4.6.1.3 Crankcase explosion relief valves are to be type tested in a configuration that represents the installation arrangements that will be used on an engine, in accordance with IRS Classification Notes on “Guidance for Type Testing of Crankcase Explosion Relief Valves”.

4.6.1.4 Where crankcase relief valves are provided with arrangements for shielding emissions from the valve following an explosion, the valve is to be type tested to demonstrate that the shielding does not adversely affect the operational effectiveness of the valve.

4.6.1.5 Crankcase explosion relief valves are to be provided with a copy of manufacturer’s installation and maintenance manual that is specific to the size and type of valve being supplied for installation on a particular engine. The manual is to contain the following information:

- Description of valve with details of function and design limits.
- Copy of type test certificate.
- Installation instructions.
- Instructions for testing and renewal of any sealing arrangements.
- Actions required after a crankcase explosion.

4.6.1.6 A copy of the installation and maintenance manual required by 4.6.1.5 is to be provided on board ship.

4.6.1.7 Plans / documentation showing details and arrangements of crankcase explosion relief valves are to be submitted for approval, as indicated in the IRS *Classification Note “Approval of I.C Engines”*.

4.6.1.8 Valves are to be provided with suitable markings that include the following information:

- Name and address of manufacturer
- Designation and size
- Month / Year of manufacture
- Approved installation orientation.

4.6.1.9 In engines having cylinders not exceeding 200 [mm] bore and having a crankcase gross volume not exceeding 0.6 [m^3], relief valves may be omitted.

4.6.1.10 In engines having cylinders exceeding 200 [mm] bore, but not exceeding 250 [mm] bore, at least two relief valves are to be fitted, each valve is to be located at or near the ends of the crankcase. Where the engine has more than 8 crank throws an additional valve is to be fitted near the center of the engine.

4.6.1.11 Engines, with cylinder bores exceeding 250 [mm], but not exceeding 300 [mm], are to have at least one relief valve in way of each alternate crank throw, with a minimum of two relief valves.

4.6.1.12 In engines having cylinders exceeding 300 [mm] bore, at least one relief valve is to be fitted in way of each main crank throw.

4.6.1.13 Additional relief valves are to be fitted for separate spaces on the crankcase, such as gear or chain cases for camshaft or similar drives, when the gross volume of such spaces exceeds 0.6 [m^3].

4.6.1.14 The free area of each crankcase relief valve is not to be less than 45 [cm^2]. The combined free area of the relief valves fitted on the engine is not to be less than 115 [cm^2/m^3] of the crankcase volume.

The free area of the relief valve is the minimum flow area at any section through the valve, when the valve is fully open.

When calculating the gross volume of the crankcase, the volume of stationary parts within the crankcase may be deducted.

4.6.1.15 A warning notice is to be fitted in a prominent position, preferably on a crankcase door on each side of the engine, or alternatively at the engine room control location. This warning notice is to specify that whenever overheating is suspected in the crankcase, the crankcase doors or sight holes are not to be opened until a reasonable time has elapsed after stopping the engine, sufficient to permit adequate cooling within the crankcase.

4.6.1.16 Where crankcase oil mist detection arrangements are to be fitted to engines (as per Pt.4, Ch.7 and Pt.5, Ch.22) they are to be of a type approved by IRS and tested in accordance with Note 1) and comply with 4.6.1.17 to 4.6.1.28. Engine bearing temperature monitors or equivalent devices used as safety devices are to be type approved by IRS for such purposes.

Note 1) : Classification Notes – “Type approval of crankcase oil mist detection and alarm equipment”.

4.6.1.17 The oil mist detection system and arrangements are to be installed in accordance with the manufacturer’s and engine designer’s instructions / recommendations. The following particulars are to be included in the instructions:

- Schematic layout of engine oil mist detection and alarm system showing location of engine crankcase sample points and piping or cable arrangements together with dimensions of the pipe to the detector.

- Evidence of study to justify the selected location of sample points and sample extraction rate (if applicable) in consideration of the crankcase arrangements and geometry and the predicted, crankcase atmosphere where oil mist can accumulate.

- The manufacturer’s maintenance and test manual.

- Information relating to type or in-service testing of the engine with engine protection system test arrangements having approved types of oil mist detection equipment.

4.6.1.18 A copy of the oil mist detection equipment maintenance and test manual required by 4.6.1.17 is to be provided on board ship.

4.6.1.19 Oil mist detection and alarm information is to be capable of being read from a safe location away from the engine.

4.6.1.20 Each engine is to be provided with its own independent oil mist detection arrangement and a dedicated alarm.

4.6.1.21 Oil mist detection and alarm systems are to be capable of being tested on the test bed and onboard under engine at standstill and engine running at normal operating conditions in accordance with test procedures that are acceptable to IRS.

4.6.1.22 Alarms and shutdowns for the oil mist detection system are to be in accordance with Pt.5, Ch.22, Sec.3 and the system arrangements are to comply with Pt.5, Ch.22, Sec.2.

4.6.1.23 The oil mist detection arrangements are to provide an alarm indication in the event of a foreseeable functional failure in the equipment and installation arrangements.

4.6.1.24 The oil mist detection system is to provide an indication when any lenses fitted in the equipment and used in determination of the oil mist level have been partially obscured to a degree that will affect the reliability of the information and alarm indication.

4.6.1.25 Where oil mist detection equipment includes the use of programmable electronic systems, the arrangements are to be in accordance with the rule requirements for such systems.

4.6.1.26 Plans of showing details and arrangements of oil mist detection and alarm arrangements are to be submitted for approval in accordance with Pt.4, Ch.7.

4.6.1.27 The equipment together with detectors is to be tested when installed on the test bed and on board ship to demonstrate that the detection and alarm system functionally operates. The testing arrangements are to be to the satisfaction of IRS.

4.6.1.28 Where sequential oil mist detection arrangements are provided the sampling frequency and time is to be as short as reasonably practicable.

4.6.1.29 Where alternative methods are provided for the prevention of the build-up of oil mist that may lead to a potentially explosive condition within the crankcase details are to be submitted for consideration. The following information is to be included in the details:

- Engine particulars – type, power, speed, stroke, bore and crankcase volume.

- Details of arrangements to prevent the build up of potentially explosive conditions within the crankcase, e.g. bearing temperature monitoring, oil splash temperature, crankcase pressure monitoring, recirculation arrangements.

- Evidence to demonstrate that the arrangements are effective in preventing the build up of potentially explosive conditions together with details of in-service experience.

- Operating instructions and the maintenance and test instructions.

4.6.1.30 Where it is proposed to use the introduction of inert gas into crankcase to minimize a potential crankcase explosion, details of the arrangements are to be submitted to IRS for consideration.

4.6.2 Scavenge spaces:

4.6.2.1 Scavenge spaces in open connection to the cylinders are to be fitted with relief valves. The valves are to open quickly in case of an explosion.

4.6.2.2 For crosshead type engines, scavenge spaces in open connection to the cylinders are to be provided with an approved fire extinguishing system, which is to be entirely separate from the fire extinguishing system of the engine room.

4.6.3 Cylinders:

4.6.3.1 Cylinder relief valves are to be fitted to engines having cylinders over 230 [mm] bore. The valves are to open at a pressure not exceeding 40 per cent above the designed maximum pressure and are to discharge where no damage can occur. Consideration will be given to any other alternative relief arrangement.

4.6.3.2 In the case of auxiliary engines, consideration will be given to the replacement of the relief valve by an efficient warning device of over pressure in the cylinders.

4.6.4 Lubrication system:

4.6.4.1 The lubricating oil drain pipes from the engine sump to drain tank are to be taken down as low as possible, to ensure that their outlet ends are submerged at all times. Where two or more engines are installed, vent pipes, if fitted, and lubricating oil drain pipes are to be installed independently of each other to prevent intercommunication between crankcases.

4.6.5 Fuel systems:

4.6.5.1 All external high-pressure fuel delivery lines between the high-pressure fuel pumps and fuel injectors are to be protected with a jacketed piping system capable of containing fuel from a high-pressure line failure. A

jacketed pipe incorporates an outer pipe into which the high-pressure fuel pipe is placed, forming a permanent assembly. The jacketed piping system is to include means for collection of leakages and arrangements provided for an alarm to be given of a fuel line failure. However, this requirement need not be applied for engines intended to be fitted on board non-passenger vessels of less than 500 GT.

4.6.5.2 Components of a diesel engine fuel system is to be designed considering the maximum peak pressure which will be experienced in service, including any high pressure pulses which are generated and transmitted back into the fuel supply and spill lines by the action of fuel injection pumps. Connections within the fuel supply and spill lines are to be constructed having regard to their ability to prevent pressurized oil fuel leaks while in service and after maintenance.

4.6.6 Starting air:

4.6.6.1 In order to protect air main against explosion arising from improper functioning of starting valves, the following are to be fitted:

a) an isolating non-return valve or equivalent at the starting air supply connection to each engine;

b) a bursting disc or flame arrestor in way of the starting valve of each cylinder for direct reversing engines having a main starting manifold or at the supply inlet to the starting air manifold for non-reversing engines.

4.6.6.2 Bursting disc or flame arrestor may be omitted for engines having a bore not exceeding 230 [mm], or where the power of the engine is less than 1100 [kW].

4.6.7 Overspeed protective devices:

4.6.7.1 Each main engine developing 220 [kW] or over, which can be declutched or which drives a controllable pitch propeller, also each auxiliary engine developing 220 [kW] and over for driving an electric generator, is to be fitted with an approved overspeed protective device.

4.6.7.2 The overspeed protective device, including its driving mechanism is to be independent of the governor required by 4.7 and is to be so adjusted that the speed does not exceed that for which the engine and its driven machinery are to be classed by more than 20 per cent for main engines and 15 per cent for auxiliary engines.

4.7 Governing

4.7.1 For main propulsion engines:

An efficient governor is to be fitted to each main engine and so adjusted that the speed of the engine does not exceed that for which the engine is to be classed by more than 15 per cent.
When electronic speed governors of main engines form part of a remote control system, they are to comply with the following:

a) if lack of power to the governor may cause major and sudden changes in the preset speed and direction of the thrust of the propeller, back up power supply is to be provided;

b) local control of engines is always to be possible;

c) electronic speed governor and its actuators are to be type tested as per *IRS Classification Notes "Type Approval of Electrical Equipment used for Control, Monitoring, Alarm and Protection Systems for use in Ships; and*

d) Also refer requirements of *IRS Classification Notes "Approval of I.C. Engines".*

4.7.2 For auxiliary engines:

Governors on diesel engines driving main or emergency electric generators are to be capable of automatically maintaining the speeds and frequency within following limits:

a) Transient frequency variations within 10% of the rated frequency with a recovery time to steady state conditions not exceeding 5 seconds, when the maximum electrical step load is switched on or off;

b) Momentary variations of 10 per cent of the maximum rated speed when the rated load of the generator is suddenly thrown off, provided this does not cause the intervention of the overspeed device;

c) Momentary variations of 10 per cent of the maximum rated speed when 50 per cent of the rated load is suddenly thrown on followed by the remaining 50 per cent load after an interval sufficient to restore the speed to steady state. Steady state conditions should be achieved in not more than 5 seconds;

Note : Steady state conditions are those at which the envelope of speed variation does not exceed +1% of the declared speed at the new power.

d) At all loads between no load and rated load the permanent speed variation is not to be more than 5 per cent of the maximum rated speed;

e) For generating sets operating in parallel, the governing characteristics of the engine are to be such that within the limits of 20 per cent and 100 per cent of total load, the load on any generating set does not normally differ from its proportionate share of the total load by more than

   i) 15 per cent of the rated output of the largest machine; or
   ii) 25 per cent of the rated output of the individual machine in question, whichever is less;

f) For generating sets intended to operate in parallel, it is to be possible to adjust the governor so that the load is kept within 5 per cent of the rated load at normal frequency;

g) For alternating current installations, the permanent speed variation of the machines intended for parallel operations are to be equal within a tolerance of $\pm$ 0.5 per cent.

h) Application of electrical load in more than 2 load steps (See Fig.4.7.2 for guidance on maximum possible sudden power increase in 4-stroke diesel engines) can only be permitted on the condition that

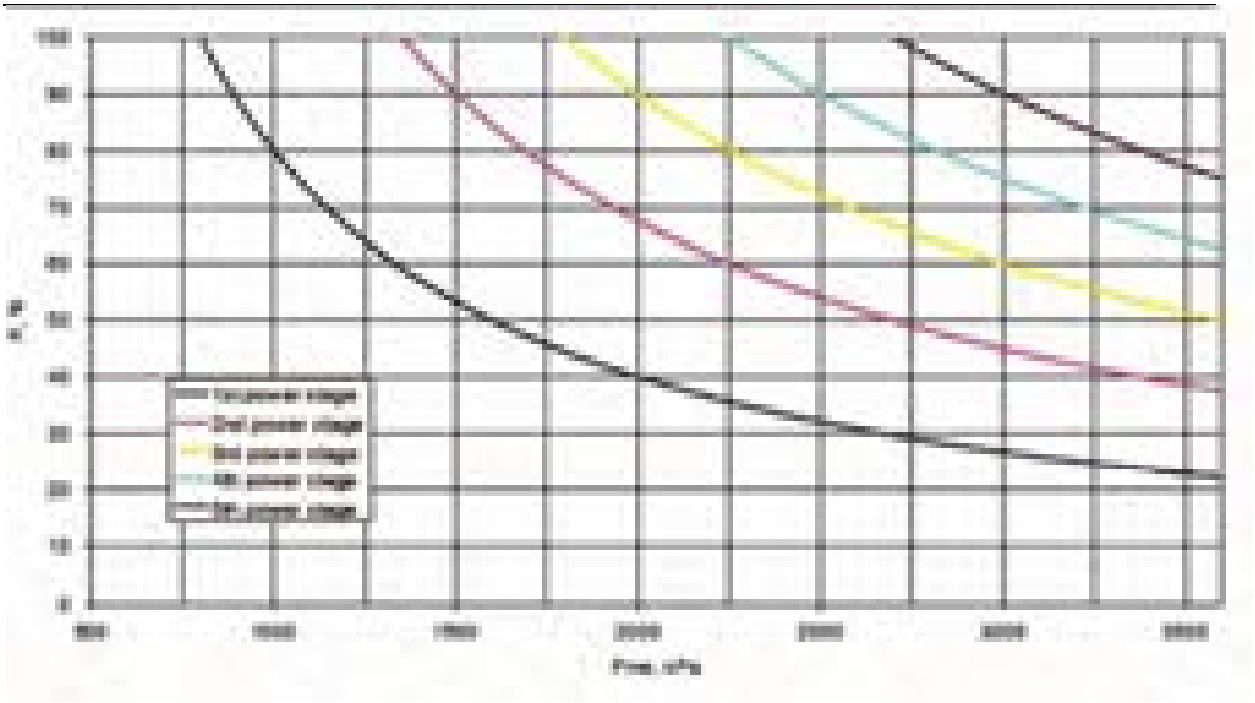
   - the design of the ship's electrical system enables the use of such generator sets
   - such a provision is made in the design stage and same is approved while scrutinising the drawings
   - the safety of the ship's electrical system in the event of parallel operation and failure of a generator is to be demonstrated at ship's trials.

4.7.3 Emergency generator sets must satisfy the above governor conditions even when :

a) their total consumer load is applied suddenly, or

b) their total consumer load is applied in steps, subject to following:

   - the total load is supplied within 45 seconds since power failure of the main switchboard
   - the maximum step load is declared and demonstrated
   - the power distribution system is designed such that the declared maximum step loading is not exceeded
   - the compliance of time delays and loading sequence with the above is to be demonstrated at the time of ship’s trials.



Legend :

Pme : Declared mean effective pressure
P : Power increase referred to declared power at site conditions
1 : First power stage
2 : Second power stage
3 : Third power stage
4 : Fourth power stage
5 : Fifth power stage

Fig. 4.7.2: Reference values for maximum possible sudden power increases as a function of brake mean effective pressure, Pme, at declared power (four-stroke diesel engines)

4.8 Oil fuel, lubricating oil, cooling water and exhaust gas systems

4.8.1 Oil fuel, lubricating oil and cooling water piping systems are to comply with the requirements of Ch.3 in so far as these are applicable.

4.8.2 Exhaust pipes which are led overboard near the waterline are to be protected against the possibility of water finding its way inboard. Where the exhaust is cooled by water spray, the exhaust pipes are to be self-draining overboard.

4.8.3 Exhaust pipes of two or more engines are not to be connected together, but are to be led separately to the atmosphere unless arranged to prevent the return of gases to an idle engine.

4.9 Engine starting arrangements

4.9.1 First start arrangement:

4.9.1.1 Equipments for starting the main and auxiliary engines are to be provided so that the necessary initial charge of starting air or initial electric power can be developed on board ship without external aid. If for this purpose an emergency air compressor or electric generator is required, these units are to be power driven by hand starting oil engines or steam engines, except in the case of small installations where a hand operated compressor of approved capacity may be accepted. Alternatively, other devices of approved type may be accepted as a means of providing the initial start.

4.9.2 Compressed air starting systems:

4.9.2.1 Two or more starting and maneuvering air compressors of sufficient total capacity for the requirements of the main engines are to be fitted. At least one of the compressors is to be driven independent of the main propulsion unit. The capacity of one of the said independently driven compressors or the combined capacity

of independently driven compressors are not to be less than 50 per cent of the total required capacity. The total capacity of air compressors is to be sufficient to supply within one hour the quantity of air needed to satisfy the requirement of 4.9.2.9 by charging the receivers from atmospheric pressure. The main air compressors are to be of approximately the same size.

4.9.2.2 The compressors are to be so designed that the temperature of the air discharged to the starting air receivers will not substantially exceed 93°C in service. A small fusible plug or an alarm device operating at 121°C is to be provided on each compressor to give warning of excessive air temperature. The emergency air compressor need not comply with these requirements.

4.9.2.3 Each compressor is to be fitted with a safety valve so proportioned and adjusted that accumulation of pressure, with the outlet valve closed, will not exceed 10 per cent of the maximum working pressure.

4.9.2.4 The castings of the cooling water spaces are to be fitted with a safety valve or bursting disc so that ample relief will be provided in the event of the bursting of an air cooler tube.

4.9.2.5 Air compressor inlets are to be located in an atmosphere reasonably free from oil vapour or, alternatively, an air duct from outside the machinery space is to be led to the compressors.

4.9.2.6 The air discharge pipe from the compressors is to be led direct to the starting air receivers. Provision is to be made for intercepting and draining oil and water in the air discharge for which purpose a separator or filter is to be fitted in the discharge pipe between compressors and receivers.

4.9.2.7 The starting air pipe system from air receivers to main and auxiliary engines is to be entirely separate from the compressor discharge system. Stop valves on the air receivers are to permit slow opening to avoid sudden pressure rises in the piping system. Valve chests and fittings in the piping systems are to be of ductile material.

4.9.2.8 Drain valves for removing accumulations of oil and water are to be fitted on compressors, separators, filters and air receivers. In the case of any low-level pipelines, drain valves are to be fitted to suitably located drain pots or separators.

4.9.2.9 The total air receiver capacity is to be sufficient to provide, without replenishment, number of starts as per Table 4.9.1.

a) If starting system serves two or more of the above specified purposes, the capacity of the system is to be the sum of the capacity required.

b) At least two air receivers of about equal capacity are to be provided.

Table 4.9.1 : Number of starts of engines

Duty of engine	No. of starts
Propulsion engines – reversible	12 consecutive starts alternating between Ahead and Astern of each engine
Propulsion engines - non-reversible, connected to a controllable pitch propeller or other device enabling the start without opposite torque	6 starts for each engine
Engines for driving electric generators and emergency generators and engines for other purposes	3 starts for each engine

4.9.3 Electric starting

4.9.3.1 Where main engines are fitted with electric starters, two batteries are to be fitted. The arrangement is to be such that batteries cannot be connected in parallel.

4.9.3.2 Each battery is to be capable of starting the engines when in cold and ready to start conditions. The combined capacity is to be sufficient without recharging to provide within 30 minutes the number of starts of the main engines as required by 4.9.2.9.

4.9.3.3 The electric starting arrangements for auxiliary engines are to have two separate batteries or may be supplied by separate circuits from main engine batteries when such are provided. In case of a single auxiliary engine, only one battery is required.

4.9.3.4 The starting batteries are to be used for starting and engine's own monitoring purposes only. Provision is to be made to maintain continuously the stored energy at all times.

4.10 Type testing of oil engines

4.10.1 General

4.10.1.1 Requirements for Type Testing of Oil Engines are specified in *Classification Note "Approval of I.C Engines"*. The documentation required and document flow between the engine designer, IRS Plan Approval Centre, engine builder/ licensee and IRS Surveyors is also indicated in the Classification Note.

4.10.1.2 Upon finalization of the engine design for production of every new engine type intended for the installation on board ships, one engine is to be presented for type testing, as detailed in the IRS *Classification Note "Approval of I.C Engines"*.

4.11 Factory Acceptance Test

4.11.1 Safety Precautions

4.11.1.1 Before any test run is carried out, all relevant equipment for the safety of attending personnel is to be made available by the manufacturer / shipyard and is to be operational.

4.11.1.2 This applies especially to crankcase explosive conditions protection, but also to over-speed protection and any other shut down function.

4.11.1.3 The overspeed protective device is to be set to a value, which is not higher than the overspeed value that was demonstrated during the type test for that engine. This set point will be verified by the surveyor.

4.11.2 General

4.11.2.1 Before any official testing, the engines are to be run-in as prescribed by the engine manufacturer.

4.11.2.2 Adequate test bed facilities for loads as required in 4.11.3.7 are to be provided. All fluids used for testing purposes such as fuel, lubrication oil and cooling water are to be suitable for the purpose intended, e.g. they are to be clean, preheated if necessary and cause no harm to engine parts. This applies to all fluids used temporarily or repeatedly for testing purposes only.

4.11.2.3 The testing consists of workshop and shipboard (quay and sea trial) testing.

4.11.2.4 Engines are to be inspected for:

- Jacketing of high-pressure fuel oil lines including the system used for the detection of leakage.
- Screening of pipe connections in piping containing flammable liquids.
- Insulation of hot surfaces by taking random temperature readings that are to be compared with corresponding readings obtained during the type test. This is to be done while running at the rated power of engine. Use of contact thermometers may be accepted at the discretion of the attending Surveyor. If the insulation is modified subsequently to the Type Approval Test, IRS may request temperature measurements as required by *Classification Note "Approval of I.C Engines" 2.8.9.*

4.11.2.5 These inspections are normally to be made during the works trials by the manufacturer and the attending surveyor, but at the discretion of IRS parts of these inspections may be postponed to the shipboard testing.

4.11.3 Works trials

4.11.3.1 The purpose of the works trials is to verify design premises such as power, safety against fire, adherence to approved limits (e.g.

maximum pressure), and functionality and to establish reference values or base lines for later reference in the operational phase.

4.11.3.2 The following environmental test conditions are to be recorded:

- Ambient air temperature
- Ambient air pressure
- Atmospheric humidity

4.11.3.3 For each required load point, the following parameters are normally to be recorded:

- Power and speed
- Fuel index (or equivalent reading)
- Maximum combustion pressures (only when the cylinder heads installed are designed for such measurement).
- Exhaust gas temperature before turbine and from each cylinder (to the extent that monitoring is required in *Classification Note "Approval of I.C Engines"* Sec 4 and Pt 5, Ch 22)
- Charge air temperature
- Charge air pressure
- Turbocharger speed (to the extent that monitoring is required in *Classification Note "Approval of I.C Engines" Sec 4*)

4.11.3.4 Calibration records for the instrumentation are, upon request, to be presented to the attending Surveyor.

4.11.3.5 For all stages at which the engine is to be tested, the pertaining operational values are to be measured and recorded by the engine manufacturer. All results are to be compiled in an acceptance protocol to be issued by the engine manufacturer. This also includes crankshaft deflections if considered necessary by the engine designer.

4.11.3.6 In each case, all measurements conducted at the various load points are to be carried out at steady state operating conditions. However, for all load points provision should be made for time needed by the Surveyor to carry out visual inspections. The readings for MCR, i.e. 100% power (rated maximum continuous power at corresponding rpm) are to be taken at least twice at an interval of normally 30 minutes.

4.11.3.7 Test loads for various engine applications are given in Tables below. In addition, the scope of the trials may be expanded depending on the engine application, service experience, or other relevant reasons.

Note:
Alternatives to the detailed tests may be agreed between the manufacturer and IRS when the overall scope of tests is found to be equivalent.

Table 4.11.3.7 (a) : Propulsion engines driving propeller or impeller only

A)	100% power (MCR) at corresponding speed n_0 :	At least 60 [min]
B)	110% power at engine speed $1.032n_0$ Note: Only required once for each different engine/turbocharger configuration.	Records to be taken after 15 [min] or after steady conditions have been reached, whichever is shorter
C)	Approved intermittent overload (if applicable)	Testing for duration as agreed with the manufacturer
D)	90% (or normal continuous cruise power), 75%, 50%, and 25% power in accordance with the nominal propeller curve, the sequence to be selected by the engine manufacturer.	
E)	Reversing manoeuvres (if applicable)	

Note:
After running on the test bed, the fuel delivery system is to be so adjusted that overload power cannot be given in service, unless intermittent overload power is approved by IRS. In that case, the fuel delivery system is to be blocked to that power.

Table 4.11.3.7 (b) : Engines driving generators for electric propulsion and Engine driving generators for auxiliary purposes		
A)	100% power (MCR) at corresponding speed n_0 :	At least 60 [min]
B)	110% power at engine speed n_0	15 [min] - after having reached steady conditions
C)	Governor tests for compliance with 4.7 are to be carried out.	
D)	75%, 50%, and 25% power and idle, the sequence to be selected by the engine manufacturer.	

Note:
After running on the test bed, the fuel delivery system is to be adjusted so that full power plus a 10% margin for transient regulation can be given in service after installation onboard.
The transient overload capability is required so that the required transient governing characteristics are achieved also at 100% loading of the engine, and also so that the protection system utilised in the electric distribution system can be activated before the engine stalls.

Table 4.11.3.7 (c) : Propulsion engines also driving power take off (PTO) generator		
A)	100% power (MCR) at corresponding speed n_0 :	At least 60 [min]
B)	110% power at engine speed n_0	15 [min] - after having reached steady conditions
C)	Approved intermittent overload (if applicable)	Testing for duration as agreed with the manufacturer.
D)	90% (or normal continuous cruise power), 75%, 50% and 25% power in accordance with the nominal propeller curve or at constant speed n_0, the sequence to be selected by the engine manufacturer.	

Note:
After running on the test bed, the fuel delivery system is to be adjusted so that full power plus a margin for transient regulation can be given in service after installation onboard. The transient overload capability is required so that the electrical protection of downstream system components is activated before the engine stalls. This margin may be 10% of the engine power but at least 10% of the PTO power.

Table 4.11.3.7 (d) : Engines driving auxiliaries		
A)	100% power (MCR) at corresponding speed n_0 :	At least 30 [min]
B)	110% power at engine speed n_0	15 [min] - after having reached steady conditions
C)	Approved intermittent overload (if applicable)	Testing for duration as agreed with the manufacturer.
D)	For variable speed engines, 75%, 50% and 25% power in accordance with the nominal power consumption curve, the sequence to be selected by the engine manufacturer.	

Note:
After running on the test bed, the fuel delivery system is normally to be so adjusted that overload power cannot be delivered in service, unless intermittent overload power is approved. In that case, the fuel delivery system is to be blocked to that power.

4.11.4 Turbocharger matching with engine

4.11.4.1 Compressor chart

.1 Turbochargers are to have a compressor characteristic that allows the engine, for which it is intended, to operate without surging during all operating conditions and also after extended periods in operation.

.2 For abnormal, but permissible, operation conditions, such as misfiring and sudden load reduction, no continuous surging is to occur.

.3 In this section, *surging* and *continuous surging* are defined as follows:

Surging means the phenomenon, which results in a high pitch vibration of an audible level or explosion-like noise from the scavenger area of the engine.

Continuous surging means that surging happens repeatedly and not only once.

4.11.4.2 Surge margin verification

.1 Category C turbochargers used on propulsion engines are to be checked for surge margins during the engine workshop testing as specified below. These tests may be waived if successfully tested earlier on an identical configuration of engine and turbocharger (including same nozzle rings).

.2 For 4 stroke engines, following are to be performed without indication of surging:

- With maximum continuous power and speed (=100%), the speed is to be reduced with constant torque (fuel index) down to 90% power.

- With 50% power at 80% speed (= propeller characteristic for fixed pitch), the speed is to be reduced to 72% while keeping constant torque (fuel index).

.3 For 2 stroke engines, the surge margin is to be demonstrated by at least one of the following methods:

- The engine working characteristic established at workshop testing of the engine is to be plotted into the compressor chart of the turbocharger (established in a test rig). There is to be at least 10% surge margin in the full load range, i.e. working flow is to be 10% above the theoretical (mass) flow at surge limit (at no pressure fluctuations).

- Sudden fuel cut-off to at least one cylinder is not to result in continuous surging and the turbocharger is to be stabilised at the new load within 20 seconds. For applications with more than one turbocharger the fuel is to be cut-off to the cylinders closest upstream to each turbocharger. This test is to be performed at two different engine loads:

    - The maximum power permitted for one cylinder misfiring.

    - The engine load corresponding to a charge air pressure of about 0.6 [bar] (but without auxiliary blowers running).

- No continuous surging and the turbocharger is to be stabilised at the new load within 20 seconds when the power is abruptly reduced from 100% to 50% of the maximum continuous power.

4.11.5 Integration tests

4.11.5.1 For electronically controlled engines, integration tests are to be made to verify that the response of the complete mechanical, hydraulic and electronic system is as predicted for all intended operational modes and the tests considered as a system are to be carried out at the works. If such tests are technically unfeasible at the works, however, these tests may be conducted during sea trial. The scope of these tests is to be agreed with IRS for selected cases based on the FMEA required in *Classification Note "Approval of I.C Engines" Sec 1.*

4.11.6 Component inspections

4.11.6.1 Random checks of components will be carried out by the attending surveyor.

4.12 Shipboard trials

4.12.1 Safety Precautions

4.12.1.1 Refer to 4.11.1

4.12.2 Objectives

4.12.2.1 The purpose of the shipboard testing is to verify compatibility with power transmission and driven machinery in the system, control systems and auxiliary systems necessary for the engine and integration of engine / shipboard control systems, as well as other items that had not been dealt with in the FAT (Factory Acceptance Testing).

4.12.3 Starting capacity

4.12.3.1 Starting manoeuvres are to be carried out in order to verify that the capacity of the starting media satisfies the required number of start attempts.

4.12.4 Monitoring and alarm system

4.12.4.1 The monitoring and alarm systems are to be checked to the full extent for all engines, except items already verified during the works trials.

4.12.5 Test loads

4.12.5.1 Test loads for various engine applications are given in tables below. In addition, the scope of the trials may be expanded depending on the engine application, service experience, or other relevant reasons.

4.12.5.2 The suitability of the engine to operate on fuels intended for use is to be demonstrated.

Note:
Tests other than those listed below may be required by statutory instruments (e.g. EEDI verification).

Table 4.12.5.1 (a) : Propulsion engines driving fixed pitch propeller or impeller		
A)	At rated engine speed n_0 :	At least 4 [Hrs]
B)	At engine speed $1.032n_0$ (if engine adjustment permits , see 4.11.3.7)	30 [min]
C)	At approved intermittent overload (if applicable)	Testing for duration as agreed with the manufacturer
D)	Minimum engine speed to be determined	
E)	The ability of reversible engines to be operated in reverse direction is to be demonstrated.	
	Note: *During stopping tests according to Resolution MSC.137 (76), see 4.12.6.1 for additional requirements in the case of a barred speed range.*	

Table 4.12.5.1 (b) : Propulsion engines driving controllable fixed pitch propellers		
A)	At rated engine speed n_0 with a propeller pitch leading to rated engine power (or to the maximum achievable power if 100% cannot be reached):	At least 4 [Hrs]
B)	At approved intermittent overload (if applicable)	Testing for duration as agreed with the manufacturer
C)	With reverse pitch suitable for manoeuvring, see 4.12.6.1 for additional requirements in the case of a barred speed range.	

Table 4.12.5.1 (c) : Engine(s) driving generator(s) for electrical propulsion and/or main power supply		
A)	At 100% power (rated electrical power of generator):	At least 60 [Min]
B)	At 110% power (rated electrical power of generator):	At least 10 [Min]
	Note: *Each engine is to be tested 100% electrical power for at least 60 min and 110% of rated electrical power of the generator for at least 10 min. This may, if possible, be done during the electrical propulsion plant test, which is required to be tested with 100% propulsion power (i.e. total electric motor capacity for propulsion) by distributing the power on as few generators as possible. The duration of this test is to be sufficient to reach stable operating temperatures of all rotating machines or for at least 4 hours. When some of the gen. set(s) cannot be tested due to insufficient time during the propulsion system test mentioned above, those required tests are to be carried out separately.*	
C)	Demonstration of the generator prime movers' and governors' ability to handle load steps as described in 4.11.3.2 and 4.11.3.3.	

Table 4.12.5.1 (d) : Propulsion engines also driving power take off (PTO) generator		
A)	100% power (MCR) at corresponding speed n_0 :	At least 4 [Hrs]
B)	100% propeller branch power at engine speed n_0 (unless already covered in A):	2 [Hrs]
C)	100% PTO branch power at engine speed n_0:	At least 1 [Hr]

Table 4.12.5.1 (e) : Engines driving auxiliaries		
A)	100% power (MCR) at corresponding speed n_0 :	At least 30 [Min]
B)	Approved intermittent overload:	Testing for duration as approved

4.12.6 Torsional vibrations

4.12.6.1 Barred speed range

.1 Where a barred speed range (BSR) is required, passages through this BSR, both accelerating and decelerating, are to be demonstrated. The times taken are to be recorded and are to be equal to or below those times stipulated in the approved documentation, if any. This also includes when passing through the BSR in reverse rotational direction, especially during the stopping test.

Note: Applies both for manual and automatic passing-through systems.

.2 The ship's draft and speed during all these demonstrations is to be recorded. In the case of a controllable pitch propeller, the pitch is also to be recorded.

.3 The engine is to be checked for stable running (steady fuel index) at both upper and lower borders of the BSR. Steady fuel index means an oscillation range less than 5% of the effective stroke (idle to full index).

4.13 Reciprocating Internal combustion engines fuelled by natural gas

4.13.1 Application

.1 The following requirements are applicable to marine reciprocating internal combustion engines supplied with natural gas as fuel. Requirements of Pt. 5, Ch. 4 for gas carriers and Pt. 5, Ch. 35 for ships burning low flashpoint fuels are also to be considered as indicated and applicable.

.2 The scope of this section is intended for natural gas fuelled engines. It may also be referred for engines using similar fuels with main component methane such as bio-methane or synthetic methane.

.3 It is to be ensured by the gas supply system that the gas supplied to the engine is always in

gaseous state. This section does not cover requirements for liquid or cryogenic gas.

.4 The engines can be dual fuel engines (hereinafter referred to as DF engines), gas fuel only engines (hereinafter referred to as GF engines), or any variations thereof including fuel sharing capability. DF engines and GF engines may not be permitted for emergency applications.

.5 Requirements of this subsection are to be applied in association with other relevant requirements for internal combustion engines, as far as found applicable to the specific natural gas burning engine design.

.6 The requirements of IGC Code (Pt.5, Ch.4) and IGF Code (Pt.5, Ch.35) are also to be considered, as applicable.

.7 Specific requirements of the IGF Code(Pt.5, Ch.35) as referenced in this subsection are to be applied to engine types covered by this subsection installed on any ship, regardless of type, size and trading area, as long as the IGC Code(Pt.5, Ch.4) is not referenced or explicitly specified otherwise.

4.13.2 Definitions (relevant to this sub-section)

.1 *Certified safe equipment* is equipment certified by an independent national test institution or competent body to be in accordance with a recognised standard for electrical apparatus in hazardous areas.
Note: Refer to IEC 60079 series, Explosive atmospheres and IEC 60092-502:1999 Electrical Installations in Ships – Tankers – Special Features

.2 *Double block and bleed valves* means the set of valves referred to in:

- Pt.5, Ch. 4, Sec. 16, 16.4.5
- Pt. 5, Ch. 35, Sec. 2, 2.2.1.9 and Sec. 9, 9.4.4 to 9.4.6

.3 *Dual fuel engine* (“DF engine”) means an engine that can burn natural gas as fuel simultaneously with liquid fuel, either as pilot oil or bigger amount of liquid fuel (gas mode), and also has the capability of running on liquid diesel fuel oil only (Diesel mode).

.4 Explosion relief device means a device to protect personnel and component against a determined overpressure in the event of a gas explosion. The device may be a valve, a rupture disc or other, as applicable.

.5 *Gas* means natural gas used as fuel consisting primarily of methane.
Note: Gas may also be bio-methane or synthetic methane etc. with methane as main component.

.6 *Gas admission valve* is a valve or injector on the engine, which controls gas supply to the cylinder(s) according to the engine’s gas demand.

.7 *Gas engine* means a DF engine, a GF engine or any variations thereof.

.8 *Gas fuel only engine* (“GF engine”) means an engine capable of operating on gas fuel only and not able to switch over to oil fuel operation.

.9 *Gas piping* means piping containing gas or air / gas mixtures.

.10 *High pressure gas* means gas with a maximum working pressure greater than 10 bar gauge.

.11 *Low pressure gas* means gas with a maximum working pressure lower or equal to 10 bar gauge.

.12 *Lower Heating Value (“LHV”)* means the amount of heat produced from the complete combustion of a specific amount of fuel, excluding latent heat of vaporization of water.

.13 *Methane Number* is a measure of resistance of a gas fuel to knock, which is assigned to a test fuel based upon operation in knock testing unit at the same standard knock intensity.
Note: Pure methane is used as the knock resistant reference fuel, that is, methane number of pure methane is 100, and pure hydrogen is used as the knock sensitive reference fuel, methane number of pure hydrogen is 0. When the antiknock quality of the gas fuel being measured is identical to that of the standard methane-hydrogen mixture fuel mixed by a certain ratio, the value of the volume percentage of the methane contained in such standard fuel is the methane value of the gas fuel.

.14 *Pilot fuel* means the fuel oil that is injected into the cylinder to ignite the main gas-air mixture on DF engines.
Note: The dual-fuel engines use “pilot fuel” to start the combustion process. A small amount of pilot fuel is injected into the cylinder, where it is ignited by the high temperature of the gas air mixture at the end of the compression cycle. Typically, the amount of pilot fuel oil is below 1% of the energy used by the engine.

.15 *Pre-mixed engine* means an engine where gas is supplied in a mixture with air through a common manifold for all cylinders, e.g. mixed before or after the turbocharger.

.16 *Recognized standards* mean applicable international or national standards acceptable to IRS or standards laid down and maintained by an organization which complies with the standards adopted by IMO and which are recognized by IRS.

.17 *Safety Concept* is a document describing the safety philosophy with regard to gas as fuel. It describes how risks associated with this type of fuel are controlled under reasonably foreseeable abnormal conditions as well as possible failure scenarios and their control measures. The results of the risk analysis, (see Section 5, of the Classification Note "*Approval of I.C Engines*")are to be reflected in the safety concept.

Note: A detailed evaluation regarding the hazard potential of injury from a possible explosion is to be carried out and reflected in the safety concept of the engine.

4.13.3 Documents and/ or drawings to be submitted, risk analysis and type approval

The documents and drawings to be submitted, risk analysis document and requirements for type approval of DF and GF engines are specified in Section 5 of the Classification Notes "*Approval of I.C. Engines*".

4.13.4 Design Requirements

4.13.4.1 General Principles

.1 The manufacturer is to declare the allowable gas composition limits for the engine and the minimum and (if applicable) maximum methane number.

.2 Components containing or likely to contain gas are to be designed to:

a) minimize the risk of fire and explosion so as to demonstrate an appropriate level of safety commensurate with that of an oil-fueled engine;

b) mitigate the consequences of a possible explosion to a level providing a tolerable degree of residual risk, due to the strength of the component(s) or the fitting of suitable explosion relief devices of an approved type.

The strength of the component(s) of arrangement of explosion relief devices is to be documented (e.g., as part of risk analysis) or otherwise demonstrated to be sufficient for a worst-case explosion.

Also refer to the Pt.5, Ch.35, Sec.10, 10.2 and 10.3.

.3. Discharge from explosion relief devices are to prevent the passage of flame to the machinery space and be arranged such that the discharge does not endanger personnel or damage other engine components or systems"

.4. Explosion relief devices are to be fitted with a flame arrester.

4.13.4.2 Gas Piping

4.13.4.2.1 General

.1 These requirements are applicable to engine mounted gas piping. The piping is to be designed in accordance with the criteria for gas piping (design pressure, wall thickness, materials, piping fabrication and joining details etc.) as given in Pt.5, Ch. 35, Section 7, or requirements of Pt. 5, Ch. 4, Sections 5.1 to 5.9 and Sec.16 as applicable.

.2 Other connections as mentioned in Pt. 5, Ch. 4, Sec. 5, 5.8 may be accepted subject to type approval in accordance with the requirements of Pt.4, Ch. 2 and Classification Notes "*Type approval of mechanical joints used in piping*".

.3 All single walled or high-pressure gas pipes are to be considered as Class I. Low pressure double walled gas pipes are to be considered as Class II. All secondary enclosures for gas pipes are to be considered as Class II.

.4 Single walled gas vent pipes, if permitted, are to be considered as Class I, except it is justified that the maximum built up pressure is less than 5 bar gauge, in which case they are to be considered as Class II. Gas vent pipes protected by a secondary enclosure are to be considered as Class II. Secondary enclosure for vent pipes are to be considered as Class III.

.5 For design condition of gas pipes refer Table 4.13.4.2.1.5

.6 Flexible bellows used in the fuel gas system on the engine is to be approved based on the requirements of Pt.5, Ch.35, Sec.16, 16.7.2 and Pt.5, Ch.4, Sec.5, 5.13.1.2, as applicable.

.7 The number of cycles, pressure, temperature, axial movement, rotational movement and transverse movement which the bellow will encounter in actual service on the engine should be specified by the engine designer.

.8 Endurance against high cycle fatigue due to vibration loads are to be verified by testing or alternatively be documented by the Expansion Joint Manufacturers Association, Inc. (EJMA) calculation or equivalent (i.e., more than 10^7 cycles).

Note: The fatigue test due to ship deformations in Pt.5, Ch.35, Sec.16, 16.7.2.4 is considered not relevant for bellows which are an integral part of the engine.

Table 4.13.4.2.1.5 : Design pressure for gas pipes

	Design pressure	
	IGF code vessels	**IGC code vessels**
Gas pipe, low pressure	Refer Pt.5, Ch.35, Sec.7, 7.3.3.1	Refer Pt.5, Ch.4, Sec.5, 5.4.1
Gas pipe, high pressure	Refer Pt.5, Ch.35, Sec.7, 7.3.3.1	Refer Pt.5, Ch.4, Sec.5, 5.4.1
outer pipe, low pressure	Refer Pt.5, Ch.35, Sec.9, 9.8.1	Refer Pt.5, Ch.4, Sec.5, 5.4.4
outer pipe, high pressure	Refer Pt.5, Ch.35, Sec.9, 9.8.2	Refer Pt.5, Ch.4, Sec.5, 5.4.4
Open ended pipes	Refer Pt.5, Ch.35, Sec.7, 7.3.3.2	Refer Pt.5, Ch.4, Sec.5, 5.4.1

4.13.4.3 Arrangement of the gas piping system on the engine

.1 Pipes and equipment containing fuel gas are defined as hazardous area Zone 0 (refer to Pt.5, Ch. 35, Sec. 12, 12.5.1).

.2 The space between the gas fuel piping and the wall of the outer pipe or duct is defined as hazardous area Zone 1 (refer to Pt.5, Ch. 35, Sec. 12, 12.5.2.6)

4.13.4.3.1 Normal “double wall” arrangement

.1 The gas piping system on the engine is to be arranged according to the principles and requirements of the Pt.5, Ch. 35, Sec. 9, 9.6. In the case of gas carriers, requirements of Pt.5, Ch. 4, Sec. 16, 16.4.3 would be applicable.

.2 The design criteria for the double pipe or duct are given in Pt. 5, Ch. 35, Sec 9.8 and Sec. 7.4.1.4.

.3 In case of a ventilated double wall, the ventilation inlet is to be located in accordance with the provisions of Pt.5, Ch.35, Sec. 13, 13.8.3. For gas carriers, Pt.5, Ch.4, Sec. 16, 16.4.3.2 applies.

.4 The pipe or duct is to be pressure tested at 1.5 times design pressure to ensure gas tight integrity and to show that it can withstand the expected maximum pressure at gas pipe rupture.

4.13.4.3.2 Alternative arrangement

.1 Single walled gas piping is acceptable in following cases:

a) for engines supplied with low pressure gas installed in ESD protected machinery spaces, as defined in Pt.5, Ch.35, Sec. 5, 5.4.1.2 and in compliance with other relevant parts of Pt.5, Ch. 35 (e.g. 5.6);

b) in the case as per note to 9.6.2 of Pt.5, Ch.35, Sec. 9.

.2 For gas carriers, the requirements of Pt.5, Ch.4 would be applicable.

.3 In case of gas leakage in an ESD-protected machinery space, which would result in the shut-down of the engine(s) in that space, a sufficient propulsion and manoeuvring capability including essential and safety systems is to be maintained.

Therefore, the safety concept of the engine is to clearly indicate application of the “double wall” or “alternative” arrangement.

Note: The minimum power to be maintained is to be assessed on a case-by-case basis from the operational characteristics of the ship.

4.13.4.4 Charge air system and exhaust gas system on the engine

.1 The charge air system and the exhaust gas system on the engine are to be designed in accordance with 4.13.4.1.2. In case of a single engine installation, the engine is to be capable of operating at sufficient load to maintain power to essential consumers after opening of the explosion relief devices caused by an explosion event. Sufficient power for propulsion capability is to be maintained.

Note: Load reduction is to be considered on a case by case basis, depending on engine configuration (single or multiple) and relief mechanism (self-closing valve or rupture disk).

4.13.4.5 Exhaust system on the engine

.1 Continuous relief of exhaust gas (through open rupture disc) into the engine room or other enclosed spaces is not acceptable.

.2 Suitable explosion relief system for air inlet manifolds, scavenge spaces and exhaust system are to be provided unless designed to accommodate the worst-case overpressure due to ignited gas leaks or justified by the safety concept of the engine. A detailed evaluation regarding the hazard potential of overpressure in air inlet manifolds, scavenge spaces and exhaust system are to be carried out and reflected in the safety concept of the engine.

.3 Explosion relief devices for air inlet and exhaust manifold are to be type approved according to Classification Note "*Type Testing Procedure of Explosion Relief Devices for Combustion Air Inlet and Exhaust Gas Manifolds of I.C. Engines using Gas as Fuel*"

.4 The necessary total relief area and the arrangement of the explosion relief devices are to be determined taking into account:

- The worst-case explosion pressure depending on initial pressure and gas concentration,
- the volume and geometry of the component, and
- the strength of the component.

.5 The arrangement is to be determined in the risk analysis (refer *Classification Notes: Approval of I.C. Engines, 5.3.4.1 (g)*) and reflected in the safety concept.

4.13.4.6 Engine crankcase

.1 Crankcase explosion relief valves

Crankcase explosion relief valves are to be installed in accordance with 4.6.1. Also refer Pt.5, Ch.35, Sec.10, 10.3.1.2. For engines not covered by 4.6.1, the detailed evaluation as required in *Classification Notes: Approval of I.C. Engines, 5.3.4.1 (i*), is to determine if crankcase explosion relief valves are necessary.

.2 Inerting

For maintenance purposes, a connection, or other means, are to be provided for crankcase inerting and ventilating and gas concentration measuring.

.3 Crankcase ventilation

Ventilation of crankcase (either supply or extraction), if arranged, is to comply with 4.6. Relevant evidence is to be documented in Safety Concept. The ventilation systems for crankcase, sump and other similar engine spaces are to be independent from the systems on the other engines.

4.13.4.7 Gas ignition in cylinder

.1 Requirements of Pt.5, Ch.35, Sec.10, 10.3 are applicable. For gas carriers, Pt.5, Ch.4, Sec.16, 16.7 applies.

4.13.4.8 Control, monitoring, alarm and safety systems

.1 The engine control system is to be independent and separate from the safety system.

.2 The gas admission valves are to be controlled by the engine control system or by the engine gas demand.

.3 Combustion is to be monitored on an individual cylinder basis.

.4 In the event that poor combustion is detected on an individual cylinder, gas operation may be allowed in the conditions specified in Pt.5, Ch.35, Sec.10, 10.3.1.6.

.5 If monitoring of combustion for each individual cylinder is not practicable due to engine size and design, common combustion monitoring may be accepted.

.6 Unless the risk analysis (required by Section 5, 5.3 of the Classification note: "*Approval of I.C. Engines*") proves otherwise, the monitoring and safety system functions for DF or GF engines are to be provided in accordance with Table 4.13.4.8 in addition to the general monitoring and safety system functions given in Chapter 7.

Note: For DF engines, Table 4.13.4.8 applies only to the gas mode.

4.13.4.9 Gas admission valves

.1 Electrically operated gas admission valves are to be certified safe as follows:

a) The inside of the valve contains gas and shall therefore be certified for Zone 0;

b) When the valve is located within a pipe or duct in accordance with 4.13.4.3.1, the outside of the valve is to be certified for Zone 1;

c) When the valve is arranged without enclosure in accordance with the "ESD-protected machinery space" (see 4.13.4.3.2) concept, no certification is required for the outside of the valve, provided that the valve is de-energized upon gas detection in the space.

However, if they are not rated for the zone they are intended for, it is to be documented that they are suitable for that zone. Documentation and analysis are to be based on IEC 60079-10-1:2015 or IEC 60092-502:1999.

.2 Hydraulically operated gas admission valves are to be provided with sealing arrangement to prevent gas from entering the hydraulic oil system.

4.13.5 Specific Design Requirements

4.13.5.1 DF Engines

4.13.5.1.1 General

.1 The maximum continuous power that a DF engine can develop in gas mode may be lower than the approved MCR of the engine (i.e. in oil fuel mode), depending in particular on the gas composition and its quality or the engine system.

.2 This maximum continuous power available in gas mode and the corresponding conditions is to be stated by the engine manufacturer.

Requirements for type testing of DF and GF engines are given in Classification notes: *Approval of I.C. Engines*.

4.13.5.1.2 Starting, changeover and stopping

.1 DF engines are to be arranged to be started using either oil fuel or gas fuel with pilot oil fuel for ignition. The engines are to be arranged for rapid changeover from gas use to fuel oil use. In the case of changeover to either fuel supply, the engines are to be capable of continuous operation using the alternative fuel supply without interruption to the power supply.

.2 Changeover to gas fuel operation is to be only possible at a power level and under conditions where it can be done with acceptable reliability and safety as demonstrated through testing.

.3 Changeover from gas fuel operation mode to oil fuel operation mode is to be possible at all situations and power levels.

.4 The changeover process itself from and to gas operation is to be automatic but manual interruption is to be possible in all cases.

.5 If the power level or other conditions do not allow safe and reliable gas operation, changeover to oil fuel mode is to be automatically performed.

.6 In case of shut-off of the gas supply, the engines are to be capable of continuous operation by oil fuel only.

4.13.5.1.3 Pilot Injection

.1 Gas supply to the combustion chamber is not to be possible without operation of the pilot oil injection.

Note: Pilot injection is to be monitored for example by fuel oil pressure and combustion parameters.

Table 4.13.4.8 : Monitoring and Safety System Functions for DF and GF Engines

Parameter	Alarm	Automatic activation of the double block-and-bleed valves	Automatic switching over to oil fuel mode [1)]	Engine shutdown
Abnormal pressures in the gas fuel supply line	X	X	X	X [5)]
Gas fuel supply systems - malfunction	X	X	X	X [5)]
Pilot fuel injection or spark ignition systems - malfunction	X	X [2)]	X	X [2),5)]
Exhaust gas temperature after each cylinder - high	X	X [2)]	X	X [2),5)]
Exhaust gas temperature after each cylinder, deviation from average – low [3)]	X	X [2)]	X	X [2),5)]
Cylinder pressure or ignition - failure, including misfiring, knocking and unstable combustion	X	X [2)4)]	X [4)]	X [2),4),5)]
Oil mist concentration in crankcase or bearing temperature [6)] - high	X	X	-	X[9)]
Pressure in the crankcase – high [8)]	X	X	X	-
Engine stops - any cause	X	X	-	-
Failure of the control-actuating medium of the block and bleed valves	X	X	X	-
Failure of crankcase ventilation system, if applicable	X	X[7)]	X[7)]	

Notes:

1) DF engine only, when running in gas mode.

2) For GF engines, the double block-and-bleed valves and the engine shutdown may not be activated in case of specific failures affecting only one cylinder, provided that the concerned cylinder can be individually shutoff and the safe operation of the engine in such conditions is demonstrated by the risk analysis (Refer Section 5, 5.3 of the Classification Note: "*Approval of I.C. Engines"* for risk analysis requirement).

3) Required only if necessary for the detection of misfiring.

4) In the case where the failure can be corrected by an automatic mitigation action, only the alarm may be activated. If the failure persists after a given time, the safety actions are to be activated.

5) GF Engine only.

6) Where required by 4.6

7) Automatic safety actions to be activated as specified by the engine manufacturer, refer 4.6.

8) Only for trunk piston engines. This pressure sensor cannot replace or substitute a gas detector.

9) Only for trunk piston engines. For crosshead engines slow down is to apply (refer Pt.5, Ch.22, Sec.3, Table 3.1.1)

4.13.5.2 GF Engines

4.13.5.2.1 Spark ignition system

.1 In case of failure of the spark ignition, the engine is to be shut down except if this failure is limited to one cylinder, subject to immediate shut off of the cylinder gas supply and provided that the safe operation of the engine is substantiated by the risk analysis and by tests.

4.13.5.3 Pre-mixed Engines

4.13.5.3.1 Charge air system

.1 Inlet manifold, turbo-charger, charge air cooler, etc. are to be regarded as parts of the fuel gas supply system. Failures of those components likely to result in a gas leakage are to be considered in the risk analysis (see Section 5, 5.3 of the Classification Note: "*Approval of I.C. Engines"*).

.2 Flame arresters are to be installed before each cylinder head, unless otherwise justified in the risk analysis, considering design parameters of the engine such as the gas concentration in the charge air system, the path length of the gas-air mixture in the charge air system, etc.

4.13.5.4 Two-stroke engines

4.13.5.4.1 Scavenge air system

.1 The risk analysis required in IRS *Classification Notes: Approval of I.C. Engines,* is to cover the possible gas accumulation in a scavenge space.

4.13.5.4.2 Crankcase

.1 The risk analysis required in IRS *Classification Notes: Approval of I.C. Engines,* is to cover the possible failure of a piston rod stuffing box.

4.13.6 Type Testing, Factory Acceptance Tests and Shipboard Trials

4.13.6.1 Type Testing

The type approval of DF and GF engines is to be carried out in accordance with the Classification Note : *Approval of I.C. Engines*.

4.13.6.2 Factory Acceptance Test

.1 General.

Factory acceptance tests of DF and GF engines are to be carried out in accordance with 4.11, taking into account the additional requirements given below:

(a) For DF engines, the load tests referred to in 4.11.3.7 are to be carried out in diesel mode and in gas mode at the different percentages of the engine's MCR. Maximum continuous power available in gas mode is to be demonstrated (see 4.13.5.1.1).

.2 Safety precautions

In addition to the safety precautions mentioned in 4.11.1, measures to verify that gas fuel piping on engine is gas tight are to be carried out prior to start-up of the engine.

.3 Records

In addition to the records required in 4.11.3.2, the following engine data are to be recorded:

- Fuel index, both gas and diesel as applicable (or equivalent reading)
- Gas pressure and temperature
- Pilot fuel temperature and pressure (supply or common rail as appropriate)

.4 Test loads

Test loads for various engine applications are given in 4.11.3.7. DF engines are to be tested in both diesel and gas mode as found applicable. In addition, the scope of the trials may be expanded depending on the engine application, service experience, or other relevant reasons.

.5 Integration Tests

a) GF and DF engines are to undergo integration tests to verify that the response of the complete mechanical, hydraulic and electronic system is as predicted for all intended operational modes.

The scope of these tests is to be agreed with IRS for selected cases based on the risk analysis required in Section 5, 5.3 of the Classification Note: "*Approval of I.C. Engines"* and is to at least include the following incidents:

- Failure of ignition (spark ignition or pilot injection systems), for one-cylinder unit
- Failure of a gas admission valve
- Failure of the combustion (to be detected by e.g. misfiring, knocking, exhaust temperature deviation, etc.)
- Abnormal gas pressure
- Abnormal gas temperature

The above tests may be carried out using simulation or other alternative methods, subject to special consideration.

4.13.6.3 Shipboard Trials

.1 A leak test is to be carried out for the gas piping system (Pt.5, Ch.35, Sec.16, 16.7.3.3) after assembly on board.

.2 Shipboard trials are to be carried out in accordance with the provisions of 4.12, considering the additional requirements below.

.3 For DF engines, the test loads required in 4.12.5 are to be carried out in all operating modes (gas mode, diesel mode, etc.) as applicable (refer 4.13.5). The maximum continuous power available in gas mode is to be demonstrated.

Note: If a test load is performed in all applicable operation modes without interruption (direct changeover at same power and speed), the duration as required in 4.1.2.5 may be considered as the total duration demonstrated in all fuel modes. However, demonstration at each mode is not to be less than one hour.

.4 The starting maneuvers required in 4.12.3 are to be carried out in diesel mode and gas mode, if applicable.

.5 For DF engines, automatic switching over to oil fuel mode is to be tested. Further, manual change over from diesel to gas mode and vice versa is to be tested.

.6 The efficiency of the ventilation arrangement, or other approved methods of safety (such as inert gas systems), of the double walled gas piping system is to be verified.

4.13.7 Certification of Engine Components

4.13.7.1 The principles, definitions, and general requirements of IRS *Classification Notes: Approval of I.C. Engines* apply. In addition to those engine components specified in 3.2.2 of the Classification Notes, the engine components listed in Table 3.2.3 of the Classification Notes are to be documented as listed in the table.

4.14 Storage and Use of Selective Catalytic Reduction (SCR) Reductants

4.14.1 General

4.14.1.1 The NOx Technical Code, in 2.2.5 and elsewhere, provides for the use of NOx Reducing Devices of which Selective Catalytic Reduction (SCR) is one option. SCR requires the use of a reductant which may be a urea/water solution or, in exceptional cases, aqueous ammonia or even anhydrous ammonia. These requirements apply to the arrangements for the storage and use of SCR reductants which are typically carried on board in bulk quantities.

4.14.2 Reductant using Urea based Ammonia (for e.g. 40% / 60% urea/ water solution)

4.14.2.1 Where urea based ammonia (e.g. AUS 40 – aqueous urea solution specified in ISO 18611-1:2014) is introduced, the storage tank is to be arranged so that any leakage will be contained and prevented from making contact with heated surfaces. All pipes or other tank penetrations are to be provided with manual closing valves attached to the tank. Tank and piping arrangements are to be approved.

4.14.2.2 Urea storage tanks are to be arranged so that they can be emptied of urea, purged and vented.

4.14.2.3 The storage tank may be located within the engine room.

4.14.2.4 The storage tank is to be protected from excessively high or low temperatures applicable to the particular concentration of the solution. Depending on the operational area of the ship, this may necessitate the fitting of heating and/ or cooling systems. The physical conditions recommended by applicable recognized standards (such as ISO 18611-3:2014) are to be taken into account to ensure that the contents of the aqueous urea tank are maintained to avoid any impairment of the urea solution during storage.

4.14.2.5 If a urea storage tank is installed in a closed compartment, the area is to be served by an effective mechanical ventilation system of extraction type providing not less than 6 air changes per hour which is independent from the ventilation system of accommodation, service spaces, or control stations. The ventilation system is to be capable of being controlled from outside the compartment. A warning notice requiring the use of such ventilation before entering the compartment is to be provided outside the compartment adjacent to each point of entry.

Alternatively, where a urea storage tank is located within an engine room a separate ventilation system is not required when the general ventilation system for the space is arranged so as to provide an effective movement of air in the vicinity of the storage tank and is to be maintained in operation continuously except when the storage tank is empty and has been thoroughly ventilated. The following are to be complied with in addition:

- The urea tank location is to be served by an extraction ventilation opening served by an exhaust fan/ blower of the engine room.

- This exhaust fan/ blower is to be provided with an alarm in the ER control panel and at the location of the urea tank, when the fan/ blower is stopping/ tripping off.

- A warning notice is to be placed at the location of the urea tank that the location is ventilated by the E.R. exhaust fan/ blower no.___.

4.14.2.6 Each urea storage tank is to be provided with temperature and level monitoring arrangements. High and low level alarms together with high and low temperature alarms are also to be provided.

4.14.2.7 Where urea based ammonia solution is stored in integral tanks, the following are to be considered during the design and construction:

a) These tanks may be designed and constructed as integral part of the hull, (e.g. double bottom, wing tanks).

b) These tanks are to be coated with appropriate anti-corrosion coating and cannot be located adjacent to any fuel oil and fresh water tank.

c) These tanks are to be designed and constructed as per the structural requirements applicable to hull and primary support members for a deep tank construction.

d) These tanks are to be included in the ship's stability calculations.

4.14.2.8 The requirements specified in 4.14.2.5 also apply to closed compartments normally entered by persons:

- when they are adjacent to the urea integral tanks and there are possible leak points(e.g. manhole, fittings) from these tanks; or
- when the urea piping systems pass through these compartments, unless the piping system is made of steel or other equivalent material with melting point above 925 degrees C and with fully welded joints.

4.14.2.9 The reductant piping and venting systems are to be independent of other ship service piping and/or systems. Reductant piping systems are not to be located in accommodation, service spaces, or control stations. The vent pipes of the storage tank are to terminate in a safe location on the weather deck and the tank venting system is to be arranged to prevent entrance of water into the urea tank.

4.14.2.10 Reductant tanks are to be of steel or other equivalent material with a melting point above 925 degrees C. Pipes/ piping systems

are to be of steel or other equivalent material with melting point above 925 degrees C, except downstream of the tank valve, provided this valve is metal seated and arranged as fail-to-closed or with quick closing from a safe position outside the space in the event of fire; in such case, type approved plastic piping may be accepted even if it has not passed a fire endurance test. Reductant tanks and pipes/ piping systems are to be made with a material compatible with reductant or coated with appropriate anti-corrosion coating.

4.14.2.11 The ship is to have on board suitable personnel protective equipment, for the protection of crew members, Eyewash is to be provided, the location and number of these eyewash stations are to be derived from the detailed installation arrangements.

4.14.2.12 Urea storage tanks are to be arranged so that they can be emptied of urea, and ventilated by means of portable or permanent systems.

4.14.3 Reductant using aqueous ammonia (28% or less concentration of ammonia)

4.14.3.1 Aqueous ammonia is not to be used as a reductant in a SCR except where it can be demonstrated that it is not practicable to use a urea based reductant. Where an application is made to use aqueous ammonia as the reductant then the arrangements for its loading, carriage and use are to be derived from a risk based analysis.

4.14.4 Reductant using anhydrous ammonia (99.5% or greater concentration of ammonia by weight)

4.14.4.1 Anhydrous ammonia is not to be used as a reductant in a SCR except where it can be demonstrated that it is not practicable to use a urea based reductant and where the Flag Administration agrees to its use. Where it is not practicable to use a urea reductant then it is also to be demonstrated that it is not practicable to use aqueous ammonia. Where an application is made to use anhydrous ammonia as the reductant then the arrangements for its loading, carriage and use are to be derived from a risk based analysis.

4.15 Safety Measures for chemical treatment fluids used in Exhaust Gas Cleaning Systems and the Residues which have Hazardous Properties

4.15.1 General

4.15.1.1 With regard to the sulphur content limits of fuel oil specified in MARPOL Annex VI Reg. 14, alternative methods of compliance may be used as allowed by MARPOL Annex VI, Reg. 4.

4.15.1.2 As some types of Exhaust Gas Cleaning Systems (EGCS) to be approved by the Administration as “alternative compliance method” consume chemicals which are typically carried on board in bulk quantities, the safety measures against chemical treatment fluids contained in this subsection apply to EGCSs using such fluids. In this context, the term “chemical treatment fluid” means the aqueous solution of sodium hydroxide (NaOH) or calcium hydroxide ($Ca(OH)_2$) that has corrosive properties or are considered to represent a hazard to personnel.

4.15.1.3 For EGCSs using chemical treatment fluids other than the above, safety measures are to be taken according to the result of a risk assessment to be conducted to analyze the risks, in order to eliminate or mitigate the hazards to personnel brought by the use of such exhaust gas cleaning systems, to an extent equivalent to systems complying with 4.15.2.

4.15.2 Requirements for EGCSs using aqueous solution of NaOH or $Ca(OH)_2$ for chemical treatment fluid

4.15.2.1 The storage tanks are to have sufficient strength to withstand a pressure corresponding to the maximum height of a fluid column in the overflow pipe, with a minimum of 2.4 m above the top plate taking into consideration the specific density of the treatment fluid. Overflow pipes are to be led to appropriate tanks, as specified for drain pipes for drip trays in 4.15.2.12.

4.15.2.2 Where chemical treatment fluid is stored in integral tanks, the following are to be considered during the design and construction:

.1 These tanks may be designed and constructed as integral part of the hull, (e.g. double bottom, wing tanks).

.2 These tanks are to be coated with appropriate anti-corrosion coating and are to be segregated by cofferdams, void spaces, pump rooms, empty tanks or other

similar spaces so as to not be located adjacent to accommodation, cargo spaces containing cargoes which react with chemical treatment fluids in a hazardous manner as well as any food stores, oil tanks and fresh water tanks.

.3 These tanks are to be designed and constructed as per the structural requirements applicable to hull and primary support members for a deep tank construction.

.4 These tanks are to be included in the ship's stability calculation.

4.15.2.3 The storage tank is to be protected from excessively high or low temperatures applicable to the particular concentration chemical treatment fluids. Depending on the operational area of the ship, this may necessitate the fitting of heating and/or cooling systems.

4.15.2.4 Each storage tank for chemical treatment fluids is to be provided with level monitoring arrangements and high/ low level alarms. In cases where heating and/ or cooling systems are provided, high and/ or low temperature alarms or temperature monitoring are also to be provided accordingly.

4.15.2.5 The storage tank may be located within the engine room. In this case, the requirements of 4.15.2.6 are to be complied with, except that a separate ventilation system is not required when the general ventilation system for the space is arranged so as to provide an effective movement of air in the vicinity of the storage tank and is maintained in operation continuously.

4.15.2.6 If a storage tank for chemical treatment fluids is installed in a closed compartment, the area is to be served by an effective mechanical ventilation system of extraction type providing not less than 6 air changes per hour which is independent from the ventilation system of other spaces. The ventilation system is to be capable of being controlled from outside the compartment. A warning notice is to be provided outside the compartment, adjacent to each point of entry, indicating that the ventilation systems to be operated for at least 15 minutes before entry into such compartments.

4.15.2.7 The requirements specified in 4.15.2.6 also apply to closed compartments normally entered by persons:

.1 when they are adjacent to the integral storage tank for chemical treatment fluids and there are possible leak points (e.g. manhole, fittings) from these tanks; or

.2 when the treatment fluid piping systems pass through these compartments, unless the piping system is made of steel or other equivalent material with melting point above 925 degrees C and with fully welded joints.

4.15.2.8 The storage tank for chemical treatment fluids is to be arranged so that any leakage will be contained and prevented from making contact with heated surfaces. All pipes or other tank penetrations are to be provided with manual closing valves attached to the tank. In cases where such valves are provided below top of tank, they are to be arranged with quick acting shutoff valves which are to be capable of being remotely operated from a position accessible even in the event of chemical treatment fluid leakages. Tank and piping arrangements are to be approved by IRS.

4.15.2.9 The chemical treatment fluid piping and venting systems are to be independent of other ship service piping and/ or systems. The chemical treatment fluid piping systems are not to be located in accommodation, service spaces, or control stations. The vent pipes of the storage tank are to terminate in a safe location on the weather deck and the tank venting system is to be arranged to prevent entrance of water into the tank for chemical treatment fluids.

4.15.2.10 Storage tanks and pipes/piping systems and drip trays for chemical treatment fluids are to be of steel or other equivalent material (with a melting point above 925 degrees C), which is compatible with the chemical treatment fluids or coated with appropriate anticorrosion coating.
Note: Several metals are incompatible with the chemical treatment fluids, e.g. NaOH is incompatible with zinc, aluminum, etc.

4.15.2.11 Regardless of design pressure and temperature, piping systems containing chemical treatment fluids only are to comply with the requirements applicable to Class I piping systems. As far as practicable, e.g. except for the flange connections that connect to tank valves, the piping systems are to be joined by welding.

4.15.2.12 The following connections are to be screened and fitted with drip trays to prevent

the spread of any spillage where they are installed:

.1 Detachable connections between pipes (flanged connections and mechanical joints, etc.);

.2 Detachable connections between pipes and equipment such as pumps, strainers, heaters, valves; and

.3 Detachable connections between equipment mentioned in the above subparagraph.

The drip trays are to be fitted with drain pipes of compatible material and size which lead to appropriate tanks of adequate capacities, such as residue tanks, which are fitted with high level alarm, or are to be fitted with alarms for leak detection. In cases where such tank is an integral tank, 4.15.2.2.1 and 4.15.2.2.2 are to be applied to the tank.

4.15.2.13 For the protection of crew members, the ship is to have on board suitable personnel protective equipment. The number of personnel protective equipment carried onboard is to be appropriate for the number of personnel engaged in regular handling operations or that may be exposed in the event of a failure; but in no case is there to be less than two sets available onboard.

4.15.2.14 Personnel protective equipment is to consist of protective clothing, boots, gloves and tight-fitting goggles. Eyewash and safety showers are to be provided, the location and number of these eyewash stations and safety showers are to be derived from the detailed installation arrangements. As a minimum, the following stations are to be provided:

.1 In the vicinity of transfer or treatment pump locations. If there are multiple transfer or treatment pump locations on the same deck then one eyewash and safety shower station may be considered for acceptance provided that the station is easily accessible from all such pump locations on the same deck.

.2 An eyewash station and safety shower are to be provided in the vicinity of a chemical bunkering station on-deck. If the bunkering connections are located on both port and starboard sides, then consideration is to be given to providing two eyewash stations and safety showers, one for each side.

.3 An eyewash station and safety shower are to be provided in the vicinity of any part of the system where a spillage/drainage may occur and in the vicinity of system connections/components that require periodic maintenance.

4.15.2.15 Storage tanks for chemical treatment fluids are to be arranged so that they can be safely emptied of the fluids and ventilated by means of portable or permanent systems.

4.15.3 Requirement for Exhaust Gas Cleaning Systems discharge water pipeline

4.15.3.1 Overboard discharges from exhaust gas cleaning system (EGCS) are not to be interconnected to other systems.

4.15.3.2 Due consideration is to be given to the location of overboard discharges with respect to vessel propulsion features, such as thrusters, propellers or to prevent any discharge water onto survival craft during abandonment.

4.15.3.3 The piping material for the EGCS discharge water pipeline system is to be selected based on the corrosive nature of the liquid media.

4.15.3.4 Special attention is to be paid to the corrosion resistivity of EGCS overboard discharge piping. Where applicable, adequate arrangements are to be provided to prevent galvanic corrosion due to the use of dissimilar metals.

4.15.3.5 In case distance piece is fitted between the outboard discharge valve and the shell plating, it to be made of corrosion resistant material steel or be coated with an anti-corrosive material suitable for the operating environment. The thickness of the distance piece is to be at least the minimum values specified in a) and b) below; otherwise Sch.160 thickness specified in piping standards, as far as practicable, is to be used.

a) 12 mm in cases where complete pipe is made of corrosion resistant material steel.

b) 15 mm for mild steel in cases where the inside of the pipe is treated with an anticorrosive coating or fitted with a sleeve of corrosion resistant material.

4.15.4 Tanks for Residues Generated from Exhaust Gas Cleaning process

4.15.4.1 Tanks for residues generated from the exhaust gas cleaning process are to satisfy the following requirements:

.1 The tanks are to be independent from other tanks, except in cases where these tanks are also used as the over flow tanks for chemical treatment fluids storage tank.

.2 Tank capacities are to be decided in consideration of the number and kinds of installed exhaust gas cleaning systems as well as the maximum number of days between ports where residue can be discharged ashore. In the absence of precise data, a figure of 30 days is to be used.

.3 Where residue tanks used in closed loop chemical treatment systems are also used as the overflow tanks for chemical treatment fluids storage tank, the requirements for storage tanks apply.

4.16 AC Generating Sets

4.16.1 General

4.16.1.1 This sub-section provides requirements for AC Generating sets (i.e. reciprocating internal combustion engines, alternators and couplings), in addition to those stated in this Chapter and Ch.8.

4.16.1.2 The requirements are applicable to AC generating sets driven by reciprocating internal combustion engines irrespective of their types (i.e. diesel engine, dual fuel engine, gas-fuel engine), except for those sets consisting of a propulsion engine which also drives power take off (PTO) generator(s).

4.16.2 Requirements

4.16.2.1 The generating set is to show torsional vibration levels which are compatible with the allowable limits for the alternator, shafts, coupling and damper.

4.16.2.2 The coupling selection for the generating set is to take into account the stresses and torques imposed on it by the torsional vibration of the system. The torsional vibration calculations are to be submitted to IRS for approval when the engine power is 110 [kW] or above.

4.16.2.3 The rated power is to be appropriate for the actual use of the generator set.

4.16.2.4 The firm responsible for assembling the generating set is to install a rating plate marked with at least the following information:

(i) the generating set manufacturer's name or mark;
(ii) serial number of the set;
(iii) date of manufacture (month/year) of the set;
(iv) the rated power (both in kW and KVA) with one of the prefixes COP, PRP (or, only for emergency Generating sets, LTP) as defined in ISO 8528-1:2018;
(v) the rated power factor;
(vi) the set rated frequency [Hz];
(vii) the set rated voltage [V];
(viii) the set rated current [A];and
(ix) the mass [kg].

4.17 Capacity and availability of compressed air for essential services onboard ships other than the supply of compressed air for engine starting

4.17.1 The arrangements for the supply of compressed air to essential services are to ensure that sufficient compressed air to satisfy the total demand of the essential services is available at all times during normal operation, during maintenance, and in the event of a failure of the compressed air system.

4.17.2 Where compressed air is supplied from the engine starting air system, either continuously in normal operation, or periodically during maintenance or in the event of a failure of the compressed air system, the required compressed air demand is not to reduce the capacity and availability of the engine starting air required by 4.9.2.

Section 5

Gearing

5.1 Scope

5.1.1 The requirements of this Section cover the construction, material and inspection of reduction gears for main propelling purposes and for driving electric generators.

5.1.2 Design of bevel gears will be specially considered.

5.1.3 For torsional vibration requirements, See Sec.8.

5.1.4 Rated power of gear is the maximum transmitted power at which the gear is designed to operate continuously at its rated speed.

5.1.5 The rated torque is defined by the rated power and speed and is the torque used in the gear rating calculations.

5.1.6 The gear rating is the rating for which the gear is designed to transmit it's rated torque.

5.2 Plans and particulars

5.2.1 The following plans, in triplicate, of the reduction gearing are to be submitted:

For Approval

a) Pinion(s) and wheel(s);

b) Shafts;

c) Hub(s);

d) Other power transmitting parts;

For information only

e) Longitudinal and transverse sections of the gear box;

f) Clutch(es) and/or coupling(s);

g) Gear casing including propeller thrust bearing housing, if applicable.

5.2.2 The plans are to show clearly all dimensions, details of all fillets and stress raisers, and material of all the parts.

5.2.3 At least the following particulars of the gearing are to be submitted along with the plans:

a) Shaft power and revolutions for each pinion;

b) Number of teeth in each gear;

c) Generating pitch diameters;

d) Helix angles at generating pitch diameters;

e) Normal pitches of teeth at generating pitch diameters;

f) Tip diameters;

g) Root diameters;

h) Face widths and gaps, where applicable;

i) Pressure angles of teeth (normal or transverse) at generating pitch diameters;

j) Minimum backlash;

k) Centre distance;

l) Basic rack tooth form;

m) Details of tooth flank corrections, if adopted;

n) Details of post hobbing process, if any;

o) Case depth for surface-hardened teeth;

p) Shrinkage allowance for shrunk-on rims and hubs;

q) Type of coupling proposed for oil engine applications.

5.2.4 Gears with Multiple Prime Mover Inputs

5.2.4.1 For single helical gears with arrangements utilizing multiple prime mover inputs, and single or multiple outputs, the following analyses for all operating modes are to be conducted:

- All bearing reactions
- Tooth modifications
- Load distributions on the gear teeth
- Contact and tooth root bending stresses

A summary of the results of these analyses for each operating mode is to be submitted for review.

5.3 Materials

5.3.1 Specifications for materials of pinions, pinion sleeves, wheel rims, gear wheels and shafting giving chemical composition, heat treatment and mechanical properties are to be submitted for approval with the plans of gearing and are to be in accordance with Pt.2.

5.3.2 Where the teeth of a pinion or gear wheel are to be surface hardened, the proposed specification and details of the procedure are to be submitted for approval.

5.3.3 In the selection of materials for pinions and wheels consideration should be given to their compatibility in operation. In general, for gears of through hardened steels, except in the case of low reduction ratios, provision should also be made for a hardness differential between pinion teeth and wheel teeth. For this purpose the specified minimum tensile strength of the wheel materials should not be more than 85 per cent of that of the pinion.

5.3.4 Subject to 5.3.3, the specified minimum tensile strength of steel gear forgings is to be selected within the following limits:

- Pinions and pinion sleeves - 550-1050 [N/mm^2];

- Gear wheels and rims - 400-850 [N/mm^2].

A tensile strength range is also to be specified and is not to exceed 120 [N/mm^2] when the specified minimum tensile strength is 600 [N/mm^2] or less. For higher strength steels, the range is not to exceed 150 [N/mm^2].

5.3.5 Unless otherwise agreed, the specified minimum tensile strength of the core is to be 800 [N/mm^2] for induction-hardened or nitrided gearing and 750 [N/mm^2] for carburized gearing.

5.4 Design and construction

5.4.1 The design and construction is to be such as to enable the gearing to meet the general requirements with respect to functional capability and reliability.

5.4.2 Detailed analysis to prove the design of the gearing is to be submitted for consideration. In this regard, Classification Notes on the design of gearing may be followed.

5.4.3 Where castings are used for wheel centres, any radial slots in the periphery are to be fitted with permanent chocks before shrinking-on the rim.

5.4.4 Where bolts are used to secure side plates to rim and hub, the bolts should be tight fit with the holes and the nuts should be suitably locked by means other than welding.

5.4.5 When welding is employed in the construction of wheels, the welding procedure is to be approved by the Surveyors before work is commenced. For this purpose, welding procedure approval tests are to be carried out with satisfactory results. Such tests are to be representative of the joint configuration and materials. Wheels are to be stress relieved after welding. All welds are to have a satisfactory surface finish and contour. Magnetic particle or liquid penetrant examination of all important welding joints is to be carried out to the satisfaction of the Surveyors.

5.4.6 In general arrangements are to be made so that the interior structure of the wheel may be examined. Alternative proposals will be specially considered.

5.5 Accuracy of gear cutting and alignment

5.5.1 Gears are to be cut only on machines which are maintained at a high standard of accuracy. Hobbing machines used in the production of large gears are to be operated under conditions of temperature control with a total temperature variations not exceeding 2°C for the finishing cut. The blank should be allowed sufficient time to stabilize to the machine temperature before cutting commences.

5.5.2 The accuracy of gear-cutting of pinions and wheels is to be demonstrated to the satisfaction of the Surveyors. For this purpose, records of measurements of pitch error, undulations, axial pitch errors, tooth thickness and backlash should be available for review by Surveyors on request.

5.5.3 The alignment is to be demonstrated in the workshop by meshing in the gearbox

without oil clearance in the bearings, or in the meshing frame without oil clearance in the bearings or on rollers. Meshing is to be carried out with the gears locating in their load positions, and a load sufficient to overcome pinion weight and axial movement is to be imposed.

5.5.4 A permanent record is to be made of the meshing contact for the purpose of re-checking the alignment when installed on board ship. The meshing contact on each helix is not to be less than following:

a) For through-hardened gears,

- 40 per cent of the working depth for 35 per cent of the length; and
- 20 per cent of the working depth for further 35 per cent of the length;

b) For through-hardened gears and for all surface hardened gears,

- 40 per cent of the working depth for 50 per cent of length; and
- 20 per cent of the working depth for a further 40 per cent of the length.

5.6 Balancing of gear pinions and wheels

5.6.1 All pinions, gear wheels and flexible couplings or sleeves whose maximum designed speed of rotation exceeds 1000 revolutions per minute are to be dynamically balanced, where the speed of rotation is 1000 revolutions per minute or less, these components are to be statically or, alternatively, dynamically balanced. Parts of couplings, etc., which are to be fixed to the gear in service are normally to be attached before balancing.

5.6.2 For static balancing the final out of balance of each assembly at the balancing planes is not to exceed 2200 [N mm/tonne] of gears whose maximum design speed is less than 300 revolutions per minute and 680 [N mm/tonnes] for gears whose maximum design speed is between 300 and 1000 revolutions per minute. For dynamic balancing the final out of balance is not to exceed $190,000/N_1$ [N mm/tonne], where N_1 = revolutions per minute appropriate to the assembly.

5.6.3 Balancing may, however, be omitted for turbine secondary pinions and for oil engines gearing, provided that the rotating components are of solid forged construction or have a solid forged centre with shrunk-on rim and in both cases are machined to give a concentric and uniform cross-section.

5.7 Gearcases

5.7.1 Gearcases and their supports are to be designed sufficiently stiff such that misalignment at the mesh due to movements of the external foundations and the thermal effects under all conditions of service do not disturb the overall tooth contact. If welding is employed in their construction they are to be stress-relieved on completion.

5.7.2 Inspection openings should be provided at the peripherals of gearcases to enable the teeth of pinions and wheels to be readily examined. When the construction of gearcases is such that sections of the structure cannot readily be moved for inspection purposes, access openings of adequate size are to be also provided at the ends of the gearcases to permit examination of the structure of the wheels. Their attachment to the shafts should be capable of being examined by removal of bearing caps or by equivalent means.

5.8 Type tests and sea trials

5.8.1 Upon completion of fabrication and assembly, reduction gear unit is to be subjected to type testing in accordance with the agreed test programme which is to be submitted by the manufacturer for approval. Type tests are to be witnessed by the Surveyor.

5.8.2 Reduction gearing units, in general, are to be type tested at maker’s works and test load and duration of testing is to be agreed upon in each case.

5.8.3 Tests are to include demonstration of satisfactory operation of clutches and couplings, if fitted.

5.8.4 After completion of type tests, all gear elements are to be examined for tooth contact marking and alignment. All gear tooth contact is to conform to the requirements given in Cl. 5.5.5.

5.8.5 The gear lub.oil system is to be provided with means of indicating the lub.oil pressure supply to them. Alarms are to be provided to indicate low lub.oil pressure, low clutch oil/air pressure and high lub.oil temperature in accordance with Part 4, Chapter 7, Table 1.9.1.

5.9 Alignment and weardown gauges

5.9.1 Reduction gears with sleeve bearings for main and auxiliary turbines and oil engines, are to be provided with weardown gauges or micrometers for testing the internal alignment of the various elements in the gearcases. In certain gears, e.g. gears of the dual tandem type, the direction of loading on the bearings of a gear element may be such that an accurate indication of its alignment under operating conditions cannot be obtained using weardown gauges. In these instances, suitable alternatives such as crown thickness micrometer are to be provided.

5.9.2 Approved means are to be provided by the gear manufacturer to enable the Surveyors to verify that no distortion of the gearcase has taken place, when chocked and secured to its seating on board ship.

5.10 Trials

5.10.1 The sea trials should be of sufficient duration to prove the gears. After these trials, the marking revealed by inspection should indicate freedom from hard bearings, particularly towards both ends of each helix.

5.10.2 In the case of through-hardened gears, not less than 70 per cent contact across effective face width should be indicated. When the teeth of such gears are finished by an approved post hobbing process or profile ground, not less than 90 per cent contact across the effective face width is to be indicated.

5.10.3 For surface hardened gears, the contact across the effective face width is also to be not less than 90 per cent.

Section 6

Main Propulsion Shafting

6.1 Scope

6.1.1 The requirements of this Section apply to shafting for main propulsion of straight forged design and which are driven by rotating machines such as diesel engines, turbines or electric motors. The requirements for couplings, coupling bolts, keys, keyways, sternbushes and associated components are also included. The diameter of shafting as calculated may require to be modified as a result of alignment considerations and vibration characteristics (See Sec.8) or the inclusion of stress raisers, other than those contained in this section.

The requirements given in this section do not cover shafts intended for following application.

- gearing shafts
- electric motor shafts
- generator rotor shafts
- turbine rotor shafts.

6.1.2 The scantlings of shafts that are integral to equipment, such as for gear boxes, podded drives, electrical motors and/or generators, thrusters, turbines and which in general incorporate particular design features are to be determined taking into account appropriate additional criteria including that for stiffness, high temperature application etc. The requirements given in this section may be applied if such shafts are subjected mainly to torsion and are having traditional design features.

6.1.3 For additional strengthening for shafts in ships classed for navigation in waters with ice condition, refer Pt.5, Ch.21 and for diesel engine crankshaft refer IRS Classification Note “Crankshaft for Internal Combustion Engines”.

6.2 Alternative calculation methods

6.2.1 Alternative calculation methods will be considered provided these calculations take into account all relevant loads in the complete dynamic shafting system under all permissible operating conditions giving due consideration to the dimensions and arrangements of all shafting connections. The alternative calculation method is to also take into account design criteria for continuous and transient operating loads for dimensional adequacy for fatigue strength and peak operating loads for yield strength. Refer 6.2.2 to 6.2.5 as guidance for alternative calculations.

6.2.2 The two important considerations that are essential for the design of propulsion shafting are:

a) Fatigue
b) Stress concentration and notch sensitivity.

***Fatigue** : The deterioration of the properties of material which takes place under conditions involving fluctuating stresses. Fatigue failures generally occur at loads, which if applied statically would be below the elastic limit. The fatigue limit of a material is the stress which will not produce failure, even if many fluctuations of it are imposed.*

***Stress concentration in shafts** : Basic stress analysis calculations assume that the components are smooth, have a uniform section and have no irregularities. In practice virtually all engineering components have to have changes in section and/or shape. Common examples are shoulders on shafts, oil holes, key ways and screw threads. Any discontinuity changes the stress distribution in the vicinity of the discontinuity, so that the basic stress analysis equations no longer apply. Such 'discontinuities' or 'stress raisers' cause local increase of stress referred to as 'stress concentration'.*

For static loading the theoretical or geometric stress concentration factors K_t or K_{ts} relate to actual maximum stress at the discontinuity to the nominal stress as follows:

K_t = maximum direct stress/nominal direct stress
K_{ts} = maximum shear stress/nominal shear stress.

The subscript 't' denotes that the stress concentration value is a theoretical calculation based only on the geometry of the component and discontinuity.

Some materials are not as sensitive to notches as implied by the theoretical stress concentration factor. For these materials a reduced value of stress concentration factor K_f may be used where the maximum stress = K_f x nominal stress. The value of K_f which depends on notch sensitivity 'q' is to be determined using the following equation:

$q = (K_f - 1) / (K_t - 1)$ where q is between 0 and 1.

If q = 0, then $K_f = 1$ as the material has no sensitivity to notches. If q = 1, then $K_f = K_t$ and the material is fully notch sensitive.

When designing, usual practice is to first find K_t from the geometry of the component, then specify the material and determine the notch sensitivity, q from the chart for the notch radius.

For cyclic loading, the theoretical stress concentration factor is to be defined as

$$K_{t1} = \frac{\text{endurance limit without stress concentration}}{\text{endurance limit with stress concentration}}$$

Using the notch sensitivity factor 'q' in cyclic loading of shaft, fatigue stress concentration factor K_f is calculated as :

$$K_f = 1 + q\,(K_{t1} - 1)$$

6.2.3 The alternative calculation methods are to take into account following fatigue related issues as have been considered in rule formulations:

a) Low cycle fatigue criterion (typically < 10^4), i.e. the primary cycles represented by zero to full load and back to zero, including reversing torque if applicable.

b) High cycle fatigue criterion (typically > 10^7), i.e. torsional vibration stresses permitted for continuous operation as well as reverse bending stresses.
The limits for torsional vibration stresses are given in 8.4.2.

c) The accumulated fatigue due to torsional vibration when passing through a barred speed range or any other transient condition with associated stresses beyond those permitted for continuous operation is addressed by the criterion for transient stresses in 8.4.2.

6.2.4 The factors k (for low cycle fatigue) and c_k (for high cycle fatigue) as given in Table 6.5.1 and Table 8.4.2 respectively take into account the influence of:

- The stress concentration factors (scf) relative to the stress concentration for a flange with fillet radius of $0.08d_o$ (geometric stress concentration of approximately 1.45).

$$c_k \approx \frac{1.45}{scf} \quad \text{and} \quad k \approx \left[\frac{scf}{1.45}\right]^x$$

where the exponent x considers low cycle notch sensitivity.

- The chosen values of the notch sensitivity are mainly representative for soft steels (σ_B < 600), while the influence of steep stress gradient s in combination with high strength steels may be underestimated.

- The size factor C_D being a function of diameter only does not purely represent a statistical size influence, but rather a combination of this statistical influence and the notch sensitivity.

6.2.5 The stress concentration factor (scf) at the end of slots can be determined by means of the following empirical formulae:

$$scf = \alpha_{t(hole)} + 0.8 \cdot \frac{(l - e)/d}{\sqrt{\left(1 - \frac{d_i}{d}\right).\frac{e}{d}}}$$

where,

e = slot width
l = length of the slot
d_o = outer diameter
d_i = inner diameter (Refer figure given under Table 6.5.1).

This formula applies to:

- slots at 120 or 180 or 360 degrees apart.

- slots with semicircular ends. (Though multi-radii slot end can reduce the local stresses, this is not included in this empirical formula).

- slots with no edge rounding (except chamfering), as any edge rounding increases the scf slightly.

$\alpha_{t(hole)}$ = factor representing the stress concentration of radial hole of diameter e:

$$= 2.3 - 3.\frac{e}{d} + 15.\left(\frac{e}{d}\right)^2 + 10.\left(\frac{e}{d}\right)^2.\left(\frac{d_i}{d}\right)^2$$

6.3 Plans and particulars

6.3.1 The following plans, in triplicate, together with the necessary particulars of the machinery, including the maximum power and revolutions per minute, are to be submitted for approval before the work is commenced.

- Power take-off arrangement if any (e.g. shaft generator), propulsion boosters or similar equipment rated for 100 [kW] and above;
- Final gear shaft;
- Thrust shaft;
- Intermediate shafting, shaft bearings;
- Tube shaft, where applicable;
- Tail shaft;
- Stern tube, shaft seals and Stern bush;
- Stern tube lubrication system;
- Couplings (integral, demountable, keyed or shrink-fit), coupling bolts and keys;
- Flexible coupling including constructional details, static and dynamic torsional stiffness, damping characteristic, rated power, torque and RPM, allowable vibratory torque for continuous and transient operation and allowable misalignment for continuous operations;
- Cardan shafts, if fitted.

6.3.2 The specified minimum tensile strength of each shaft is to be stated.

6.3.3 A shafting arrangement plan indicating the relative position of the main engines, flywheel, flexible coupling, gearing, thrust block, line shafting and bearings, stern tube, 'A' brackets and propeller, as applicable, is to be submitted for information.

6.4 Materials for shafting

6.4.1 The materials are to comply with the relevant requirements of Pt.2, Ch.5. The specified minimum tensile strength of forgings is to be selected within the following general limits:

a) Carbon and carbon-manganese steel 400-760 [N/mm^2];

b) Alloy steels - 400-800 [N/mm^2];

Where shafts may experience vibratory stresses close to the permissible stresses for transient operation, the materials are to have a specified minimum tensile strength of 500 [N/mm^2].

6.4.2 If materials with greater specified or actual tensile strength than the limitations given in 6.4.1 are used, no consideration will be given

for reduction of shaft diameter; when derived from the formulae given in this chapter. Reduction in shaft diameter may be allowed for intermediate shaft of alloy steel, when it is verified that the material used exhibit fatigue life as conventional steel when tested as per 6.20 of this chapter.

6.4.3 Ultrasonic tests are required on shaft forgings where the diameter is 250 [mm] or greater.

6.5 Intermediate and thrust shafts

6.5.1 The diameter, d, of the shaft is to be not less than determined by the following formula:

$$d = Fk \sqrt[3]{\frac{P}{n}\left(\frac{560}{\sigma B + 160}\right)} \text{ [mm]}$$

where,

F = 95 for turbine installations, electric propulsion installations and oil engine installations with slip type couplings;

= 100 for other oil engine installations;

k = shaft design factors as given in Table 6.5.1;

σB = specified minimum tensile strength of the material [N/mm^2] as per 6.4.1.

P = maximum shaft power, in [kW];

n = Revolutions per minutes corresponding to maximum shaft power giving maximum torque.

6.5.2 For shafts with design features other than stated in Table 6.5.1, the value of k will be specially considered.

6.6 Tailshafts and stern tube shafts

6.6.1 The diameter, d_p, of the tailshaft immediately forward of the forward face of the propeller boss or, if applicable, the forward face of the tailshaft flange, is to be not less than determined by the following formula:

$$d_p = 100\,k \sqrt[3]{\frac{P}{n}\left(\frac{560}{\sigma B + 160}\right)} \text{ [mm]}$$

where,

k = shaft design factors as given in Table 6.6.1;

σB = specified minimum tensile strength of the material [N/mm^2]. For calculation purposes, this value is not to be taken greater than 600 [N/mm^2] (for carbon, carbon manganese and alloy steels);

P and n are defined in 6.5.

6.6.2 The diameter, d_p of the tailshaft determined in accordance with the formula in 6.6.1 is to extend over a length not less than that to the forward edge of the bearing immediately forward of the propeller or 2.5 d_p whichever is the greater.

6.6.3 The diameter of the portion of the tailshaft and tubeshaft forward of the length required by 6.6.2 to the forward end of the forward sterntube seal is to be determined in accordance with the formula in 6.6.1 except that:

k = 1.15, where k = 1.22 or 1.26 as required by 6.6.1 (shafts fitted with continuous liner or oil lubricated);

k = 1.18, where k = 1.25 or 1.29 as required by 6.5.1 (shafts with water lubricated bearings).

The change of diameter from that required by 6.6.1 to that required by this clause should be gradual.

6.6.4 Tailshafts which run in sterntubes and tube shafts may have the diameter forward of the forward stern tube seal gradually reduced to the diameter of the intermediate shaft. Abrupt changes in shaft section at the tailshaft/tubeshaft to intermediate shaft couplings are to be avoided.

Table 6.5.1 : Shaft design factors k for line shafts and thrust shafts

Factor	Intermediate shaft with					Thrust shafts external to engine		
	Integral coupling flange [1]	Shrink fit coupling [2]	Key-ways cylindrical and tapered [3], [4]	Radial holes, transverse holes [5]	Longitudinal slots [6]	On both sides of thrust collars [1]	In way of axial bearings where a roller bearing is used for taking up thrust	Straight sections
k	1.0	1.0	1.1	1.1	1.2	1.1	1.1	1.0

Notes:

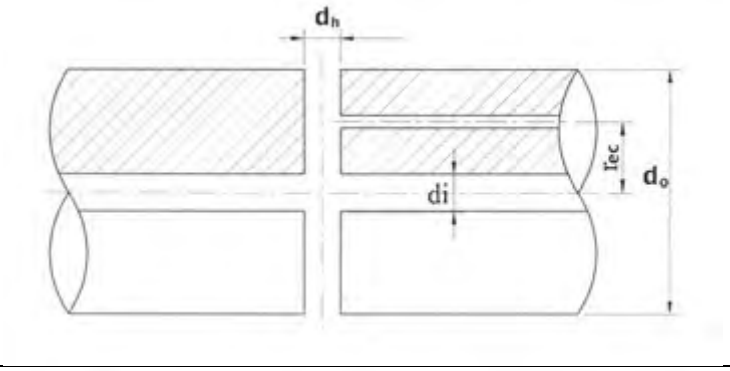
1) Fillet radius is not to be less than 0.08d.

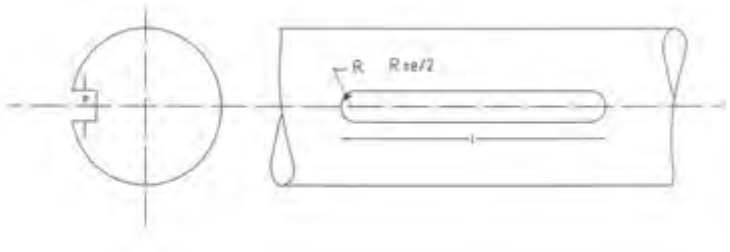
2) k refers to the plain shaft section only. Where shafts may experience vibratory stresses close to the permissible stresses for continuous operation, an increase in diameter to the shrink fit diameter is to be provided, e.g. a diameter increase of 1 to 2% and a blending radius nearly equal to the change in diameter are to be provided.

3) At a distance of not less than 0.2d from the end of the keyway the shaft diameter may be reduced to the diameter calculated with k = 1.0. Fillet radii in the transverse section of the bottom of the key way are not to be less than 0.0125d.

4) It is recommended that keyways are in general not to be used in installations with a slow speed crosshead or 2-stroke engines with a barred speed range.

5) Diameter of radial bore (d_h) not to exceed $0.3d_o$.
The intersection between a radial and an eccentric (r_{ec}) axial bore (see below) the value will be determined on the basis of data submitted in each case.





6) Subject to following limitations being complied with -

i) slot length (l)/outside diameter < 0.8 and
ii) inner diameter (d_i)/outside diameter d_o < 0.7 and
iii) slot width (e)/outside diameter d_o > 0.15.
The end rounding of the slot is not to be less than e/2. An edge rounding should preferably be avoided as this increases the stress concentration slightly. The k value is valid for 1, 2 and 3 slots and they are to be arranged 360, 180 or 120 degrees apart from each other respectively.

Table 6.6.1 : Shaft design factors k for tailshafts [1] and stern tube shafts						
Factor	**Propulsion drive**	**Stern tube configuration**	**Tailshafts : propeller attachment method**			**Stern tube shafts**
			Keyed	**Key less attachment by shrink fit**	**Flanged**	
k	All	Oil lubricating bearings and provided with an approved type of oil seating gland	1.26	1.22	1.22	1.15
	All	Water lubricated bearings : continuous shaft liners / shafts of corrosion resistant material or equivalent	1.26	1.22	1.22	1.15
	All	Water lubricated bearings : non-continuous shaft liners	1.29	1.25	1.25	1.18
Note : 1) Fillet radii in the transverse section at the bottom of the keyway are not to be less than $0.0125d_p$						

6.7 Hollow shafts

6.7.1 For hollow shafts where the bore exceeds 40 per cent of the outside diameter the minimum shaft diameter is not to be less than that given by the following equation:

$$d_o = d \sqrt[3]{\frac{1}{1-\left(\frac{d_i}{d_o}\right)^4}} \quad [mm]$$

where,

d_o = outside diameter [mm];

d = Rule size diameter of shaft [mm], calculated in accordance with 6.5 or 6.6;

d_i = diameter of central hole [mm].

6.7.2 Where the diameter of central hole does not exceed 0.4 times the outside diameter, no increase over Rule size need be provided.

6.8 Integral couplings

6.8.1 The thickness of coupling flanges is not to be less than the minimum required diameter of the coupling bolts calculated as in para 6.9, with tensile strength of the bolt material being taken as the tensile strength of the corresponding shaft material or 0.2 times the rule diameter of the shaft under consideration, whichever is greater. Special consideration will be given by IRS for flanges having non-parallel faces; however, in such cases the thickness of the flanges is not be less than the coupling bolt diameter.

6.8.2 The fillet radius at the base of the coupling flange is to be not less than 0.08 of the diameter of the shaft at the coupling. The fillets are to have a smooth finish and are not to be recessed in way of nuts and bolt heads. The fillet may be formed of multiradii in such a way that the stress concentration factor will not be greater than for a circular fillet with radius 0.08 times the actual shaft diameter.

6.8.3 Where the propeller is attached by means of a flange, the thickness of the flange is to be not less than 0.25 times the actual diameter of the adjacent part of the tailshaft. The fillet radius at the base of the coupling flange is to be not less than 0.125 times the diameter of the shaft at the coupling.

6.9 Demountable couplings

6.9.1 Couplings are to be made of steel or other approved ductile material. The strength of demountable couplings and keys is to be equivalent to that of the shaft. Couplings are to be accurately fitted to the shaft.

6.9.2 Hydraulic and other shrink fit couplings will be specially considered upon submittal of detailed preloading and stress calculations and fitting instructions. In general, the torsional holding capacity is to be at least 2.8 times the transmitted torque and preload stress is not to exceed 70 per cent of the yield strength.

6.9.3 Provision is to be made to resist astern pull.

6.10 Tooth couplings

6.10.1 The contact stress, σ_c, at the flanks of mating teeth of a gear coupling is not to exceed that given in Table below, where:

$$\sigma_c = \frac{24x10^6 P}{nd_p bhz} \ [N/mm^2]$$

P and n are defined in 6.4.1.

d_p = pitch circle diameter of coupling teeth [mm]

b = tooth facewidth [mm]

h = tooth height [mm]

z = number of teeth (per coupling half).

Allowable σ_c values	
Tooth material surface treatment	**Allowable σ_c value [N/mm^2]**
Surface hardened teeth	19
Through hardened teeth	11

6.10.2 Where experience has shown that under similar operating and alignment conditions, a higher tooth loading can be accommodated full details are to be submitted for consideration.

6.11 Flexible couplings

6.11.1 Details of flexible couplings are to be submitted together with the manufacturers' rating capacity, for the designed operating conditions including short term high power operation. Verification of coupling characteristics will be required.

6.11.2 In determining the allowable mean, maximum and vibratory torque ratings, consideration of the mechanical properties of the selected elastic element type in compression, shear and fatigue loading together with heat absorption/generation is to be given.

6.11.3 In determining the allowable torque ratings of the steel spring couplings, consideration of the material mechanical properties to withstand fatigue loading and overheating is to be given.

6.12 Interference fit assemblies

6.12.1 The interference fit assembly is to have a capacity to transmit a torque Q without slippage.

$$Q = 9550 \frac{P}{n} (1+C) . S \ [N-m]$$

Where,

P = power transmitted, kW

n = RPM of the shaft

C = coefficient as per Table 6.12.1

S = 2.0 for assemblies accessible from within the vessel

= 2.5 for assemblies not accessible from within the vessel.

Table 6.12.1 : 'C' values for guidance purposes	
Coupling Location	**C**
High Speed Shafting - IC engine driven	0.3
High Speed Shafting - Electric Motor or Turbine driven	0.1
Low Speed Shafting - Main or PTO stage gearing	0.1

6.12.2 The effect of any axial load acting on the assembly is to be considered.

6.12.3 The resulting equivalent von Mises stress in the assembly is not to be greater than the yield strength of the component material.

6.12.4 Reference marks are to be provided on the adjacent surfaces of parts secured by shrinkage alone.

6.13 Coupling bolts

6.13.1 The diameter of the fitted bolts at the joining faces of the coupling is to be not less than that given by the following formula:

$$d_b = 0.65 \sqrt{\frac{d^3 (T + 160)}{iD T_b}}$$

where,

d_b = diameter of the fitted coupling bolts [mm];

d = required diameter [mm], of the intermediate shaft taking into account ice strengthening requirements, if applicable;

T = specified minimum tensile strength of the shaft material [N/mm^2];

T_b = specified minimum tensile strength of the bolt material [N/mm^2];

= and also $T \leq T_b \leq 1.7\ T$, but not higher than 1000 [N/mm^2]

i = number of bolts in the coupling;

D = pitch circle diameter of bolt holes [mm].

6.13.2 The diameter of the non-fitted bolts will be specially considered upon the submittal of detailed preloading and stress calculations and fitting instructions.

6.14 Tailshaft liners

6.14.1 The thickness, t, of bronze or gunmetal liners fitted on tailshafts, in way of bearings, is not to be less than given by following formula:

$$t = \frac{168 + d_p}{28} \ [mm]$$

where,

t = thickness of liner [mm];

d_p = diameter of tailshaft under the liner [mm].

6.14.2 The thickness of the continuous liner between the bearings is not be less than 0.75t.

6.14.3 Continuous liners are preferably to be cast in one length. If made of several lengths, the joining of the separate pieces is to be made by welding through the whole thickness of liner before shrinking. In general, the lead content of the gunmetal of each length forming a butt welded liner is not to exceed 0.5 per cent. The composition of the electrode or filler rods is to be substantially lead free.

6.14.4 The liners are to withstand a hydraulic pressure of 2.0 bar after rough machining.

6.14.5 The liners are to be carefully shrunk or forced upon the shaft by hydraulic pressure, and they are not to be secured by pins.

6.14.6 Effective means are to be provided for preventing water from reaching the shaft at the part between the after end of the liner and the propeller boss.

6.14.7 If the liner does not fit the shaft tightly between the bearing portions in the stern tube, the space between the shaft and the liner is to be filled with a plastic insoluble non-corrosive compound.

6.15 Keys and keyways for propeller connections

6.15.1 Round ended or sled-runner ended keys are to be used, and the key ways in the propeller boss and cone of the tailshaft are to be provided with a smooth fillet at the bottom of the keyways. The radius of the fillet is to be at least 0.0125 of the diameter of the tailshaft at the top of the cone. The sharp edges at the top of the keyways are to be removed.

6.15.2 Two screwed pins are to be provided for securing the key in the keyway, and the forward pin is to be placed at least one-third of the length of the key from the end. The depth of the tapped holes for the screwed pins is not to exceed the pin diameter and the edges of the holes are to be slightly beveled.

6.15.3 The distance between the top of the cone and the forward end of the keyway is to be not less than 0.2 of the diameter of the tailshaft at the top of the cone.

6.15.4 The effective sectional area of the key in shear, is to be not less than $\frac{d^3}{2.6 d_1}$ [mm^2]

where,

d = diameter [mm], required for the intermediate shaft determined in accordance with 6.4, based on material having a specified minimum tensile strength of 400 [N/mm^2] and k = 1;

d_1 = diameter of shaft at mid-length of the key [mm].

6.16 Stern tube and bearings

6.16.1 The length of the bearing in the sternbush next to and supporting the propeller is to be as follows:

a) For water lubricated bearings; the length is to be not less than 4 times the rule diameter for the tailshaft under the liner;

   i. For a bearing of synthetic material, consideration may be given to a bearing length not less than twice the rule diameter for the tail shaft, provided the bearing design and material is substantiated by experiments to the satisfaction of IRS.

   ii. Synthetic materials for application as water lubricated stern tube bearings are to be type approved.

b) For bearings which are white-metal lined, oil lubricated and provided with an approved type of oil sealing gland;

   i. the length of the bearing is to be not less than twice the rule diameter for the tailshaft.

   ii. the length of the bearing may be less provided the nominal bearing pressure will not exceed 0.8 [N/mm^2] as determined by static bearing reaction calculation taking into account shaft and propeller weight which is deemed to be exerted solely on the aft bearing divided by the projected area of the shaft. However, the length of the bearing is to be not less than 1.5 times its actual diameter;

c) For bearings of cast iron, bronze which are oil lubricated and fitted with an approved oil sealing gland; the length of the bearing is, in general, to be not less than 4 times the rule diameter for tailshaft;

d) For bearings which are grease lubricated, the length of bearing is to be not less than 4 times the rule diameter for the tailshaft;

e) For water lubricated bearings lined with two or more circumferentially spaced sectors of an approved plastics material, in which it can be shown that the sectors operate on hydrodynamic principles, the length of the bearing is to be such that the nominal bearing pressure will not exceed 0.55 [N/mm^2]. The length of the bearing is not to be less than twice its rule diameter;

f) For approved oil lubricated bearings of synthetic rubber, reinforced resin or plastic materials, the length of the bearing is to be not less than 2.0 times the rule diameter of the shaft in way of the bearing. The length of the bearing may be reduced provided the nominal pressure is not more than 6 bar as determined by static bearing reaction calculation taking into account shaft and propeller weight which is deemed to be exerted solely on the aft bearing divided by the projected area of the shaft. In any case the length is not to be less than 1.5 times the actual diameter. Where the material has proven satisfactory testing and operating experience, consideration may be given to an increased bearing pressure. Synthetic materials for application as oil lubricated stern tube bearings are to be type approved.

6.16.2 Forced water lubrication is to be provided for all bearings lined with rubber or plastics where the shaft diameter is 380 [mm] or over. The supply water may come from a circulating pump or other pressure source. The water grooves in the bearings are to be of ample section and of a shape which will be little affected by weardown, particularly for bearings of the plastic type.

6.16.3 The shut off valve or cock controlling the supply of water is to be fitted direct to the after peak bulkhead, or to the sterntube where the water supply enters the sterntube forward of the bulkhead.

6.16.4 Where a tank supplying lubricating oil to the sterntube is fitted, it is to be located above the load water line and is to be provided with a low level alarm device in the engine room.

6.16.5 For vessels with TAILSHAFT CONDITION MONITORING (TCM) notation, the following arrangements are to be provided/ requirements are to be met:

(a) Oil Lubricated Bearings:

(i) Where sternbush bearings are oil lubricated, provision is to be made for cooling the oil by maintaining water in the after peak tank above the level of the sterntube or by other approved means. Means of ascertaining the temperature of the oil in the sternbush are also to be provided;

(ii) At least two independent temperature sensors or other approved arrangements are to be provided for measuring the aft bearing temperature;

(iii) The oil sealing glands used for sterntube bearings are to be of approved type, which will allow for their replacement without shaft withdrawal and removal of the propeller;

(iv) An arrangement for readily obtaining accurate oil samples is to be provided. The sampling point is to be taken from the lowest point in the lub.oil system as far as practicable. Also the arrangements are to be such as to permit the effective removal of the contaminants from the oil lubricating system. The oil sampling points are to be arranged with a test cock and fitted with a signboard;

(v) Possible water content in stern tube lubricating oil is to be monitored by either a test kit provided onboard or by an accredited laboratory;

(vi) An arrangement for bearing wear down measurements is to be provided. Hand operated gauges (like poker gauges) are considered to be acceptable.

(b) Water Lubricated Bearings

(i) An arrangement for bearing wear down measurements is to be provided. Hand operated gauges (like poker gauges) are acceptable. Where used, methods to remotely monitor the aft propeller shaft bearing performance and wear are to be approved and provided with redundancy. Sensors used for wear down monitoring are to be of approved type. Where a single sensor is installed, spare sensor is to be kept onboard the ship. Documentation for trending of rate of bearing weardown obtained from performance monitoring devices is to be in place onboard;

(ii) The lubricant sampling points are to be arranged with a test cock and fitted with a signboard. The open end of the sample pipe is to be located such that the condition of the lubricant and shafting arrangements are most accurately reflected. The sample is not to be taken downstream of filters fitted in the system;

(iii) Filters in the system are to be provided with sufficient redundancy to ensure safe and uninterrupted operation of the propulsion system. Automatic start of pumps is to be arranged on failure of circulation of the lubricant below acceptable limits;

(iv) Provision for alternative means of lubricant supply is to be arranged in order to maintain lubrication in case of loss of system integrity;

(v) Monitoring of lubricant temperature, flow and pressure is to be provided on the lubricant supply piping to the stern tube with means of warning;

(vi) Means of warning to detect contamination by sea water are to be provided (for closed loop system)

(vii) High / low level alarm on the lubricant header tanks are to be provided;

(viii) For closed loop systems, suitable provisions (such as relief valves, vents) for relieving the pressure are to be provided, if the system is capable of building up pressure above the maximum pressure, that the sealing devices are designed to.

(ix) The sealing glands used for sterntube bearings are to be of approved type, which will allow for their replacement without shaft withdrawal and removal of the propeller.

6.16.6 Stern seals are to be of the axially direct face type. Soft packing glands are to be used only if specified by Owners.

6.16.7 Where bulkhead glands are fitted, a watertight sealing arrangement is to be provided. Bulkhead seals is not to be formed by a bulkhead mounted plummer bearing.

6.16.8 Plummer bearings are to be either bulkhead mounted or of pedestal type.

6.17 Roller element bearings

6.17.1 Roller element bearings are to have design life, L_{10h} not less than:

- 40,000 hours for propeller thrust bearing;

- 30,000 hours for other bearings.

Where L_{10h} is the basic rating life in hours which 90% of a sufficiently large group of apparently identical bearings is expected to attain.

6.18 Shaft bearing materials

6.18.1 Shaft bearing fitted in stern bushes and shaft bossings in "A" and "P" brackets are to be constructed from an approved material and effectively secured to prevent rotational and axial movement in the stern tube(s) and stern bush(es)

6.19 Glass Reinforced Plastic coating

6.19.1 The tail shaft may be protected by a fiberglass reinforced plastic coating between liners in accordance with the following procedure, which effectively prevents sea water from contacting the steel shaft. In such cases, the tailshaft survey interval would be 5 years as applicable for the tailshaft survey notation TS(CL). The procedure is to be approved in each case:

a) Coatings are to consist of at least 4 plies of cross-woven glass tape impregnated with resin or equivalent process.

b) The shaft is to be cleaned with solvent or grit blasted.

c) Shaft is to be examined and 1st coat is to be given in presence of Surveyors.

d) Shaft is to be subjected to spark test after coating. There should be freedom from porosity.

e) Effective means are to be provided to prevent water gaining access to the metallic region of the shaft.

f) It is to be ensured that provision is made for overlapping and adequate bonding of the coating.

g) The end of the liner is to stepped and tapered as required to protect the end of the wrapping.

6.20 Special approval of alloy steel used for intermediate shaft material

6.20.1 This sub-section applies to the approval of alloy steel which has a minimum specified tensile strength greater than 800 [N/mm^2], but less than 950 [N/mm^2] intended for use as intermediate shaft material.

6.20.2 Torsional fatigue test

6.20.2.1 A torsional fatigue test is to be performed to verify that the material exhibits similar fatigue life as conventional steels. The torsional fatigue strength of said material is to be equal to or greater than the permissible torsional vibration stress given by the formulae in 8.4.2.

6.20.2.2 The test is to be carried out with notched and unnotched specimens respectively. For calculation of the stress concentration factor of the notched specimen, fatigue strength reduction factor β should be evaluated in consideration of the severest torsional stress concentration in the design criteria.

6.20.2.3 Test Conditions

.1 Test conditions are to be in accordance with Table 6.20.2.3. Mean surface roughness is to be less than 0.2μm Ra with the absence of localized machining marks verified by visual examination at low magnification (x20) as required by section 8.4 of ISO 1352:2021.

.2 Test procedures are to be in accordance with section 10 of ISO 1352:2021.

Table 6.20.2.3: Test Condition

Loading Type	Torsion
Stress ratio	R = -1
Load waveform	Constant-amplitude sinusoidal
Evaluation	S-N Curve
Number of cycles for test termination	1 x 10^7 cycles

6.20.2.4 Acceptance criteria

.1 Measured high-cycle fatigue strength τ_{C1} and low cycle torsional fatigue strength τ_{C2} are to be equal to or greater than the values given by the following formulae:

$$\tau_{C1} \geq \tau_{C,\lambda=0} = \frac{\sigma_B + 160}{6} C_K C_D$$

$$\tau_{C2} \geq 1.7 \frac{1}{\sqrt{c_k}} \tau_{C1}$$

Where

C_k = factor for the particular shaft design features, see 6.2.4

scf = stress concentration factor , see 6.2.4

C_D = Size factor, see 8.4.2

σ_B = specified minimum tensile strength in [N/mm^2] of the shaft material.

6.20.3 Cleanliness requirements

6.20.3.1 The steels are to have a degree of cleanliness as shown in Table 6.20.3.1 when tested according to ISO 4967:2013 method A. Representative samples are to be obtained from each heat of forged or rolled products.

6.20.3.2 The steels are generally to comply with the minimum requirements of Pt.2, Ch.5 Sec.2, Table 2.2.2, with particular attention given to minimizing the concentrations of sulphur, phosphorus and oxygen in order to achieve the cleanliness requirements. The specific steel composition is required to be approved by IRS.

Table 6.20.3.1 : Cleanliness Requirements

Inclusion Group	Series	Limiting chart diagram index
Type A	Fine	1
	Thick	1
Type B	Fine	1.5
	Thick	1
Type C	Fine	1
	Thick	1
Type D	Fine	1
	Thick	1
Type DS	-	1

6.20.4 Inspection

6.20.4.1 The ultrasonic testing required by Pt 2 Ch5 is to be carried out prior to acceptance. The acceptance criteria are to be in accordance with *IRS Classification Note "Guidelines for Non-Destructive Testing of Hull and machinery Steel Forgings*" or a recognized national or international standard.

Section 7

Propellers

7.1 Scope

7.1.1 The requirements of this Section cover the construction, materials and inspection of propellers.

7.2 Plans and particulars

7.2.1 A plan, in triplicate, of the propeller is to be submitted for approval, together with the following particulars:

a) Maximum shaft power, P, in [kW];

b) Revolutions per minute of the propeller at maximum power, R;

c) Propeller diameter, D [m];

d) Pitch at 25 per cent radius (for solid propellers only), $P_{0.25}$ [m];

e) Pitch at 35 per cent radius (for controllable pitch propellers only), $P_{0.35}$ [m];

f) Pitch at 70 per cent radius, $P_{0.7}$ [m];

g) Length of blade section of the expanded cylindrical section at 25 per cent radius (for solid propeller only), $L_{0.25}$ [mm];

h) Length of blade section of expanded cylindrical section at 35 per cent radius (for controllable pitch propellers only) $L_{0.35}$ [mm];

i) Rake at blade tip measured at shaft axis (backward rake positive, forward rake negative), K [mm];

j) Number of blades, N;

k) Developed area ratio, a.

7.2.2 In case of controllable pitch propeller following additional plans / data is to be submitted:

- Hub and it's attachments to tailshaft flange with connecting bolts
- Propeller blade flange and it's attachment bolts
- Internal control mechanisms
- Hydraulic piping control systems
- Instrumentation and alarm systems
- Strength calculations for internal components

In case of highly skewed propellers with skew angle greater than 50 degree and controllable pitch propeller skew angle greater than 25 degrees, propeller load and stress analysis proving adequacy of blade strength are to be submitted.

7.3 Materials

7.3.1 Castings for propellers and propeller blades are to comply with the requirement of Pt.2, Ch.8. The specified minimum tensile strength is to be not less than stated in Table 7.4.1.

7.3.2 When it is proposed to use materials which are not included in Table 7.4.1, details of the chemical composition, mechanical properties and density are to be submitted for approval.

7.4 Design

7.4.1 Minimum blade thickness

7.4.1.1 Where the propeller blades are of conventional design, the thickness, t, of the propeller blades at 25 per cent radius for solid propellers, at 35 per cent for controllable pitch propellers, neglecting any increase due to fillets, is to be not less than:

Table 7.4.1 : Material constants			
Materials	**Specified min. UTS [N/mm²]**	**f**	**w**
Manganese bronze Grade Cu 1	440	20.6	8.3
Ni-Manganese bronze Grade Cu 2	440	20.9	8.0
Ni-Aluminium bronze Grade Cu 3	590	25.7	7.5
Mn-Aluminium bronze Grade Cu 4	630	23.25	7.5
Cast iron	250	11.77	7.2
Carbon and low alloy steels	400	14.0	7.9
Note : The value of f may be increased by 10 percent for twin screw and outboard propellers of triple screw ships.			

a) For fixed propellers

$$t_{0.25} = 1055\sqrt{\frac{AP}{C_n CRN}} + \frac{2.5BKC_s}{CC_n}$$

b) For controllable pitch propellers

$$t_{0.35} = 847\sqrt{\frac{AP}{C_n CRN}} + \frac{1.6BKC_s}{CC_n}$$

where,

$t_{0.25}$ = minimum blade thickness required at 25 per cent radius;

$t_{0.35}$ = minimum blade thickness required at 35 per radius;

C_n = section modulus coefficient at 25 per cent radius or 35 per cent radius as applicable;

$= \frac{l_o}{U_f L T^2}$ and is not to be taken greater than 0.10;

l_o = moment of inertia of the expanded cylindrical section at 25 per cent radius or 35 per cent radius, as applicable, about a straight line passing through the center of gravity parallel to the pitch line or to the nose-tail line [mm⁴];

U_f = maximum normal distance from the moment of inertia axis to points on the face boundary (tension side) of the section at 25 per cent radius or 35 per cent radius, as applicable [mm];

L = length of the blade section of the expanded cylindrical section at 25 per cent radius or 35 per cent radius, as applicable [mm];

T = maximum thickness of the expanded cylindrical section as approved at 25 per cent or 35 per cent radius, as applicable [mm];

C_s = section area coefficient at 25 per cent radius or 35 per cent radius as applicable;

$$= \frac{a_s}{LT}$$

a_s = area of the expanded cylindrical section at 25 per cent radius or 35 per cent radius, as applicable [mm²];

f = material constant as per Table 7.4.1;

w = material constant as per Table 7.4.1;

a) For fixed-pitch propellers

$$A = 1.0 + \frac{6.0D}{P_{0.7}} + \frac{4.3P_{0.25}}{D}$$

$$B = \left(\frac{4300\,w\,a}{N}\right)\left(\frac{R}{100}\right)^2\left(\frac{D}{20}\right)^3$$

$$C = \left(1 + \frac{1.5P_{0.25}}{D}\right)\left(L_{0.25}\,f - B\right)$$

b) For controllable pitch propellers

$$A = 1.0 + \frac{6.0D}{P_{0.7}} + \frac{3.0P_{0.35}}{D}$$

$$B = \left(\frac{4900\,w\,a}{N}\right)\left(\frac{R}{100}\right)^2\left(\frac{D}{20}\right)^3$$

$$C = \left(1 + \frac{0.6P_{0.25}}{D}\right)\left(L_{0.35}\,f - B\right)$$

7.4.1.2 Propellers of unusual design or application will be subject to special consideration upon submittal of detailed stress calculations.

7.4.1.3 Fillets at the root of the blades are not to be considered in the determination of blade thickness.

7.4.2 Controllable pitch propellers

7.4.2.1 In the case of controllable - pitch propellers, means are to be provided to lock the blades in ahead position in case of the failure of the pitch operating mechanism.

7.4.2.2 A propeller pitch indicator is to be fitted at each location from which it is possible to control the pitch of the propeller.

7.5 Fitting of propellers

7.5.1 The propeller boss is to be a good fit on the tailshaft cone. The forward edge of the bore of the propeller boss is to be rounded to about 6 [mm] radius. In general the contact area between propeller hub and tailshaft taper is to be not less than 70 per cent of the theoretical contact area. On completion of final pull-up propeller is to be secured.

7.5.2 The exposed part of the tailshaft is to be protected from the action of water by filling all spaces between propeller hub, cap and shaft with a suitable filling material. The propeller assembly is to be sealed at the forward end with a well-fitted soft rubber packing ring. When the rubber ring is fitted in an external gland, the hub counterbore is to be filled with suitable material, and clearances between shaft liner and hub counterbore are to be kept to a minimum. When the rubber ring is fitted internally, ample clearance is to be provided between liner and hub and the ring is to be sufficiently sized to squeeze in to the clearance space when the propeller is driven up on the shaft, and, where necessary, a filler piece is to be fitted in the propeller - hub keyway to provide a flat unbroken seating for the ring. The recess formed at the small end of the taper by the over hanging propeller hub is to be packed with red lead putty or rust-preventing compound before the propeller nut is put on.

7.5.3 Effective means are to be provided to prevent the slackening of the propeller nut.

7.6 Keyless fittings of propellers without ice strengthening

7.6.1 Design criteria

7.6.1.1 The formulae, etc., given herein are not applicable for propellers where a sleeve is introduced between shaft and boss.

7.6.1.2 The taper of the propeller shaft cone is not to exceed 1/15.

7.6.1.3 Prior to final pull-up, the contact area between the mating surfaces is to be checked and is not to be less than 70% of the theoretical contact area (100%). Non-contact bands extending circumferentially around the boss or over the full length of the boss are not acceptable.

7.6.1.4 After final pull-up, the propeller is to be secured by a nut on the propeller shaft. The nut should be secured to the shaft.

7.6.1.5 The factor of safety against friction slip at 35°C is not to be less than 2.8 under the action of rated torque (based on rated power r.p.m.) plus torque due to torsionals.

7.6.1.6 For the oil injection method the coefficient of friction is to be should be 0.13 for bosses made in copper-based alloy and steel.

7.6.1.7 The maximum equivalent uniaxial stress in the boss at 0°C based on the Mises-Hencky criterion(σ_E) is not to exceed 70% of the yield point or 0.2% proof-stress (0.2% offset yield strength) for the propeller material based on the test piece value. For cast iron the value is not to exceed 30% of the nominal tensile strength.

7.6.1.8 Stress calculations and fitting instructions are to be submitted and are to include at least the following:

i)Theoretical contact surface area

ii)The maximum permissible pull-up length at 0°C as limited by the maximum permissible uniaxial stress specified above

iii)The minimum pull-up length and contact pressure at 35°C to attain a safety factor against slip of 2.8

iv)The proposed pull-up length and contact pressure at fitting temperature

v) The rated propeller ahead thrust

7.6.2 Material Constants

Modulus of elasticity	
Cast and forged steel	20.58 x 10^4 N/mm^2
Cast iron	9.8 x 10^4 N/mm^2
Copper based alloys, Cu 1 and Cu 2	10.78 x 10^4 N/mm^2
Copper based alloys, Cu 3 and Cu 4	11.76 x 10^4 N/mm^2

Possion's ratio	
Cast and forged steel	0.29
Cast iron	0.26
All copper-based alloys	0.33

Coefficient of linear expansion	
Cast and forged steel and cast iron	12 x 10^{-6} mm/mm ˚C
All copper-based alloys	17.5 x 10^{-6} mm/mm ˚C

7.6.3 Formulae used

7.6.3.1 The formulae given below, for the ahead condition, will also give sufficient safety in the astern condition.

7.6.3.2 The formulae are applicable for solid shafts only.

7.6.3.3 Minimum required surface pressure at 35°C is to be:

$$P_{35} = \frac{ST}{AB}\left[-S\theta + \sqrt{\mu^2 + B\left(\frac{F_v}{T}\right)^2}\right]$$

Where

$$B = \mu^2 - S^2\theta^2$$

P_{35} = surface pressure (N/mm^2) between mating surfaces at 35°C

A = 100% theoretical contact area (mm^2) between boss and shaft, as read from drawings and disregarding oil grooves

S = factor of safety against friction slip at 35°C

θ = half taper of propeller shaft, e.g. taper = 1/15. θ = 1/30

μ = coefficient of friction between mating surfaces

T = rated thrust (N)

Corresponding minimum pull-up length at temperature 35°C

$$\delta_{35} = P_{35}\frac{D_s}{2\theta}\left[\frac{1}{E_b}\left(\frac{K^2+1}{K^2-1} + v_b\right) + \frac{1}{E_s}(1 - v_s)\right]$$

δ_{35} = pull-up length (mm) at temperature 35°C

K = D_b/D_s

E_s = modulus of elasticity (N/mm2) of shaft material

E_b = modulus of elasticity (N/mm2) of boss material

D_s = diameter (mm) of propeller shaft at the midpoint of the taper in the axial direction

D_b = mean outer diameter (mm) of propeller boss at the axial position corresponding to D_s

vs = Poisson's ratio for shaft material

vb = Poisson's ratio for boss material

7.6.3.4 Minimum pull-up length at temperature t (where t<35°C)

$$\delta_t = \delta_{35} + \frac{D_s}{2\theta}(\alpha_b - \alpha_s)(35 - t)$$

Corresponding minimum surface pressure at temperature t

$$P_t = P_{35}\frac{\delta_t}{\delta_{35}}$$

Minimum push-up load at temperature t

$$W_t = AP_t(\mu + \theta)$$

δ_t = pull-up length (mm) at temperature *t*°C

*D*s = diameter (mm) of propeller shaft at the midpoint of the taper in the axial direction

α_s = coefficient of linear expansion (mm/mm°C) of shaft material

α_b = coefficient of linear expansion (mm/mm°C) of boss material

*P*t = surface pressure (N/mm^2) between mating surfaces at temperature *t*°C

W_t = push-up load (N) at temperature *t*°C

7.6.3.5 Maximum permissible surface pressure at 0°C

$$P_{max} = \frac{0.7\sigma_y(K^2-1)}{\sqrt{3K^4+1}}$$

Corresponding maximum permissible pull-up length at 0°C

$$\delta_{max} = \frac{P_{max}}{P_{35}}\delta_{35}$$

P_{max} = maximum allowable surface pressure (N/mm^2) at 0°C

σ_y = yield point or 0.2% proof stress (0.2% offset yield strength) of propeller material (N/mm^2)

P_{35} = surface pressure (N/mm^2) between mating surfaces at 35°C

δ_{max} = maximum allowable pull-up length (mm) at temperature 0°C

7.6.3.6 Shear force at interface

$$F_v = \frac{2cQ}{D_s}$$

*F*v = shear force at interface (N)

c = constant,

c = 1.0 for turbines, geared diesel drives, electric drives and for direct diesel drives with a hydraulic or an electromagnetic or high elasticity coupling

c = 1.2 for a direct diesel drive.
IRS reserves the right to increase the *c* constant if the shrinkage has to absorb an extreme high pulsating torque.

Q = rated torque (N mm) transmitted according to rated horsepower, *H*, and speed of propeller shaft

7.6.3.7 Rated thrust developed for free running vessels (if not given)

$$T = 9.8 \times 132\frac{H}{V_s}$$

Or

$$T = 9.8 \times 4.3 \,.\, 10^6 \,\frac{H}{PN}$$

T = rated thrust (N)

H = rated brake horsepower (PS)

*V*s = ship speed (knots) at rated horsepower

P = mean propeller pitch (mm)

N = propeller speed (r.p.m.) at rated brake horsepower

Section 8

Vibrations and Alignment

8.1 Scope

8.1.1 The requirements of this Section are applicable to the following systems:

a) Main oil engine propulsion systems, except in the case of ships classed for smooth water service, when fitted with engines having powers less than 200 [kW].

b) Auxiliary oil engine machinery systems used for essential services, where the power developed by auxiliary engines is 200 [kW] and over.

c) Main propulsion systems formed by turbines or electric motors geared to the shafting and situated aft.

8.1.2 Unless otherwise advised, it is the responsibility of the Shipbuilder as the main contractor to ensure, in co-operation with the Engine builders, that the information required by this Section is prepared and submitted.

8.2 Basic system requirements

8.2.1 The systems are to be free from excessive torsional, axial and lateral vibration, and are to be aligned in accordance with tolerances agreed with the respective manufacturers.

8.2.2 Where changes are subsequently made to a dynamic system which has been approved, revised calculations are to be submitted for consideration.

8.3 Resilient mountings

8.3.1 Where the machinery is installed on resilient mountings, linear vibration (steady state and transient) is not to exceed the limiting values agreed with the manufacturers of the machinery nor those of the resilient mountings.

8.3.2 Misalignment arising from such vibration is not to impose excessive loading on machinery components within the system.

8.4 Torsional vibration

8.4.1 General

8.4.1.1 Torsional vibration calculations, including an analysis of the vibratory torques and stresses for the dynamic systems formed by the oil engines, turbines, motors, generators, flexible couplings, gearing, shafting and propeller, where applicable, including all branches, are to be submitted for approval together with the associated plans.

8.4.1.2 Particulars of the division of power developed throughout the speed range for turbines or from all intended combinations of operation in oil engine installations having more than one engine and/or with power take-off systems are to be submitted.

8.4.1.3 Any special speed requirements for prolonged periods in service are to be indicated, e.g., range of trawling revolutions per minute, range of operation revolutions per minute with a controllable pitch propeller, idling speed, etc.

8.4.1.4 The calculations and/or measurements carried out on oil engine installations containing transmission items sensitive to vibratory torque, e.g. gearing, flexible couplings, or generator rotors and their drives, are to take into account the effects of engine malfunction commonly experienced in service, such as cylinder(s) not firing.

8.4.1.5 Restricted speed ranges will be imposed in regions of speed where stresses are considered to be excessive for continuous running. Similar restrictions will be imposed, or other protective measures required to be taken, where vibratory torques are considered to be excessive for particular machinery items.

8.4.1.6 Where calculations indicate the possibility of excessive torsional vibration within the range of working speeds, torsional vibration measurements, using the appropriate recognized techniques, may be required to be taken from the machinery installation for the purpose of determining the need for restricted speed ranges.

8.4.2 Permissible limits of stresses due to torsional vibrations

8.4.2.1 Alternating torsional vibration stresses are stresses resulting from the alternating torque which is superimposed on the mean torque.

8.4.2.2 In no part of the propulsion system may the alternating torsional vibration stresses exceed the values of $\tau 1$ for continuous operation and $\tau 2$ for transient running.

8.4.2.3 For continuous operation the permissible stresses due to alternating torsional vibrations are not to exceed the following values:

$$\tau_1 = \pm \frac{\sigma B + 160}{18} C_k \, C_D \, (3 - 2\lambda^2) \text{ for } \lambda < 0.9$$

$$\tau_1 = \pm \frac{\sigma B + 160}{18} 1.38 \, C_k \, C_D \text{ for } 0.9 \le \lambda < 1.05$$

where,

τ_1 = permissible stress due to torsional vibrations for continuous operation [N/mm^2];

σB = tensile strength of shaft material [N/mm^2];

For calculation purposes, this value is not to be taken greater than:

- 600 [N/mm^2] for carbon and carbon manganese steels; and
- 800 [N/mm^2] for alloy steels;

C_k = factor for different shaft design features as given in Table 8.4.2;

C_D = size factor = $0.35 + 0.93d^{-0.2}$;

d_o = shaft outside diameter under consideration [mm];

λ = speed ratio = n/n_o;

n = speed in rpm under consideration at rated power;

n_o = rated speed in rpm.

8.4.2.4 Where a vessel, because of its type of employment, is operated predominantly in the lower speed range, special consideration may be given to the permissible stresses for continuous operation.

8.4.2.5 Where the stresses exceed the limiting values of τ_1 for continuous operation, restricted speed ranges are to be imposed which are only allowed to be passed through rapidly. Cl.4.12.6.1 may also be referred for barred speed range requirements.

8.4.2.6 Restricted speed ranges are not acceptable, in the speed range between 0.8 to 1.05 of the rated speed. The limits of the barred speed range are to be calculated in accordance with the following formula unless proved to be otherwise.

$$\frac{16\mathrm{N}_c}{18-\lambda} \le n \le \frac{(18-\lambda)\mathrm{N}_c}{16}$$

where,

n_c = critical speed in [rpm].

Table 8.4.2 : c_k factors for different design features

Intermediate shafts with						Thrust shafts external to engines		Tailshafts		
Integral coupling flange and straight section	shrink fit couplings	Keyway, tapered connection	Keyway, cylindrical connection	Radial hole	Longitudinal slot[1]	On both sides of thrust collar	In way of bearing when a roller bearing is used	Flange mounted or keyless taper fitted propellers	Key fitted propellers	Between forward end of aft most bearing and forward stern tube seal
C_k = 1.0	1.0	0.60	0.45	0.50	0.30 [2)]	0.85	0.85	0.55	0.55	0.80

Note:

1) The c_k value is valid for 1, 2 and 3 slots and they are to be arranged 360, 180 or 120 degrees apart from each other respectively.
2) C_k = 0.3 is an approximation within the limitations given in Note No.6 under Table 6.5.1. More accurate estimate of the stress concentration factor (scf) may be determined from 6.2.3 c) or by direct application of FEM calculation. In which case:

   C_k = 1.45/scf

   The scf is defined as the ratio between the maximum local principal stress and √3 times the nominal torsional stress (determined for the bored shaft without slots).

8.4.2.7 For transient running the permissible stresses due to the alternating torsional vibrations are not, in any case, to exceed the values given by the following formula:

$$\tau_2 = \frac{1.7\,\tau_1}{\sqrt{C_k}} \text{ for } \lambda \le 0.8$$

where,

τ_2 = permissible stress due to torsional vibrations for transient running.

8.4.2.8 If materials with greater specified or actual tensile strength than the limitations given in 8.4.2.3 are used higher permissible vibration stresses are not acceptable when derived from formulae in 8.4.2.3. Higher permissible stress may be allowed for intermediate shaft using alloy steel, when it is verified that the material used exhibit fatigue life as conventional steel when tested as per 6.20 of this chapter.

8.5 Axial vibrations

8.5.1 For all main propulsion shafting systems, the Shipbuilders are to ensure that amplitudes due to axial vibrations are satisfactory throughout the speed range, so far as practicable. Where appropriate, amplitudes may be reduced by the use of suitable vibration dampers or phasing of propeller and engine, etc.

8.5.2 Unless previous experience of similar installation shows it to be unnecessary, calculations of the shafting system are to be carried out. These calculations are to include the effect of the thrust block seating and the surrounding hull structure taking part in the vibration. The result of these calculations or the evidence of previous experience is to be submitted for consideration.

8.5.3 Where calculations indicate the possibility of excessive axial vibration amplitudes within the range of working speeds, measurements using an appropriate recognized technique may be required to be taken from the shafting systems for the purpose of determining the need for restricted speed ranges.

8.6 Lateral vibrations

8.6.1 For all main propulsion shafting systems, the Shipbuilders are to ensure that amplitudes due to lateral vibrations are satisfactory throughout the speed range.

8.6.2 Unless previous experience of similar installations shows it to be unnecessary, calculations of lateral, or bending, vibration characteristics of the shafting system are to be carried out. These calculations, taking account of dynamic bearing stiffnesses, are to cover the frequencies giving rise to all critical speeds which may result in significant amplitudes within

the speed range, and are to indicate relative deflections and bending moments throughout the shafting system.

8.6.3 The results of these calculations, or the evidence of previous experience, is to be submitted for consideration.

8.6.4 Where calculations indicate the possibility of excessive lateral vibration amplitudes within the range of working speeds, measurements using an appropriate recognized technique may be required to be taken from the shafting system for the purpose of determining the need for restricted speed ranges.

8.7 Shaft alignment

8.7.1 For main propulsion installations, the shafting is to be aligned to give reasonable bearing reactions, and bending moments, taking into consideration following factors :

- Forces which may affect the reliability of the propulsion shafting system including weight of the propeller and shafts,
- Hydrodynamic forces acting on the propeller,
- Number of propeller blades in relation to diesel engine cylinders,
- Misalignment forces,
- Thermal expansion,
- Flexibility of engine and thrust bearing foundations,
- Engine induced vibrations, gear tooth loadings, flexible couplings,
- Effect of power take-off,
- Effect of hull deformations at all conditions of ship loading and operation.

Consideration is also to be given to any limits of vibrations and loadings specified by the equipment manufacturer. The Shipbuilder is to position the bearings and construct the bearing seatings to minimize the effects of movements under all operating conditions.

8.7.2 For geared installations, where two or more pinions are driving the final reduction wheel, calculations are to be submitted to verify that shaft alignment is such that proper bearing reactions are maintained under all operating conditions.

8.7.3 Shaft alignment calculations are to be submitted for the following alignment-sensitive types of installations for review:

i) Propulsion shafting with power take-off or with booster power arrangements.
ii) Propulsion shafting for which the tail shaft bearings are to be slope bored.
iii) Propulsion shaft having diameter 300mm. and above in way of after most stern tube bearing
iv) Propulsion shafting arrangement requiring long shaft line.

The alignment calculations are to include bearing reactions, shear forces and bending moments along the shafting.

The alignment calculations are to be performed for the following conditions, as applicable:

- Theoretically aligned cold and hot conditions of the shaft with specified alignment tolerances.
- Deviation from the theoretical aligned conditions due to the forces exerted by power take-off or booster power.

Calculations are to be performed for the maximum allowable alignment tolerances and are to show that:

- Bearing loads under all operating conditions are within the acceptable limits specified by the bearing manufacturer.
- Bearing reactions are always positive (i.e. supporting the shaft).
- Shear forces and bending moments on the shaft are within acceptable limits in association with other stresses in the shaft.
- Forces and moments on propulsion equipment are within the limits specified by the machinery manufacturers.

8.7.4 Shaft alignment is to be verified by measurement.

Section 9

Thrusters

9.1 Scope

9.1.1 The requirements of this section are applicable to:

- fixed thruster for propulsion
- steerable thruster units (azimuth thrusters) for propulsion and steering
- tunnel thruster for transverse propulsion aid to manoeuvring.

9.2 Plans and particulars

The following plans and information in triplicate are to be submitted.

9.2.1 Fixed/azimuth propulsion thrusters

a) A general arrangement sectional assembly plan showing all the connections of the torque transmitting components from the prime mover to the propeller, together with the azimuthing mechanism and if a nozzle is provided, the nozzle ring structure and nozzle support struts.

b) Detailed and dimensional plans of the individual torque transmitting components.

c) Schematic plans for lubricating and hydraulic systems, together with pipe material, relief valves and working pressures.

9.2.2 Tunnel thrusters

In addition to applicable requirements of 9.2.1, structural assembly plan including connections to tunnel.

9.2.3 Calculations and specifications

a) Thruster prime mover type and operational power/speed envelop.

b) Rating and type of motor for the azimuthing mechanism (e.g. type hydraulic or electric).

c) Gearing calculations for the azimuthing and propulsion mechanism which is to be designed in accordance with classification notes on the design of gearing. Calculation for bevel gears is to be on the basis of a conversion to equivalent helical gear.

d) Bearing specifications.

e) Details of control engineering aspects in accordance with Chapter 7.

f) Calculations indicating suitability of components for short term high power operation, where applicable.

g) Where design is carried out using fatigue analysis, a fatigue strength analysis of components indicating a factor of safety of 1.5 at the design loads based on a suitable fatigue failure criteria is required to be submitted for review.

9.3 Materials

9.3.1 The materials used on the construction are to be manufactured and tested in accordance with Part 2.

9.3.2 The grades for various components to be analogous to relevant section of the Rules, Pt.4, Ch.4, Sec.7 for propellers, Pt.4, Ch.4, Sec.6 for shafting and Pt.4, Ch.4, Sec.5 for gearing.

9.4 Design and construction

9.4.1 General

9.4.1.1 The arrangement of all types of thrusters is to be such that the craft can be manoeuvred in accordance with the design specifications.

9.4.1.2 The requirements associated with the structural and watertight integrity and the installation arrangement are to be in accordance with Pt.3.

9.4.1.3 In addition to the requirements of this section reference is to be made to:

- Main transmission gearing (Pt.4, Ch.4, Sec.5). Bevel gears will be specially considered on the basis of a conversion to equivalent helical gears.

- Main transmission shafting (Pt.4, Ch.4, Sec.6).

- Propeller (Pt.4, Sec.7).

- Torsional vibration (Pt.4, Ch.4, Sec.8 of the 'Rules and Regulations for the Construction and Classification of Steel Ships').

- Lateral vibration for shafting systems which include cardan shafts (Pt.4, Ch.4, Sec.8 of the 'Rules and Regulations for the Construction and Classification of Steel Ships').

9.4.2 Azimuth thrusters

9.4.2.1 The following requirements are to be complied with:

a) The azimuthing mechanism is to be capable of a maximum rotational speed of not less than 1.5 rev/min.

b) Gearing for the azimuthing mechanism is to be designed in accordance with classification notes on the design of gearing. Bevel gears will be specially considered on the basis of a conversion to equivalent helical gears.

i) Under dynamic operating conditions, the gear is to be considered for:

- Design maximum dynamic duty steering torque.

- Variable loading, where applicable. A spectrum (duty) factor may be used. The load spectrum value is to be derived using load measurements of similar units, where possible.

ii) Under a static duty (< 10^3 load cycles) steering torque. (for azimuth thruster with nozzle see 9.4.3.1).

iii) The following minimum factor of safety values are to be achieved:

Surface stress S_{Hmin} = 1.2

Bending Stress S_{Fmin} = 1.55

c) For hydraulic pressure retaining parts and load bearing (See Chapter 5).

9.4.3 Azimuth thrusters with a nozzle

9.4.3.1 For steerable rudder propellers contained within a nozzle, the design lateral force Fr and the turning moment Q_r is to be calculated as follows:

$$F_r = 376 \cdot A \cdot V^2 \quad [N]$$

$$Q_r = F_r \cdot r \quad [N\text{-}m]$$

where,

A = projected area of nozzle [M^2]

V = Maximum service speed [knots] with the ship on summer load waterline. When the speed is less than 10 knots, V is to be replaced by the expression $V_{min} = (V+20)/3$

r = the horizontal distance from centre line of stock to centre of pressure of nozzle, but not to be taken less than 10% of the chord length of the nozzle.

The nozzle stock diameter in way of tiller, is to be not less than:

$$d_u = 4.2\sqrt[3]{Q_r.K} \quad [mm]$$

where,

k = material factor for nozzle stock.

9.4.3.2 The scantlings of the nozzle stock or steering tube are to be such that the equivalent stress, σ,does not exceed 118/k [N/mm^2] i.e.

$$\sigma_e = \sqrt{\sigma^2 + 3\tau_t^2} \leq 118/k \ [N/mm^2]$$

where,

σ is the bending stress [N/mm^2] calculated using the maximum bending moment, BM, on the nozzle stock or steering tube.

For nozzles without bottom support :

$$BM = \sqrt{F_r^2 + T^2} \ x\ a \ [Nm]$$

T = Maximum thrust developed by the thruster [N]

F_r = design lateral force [N/mm^2] as per 9.4.3.1

a = Vertical distance from centre line of nozzle to the section under consideration [m] (See Fig.9.4.3.2).

τ_t is the torsional shear stress [N/mm^2] calculated using the torque Qr as per 9.4.3.1.

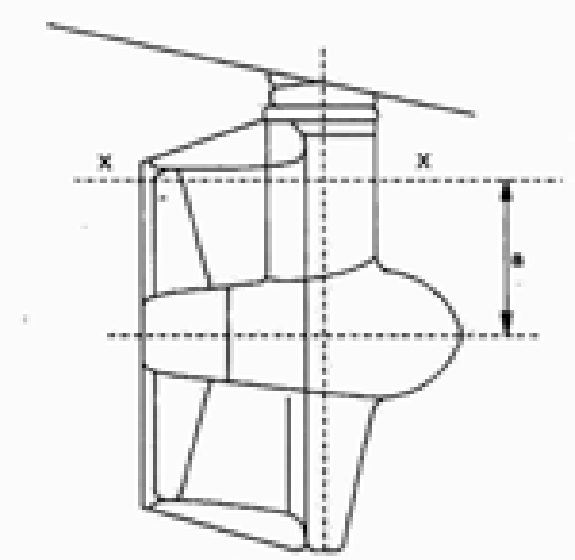


Fig.9.4.3.2 : Azimuth thrusters

9.5 Piping systems

9.5.1 General

The piping system for azimuth thrusters is to comply with the general design requirements given in Pt.4, Ch.2.

The specific requirements for lubricating/ hydraulic oil systems and standby arrangements are given in Pt.4, Ch.3.

9.5.2 Azimuth thruster

The hydraulic power operating systems for each azimuth thruster are to be provided with the following:

a) Arrangements to maintain the cleanliness of the hydraulic fluid, taking into consideration the type and design of the hydraulic system.

b) A fixed storage tank having sufficient capacity to recharge at least one azimuth power actuating system including the reservoir. The piping from the storage tank is to be permanent and arranged in such a manner as to allow recharging from within the thruster space.

c) Where the lubricating oil for the azimuth thrusters is circulated under pressure, provision is to be made for the efficient filtration of the oil. The filters are to be capable of being cleaned without stopping the thruster or reducing the supply of filtered oil.

9.6 Control and monitoring

9.6.1 General

9.6.1.1 Except where indicated in this section the control engineering systems are to be in accordance with Pt.4, Ch.7.

9.6.1.2 Azimuthing control for azimuth thruster(s) and propeller pitch control for azimuth and/or tunnel thruster(s) are to be provided from the navigating bridge, the main machinery control location and locally.

9.6.1.3 Means are to be provided at the remote control location(s) to stop each azimuth or tunnel thruster unit.

9.6.2 Monitoring and alarms

9.6.2.1 Alarms and monitoring requirements are indicated in 9.6.2.2, 9.6.2.3 and Table 9.6.2.

Table 9.6.2		
Item	**Alarm**	**Note**
Thruster, azimuth or tunnel		Indicators, see 9.6.2.2
Azimuthing motor	Power failure, single phase	Also running indication on bridge and at machinery control location
Propeller pitch motor	Power failure	In case of failure the propeller pitch should be locked in full ahead position. Also running indication on bridge and at machinery control location
Electric propulsion motor	Overload, power failure	Also running indication on bridge and at machinery control location
Control system	Failure	
Hydraulic oil supply tank level	Low	
Hydraulic oil system pressure	Low	
Hydraulic oil system temperature	High	Where oil cooler is fitted
Hydraulic oil filters differential pressure	High	Where oil filters are fitted
Lubricating oil supply pressure	Low	If separate forced lubrication

9.6.2.2 An indication of the angular position of the azimuth thruster(s) and the propeller pitch position for azimuth and/or tunnel thruster(s) are to be provided at each location from which it is possible to control the direction of thrust or the pitch.

9.6.2.3 All alarms associated with thruster unit faults are to be indicated individually on the navigating bridge and in accordance with the alarm system specified by Chapter 7.

9.7 Electrical systems

9.7.1 General

The electrical installation is to be designed, constructed and installed in accordance with the requirements of Pt.4, Ch.8.

9.7.2 Emergency power for steering systems and drives

The arrangement to comply with Pt.4, Ch.6, Sec.6, Cl.6.1.1

9.7.3 Circuits

Azimuth thruster auxiliaries and controls are to be served by individual circuits. Services that are duplicated are to be separated throughout their length as widely as is practicable and without the use of common feeders, transformers, converters, protective devices or control circuits.

9.8 Tests

9.8.1 Azimuth thrusters

9.8.1.1 The performance specified for the craft is to be demonstrated.

9.8.1.2 The actual values of steering torque are to be verified during sea trials to confirm that the design maximum dynamic duty torque has not been exceeded.

9.8.2 Tunnel thrusters

It is to be demonstrated that the thruster unit meets the specified performance.

End of Chapter

Chapter 5

Boilers and Pressure Vessels

Contents

Section

1 *General*

2 *Design Requirements*

3 *Fittings and Mountings*

4 *Hydraulic Tests*

Section 1

General

1.1 Scope

1.1.1 The requirements of this Chapter are applicable to pressure vessels of seamless and fusion welded construction, and their mountings and fittings, for the following uses :

a) Fired boilers;

b) Exhaust gas heated boilers;

c) Economizers, superheaters, reheaters and steam receivers for, and associated with (a) and(b);

d) Steam heated steam generators;

e) Other pressure vessels containing:

- toxic fluids;
- fluids with pressure above 40 bar; and
- vapours or gases, e.g. air receivers, hydrophore or similar vessels, CO_2 containers, etc. and having $pV \geq 1.5$, where p is the design pressure in bar and V is the volume of the vessel [m^3].

1.1.2 Consideration will be given to arrangements or details of boilers, pressure vessels and equipment which can be shown to comply with other recognized standards, provided they are not less effective.

1.2 Design pressure

1.2.1 The design pressure is the maximum permissible working pressure.

1.2.2 The calculations made to determine the scantlings of the pressure parts are to be based on the design pressure, adjusted where necessary to take account of pressure variations corresponding to the most severe operational conditions.

1.2.3 It is desirable that there should be a margin between the normal pressure at which the boiler or pressure vessel operates and the lowest pressure at which any safety valve is set to lift, to prevent unnecessary lifting of the safety valve.

1.3 Metal temperature

1.3.1 The metal temperature, T, used to evaluate the allowable stress, σ, is to be taken as the actual metal temperature expected under operating conditions for the pressure part concerned, and is to be stated by the manufacturer when plans of the pressure parts are submitted for consideration.

1.3.2 For boilers, the design metal temperature is not to be taken less than the following values, unless justified by an exact calculation of the temperature drop and is in no case to be taken less than 250°C:

a) For steam heated steam generators, secondary drums of double evaporation boilers, steam receivers and pressure parts of fired pressure vessels not heated by hot gases and adequately protected by insulation, the metal temperature, T is to be taken as the maximum temperature of the internal fluid;

b) For pressure parts heated by hot gases, T is to be taken as not less than 25°C in excess of the maximum temperature of the internal fluid;

c) For combustion chambers of the type used in horizontal wet-back boilers, T is to be taken as not less than 50°C in excess of the maximum temperature of the internal fluid;

d) For furnaces, fire boxes, rear-tube plates of dry-back boilers and pressure parts subject to similar rates of heat transfer, T is to be taken as not less than 90°C in excess of the maximum temperature of the internal fluid;

e) For boiler, superheater, reheater and economizer tubes, the design temperature is to be taken as under :

   i) For boiler tubes the design temperature is to be taken as not less than saturated steam temperature plus 25°C for tubes mainly subject to convection heat, or plus 50°C for tubes mainly subject to radiant heat;

   ii) For superheater and reheater tubes, the design temperature is to be taken as not less than steam temperature expected in the part being considered, plus 35°C for tubes mainly subject to convection heat. For tubes mainly subject to radiant heat the design temperature is to be taken as not less than the steam temperature expected in the part being considered, plus 50°C, but the actual metal temperature expected is to be stated when submitting plans;

   iii) The design temperature for economizer tubes is to be taken as not less than 35°C in excess of the maximum temperature of the internal fluid.

1.3.3 In general, any part of boiler drums or headers not protected by tubes, and exposed to radiation from the fire or to the impact of hot gases, is to be protected by a shield of good refractory material or by other approved means.

1.3.4 Drums and headers of thickness greater than 30 [mm] are not to be exposed to combustion gases having an anticipated temperature in excess of 650°C unless they are efficiently cooled by closely arranged tubes.

1.4 Plans and particulars

1.4.1 The following plans, in triplicate, for boiler and pressure vessels are to be submitted for approval, in so far as applicable:

a) General arrangement, including arrangement of valves and fittings;

b) Sectional assembly;

c) Seating arrangements;

d) Steam, water drum and header details;

e) Water wall details;

f) Steam and superheater tubing, including the tube support arrangements;

g) Economizer details;

h) Casing arrangement;

i) Reheat section;

j) Fuel oil burning arrangement;

k) Forced draft system;

l) Boiler mountings including steam stop valves, safety valves and their relieving capacities, feed water connections, blow-off arrangements, watergauges, test cocks, etc.

1.4.2 The plans are to include the following particulars, in so far as applicable :

a) Scantlings;

b) Materials;

c) Weld details;

d) Design pressures and temperatures;

e) Heating surface areas of boilers and superheaters;

f) Estimated pressure drop through superheater;

g) Estimated evaporation rate;

h) Proposed setting pressure of safety valves on steam drum and superheater;

i) Pressure vessel class;

j) Details of heat treatment and testing of welds;

k) Calculations of thicknesses, when required;

l) Test pressures.

1.5 Classification of pressure vessels

1.5.1 For Rule purposes, boilers and pressure vessels are graded as shown in Table 1.5.1.

1.5.2 Pressure vessels which are constructed in accordance with the requirements of Class 2 or Class 3 will, if manufactured in accordance with the requirements of a superior class, be approved with the scantlings appropriate to that class.

1.5.3 In special circumstances relating to service conditions, materials, operating temperature, the carriage of dangerous gases and liquids, etc., it may be required that certain pressure vessels be manufactured in accordance with the requirements of a superior class.

1.6 Definition of symbols

1.6.1 The symbols used in the various formulae in this Chapter are defined as follows and are applicable to the specific part of the pressure under consideration :

d = diameter of hole or opening [mm];

D_i = inside diameter [mm];

D_o = outside diameter [mm];

J = joint factor applicable to the welded seams or ligament efficiency between tube holes, expressed as a fraction;

p = design pressure, in bar;

R_i = inside radius [mm];

R_o = outside radius [mm];

r_o = outside knuckle radius [mm];

r_i = inside knuckle radius [mm];

s = pitch [mm];

T = design temperature, °C;

t = minimum thickness [mm];

σ = allowable stress [N/mm^2].

1.7 Materials

1.7.1 Materials used in the construction of Class 1 & 2 pressure vessels are to be manufactured and tested in accordance with the requirements of Pt.2 under the supervision of IRS Surveyors.

Materials for Class 3 pressure vessels will be accepted with manufacturer's certificate.

Table 1.5.1 : Grading of pressure vessels			
	Boilers	**Steam-heated steam generators**	**Other pressure vessels**
Class 1	p > 3.5	$p > \frac{15000}{D_i + 1000}$	p > 50 or t > 38
Class 2	p ≤ 3.5	$p \leq \frac{15000}{D_i + 1000}$	$\frac{20000}{D_i + 1000}$ < p ≤ 50 or 16 < t ≤ 38 or material temperature > 150°C
Class 3			Pressure vessels not included in Class 1 and 2
Note: p = design pressure, in bar; D_i = internal diameter [mm]; t = shell thickness [mm]			

Valves and fittings for pressure vessels are to be manufactured and tested under the supervision of IRS Surveyors in the following cases:

- cast steel and nodular cast iron valves and fittings - when D > 50 [mm] and PD > 2000
- cast steel valves and fittings - when D > 50 [mm] and T > 400°C or T < -10°C
- copper alloy valve and fittings - when D >50 [mm] and pD > 1000
- Where p is the design pressure in bar and D is the nominal diameter in [mm].

1.7.2 The specified minimum tensile strength of carbon and carbon manganese steel plates, pipes, forgings and castings is to be within the following general limits :

a) For seamless and fusion welded pressure vessels - 340 - 520 [N/mm^2];

b) For boiler furnaces, combustion chambers and flanged plates - 400 - 520 [N/mm^2].

1.7.3 The specified minimum tensile strength of low alloy steel plates, pipes, forgings and castings is to be within the general limits of 400 - 500 [N/mm^2], and pressure vessels made in these steels are to be either seamless or Class 1 fusion welded.

1.7.4 The specified minimum tensile strength of boiler and superheater tubes is to be within the following general limits :

a) Carbon and carbon-manganese steels - 320 - 460 [N/mm^2];

b) Low alloy steels - 400 - 500 [N/mm^2].

1.7.5 Semi-killed, fully killed and fine grain, normal strength structural steels complying with the requirements of Pt.2, Ch.3 will be accepted for following Class 3 pressure vessels when:

$$p < \frac{15000}{D_i + 2000}$$

1.7.6 Where it is proposed to use materials other than those specified in Pt.2, details of the chemical compositions, heat treatment and mechanical properties are to be submitted for approval. In such cases the values of the mechanical properties used for deriving the allowable stress are to be subject to agreement by IRS.

1.7.7 Where a fusion welded pressure vessel is to be made of alloy steel and approval of the scantlings is required on the basis of the high temperature properties of the material, particulars of the welding consumables to be used, including typical mechanical properties and chemical composition of the deposited weld metal, are to be submitted for approval.

1.8 Allowable stress

1.8.1 The term "allowable stress",σ, is the stress to be used in the formulae for calculation of scantlings of pressure parts.

1.8.2 The allowable stress, σ, is to be the lowest of the following values:

$$= \frac{E_t}{1.6} \text{ or } \frac{E_{20}}{1.8} \text{ or } \frac{R_{20}}{2.7} \text{ or } \frac{S_R}{1.6}$$

where,

E_t = specified minimum lower yield strength or 0.2 per cent proof stress at temperature T;

E_{20} = specified minimum lower yield strength or 0.2 per cent proof stress at ambient temperature;

R_{20} = specified minimum tensile strength at room temperature;

S_R = average stress to produce rupture in 100,000 hours at temperature T;

T = metal temperature (see 1.6).

1.8.3 The allowable stress for steel castings is to be taken as 80 per cent of the value determined by the method indicated in 1.8.2, using the appropriate values for cast steel.

1.8.4 Where steel castings, which have been tested in accordance with Pt.2, are also subjected to non-destructive tests, consideration will be given to increasing the allowable stress using a factor up to 90 per cent in lieu of the 80 per cent referred to in 1.8.3. Particulars of the non-destructive test proposals are to be submitted for consideration.

1.9 Joint factors

1.9.1 The following joint factors are to be used in equations in this chapter, where applicable. Fusion welded pressure parts are to be made in accordance with Ch.10 :

Pressure vessel	Joint factor
Class 1	1.0
Class 2	0.80
Class 3	0.60

1.9.2 The longitudinal joints for all classes of vessels are to be butt joints. Circumferential joints for Classes 1 and 2 vessels are also to be butt joints.

1.10 Pressure parts of irregular shape

1.10.1 Where pressure parts are of such irregular shape that it is impracticable to design their scantlings by the application of formulae given in this Chapter, the suitability of their construction is to be determined by hydraulic proof test of a prototype or by an agreed alternative method.

1.11 Adverse working conditions

1.11.1 Where working conditions are adverse, special consideration may be required to be given to increasing the scantlings derived from the formulae, e.g. by increasing the corrosion or other allowance at present shown in the formulae, or by adopting a design pressure higher than defined in 1.2, to offset the possible reduction of life in service caused by the adverse conditions. In this connection, where necessary, account should also be taken of any excess of loading resulting from :

a) impact loads, including rapidly fluctuating pressures;

b) weight of the vessel and normal contents under operating and test conditions;

c) superimposed loads such as other pressure vessels, operating equipment, insulation, corrosion-resistant or erosion-resistant linings and piping;

d) reactions of supporting lugs, rings, saddles or other types of supports; or

e) the effect of temperature gradients on maximum stress.

1.12 Minimum shell thickness

1.12.1 Only plus tolerances are allowed on the design shell thickness.

1.12.2 The thickness after forming of any shell or head is not to be less than $3 + \frac{D_i}{1500}$ [mm] for carbon, carbon-manganese and low-alloy steels or 3 [mm] for stainless steel and non-ferrous materials. For pressure vessels, where the cylindrical part is made of a pipe, a smaller minimum thickness may be approved. See also Sec.2 for minimum thicknesses of plates in case of boilers.

1.13 Heat treatment, non-destructive examination and routine tests

1.13.1 Details regarding heat treatment, non-destructive examination and routine tests are to be in accordance with the requirements of Ch.10.

Section 2

Design Requirements

2.1 Cylindrical shells and drums subject to internal pressure

2.1.1 Minimum thickness

2.1.1.1 The minimum thickness, t, of a cylindrical shell is to be determined by the following formula:

$$t = \frac{p R_i}{10 \sigma J - 0.5p} + 0.75 \text{ [mm]}$$

where,

t, p, R_i and σ are defined in Sec.1;

J = efficiency of ligaments between tube holes or other openings in the shell or the joint factor of the longitudinal joints (expressed as a fraction), as defined in Sec.1, whichever applies. In the case of seamless shells clear of tube holes or other openings, J = 1.0.

2.1.1.2 The formula in 2.1.1.1 is applicable only where the resulting thickness does not exceed half the internal radius, i.e. where R_o is not greater than 1.5 R_i.

2.1.1.3 Irrespective of the thickness determined by 2.1.1.1, t is not to be less than:

For Boilers (Fired and exhaust gas heated), economizers, superheaters, reheaters, steam receivers, steam-heated steam generators and similar vessels	6.0 [mm] for cylindrical shell plates. For tube plates, such thickness as will give a minimum parallel seat of 9.5 [mm], or such greater width as may be necessary to ensure tube tightness.

2.1.2 Efficiency of ligaments between tube holes

2.1.2.1 Where tube holes are drilled in a cylindrical shell in a line or lines parallel to its axis, the efficiency, J, of the ligaments is to be determined as follows:

a) for regular drilling (See Fig.2.1.2.1)

$$J = \frac{s - d}{s}$$

b) for irregular drilling (See Fig.2.1.2.2)

$$J = \frac{S_1 + S_2 - 2d}{S_1 + S_2}$$

where,

d = the mean effective diameter of the tube holes, [mm], after allowing for any serrations, counterboring of recessing, or the compensating effect of tube stub, see 2.1.3 and 2.1.4;

s = pitch of tube holes [mm];

s_1 = the shorter of any two adjacent pitches [mm];

s_2 = the longer of any two adjacent pitches [mm].

2.1.2.2 When applying the formula in 2.1.2.1, the double pitch ($s_1 + s_2$) chosen is to be that which makes J a minimum, and in no case is s_2 to be taken as greater than twice s_1.

2.1.2.3 Where the circumferential pitch between tube holes measured on the mean of the external and internal drum or header diameters is such that the ligament efficiency determined by the formula in 2.1.2.1 is less than one- half of the ligament efficiency of the longitudinal axis, J is to be taken as twice the circumferential efficiency.

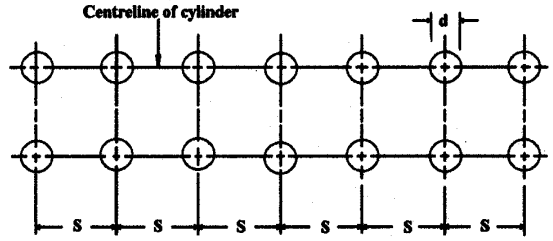

Fig. 2.1.2.1 : Regular drilling

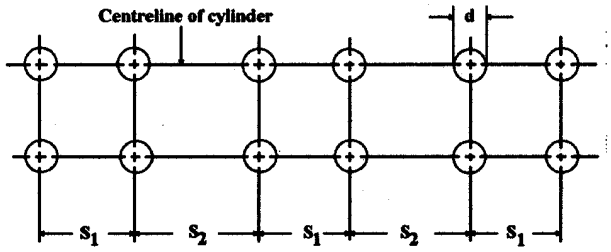

Fig. 2.1.2.2 : Irregular drilling

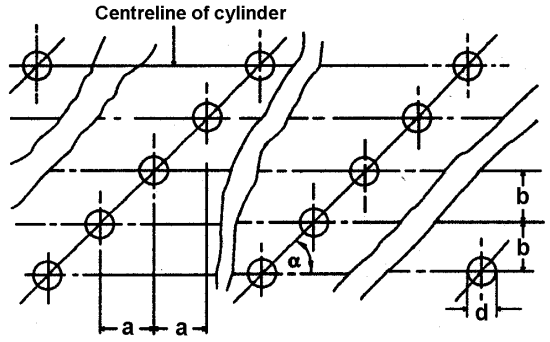

Fig. 2.1.2.3 : Spacing of holes on a diagonal line

2.1.2.4 Where tube holes are drilled in a cylindrical shell along a diagonal line with respect to the longitudinal axis, the efficiency, J, of the ligament is to be determined as in 2.1.2.5 to 2.1.2.8.

2.1.2.5 For spacing of tube holes on a diagonal line as shown in Fig.2.1.2.3, or in a regular saw-tooth pattern as shown in Fig.2.1.2.4, J is to be obtained from the series of curves given in Fig 2.1.2.6 where a and b, as shown in Fig.2.1.2.3 and Fig.2.1.2.4, are measured, in millimeters, on the median line of the plate and d is as defined in 2.1.2.1.

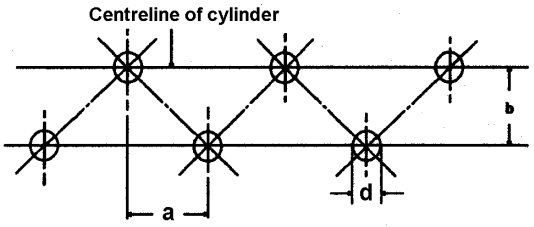

Fig. 2.1.2.4 : Regular saw-tooth pattern of holes

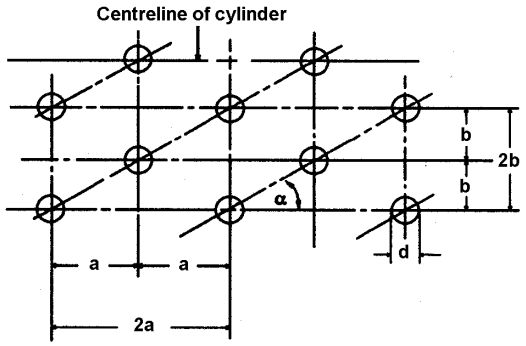

Fig. 2.1.2..5 : Regular staggering of holes

2.1.2.6 The data for Fig.2.1.2.6 is based on the following:

$$J = \frac{2}{A + B + \sqrt{(A - B)^2 + 4C^2}}$$

where,

$$A = \frac{a\,(\mathrm{Cos}^2\,\alpha + 1)}{2\,(a - d\,Cos\alpha)}$$

$$B = 0.5\left(1 - \frac{d\,\mathrm{Cos}\alpha}{a}\right)\left(\mathrm{Sin}^2\alpha + 1\right)$$

$$C = \frac{a\,\mathrm{Sin}\alpha\,Cos\alpha}{2\,(a - d\,Cos\alpha)}$$

$$\mathrm{Cos}\alpha = \frac{a}{\sqrt{a^2 + b^2}}$$

$$\mathrm{Sin}\alpha = \frac{b}{\sqrt{a^2 + b^2}}$$

α = angle between centerline of cylinder and centerline of diagonal holes.

2.1.2.7 For regularly staggered spacing of tube holes as shown in Fig.2.1.2.5, the smallest value of the efficiency, J, of all ligaments (longitudinal, circumferential and diagonal) is obtained from Fig.2.1.2.7, where a and b, as shown in Fig.2.1.2.5 are measured, in millimeters, on the median line of the plate, and d as defined in 2.1.2.1.

2.1.2.8 For irregularly spaced tube holes whose centers do not lie on a straight line, the formula 'b' in 2.1.2.1 is to apply, except that an equivalent longitudinal width is to be used. An equivalent longitudinal width is that which gives, using the formula 'a' in 2.1.2.1 the same efficiency as would be obtained using Fig.2.1.2.6 for the diagonal ligament in question.

2.1.2.9 The spacing of tube holes is to be such that the minimum width, in [mm], of any ligament between tube holes is not less than:

$$0.125\ d + 12.5\ [mm]$$

where,

d = diameter of tube holes [mm].

2.1.3 Compensating effect of tube stubs

2.1.3.1 Where a drum or header is drilled for tube stubs fitted by strength welding, either in line or in staggered formation, the effective diameter of holes is to be taken as follows:

$$d_e = d_a - \frac{A}{t}$$

where,

d_e = the equivalent diameter of the hole [mm];

d_a = the actual diameter of the hole [mm];

A =the compensating area provided by each tube stub and its welding fillets [mm^2];

t = thickness of the shell [mm].

2.1.3.2 The compensating area, A, is to be measured in a plane through the axis of the tube stub parallel to the longitudinal axis of the drum or header and is to be calculated as follows (See Fig.2.1.3.1 and Fig.2.1.3.2):

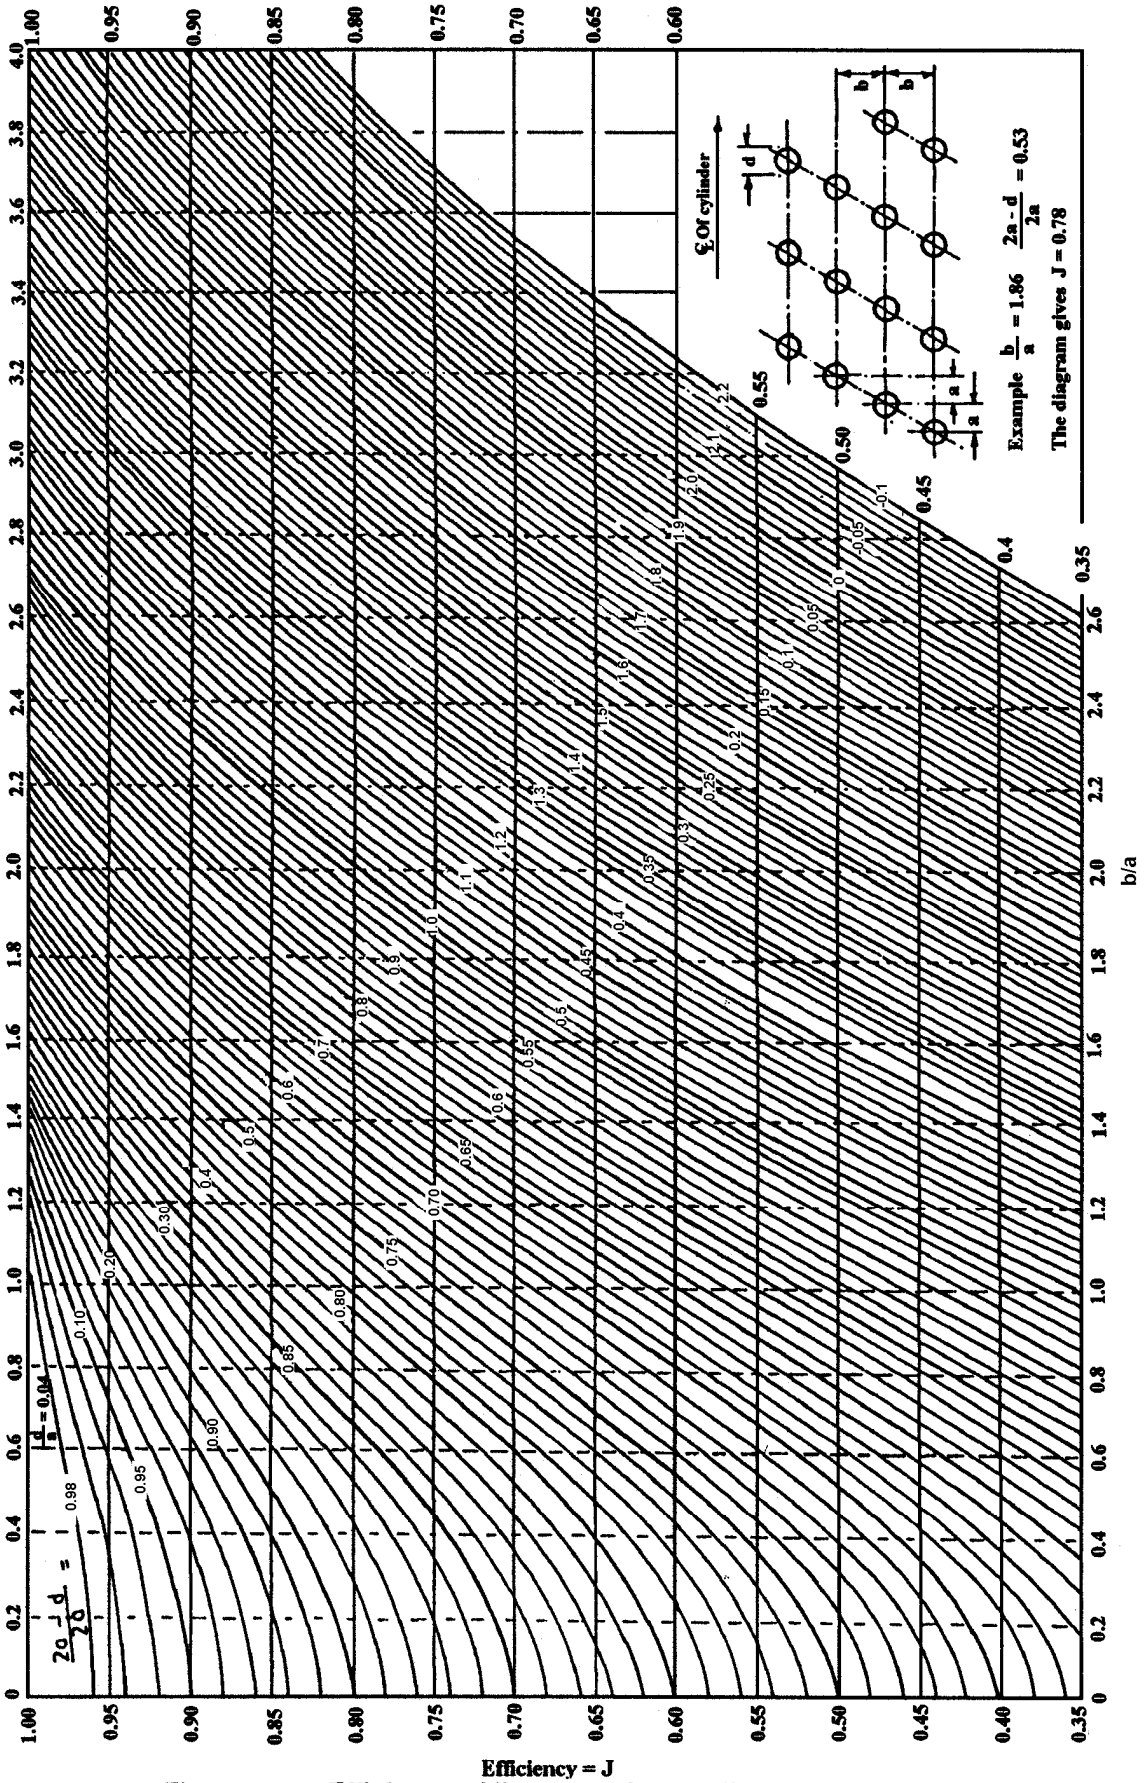

Fig. 2.1.2.6 : Efficiency of ligament along a diagonal line

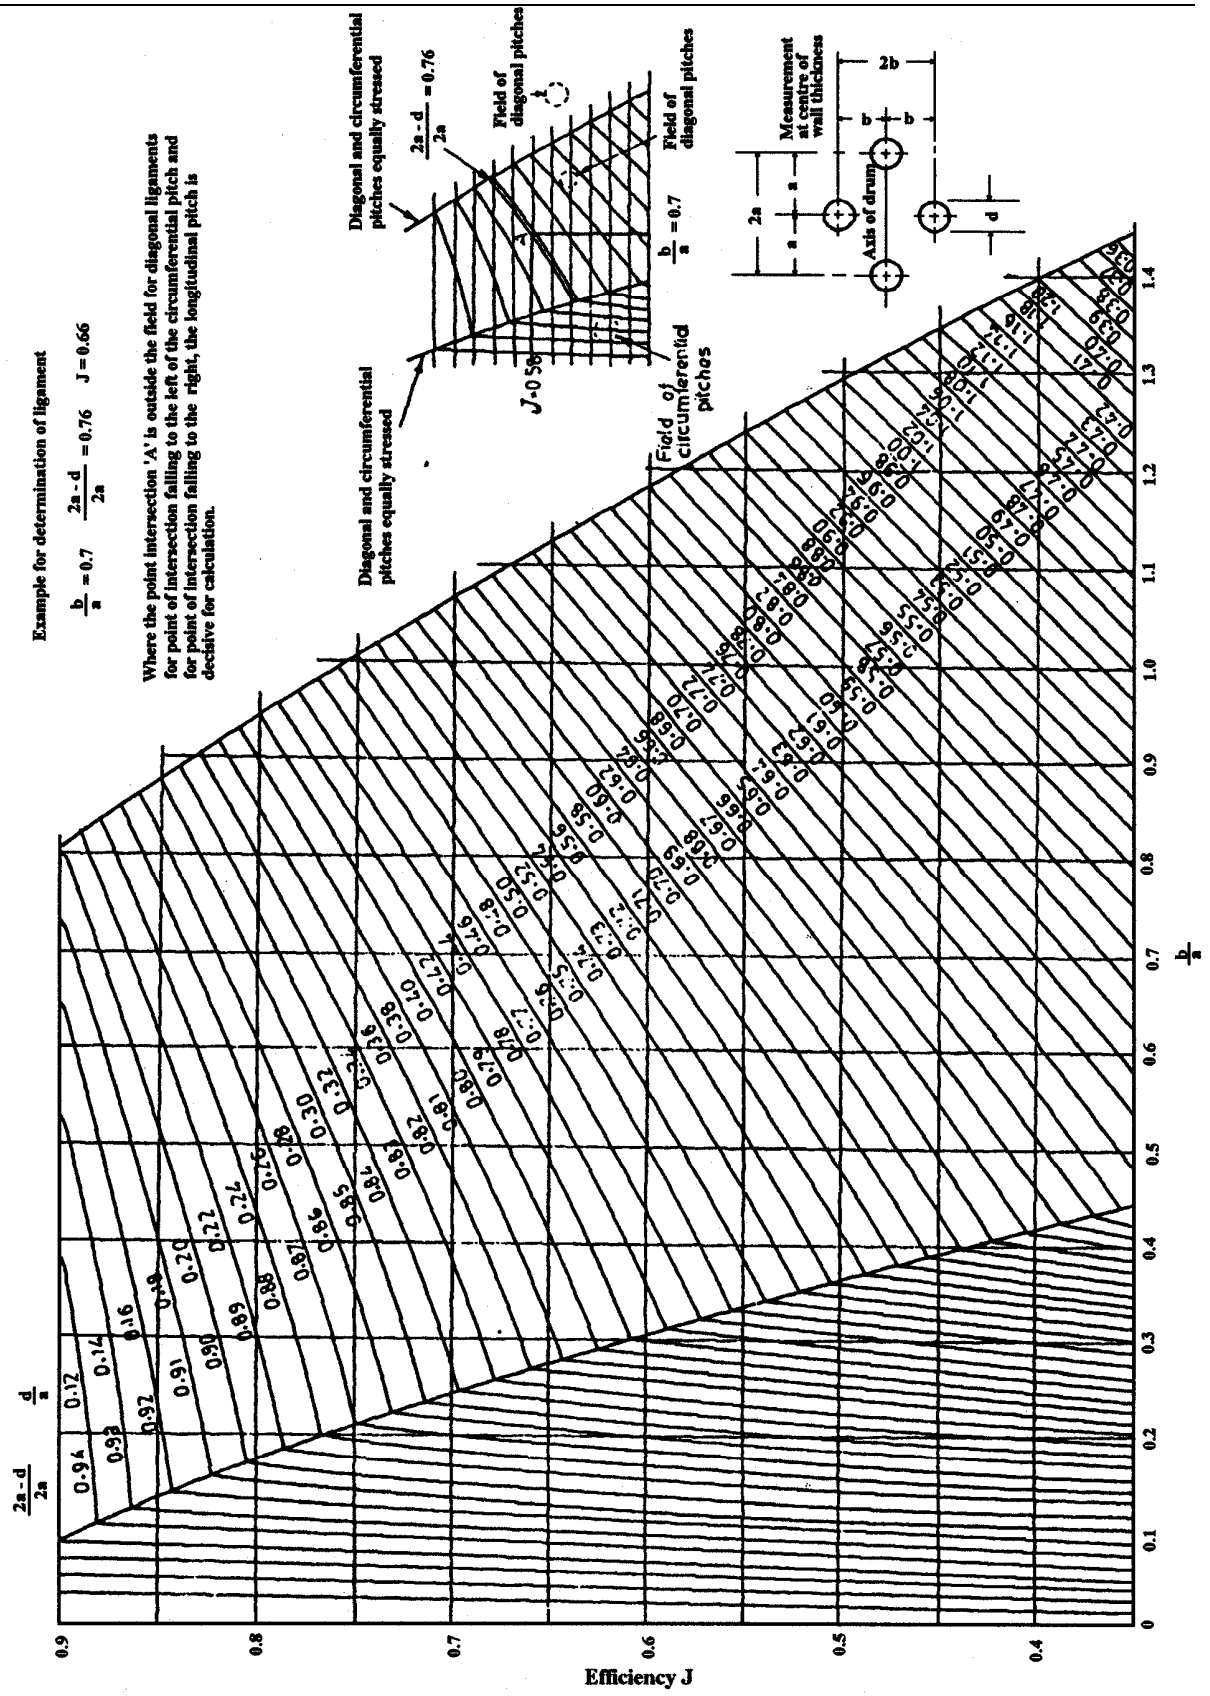

Fig. 2.1.2.7 : Efficiency of ligaments between holes

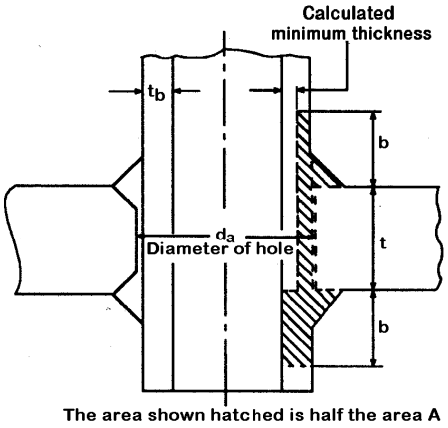

Fig. 2.1.3.1 : Compensation of welded tube stubs

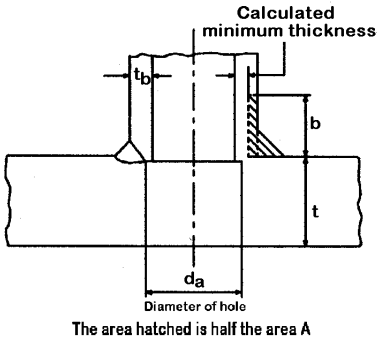

Fig. 2.1.3.2 : Compensation of welded tube stubs

- The cross-sectional area of the stub, in excess of that required by 2.7.1 for the minimum tube thickness, from the interior surface of the shell up to a distance b from the outer surface of the shell;

- plus the cross-sectional area of the stub projecting inside the shell within a distance b from the inner surface of the shell;

- plus the cross-sectional area of the shell welding fillets inside and outside the shell;

where,

$$b = \sqrt{d_a\ t_b}$$

t_b = actual thickness of tube stub [mm].

2.1.3.3 Where the material of the tube stub has an allowable stress lower than that of the shell, the compensating cross-sectional area of the stub is to be multiplied by the ratio:-

$$\frac{\text{allowable stress of stub at design metal temperature}}{\text{allowable stress of shell at desgn metal temperature}}$$

2.1.3.4 No credit will be given for the additional strength of tube stub material having an allowable stress greater than that of the shell.

2.1.4 Unreinforced openings

2.1.4.1 Openings in a definite pattern such as tube holes, may be designed in accordance with the rules for ligaments in 2.1.2, provided that the diameter of the largest hole in group does not exceed that permitted by 2.1.4.2.

2.1.4.2 The maximum diameter, d, of any isolated unreinforced openings is to be obtained from the curves in Fig.2.1.4.1 and Fig.2.1.4.2. The value of K to be used is calculated from the following formula:

$$K = \frac{p\,D_o}{18.2\,\sigma\,t}$$

where,

p, D_o and σ are defined in Sec.1;

t = actual thickness of shell [mm].

2.1.4.3 For elliptical or oval holes, d refers to the major axis when this lies longitudinally or to the mean of the major and minor axes when minor axis lies longitudinally.

2.1.4.4 No unreinforced opening is to exceed 200 [mm] in diameter.

2.1.4.5 Openings may be considered isolated if the center distance between two openings on the longitudinal axis of the cylindrical shell is not less than:

$d+1.1\sqrt{Dt}$ with a minimum of 5d

where,

d = diameter of openings in shell (mean diameter if dissimilarly sized openings are involved)

D = mean diameter of shell

t = actual thickness of shell

Where the center distance is less than so derived, the openings are to be fully compensated.

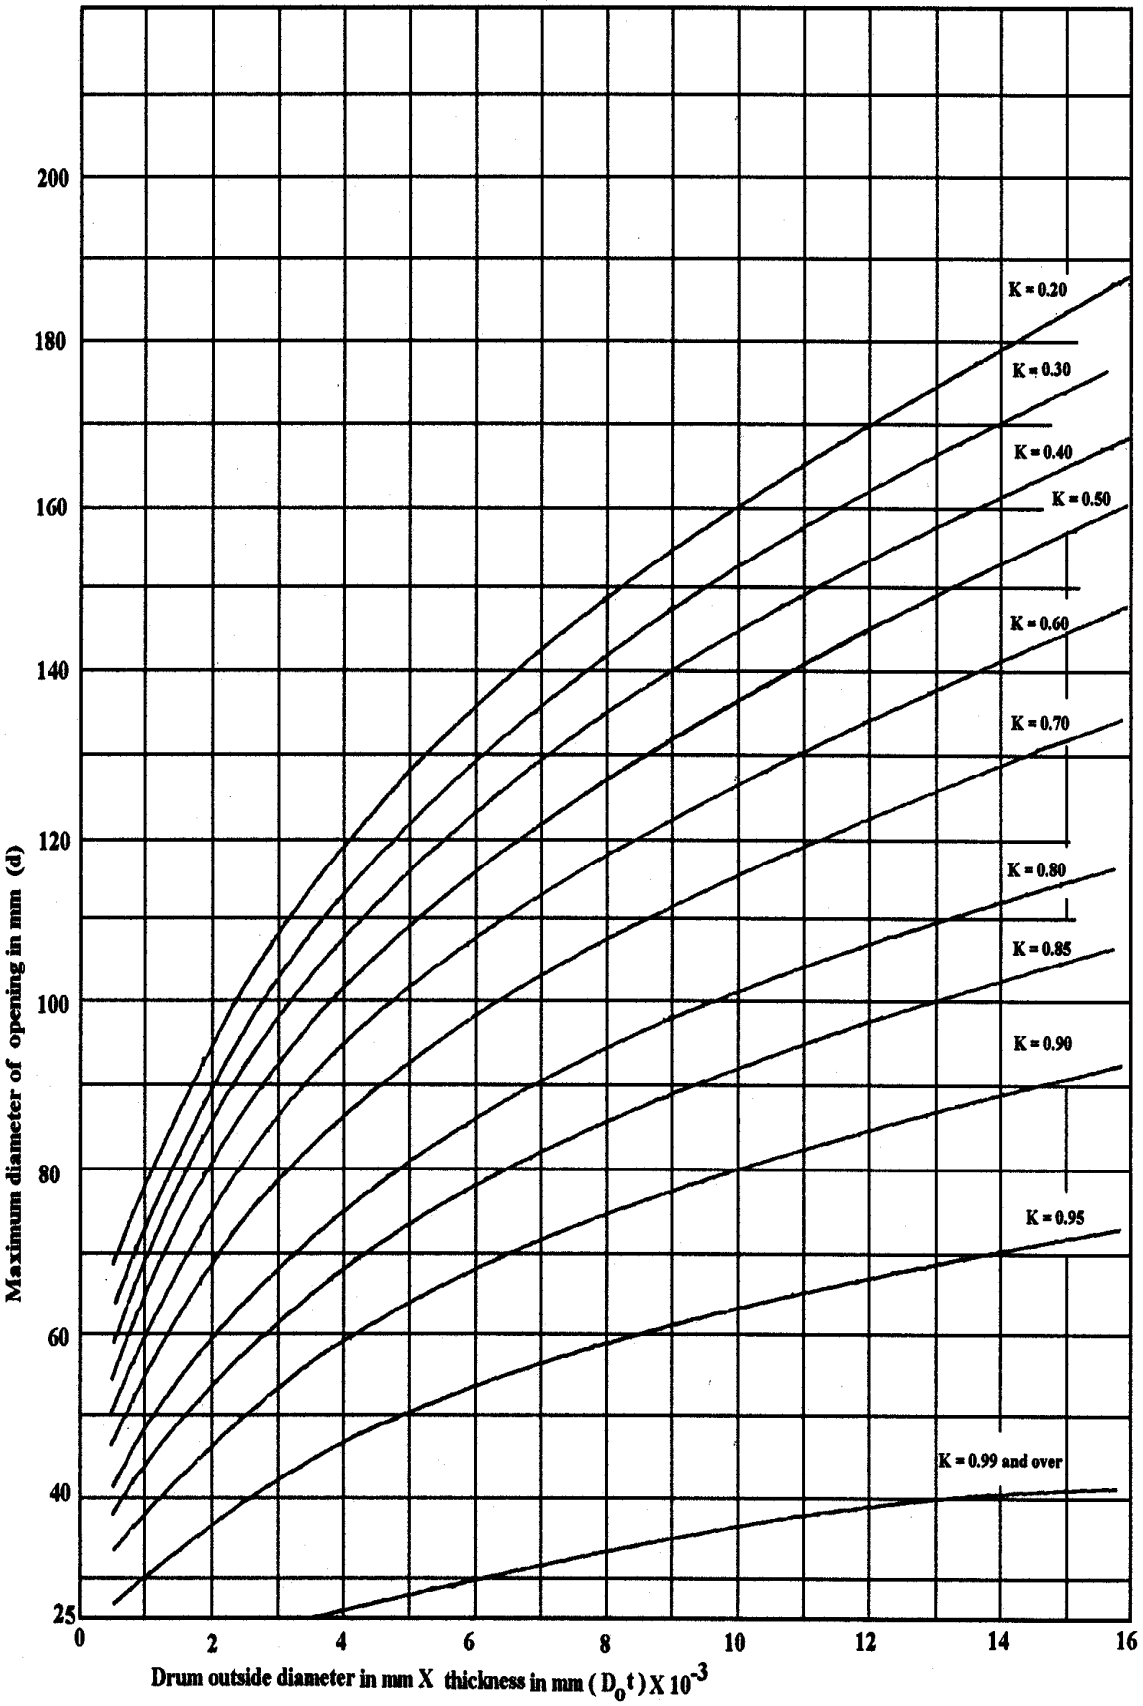

Fig. 2.1.4.1 : Maximum diameter of unreinforced openings

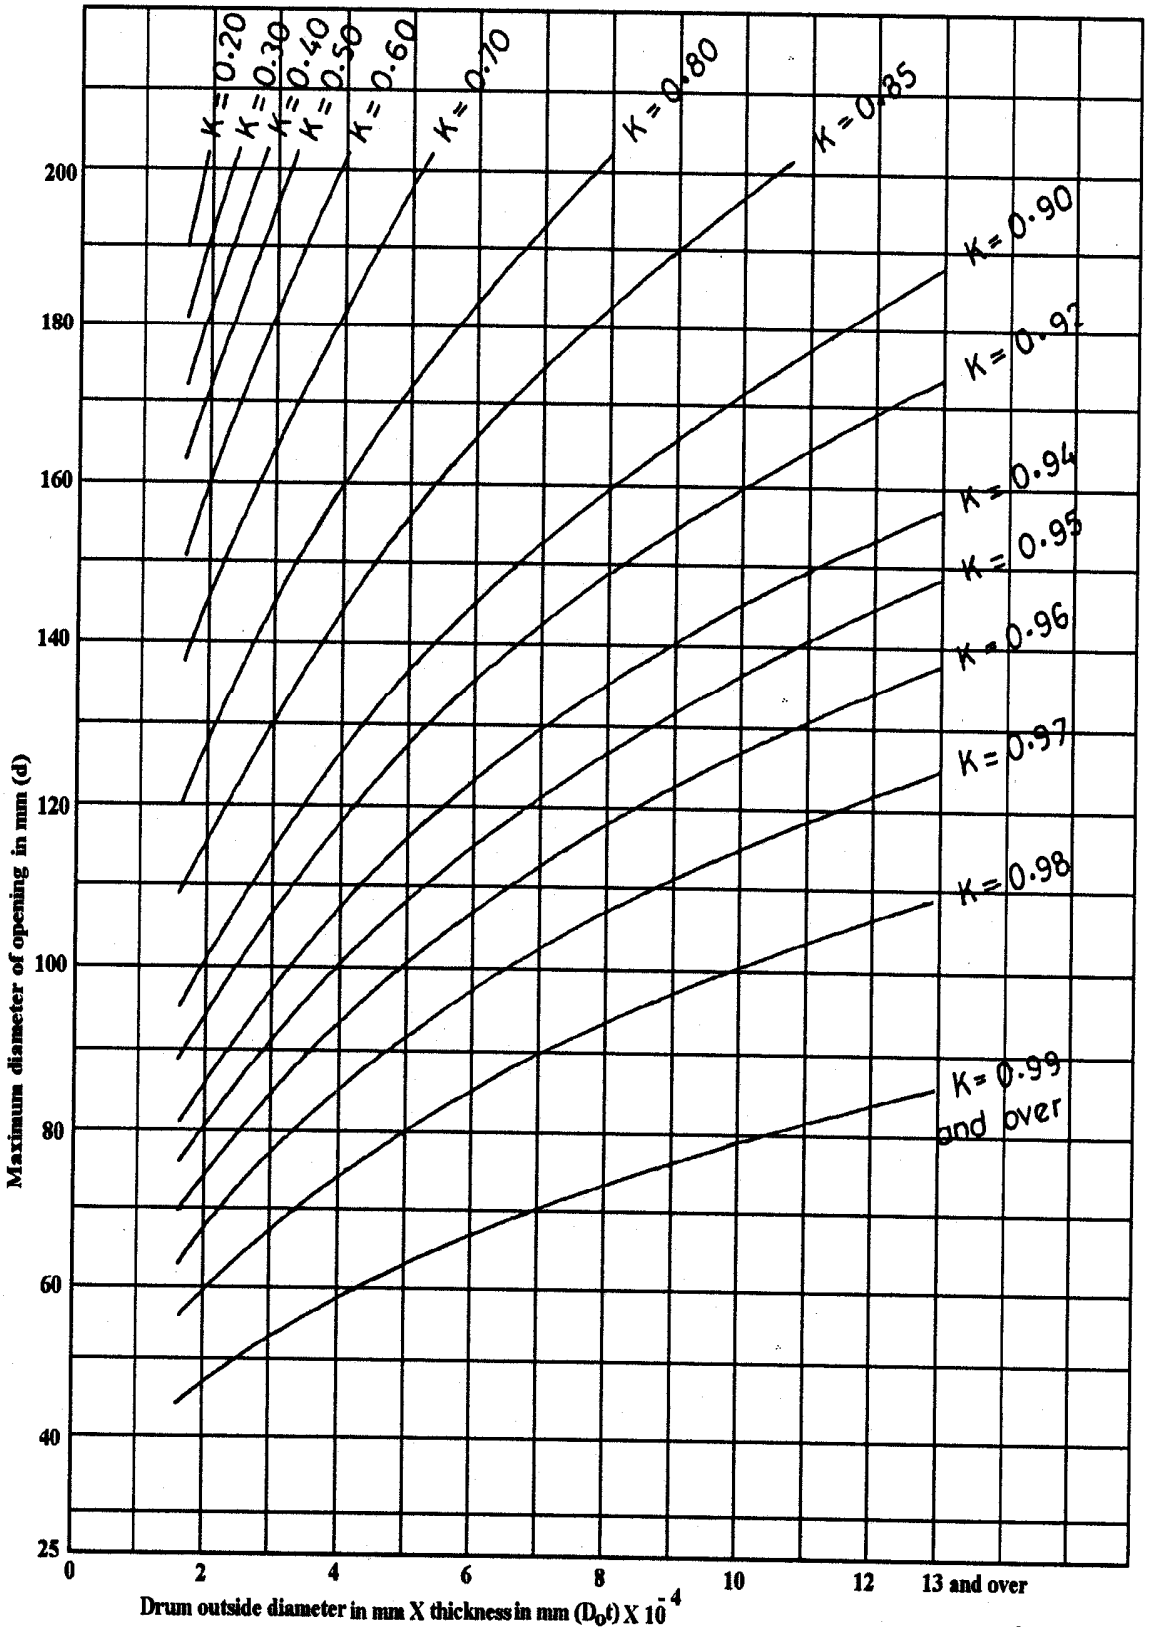

Fig. 2.1.4.2 : Maximum diameter of unreinforced openings

Where two openings are offset on a diagonal line, the diagonal efficiency from Fig.2.1.2.7 may be used to derive an equivalent longitudinal center distance for the purpose of this paragraph.

2.1.5 Reinforced openings

2.1.5.1 The following notations are used in Fig.2.1.5.1(a),(b) and (c):

A = calculated thickness of shell without joint or opening;

B = thickness calculated in accordance with 2.7.1;

$C = 0.8\sqrt{d_i\, t_b}$

$D = \sqrt{D_i\, t_a}$ and is not to exceed 0.5 d_i;

t_a = actual thickness of shell plate [mm];

t_b = actual thickness of standpipe stem or branch [mm];

t_r = thickness of added reinforcement [mm] (t_r will be zero when there is no compensating plate on the side of the shell under consideration);

d_i = internal diameter of standpipe or branch [mm];

D_i = internal diameter of cylindrical shell [mm].

2.1.5.2 Openings larger than those permitted by 2.1.4 are to be reinforced by the method shown in Fig.2.1.5.1. Compensation will be considered adequate when:

$$Y + Z\frac{\sigma_s}{\sigma} \geq X$$

where,

X = the area to be compensated and is indicated by X in Fig.2.1.5.1;

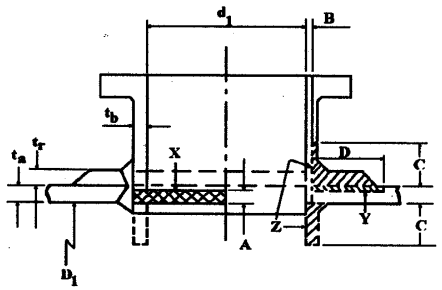
Y = the compensating area available in the shell material and is indicated by Y in Fig.2.1.5.1;

Z = the compensating area available in the standpipe material and is indicated by Z in Fig.2.1.5.1;

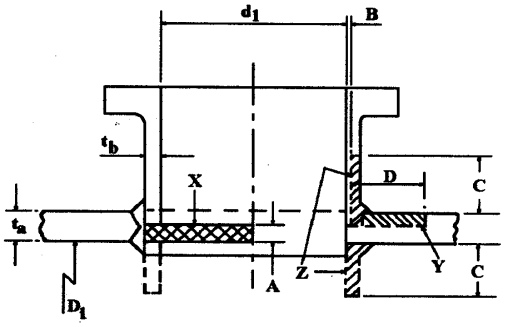
σ_s = the allowable stress of the standpipe material at design temperature;

σ = the allowable stress of shell material at design temperature;

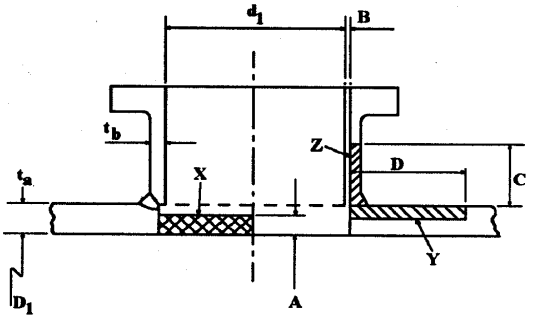
$\frac{\sigma_s}{\sigma}$ is to be taken as not greater than 1.



(a) Welded set-through nozzle with compensating plate



(b) Welded set-through nozzle



(c) Welded set-on nozzle

Fig. 2.1.5.1 : Compensation for welded

2.1.5.3 Area X is to be such that the reinforcement is provided on all planes through the center of the opening and normal to the shell surface, and is to be calculated as the product of the radius of the hole cut in the shell and the thickness, A, that would be required for an equivalent seamless unpierced shell.

2.1.5.4 Area Y is to be measured in the same plane as area X, and is to be calculated as the product of the difference between the actual shell thickness and the equivalent unpierced shell thickness, A, and the dimension from the edge of the opening in shell to limit D.

2.1.5.5 Area Z is to be measured in the same plane as area X, and is to be calculated as follows:

- For that part of standpipe which projects outside the shell, calculate the full cross-sectional area of the stem up to a distance C from the actual outer surface of the shell plate, and deduct from it the cross-sectional area which the stem would have if its thickness was as calculated in accordance with 2.7.1;

- **plus**, in the case of set- through nozzles (see Fig.2.1.5.1 (a) and (b), the full cross-sectional area of that part of the stem which projects inside the shell up to a distance of C, from the inside surface of the shell;

- **plus**, the cross-sectional area of all

- appropriate fillet welds;

- **plus**, if additional reinforcement is fitted as illustrated in Fig.2.1.5.1(b), the cross-sectional area of the reinforcement and the sectional area of its fillet welds.

2.1.5.6 The welds attaching standpipes and reinforcing plates to the shell are to be of sufficient size to transmit the full strength of the reinforcing areas and all other loadings to which they may be subjected.

2.2 Spherical shells subject to pressure on the concave side

2.2.1 Minimum thickness

2.2.1.1 The minimum thickness of a spherical shell is to be determined by the following formula:

$$t = \frac{p R_i}{20 \sigma J - 0.5p} + 0.75 \text{ [mm]}$$

where,

p, R_i, σ, J and t are defined in Sec.1.

2.2.1.2 The formula in 2.2.1.1 is applicable only where the resulting thickness does not exceed half the internal radius.

2.2.2 Openings

2.2.2.1 Openings in spherical shells are to comply with the relevant requirements of 2.3.

2.3 Dished ends subject to pressure on concave side

2.3.1 Minimum thickness

2.3.1.1 The thickness, t, of semi-ellipsoidal, torispherical and hemispherical unstayed ends, dished from plate, having pressure on the concave side and satisfying the conditions listed below, is to be determined by the following formula:

$$t = \frac{p D_o K}{20 \sigma J} + 0.75 \text{ [mm]}$$

where,

p, D_o, σ and J are defined in Sec.1;

K = a shape factor in accordance with 2.3.2 and Fig.2.3.1.1.

2.3.1.2 For semi-ellipsoidal ends:

the external height, H ≥ 0.18 Do, where D_o = the external diameter of the parallel portion of the end [mm].

2.3.1.3 For torispherical ends:

the internal radius, $R_i \leq D_o$;

the internal knuckle radius, $r_i \geq 0.1\ D_o$;

the internal knuckle radius, $r_i \geq 3t$;

the external height, H ≥ 0.18 D_o, and is to be determined as follows:

$$H = R_o - \sqrt{(R_o - 0.5 D_o)(R_o + 0.5 D_o - 2 r_o)}$$

2.3.1.4 In addition to the formula in 2.3.1.1, the thickness, t, is to be not less than that determined by 2.2.

2.3.1.5 In all cases, H is to be measured from the commencement of curvature, see Fig.2.3.1.2(a), (b), (c) and (d).

2.3.1.6 For boilers (fired and exhaust gas heated), economisers, superheaters, reheaters, steam receivers, steam heated steam generators and similar vessels, the minimum thickness of the head, t, is to be not less than 9.5 [mm]. In special cases where it is proposed to use less than 9.5 [mm] thickness, the proposals will be subject to special consideration.

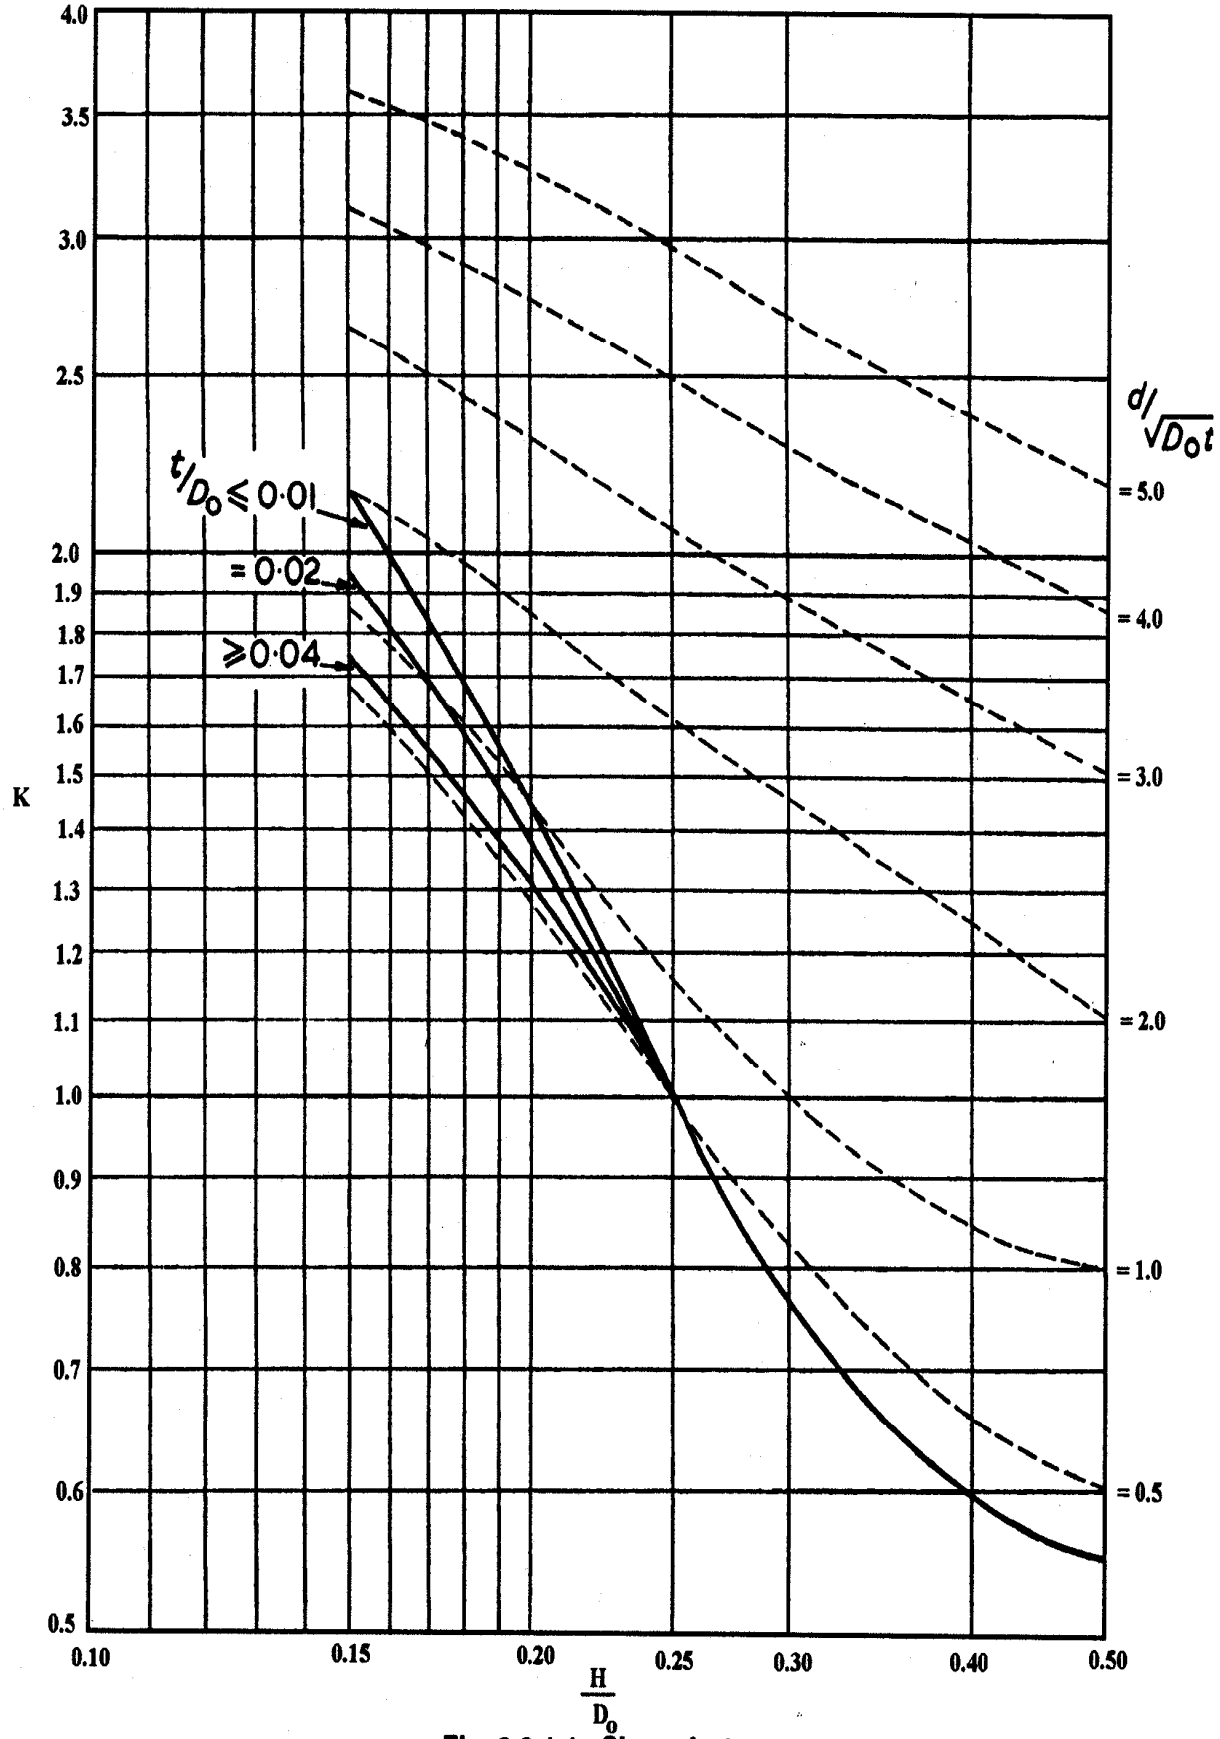


Fig. 2.3.1.1 : Shape factor

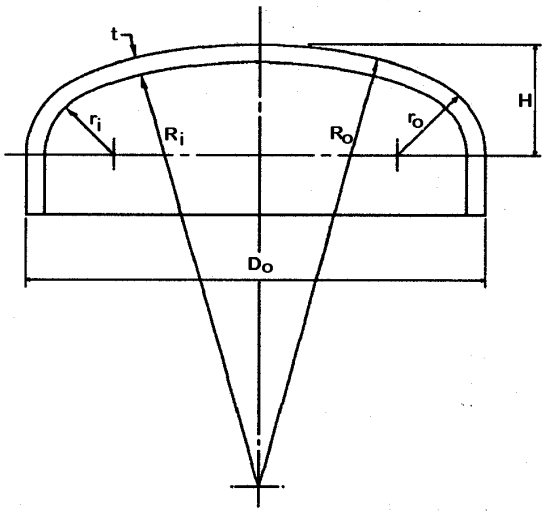

Fig. 2.3.1.2 (a) : Torispherical end

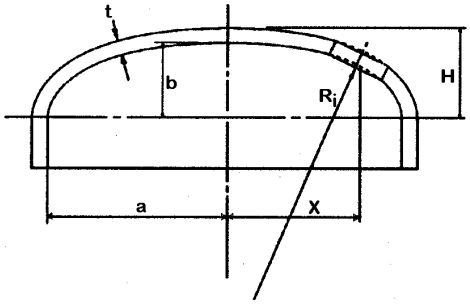

Fig. 2.3.1.2 (b) : Semi-ellipsoidal end

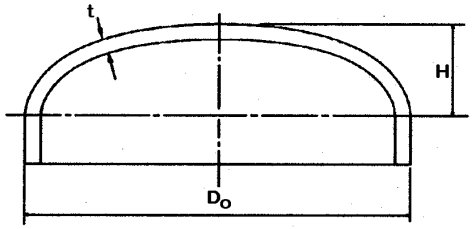

Fig. 2.3.1.2 (c) : Semi-ellipsoidal end (Radius of curvature at opening)

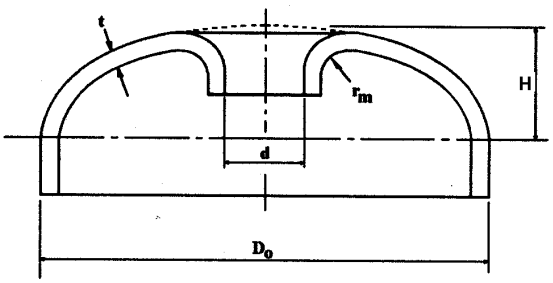

Fig. 2.3.1.2 (d) : End with manhole (Semi-ellipsoidal or torispherical)

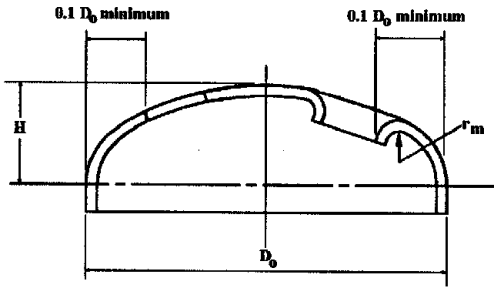

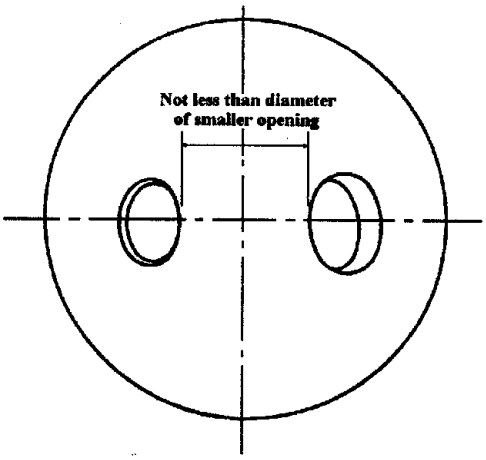

Fig. 2.3.1.3 : Openings in dished ends

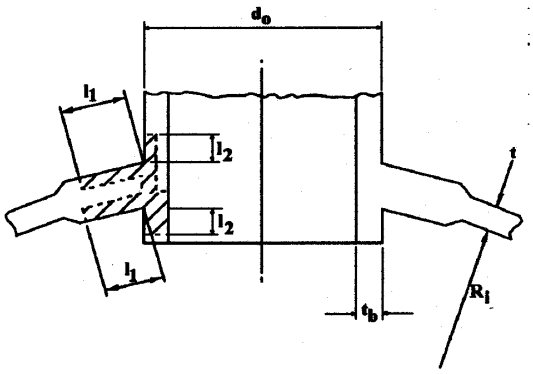

Fig. 2.3.1.4 : Limits of reinforcement

2.3.1.7 For ends which are butt welded to the drum shell, the thickness of the edge of the flange for connection to the shell is to be not less than the thickness of an unpierced seamless or welded shell, whichever is applicable, of the same diameter and material and determined by 2.1.

2.3.2 Shape factors for dished ends

2.3.2.1 The shape factor, K, to be used in 2.3.1.1 is to be obtained from the curves in

Fig.2.3.1.1, and depends upon the ratio of height to diameter H/D_o.

2.3.2.2 The lowest curve in the series provides the factor K for plain ends without openings or with small openings not requiring reinforcement. For lower values of H/D_o, the shape factor, K, depends on the ratio of thickness to diameter, t/D_o, as well as the ratio H/D_o and a trial calculation may be necessary to arrive at the correct value of K.

2.3.3 Dished ends with unreinforced openings

2.3.3.1 The openings in dished ends may be circular or approximately elliptical.

2.3.3.2 The upper curves in Fig.2.3.1.1 provide values of K to be used in 2.3.1.1 for ends with unreinforced openings. The selection of the correct curve depends on the value $\frac{d}{\sqrt{D_o t}}$ and a trial calculation is necessary to select the correct curve.

where,

d = the diameter of the largest opening in the end plate [mm] (in the case of an elliptical opening, the larger axis of the ellipse);

t = minimum thickness, after dishing [mm];

D_o = outside diameter of dished end [mm].

2.3.3.3 The following requirements must in any case be satisfied:

$$\frac{t}{D_o} \leq 0.1$$

$$\frac{d}{D_o} \leq 0.7$$

2.3.3.4 From Fig.2.3.1.1 for any selected ratio H/D_o, the curve for unpierced ends gives a value for $\frac{d}{\sqrt{D_o t}}$ as well as for K. Openings giving a value of $\frac{d}{\sqrt{D_o t}}$ not greater than the value so obtained may thus be pierced through an end designed as unpierced without any increase in thickness.

2.3.4 Flanged openings in dished ends

2.3.4.1 The requirements in 2.3.3 apply equally to flanged openings and to unflanged openings cut in the plate of an end. No reduction may be made in the end plate thickness on account of flanging.

2.3.4.2 Where openings are flanged, the radius, r_m, of the flanging is to be not less than 25 [mm], See Fig.2.3.1.2(d). The thickness of the flanged portion may be less than the calculated thickness.

2.3.4.3 Unreinforced and flanged openings in dished ends are to be so arranged that the distance from the edge of the hole to the outside edge of the plate and the distance between openings are not less than those shown in Fig.2.3.1.3.

2.3.5 Dished ends with reinforced openings

2.3.5.1 Where it is desired to use a large opening on a dished end of less thickness than would be required by 2.3.3, the end is to be reinforced. This reinforcement may consist of a ring or standpipe welded into the hole, or of reinforcing plates welded to the outside and/or inside of the end in the vicinity of the hole, or a combination of both methods, see Fig.2.3.1.4. Forged reinforcement may be used.

2.3.5.2 Reinforcing material within the following limits may be taken as effective reinforcement:

a) The effective width l_1, of reinforcement is not to exceed $\sqrt{2 R_i t}$ or 0.5 d_o whichever is the lesser;

b) The effective length l_2 of a reinforcing ring is not exceed $\sqrt{d_o t_b}$;

where,

R_i = The internal radius of the spherical part of a torispherical end [mm]; or

= the internal radius of the meridian of the ellipse at the center of the opening, of a semi-ellipsoidal end, [mm], and is given by the following formula:

$$\frac{[a^4 - x^2(a^2 - b^2)]^{1.5}}{a^4 b}$$

where,

a, b and x are shown in Fig.2.3.1.2(c);
t_b = actual thickness of ring or standpipe [mm];
d_o = external diameter of ring or standpipe [mm];
l_1 and l_2 are shown in Fig.2.3.1.4.

2.3.5.3 The shape factor, K, for a dished end having a reinforced opening can be read from Fig.2.3.1.1 using the value obtained from:

$$\frac{d_o - A/t}{\sqrt{D_o\, t}} \text{ instead of from } \frac{d}{\sqrt{(D_o\, t)}}$$

where,

A = the effective cross-sectional area of reinforcement and is to be twice the area shown shaded on Fig.2.3.1.4.

A trial calculation is necessary to select the correct curve.

2.3.5.4 The area shown in Fig.2.3.1.4 is to be obtained as follows:-

- calculate the cross-sectional area of reinforcement both inside and outside the end plate within the length l_1;
- **plus** the full cross-sectional area of that part of the ring or standpipe which projects inside the end plate up to the distance l_2;
- **plus** the full cross-sectional area of that part of the ring or standpipe which projects outside the internal surface of the end plate up to a distance l_2;
- and **deduct** the sectional area which the ring or standpipe would have if its thickness were as calculated in accordance with 2.7.1.

2.3.5.5 If the material of the ring or the reinforcing plates has an allowable stress value lower than that of the end plate, then the effective cross-sectional area, A, is to be multiplied by the ratio:-

$$\frac{\text{allowable stress of reinforcing plate at design temperature}}{\text{allowable stress of end plate at design temperature}}$$

2.4 Conical ends subject to internal pressure

2.4.1 Minimum thickness

2.4.1.1 The minimum thickness, t, of the cylinder, knuckle and conical section at the junction and within the distance L from the junction is to be determined by the following formula, but in no case is to be less than the thickness determined by 2.4.1.3:-

$$t = \frac{p\, D_o\, K}{20\, \sigma\, J} + 0.75 \text{ [mm]}$$

where,

t, p, σ and J are defined in Sec.1;

D_o = outside diameter, in [mm], of the conical section or end, see Fig.2.4.1.1(a),(b),(c) and (d);

K = a factor, taking in to account the stress in the knuckle, see Table 2.4.1.1.

2.4.1.2 If the distance of a circumferential seam from the knuckle or junction is not less than L, then J is to be taken as 1.0, otherwise J is to be taken as the weld joint factor appropriate to the circumferential seam;

where,

L = distance, in [mm], from knuckle or junction within which meridional stresses determine the required thickness, see Fig.2.4.1.1;

$$= 0.5\sqrt{\frac{D_o\, t}{\text{Cos}\,\psi}}$$

r_i = inside radius of transition knuckle, in [mm], which is to be taken as 0.01 Dc in case of conical sections without knuckle transition.

2.4.1.3 The minimum thickness, t, of those parts of conical sections not less than a distance L from the junction with a cylinder or other conical section is to be determined by the following formula:-

$$t = \frac{p\, D_c}{(20\, \sigma\, J - p)\, Cos\alpha} + 0.75 \text{ [mm]}$$

where,

D_c = inside diameter, in [mm], of conical section or end at the position under consideration, see Fig.2.4.1.1;

$\alpha 1$, $\alpha 2$, $\alpha 3$ = angle of slope of conical section (at the point under consideration) to the vessel axis, see Fig.2.4.1.1.

2.4.1.4 Conical ends may be constructed of several ring sections of decreasing thickness, as determined by the corresponding decreasing diameter.

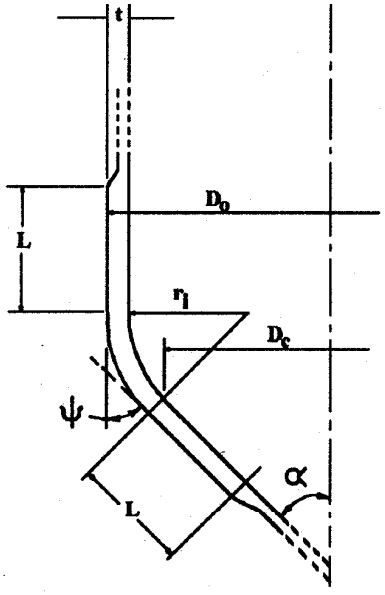

Fig. 2.4.1.1 (a) : Cone/cylinder with knuckle

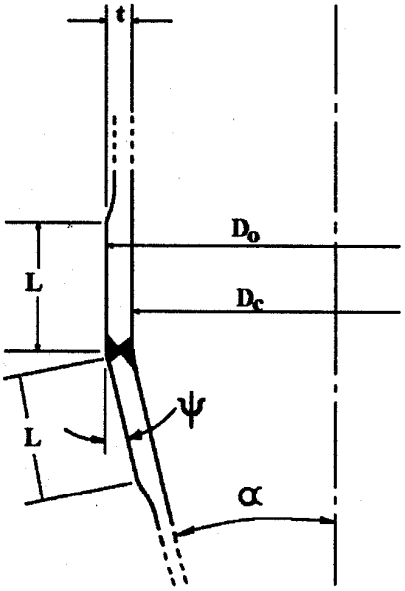

Fig. 2.4.1.1 (b) : Cone/cylinder without knuckle

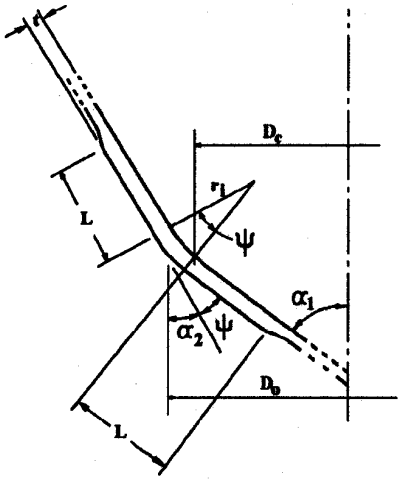

Fig. 2.4.1.1 (c) : Cone/cone with knuckle

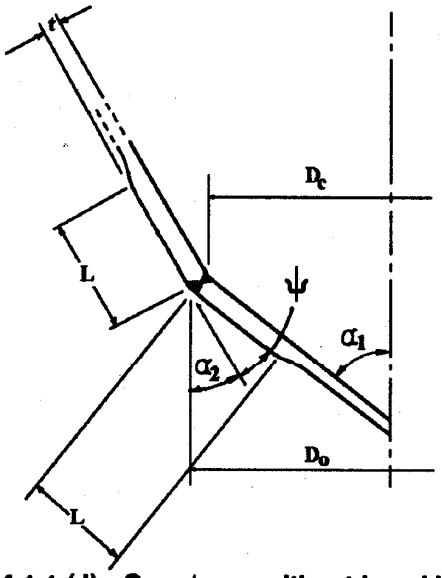

Fig. 2.4.1.1 (d) : Cone/cone without knuckle

Table 2.4.1.1 : Values of K as a function of ψ and r_i/D_o

	Values of K for r_i/D_o ratios											
ψ	**0.01**	**0.02**	**0.03**	**0.04**	**0.06**	**0.08**	**0.10**	**0.15**	**0.20**	**0.30**	**0.40**	**0.50**

2.4.1.5 The thickness of conical sections having an angle of inclination to the vessel axis of more than 75 degrees is to be determined as for a flat plate.

2.5 Unstayed flat end plates

2.5.1 Minimum thickness

2.5.1.1 The thickness of an unstayed flat end plate is to be determined in accordance with 2.7.3.3 or 2.8.1.7 or 2.8.1.8 as applicable.

2.6 Standpipe and branches

2.6.1 Minimum thickness

2.6.1.1 The minimum wall thickness of standpipes and branches is to be not less than that determined by 2.7.1. In determining the wall thickness of branches, internal pressure in addition to loads by connected piping and vibrations are to be taken into account. The thickness, however, is not to be less than:

$t = 0.04\ D_o + 2.5$ [mm]

where,

t and D_o are as defined in Sec.1.

2.6.1.2 In no case need the wall thickness exceed that of the shell.

2.6.1.3 Where standpipe or branch is connected by screwing, the thickness is to be measured at the root of the threads.

2.7 Particular design requirements for boilers, superheaters, economizers, steam receivers and similar vessels

2.7.1 Boiler tubes subject to internal pressure

2.7.1.1 The minimum wall thickness of straight tubes subject to internal pressure is to be determined by the following formula:

$$t = \frac{p\,D_o}{20\sigma + p}\ [mm]$$

where,

t, p, D_o and σ are as defined in Sec.1. The thickness is in no case to be less than that shown in Table 2.7.1.

2.7.1.2 If the tube is ordered with a minus tolerance, the minimum thickness according to the formula in 2.7.1.1 is to be increased by the necessary amount. Where tubes are bent, the thickness of the thinnest part of the tube is not to be less than the calculated thickness, unless it can be demonstrated that the method of bending results in no decrease in strength at the bend as compared with the straight tube. In connection with any new method of bending, the manufacturer is to prove that this condition is satisfied.

2.7.1.3 For boiler, superheater and economizer tubes, the wall thickness required for the drum or header connection or tube stub is to be calculated as part of the tube.

2.7.1.4 The minimum thickness of downcomer tubes and pipes which form an integral part of the boiler and which are not exposed to combustion gases is to comply with the requirements for steam pipes.

Table 2.7.1 : Minimum thickness of tubes

Nominal outside diameter of tube [mm]	Minimum thickness [mm]	Minimum thickness [mm], See Note
≤ 38	1.75	2.95
> 38 ≤ 50	2.16	2.95
> 50 ≤ 70	2.40	2.95
> 70 ≤ 75	2.67	3.28
> 75 ≤ 95	3.05	3.28
> 95 ≤ 100	3.28	3.28
> 100 ≤ 125	3.50	3.50

Note : Applicable to tubes subject to internal pressure and fitted in cylindrical boilers and also for the tubes of low pressure water tube boilers having a design pressure of 1.72 [N/mm^2] and under with open feed system.

2.7.2 Boiler tubes subject to external pressure

2.7.2.1 The wall thickness of tubes with outside diameter 100 [mm] and less is not to be less than:

$$t = \frac{p D_o}{157 \sigma} \text{ [mm]}$$

where,

t, p, D_o and σ are as defined in Sec.1;

The nominal thickness of plain boiler tubes is, however, in no case to be less than given in Table 2.7.2.

Table 2.7.2 : Thickness of plain tubes under external pressure

Outside diameter of tube [mm]	Nominal thickness of tube [mm]				
	2.9	**3.2**	**3.6**	**4.0**	**4.5**
Design pressure [N/mm^2]					
51	1.1	1.5	2.1		
57	1.0	1.35	1.8	2.2	
63.5	0.9	1.25	1.6	2.1	
70	0.8	1.1	1.5	1.95	
76.1		1.0	1.35	1.75	2.1
82.5		0.9	1.25	1.6	1.95
88.9		0.85	1.15	1.5	1.8

2.7.2.2 Regarding minus tolerance and reduction in thickness due to bending, see 2.7.1.2.

2.7.2.3 Plain tubes may be seal welded at both ends, seal welded at the inlet end and expanded at the outlet end or expanded at both the ends. Where the tubes are seal welded, the tubes are to be expanded into the tube plates in addition to welding.

2.7.2.4 Where plain tubes are expanded only, the process is to be carried out with roller expanders, and the expanded portion of the tube is to be parallel through the full thickness of the tube plate. In addition to expanding, tubes may be bellmouthed or beaded at the inlet end.

2.7.2.5 Where the total number of tubes are arranged in one nest and no stay tubes are fitted, the ends of all tubes are to be welded or expanded and beaded at the inlet end, and welded or expanded at the outlet end.

2.7.2.6 The spacing of the tube holes is to be such that the minimum width, in [mm], of any ligament between the tube holes is not less than:

$$0.125\, d + 12.5 \text{ [mm]}$$

where,

d = diameter of tube hole [mm].

2.7.3 Headers

2.7.3.1 Circular headers

2.7.3.1.1 The minimum thickness of circular section headers is to be calculated in accordance with 2.1.

2.7.3.2 Rectangular section headers

2.7.3.2.1 The thickness of flat surfaces of rectangular solid forged headers is to be not less than (t + 0.75) [mm], where t = the greatest basic thickness, in [mm], derived by the use of Fig.2.7.3.1.

2.7.3.2.2 Fig.2.7.3.1 shows values of t/B corresponding to the values of term K, for parameters of A/B;

where,

A = the distance, in [mm], between centerline of the openings and the limit of the effective width, B, of the header. Where there is more than one row of holes, A is the distance to the row showing the lowest efficiency;

B = the effective width, in [mm], of the pierced surface under consideration measured between the supporting sides of the headers, minus one corner radius. The effective width is not to be taken as less than 0.9 of the full distance between the sides;

$$K = \frac{10\sigma J}{p}$$

where,

σ and p are as defined in Sec.1;

J = the efficiency of the ligaments as calculated in 2.1.2. Where there are several rows of tube holes, the lowest calculated efficiency is to be used.

2.7.3.2.3 Investigations of two stresses are necessary:

- the stress at the corner of the header, where A/B = 0 and J = 1, see Fig.2.7.3.1;
- and the stress in the ligaments between tube holes or other openings piercing the flat face of the header.

2.7.3.2.4 The corner radius is not to be less than 6.5 [mm].

2.7.3.2.5 Where the header surfaces are machined locally at hand holes, the total thickness may be reduced by a maximum of 4 [mm].

2.7.3.2.6 Except for small areas not exceeding 325 [mm^2], where a reduction of designed thickness up to 50 per cent may be permitted, the thickness derived from the use of Fig.2.7.3.1 is to be the minimum. Such minimum is in no case to be less than 7.5 [mm] or where tube holes are drilled, to be less than:-

$$t = 0.5\sqrt{d} + 6.35 \text{ [mm]}$$

where,

d = the diameter of the tube holes [mm].

2.7.3.3 Header ends

2.7.3.3.1 The shape and thickness of ends forged integrally with the bodies of headers are to be the subject of special consideration. Where sufficient experience of previous satisfactory service of headers with integrally forged ends cannot be shown, the suitability of a proposed form of end is to be proved in accordance with 1.10.

2.7.3.3.2 Ends attached by welding are to be designed as follows:-

a) Dished Ends: these are to be in accordance with 2.3

b) Flat Ends: the minimum thickness of flat end plates is to be determined by the following formula:-

$$t = d_i\sqrt{\frac{pC}{10\sigma}}$$

where,

p and σ are as defined in Sec.1;

t = minimum thickness of end plate [mm];

d_i = internal diameter of circular header or least width between walls of rectangular header [mm];

C = a constant depending on method of end attachment, see Fig.2.7.3.2

For end plates welded as shown in Fig.2.7.3.2 (a):

C = 0.19 for circular headers;

= 0.32 for rectangular headers;

For end plates welded as shown in Fig.2.7.3.2 (b) and (c):

C = 0.28 for circular headers;

= 0.40 for rectangular headers.

2.7.3.3.3 Where flat end plates are bolted to flanges attached to the ends of headers, the flanges and end plates are to be in accordance with recognized pipe flange standards.

2.7.4 Flat surfaces and flat tube plates

2.7.4.1 Stayed flat surfaces

2.7.4.1.1 Where flat end plates are flanged for connection to the shell, the inside radius of flanging is to be not less than 1.75 times the thickness of the plate, with a minimum of 38 [mm].

2.7.4.1.2 Where combustion chamber of firebox plates are flanged for connection to the wrapper plate, the inside radius of flanging is to be equal to the thickness of the plate, with a minimum of 25 [mm].

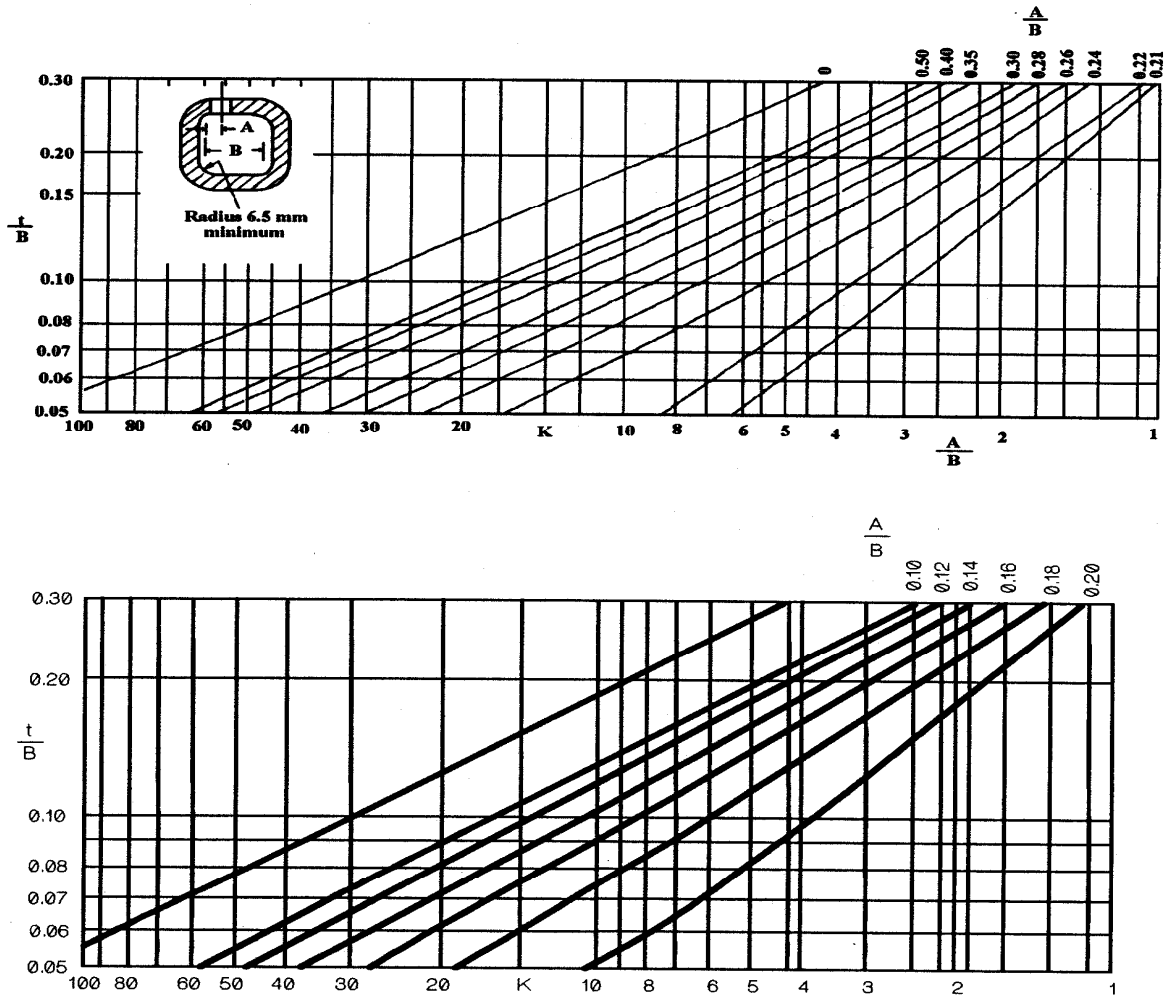

Fig. 2.7.3.1 : Rectangular section headers

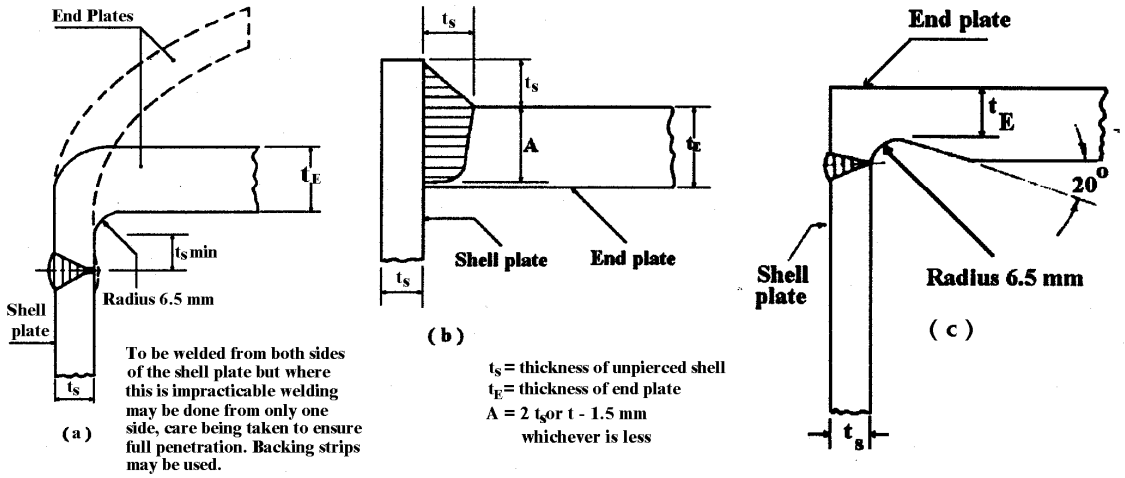

Fig. 2.7.3.2 : Typical methods of attachment of headers and closures

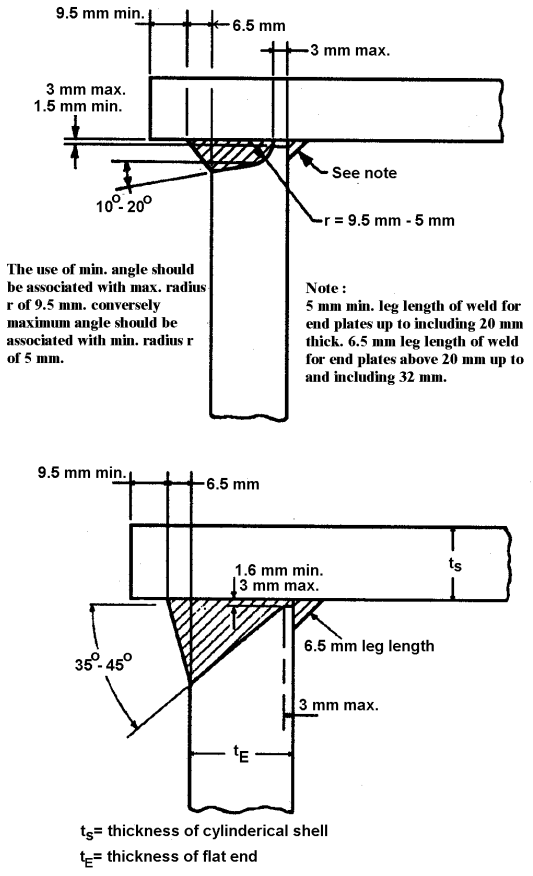

Fig.2.7.4.1 : Attachment of unflanged end plate to shell

2.7.4.1.3 Where unflanged flat plates are connected to the shell by welding, the methods of attachment are to be as shown in Fig.2.7.4.1. Similar forms of attachment may be used where unflanged combustion chamber or firebox plates are connected to the wrapper plate by welding.

2.7.4.1.4 Where the flange curvature is a point of support, this is to be taken at the commencement of curvature, or at a line distant 3.5 times the thickness of the plate from the outside of the plate, whichever is nearer to the flange.

2.7.4.1.5 Where a flat plate is welded directly to a shell or wrapper plate, the point of support is to be taken at the inside of the shell or wrapper plate.

2.7.4.1.6 The thickness, t, of those portions of flat plates supported by stays is to be determined by the following formula:

$$t = C\,d\sqrt{\frac{p}{10\sigma_1}} + 0.75 \ \text{[mm]}$$

where,

t and p are as defined in Sec.1;

σ_1 = 0.85 σ, where σ is as defined in Sec.1;

d = $\sqrt{A^2 + B^2}$ where the stays are regularly pitched

A = horizontal pitch of the stays

B = vertical pitch of the stays

where the tubes are irregularly pitched

d = diameter of the largest circle which can be drawn through three points of support without enclosing another point of support. Only two points of support may lie on one side of any diameter of the circle.

C = a constant, dependent on the method of support as detailed in 2.7.4.1.7. Where various forms of support are used, C is to be the mean of the values for the respective methods adopted.

2.7.4.1.7 All constants given in this paragraph relate to plates which are stress relieved and not exposed to flame. Where the plates are exposed to flame the thickness of the plate is to be increased by 10 per cent. The values of C in the formula in 2.7.4.1.6 is to be as follows:-

a) Where plain bar stays are strength welded in to the plates as shown in Fig.2.7.4.2.

   C = 0.39

b) Where plain bar stays pass through holes in the plates and are fitted on the outside with washers as shown in Fig.2.7.4.3.

   C = 0.35 where the diameter of the washer is 3.5 times the diameter of the stay.

   C = 0.33 where the diameter of the washer is 0.67 times the pitch of the stays.

c) Where the flat plate is flanged for attachment to the shell, flue, furnace or wrapper or, alternatively, is welded directly to the shell, flue, furnace or wrapper.

C = 0.33

d) where the support is a gusset or link stay

C = 0.39

2.7.4.1.8 Alternative methods of support will be specially considered.

2.7.4.1.9 Where a flat plate has a manhole or sighthole and the opening is strengthened by flanging, the total depth, H, of the flange, measured from the outer surface of the plate, is to be not less than:

$$H = \sqrt{t\,W}$$

where,

H = depth of flange [mm];

t = thickness of plate [mm];

W = minor axis of manhole or sight hole [mm].

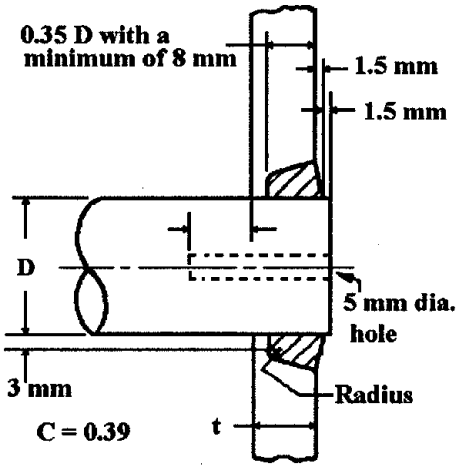

Fig. 2.7.4.2 : Attachment of firebox, combustion chamber and bar stays

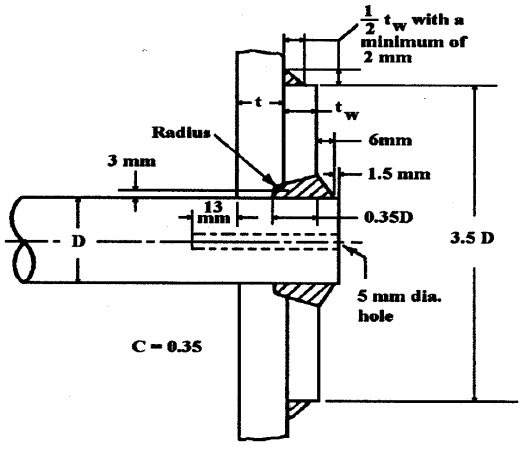

Fig. 2.7.4.3 : Attachment of bar stays

2.7.4.1.10 Where the flat top plates of combustion chambers are supported by welded-on girders, the equation in 2.7.4.1.6 is to apply as follows:

a) In the case of welded-on girders provided with waterways;

C = 0.42;

$$d = \sqrt{X^2 + Y^2}$$

where,

X = width of waterway in the girder plus the thickness of the girder [mm];

Y = pitch of girder [mm];

b) In the case of the continuously welded-on girders;

C = 0.51;

d = D;

where,

D = distance between inside faces of girders [mm].

2.7.4.2 Flat tube plates within tube nests

2.7.4.2.1 Stay tubes are to be fitted:

a) Where the total number of tubes are arranged in one nest, the area of which exceeds 0.65 [m^2] in the case of direct fired boilers, and 2.0 [m^2] in the case of waste heat boilers;

b) In all cases where the total number is arranged in more than one nest.

2.7.4.2.2 Where stay tubes are not fitted, the ends of all tubes are to be welded or expanded and beaded at the inlet end, and welded or expanded at the outlet end. For details of seal welding of plain tubes, see Fig.2.7.4.4.

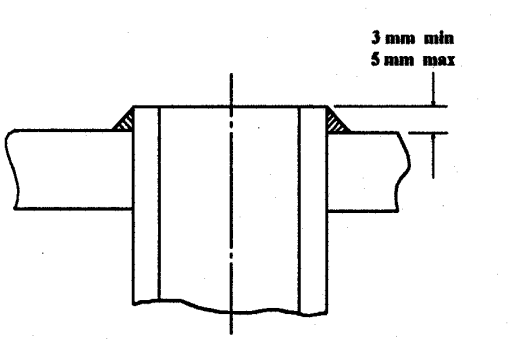

Fig. 2.7.4.4 : Detail of seal weld for plain tube

2.7.4.2.3 Where stay tubes are required to be fitted, the thickness of those parts of the tube plates within the tube nests is to be determined by the following formula:

$$t = C\,M\sqrt{\frac{p}{10\sigma_1}} + 0.75 \ \ [mm]$$

where,

t = thickness of tube plate [mm];

p = design pressure [N/mm^2];

σ_1 = 0.85 σ, where σ is as defined in Sec.1;

M = mean pitch, in [mm], of the stay tubes supporting any positions of the plate (being the sum of the four sides of any quadrilateral divided by 4);

C = 0.42 for plates not exposed to flame with stay tube secured as shown in Fig.2.7.4.5;

C = 0.46 for plates exposed to flame.

2.7.4.2.4 Where the area of the tube nest does not exceed 0.65 [m^2] in the case of direct fired boilers, or 2.0 [m^2] in the case of waste heat boilers, and stay tubes are not fitted, the thickness of the plate is to be determined by the formula in 2.7.4.2.3;

where,

M = Four times the mean pitch [mm], of the plain tubes in the nest;

C = 0.45 for plates not exposed to flame;

= 0.49 for plates exposed to flame.

2.7.4.2.5 The thickness, t, of any tube plate in the tube area is to be not less than:

a) 12.5 [mm], where the diameter of the tube hole does not exceed 50 [mm]; and

b) 14 [mm], where the diameter of the tube hole is greater than 50 [mm].

2.7.4.3 Flat tube plates between wide water spaces and around tube nests

2.7.4.3.1 The thickness of the tube plate in the wide water space between tube nests is to be determined by the following formula:

$$t = C\,d\sqrt{\frac{p}{10\sigma_1}} + 0.75 \ \ [mm]$$

where,

t = thickness of the tube plate [mm];

p = design pressure [N/mm^2];

σ_1 = 0.85 σ, where σ is as defined in Sec.1;

$$d = \sqrt{A^2 + B^2}$$

A = width [mm], of the wide water space between the tube nests (measured from the centerline of the stay tubes);

B = pitch [mm], of the stay tubes in boundary rows of wide water space;

C = 0.42, if the plates are not exposed to flame;

= 0.46, if the plates are exposed to flame.

2.7.4.3.2 The values of C and the method of securing the stay tubes are as indicated in 2.7.4.2.3.

2.7.4.3.3 Where stay tubes are irregularly pitched, d is to be taken as the diameter of the largest circle which can be drawn through any three points of support without enclosing another point of support. Where various forms of supports are used, the value of C is to be the mean of the values for the respective methods adopted.

2.7.4.3.4 For the portions of the end plates between the top rows of tubes and steam

space stays, the formula in 2.7.4.3.1 is to apply, B being taken as the distance between the centerline of the top row of tubes and the center of the bar stays or other point of support, and A being taken as $\frac{A_1 + A_2}{2}$ where A_1 is the horizontal distance between the centers of bar stays or other methods of support, and A_2 is the horizontal distance between the center of one stay tube and the center of next stay tube in the top boundary row. Where no stay tubes are fitted, A_2 is to be taken as equal to four times the horizontal pitch of the plain tubes.

2.7.4.3.5 Where no stay tubes are fitted, the support afforded by the plain tubes are not to be taken to extend beyond the line enclosing the outer surfaces of the tubes except that, between the outside of the wing row of tubes and the attachment of the end plate to shell, there may be an unsupported width equal to the flat plate margin, as given by the formula in 2.7.4.6.1.

2.7.4.4 Combustion chamber tube plates under compression

2.7.4.4.1 The thickness of combustion chamber tube plates under compression due to the pressure on the top plate, based on a compressive stress not exceeding 960 bar is to be determined by the following formula:

$$t = \frac{pWs}{1930(s - d)} \text{ [mm]}$$

where,

t and p are as defined in Sec.1;

W = internal width of combustion chamber [mm], measured from tube plate to back chamber plate;

s = pitch of tubes [mm], measured horizontally where tubes are chain pitched, or diagonally where the tubes are staggered pitched and the diagonal pitch is less than the horizontal pitch;

d = internal diameter of plain tubes.

2.7.4.5 Girders for combustion chamber top plates

2.7.4.5.1 The formula in 2.7.4.5.2 is applicable to plate girders welded continuously to the top combustion chamber plates by means of a full penetration weld.

2.7.4.5.2 The proportion of steel plate girders supporting the tops of combustion chambers is to be determined by the following formula:

$$t = \frac{0.32\, p\, l^2\, s}{d^2\, R_{20}} \text{ [mm]}$$

where,

t and p are as defined in Sec.1;

d = depth of girder [mm];

l = length of girder [mm], measured internally from tube plate to back chamber plate;

s = distance apart of the girders [mm];

R_{20} = specified minimum tensile strength of the girder plate [N/mm^2].

2.7.4.6 Flat plate margins

2.7.4.6.1 The width of margin, b, of a flat plate which may be regarded as being supported by the shell, furnaces or flues to which the flat plate is attached is not to exceed that determined by the following formula:

$$b = \frac{C(t - 0.75)}{\sqrt{p}} \text{ [mm]}$$

where,

t and p are as defined in Sec.1;

b = width of margin [mm];

C = 31.0 for plates not exposed to flame;

= 28.8 for plates exposed to flame.

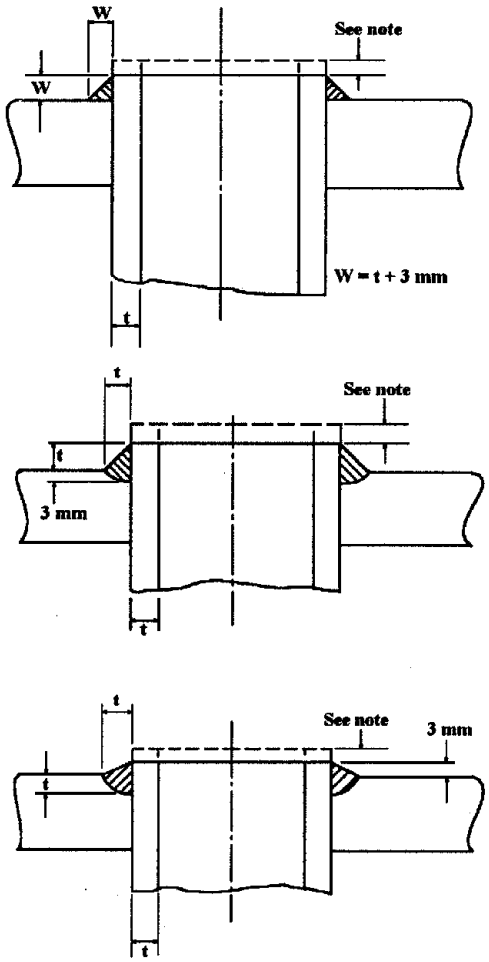
2.7.4.6.2 Where an unflanged flat plate is welded directly to shell, furnaces or flues and it is not practicable to effect the full penetration weld from both sides of the flat plate, the constant C used in formula in 2.7.4.6.1 is to be:

C = 23.6 for plates not exposed to flame;

= 22.3 for plates exposed to flame.

2.7.4.6.3 In the case of plates which are flanged, the margin is to be measured from the commencement of curvature of flanging, or from a line 3.5 times the thickness of the plate, measured from the outside of the plate, whichever is nearer to the flange.

2.7.4.6.4 Where the flat plate is not flanged for attachment to the shell, furnaces or flues, the margin is to be measured from the inside of the shell or the outside of the furnaces or flues, whichever is applicable.



Note : The ends of the tubes are to be dressed flush with the welds and then exposed to flame or comparitively high temperature. When not exposed, the ends of the tubes may extend a maximum of 9.5 [mm] beyond the weld.

Fig. 2.7.4.5 : Attachment of stay tubes

2.7.4.6.5 In no case is the diameter, D, in [mm], of the circle forming the boundary of the margin supported by the uptake of a vertical boiler to be greater than determined by the following formula:

$$D = \sqrt{\frac{345}{p} + d^2} \ [mm]$$

where,

A = cross-sectional area of the uptake tube [mm^2];

p = design pressure in bar;

d = external diameter of uptake [mm].

2.7.5 Flat plates and ends of vertical boilers

2.7.5.1 Tube plates of vertical boilers

2.7.5.1.1 Where vertical boilers have a nest or nests of horizontal tubes, so that there is direct

tension on the tube plates due to the vertical load on the boiler ends or to their acting as horizontal ties across the shell, the thickness of the tube plates in way of the outer rows of tubes are to be determined by the following formula:

$$t = \frac{pD}{5JR_{20}} + 0.75 \text{ [mm]}$$

where,

t and p are as defined in Sec.1;

D = twice the radial distance of the center of the outer row of tube holes from the axis of the shell [mm];

R_{20} = specified minimum tensile strength of tube plate [N/mm^2];

J = efficiency of ligaments between tube holes in the outer vertical rows (expressed as a fraction);

$$= \frac{s - d}{s}$$

where,

s = vertical pitch of tubes [mm];

d = diameter of tube holes [mm].

2.7.5.1.2 Each alternate tube in the outer vertical rows of tubes is to be a stay tube. Further, the arrangement of stay tubes in the nests is to be such that the thickness of the tube plates meets the requirements of 2.7.4.2. and 2.7.4.3.

2.7.5.1.3 Where the vertical height of the tube plates between the top and bottom shelves exceeds 0.65 times the internal diameter of the boiler, the staying of the tube plates, and the scantlings of the tube plates and shell plates to which the sides of the tube plates are connected will require to be specially considered. It is recommended, however, that for this type of boiler the vertical height of the tube plates between the top and bottom shelves should not exceed 1.25 times the internal diameter of the boiler.

2.7.5.2 Horizontal shelves of tube plates forming part of the shell

2.7.5.2.1 For vertical boilers of the type referred to in2.7.5.1, in order to withstand the vertical load due to pressure on the boiler ends, the horizontal shelves of the tube plates are to be supported by gussets in accordance with the following formula:

$$C = \frac{A D_i p}{t}$$

where,

A = maximum horizontal dimension of the shelf from the inside of the shell plate to the outside of the tube plate [mm];

D_i = inside diameter of the boiler [mm];

p = design pressure, in bar;

t = thickness of the tube plate [mm].

2.7.5.2.2 For the combustion chamber tube plate the minimum number of gussets are to be:

- 1 gusset where C exceeds 255 000
- 2 gussets where C exceeds 350 000
- 3 gussets where C exceeds 420 000

2.7.5.2.3 For the smoke box tube plate the minimum number of gussets are to be:

- 1 gusset where C exceeds 255 000
- 2 gussets where C exceeds 420 000

2.7.5.2.4 The shell plates to which the sides of the tube plates are connected are to be not less than 1.5 [mm] thicker than is required by the formula applicable to shell plates with continuous circularity; and where gussets or other stays are not fitted to the shelves, the strength of the parts of the circumferential seams at the top and bottom of these plates from the outside of one tube plate to the outside of the other, is to be sufficient to withstand the whole load on the boiler end with a factor of safety of not less than 4.5 related to R_{20} (where R_{20} is the specified minimum tensile strength
of the shell plates [N/mm^2].

2.7.5.3 Dished and flanged ends for vertical boilers

2.7.5.3.1 The minimum thickness, t, of dished and flanged ends for vertical boilers which are subject to pressure on the concave side and are supported by central uptakes is to be determined by the following formula:

$$t = \frac{P R_i}{10\sigma_2} + 0.75 \text{ [mm]}$$

where,

t, p and R_i are as defined in Sec.1;

$\sigma_2 = 1.3\ \sigma$, where σ is defined in 1.6.

2.7.5.3.2 The inside radius of curvature, R_i, of the end plate is to be not greater than the external diameter of the cylinder to which it is attached.

2.7.5.3.3 The inside knuckle radius, r_i, of the arc joining the cylindrical flange to the spherical surface of the end is to be not less than four times the thickness of the end plate, and in no case less than 65 [mm].

2.7.5.3.4 The inside radius of curvature of flange to uptake is to be not less than twice the thickness of the end plate, and in no case less than 25 [mm].

2.7.5.3.5 If the dished end has a manhole, the opening is to be strengthened by flanging. The total depth, H, of the flange, measured from the outer surface of plate on the minor axis, is to be not less than:

$$H = \sqrt{t\,W}$$

where,

H = depth of flange [mm];

t = thickness of the plate [mm];

W = minor axis of manhole [mm].

2.7.5.4 Flat crowns of vertical boilers

2.7.5.4.1 The minimum thickness of flat crown plates of vertical boilers is to be determined as in 2.7.4; d and c are defined as follows:

a) Where the crown is supported by an uptake only;

   d = diameter [mm], of the largest circle which can be drawn between the connections to the shell or fire box and uptake (see 2.7.4.1.1 to 2.7.4.1.5);

   c = 0.47, if the plates are not exposed to flame;

   = 0.51, if the plates are exposed to flame;

b) Where bar stays are fitted in accordance with 2.7.4.1.6 and 2.7.4.1.7;

   d = diameter, in [mm], of the largest circle which can be drawn through three points of support without enclosing another point of support;

   c = the mean of the values for the respective points of support through which the circle passes.

2.7.5.5 Dished and flanges ends for supported vertical boiler furnaces

2.7.5.5.1 The minimum thickness, t, of dished and flanged ends for vertical boiler furnaces that are subject to pressure on the convex side and are supported by central uptake, is to be determined by the following formula:

$$t = \frac{p R_o}{10\sigma} + 0.75 \text{ [mm]}$$

where,

t, p, R_o and σ are as defined in Sec.1.

2.7.5.5.2 The inside radius of dishing and flanging are to be as required by 2.7.5.3.

2.7.5.6 Dished and flanged ends for unsupported vertical boiler furnaces:

2.7.5.6.1 The minimum thickness, t, of dished and flanged ends for vertical boiler furnaces that are subject to pressure on the convex side and are without support from stays of any kind, is to be determined by the following formula, but is in no case to be less than the thickness of the firebox:

$$t = \frac{C\,p\,R_o}{660} + 0.75 \text{ [mm]}$$

where,

t and p are as defined in Sec.1;

R_o = outside radius of the crown plate, in [mm], (in no case Ro/t to exceed 88);

C = $\frac{2x}{x+\sigma}$ or 0.85 whichever is greater

x = specified minimum 0.2 per cent proof stress in [N/mm^2], at a temperature 90°C above the saturated steam temperature corresponding to the design pressure for carbon and carbon-manganese steel with a specified minimum tensile strength of 400 [N/mm^2];

σ = specified minimum 0.2 per cent proof stress in [N/mm^2], at a temperature 90°C above the saturated steam temperature corresponding to the design pressure for the steel actually used.

2.7.5.6.2 The inside radius of curvature, R_i, see Fig.2.3.1.2 (a), of the end plate is to be not greater than the external diameter of the cylinder to which it is attached.

2.7.5.6.3 The inside knuckle radius, r_i, see Fig.2.3.1.2 (a), of the arc joining the cylindrical flange to the spherical surface of the end is to be not less than four times the thickness of the end plate and in no case less than 65 [mm].

2.7.6 Cylindrical furnaces subject to external pressure

2.7.6.1 Maximum thickness

2.7.6.1.1 Furnaces, plain or corrugated, are not to exceed 22.5 [mm] in thickness.

2.7.6.2 Corrugated furnaces

2.7.6.2.1 The minimum thickness, t, of corrugated furnaces is to be determined by the following formula:

$$t = \frac{P D_o}{C} + 0.75 \text{ [mm]}$$

where,

p is as defined in Sec.1;

D_o = external diameter of the furnace measured at the bottom of the corrugations [mm];

t = thickness, of the furnace plate measured at the bottom of the corrugations [mm];

C = 1060 for Fox, Morision and Deighton corrugations;

= 1130 for suspension and bulb corrugations.

2.7.6.3 Plain furnaces, flue sections and combustion chamber bottoms

2.7.6.3.1 The minimum thickness, t, of plain furnaces or furnaces strengthened by stiffening rings, of flue sections and of the cylindrical bottoms of combustion chambers is to be determined by the following formulae, the greater of two thicknesses being taken:

$$t = \sqrt{\frac{p D_o (L+160)}{102400}} + 0.75 \text{ [mm]}$$

$$t = \frac{CpD_o}{1100} + \frac{L}{320} + 0.75 \text{ [mm]}$$

where,

t and p are as defined in Sec.1;

D_o = external diameter of the furnace, flue or combustion chamber [mm];

L = length of section between the center of points of substantial support [mm];

$$C = \frac{2x}{x+\sigma}$$

where,

x and σ are as defined in 2.7.5.6.

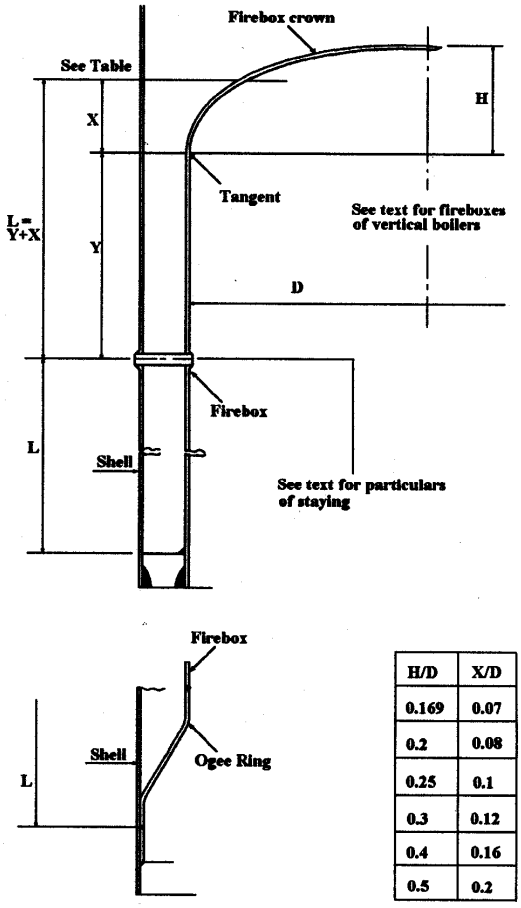
2.7.6.4 Plain furnaces of vertical boilers

2.7.6.4.1 The thickness of plain furnaces not exceeding 1700 [mm] in external diameter is to be determined by the formulae given in 2.7.6.3.1, the greater of the two thicknesses being taken;

where,

D = external diameter of the furnace, in [mm]; where the furnace is tapered, the diameter is to be the mean of that at the top and that at the bottom where it meets substantial support from flange, ring or row of stays;

L = effective length, in [mm], of the furnace between the points of substantial support as indicated in Fig.2.7.6.4.1.



H/D	X/D
0.169	0.07
0.2	0.08
0.25	0.1
0.3	0.12
0.4	0.16
0.5	0.2

Fig. 2.7.6.4.1 : Effective length, L

2.7.6.4.2 For furnaces under 760 [mm] in external diameter, the thickness is to be not less than 8 mm, and for furnaces 760 [mm] in external diameter and over, the thickness is to be not less than 9.5 [mm]. Furnaces exceeding 1700 [mm] in external diameter will be subject of special consideration.

2.7.6.4.3 A circumferential row of stays connecting the furnace to the shell will be considered to provide substantial support to the furnace, provided that:

a) the diameter of the stay is not less than 22.5 [mm] or twice the thickness of the furnace, whichever is the greater. In case of screwed stays the diameter is to be measured over the threads;

b) the pitch of the stays at the furnace does not exceed 14 times the thickness of the furnace.

2.7.6.5 Hemispherical furnaces

2.7.6.5.1 The minimum thickness, t, of unsupported hemispherical furnaces subject to pressure on convex surface is to be determined by the following formula:

$$t = \frac{CpR_o}{608} + 0.75 \text{ [mm]}$$

where,

t and p are as defined in Sec.1;

R_o = outer radius of curvature of furnace [mm];

$C = \frac{2x}{x + \sigma}$ or 0.85, whichever is greater

where,

x and σ are as defined in 2.7.5.6.

2.7.6.5.2 In no case is the minimum thickness to exceed 22.5 mm, or the ratio $\frac{R_o}{(t - 0.75)}$ to exceed 100.

2.7.6.6 Ogee rings

2.7.6.6.1 The minimum thickness, t, of the ogee ring which connects the bottom of the furnace to the shell of a vertical boiler and sustains the whole vertical load on the furnace is to be determined by the following formula:

$$t = \sqrt{\frac{p D_i (D_i - D_o)}{9000}} + 0.75 \text{ [mm]}$$

where,

t and p are as defined in Sec.1;

D_i = inside diameter of boiler shell [mm];

D_o = outside diameter of lower part of the furnace where it joins the ogee ring [mm].

2.7.6.7 Uptakes of vertical boiler

2.7.6.7.1 The minimum thickness, t, of internal uptakes of vertical boiler is to be determined by the following formulae, the greater of the two thicknesses being taken:

$$t = \sqrt{\frac{p\,D_o\,(L + 610)}{102400}} + 4 \ [mm]$$

$$t = \frac{pD_o}{1100} + \frac{L}{320} + 4 \ [mm]$$

where,

t and p are as defined in Sec.1;

D_o = external diameter of uptake [mm];

L = length of uptake between the centers of points of substantial support [mm].

2.7.7 Stay tubes and bar stays for cylindrical boilers

2.7.7.1 Stay tubes

2.7.7.1.1 Each stay tube is to be designed to carry its due proportion of the load on the plates which it supports. No stay tube is to be less than 5 [mm] thick at its thinnest part.

2.7.7.1.2 The thickness of stay tubes welded to the tube plates is to be such that the maximum stress on the thinnest part of the tube does not exceed 69 [N/mm^2].

2.7.7.1.3 Welded-in stay tubes are to be expanded into tube plate in addition to welding.

2.7.7.1.4 Stay tubes may be welded into the boiler after stress relief, provided they are not adjacent in the same tube nest.

2.7.7.2 Combustion chamber and longitudinal bar stays.

2.7.7.2.1 The permissible stress in combustion chamber and other similar bar stays, calculated on minimum sectional area, is not to exceed 62 [N/mm^2].

2.7.7.2.2 The diameter of any stay is to be not less than 19 [mm].

2.7.7.2.3 The permissible stress in longitudinal stays, calculated on the minimum cross-sectional area, is not to exceed:

$$\frac{\text{minimum specified tensile strength [N/mm}^2\text{]}}{5.3}$$

2.7.7.2.4 In no case is the diameter of the longitudinal stays at any section to be less than 25 [mm].

2.7.7.3 Loads on stay tubes and bar stays

2.7.7.3.1 Stay tubes and bar stays are to be designed to carry the whole load due to pressure on the area to be supported.

2.7.7.3.2 For a stay tube or bar stay, the net area to be supported is to be the area [mm^2], enclosed by the lines bisecting at right angles the lines joining the stay and the adjacent points of support, less the area of any tubes or stays embraced. In the case of a stay tube or bar stay in the boundary rows, the support afforded by the flat plate margin, where applicable, should be taken into account.

2.7.7.3.3 Where there are no stay tubes in the tube nest, the area to be supported by a bar stay is to extend to the tangential boundary of the tube nest.

2.8 Access arrangements

2.8.1 General

2.8.1.1 All pressure vessels are to be so made that the internal surfaces may be examined. Wherever practicable, the openings for this purpose are to be sufficiently large for access and for cleaning the inner surfaces.

2.8.1.2 Manholes in cylindrical shells should preferably have their shorter axes arranged longitudinally, and are to be located clear of the welded joints in the shell.

2.8.1.3 Doors for manholes and sightholes are to be formed from steel plate or of other approved construction, and all jointing surfaces are to be machined.

2.8.1.4 Doors of the internal type are to be provided with spigots which have a clearance of not more than 1.5 [mm] all round, i.e. the axes of the opening are not to exceed those of the door by more than 3 [mm].

2.8.1.5 Doors of the internal type for openings not larger than 230 x 180 [mm] need be fitted with only one stud, which may be forged integral with the door. Larger doors are to be

provided with two studs screwed through the door and fitted with nuts on the inside. Alternatively, bolts may be used, screwed through the door with the heads inside. Other methods of attachment may be accepted, provided that details are submitted for consideration.

2.8.1.6 The crossbars or dogs for doors are to be of steel.

2.8.1.7 Circular flat cover plates may be fitted to raised circular manhole frames not exceeding 400 [mm] diameter, and for an approved design pressure not exceeding 18 bar. Thickness of the frames are to be not less than 19 [mm] in all parts. The circular cover plates and joint flanges for such frames are to be not less than:-

a) 25 [mm] thick for an approved design pressure: $\leq$ 8.6 bar;

b) 29 [mm] thick for an approved design pressure: > 8.6 bar $\leq$ 14.5 bar;

c) 32 [mm] thick for an approved design pressure: > 14.5 bar $\leq$ 18 bar.

2.8.1.8 The cover plates are to be provided with spigots and are to be secured by at least 16 bolts not less than 25 [mm] diameter, so that the stress in the bolts at the root of the thread due to pressure does not exceed:

- 34 [N/mm^2] for 25 [mm] diameter bolts
- 41 [N/mm^2] for 28 [mm] diameter bolts
- 45 [N/mm^2] for 32 [mm] diameter bolts

2.8.1.9 For the purpose of calculation, the pressure may be assumed to act on the whole area within the pitch circle of the bolts.

2.8.1.10 For smaller circular openings in headers and similar fittings, an approved type of plug may be used.

2.8.2 Additional requirements for boilers, superheaters, economizers, and similar vessels

2.8.2.1 In water tube boilers, manholes are to be provided in all drums of sufficient size to allow access for internal examinations and cleaning and for fitting and expanding the tubes. In the case of headers for water walls, superheaters or economizers, and of drums which are too small to permit entry, sight holes or mudholes sufficiently large and numerous for these purposes are to be provided.

2.8.2.2 Cylindrical boilers are to be provided, where possible, with means for ingress to permit examination and cleaning of the inner surfaces of plates and tubes exposed to flame. Where the boilers are too small to permit this there are to be sightholes and mudholes sufficiently large and numerous to allow the inside to be satisfactorily cleaned.

2.8.2.3 Where the cross tubes of vertical boilers are large, there is to be a sight hole in the shell opposite to one end of each tube sufficiently large to allow the tube to be examined and cleaned. These sight holes are to be in positions accessible for that purpose.

2.9 Shell type exhaust gas heated economizers that may be isolated from the steam plant system

2.9.1 Scope

2.9.1.1 This requirement is applicable to shell type exhaust gas heated economizers that are intended to be operated in a flooded condition and that may be isolated from the steam plant system and intended to be fitted on board ships contracted for construction on or after 1 January 2007.

2.9.2 Design and construction

2.9.2.1 Design and construction of shell type economizers are to pay particular attention to the welding, heat treatment and inspection arrangements at the tube plate connection to the shell.

2.9.2.2 Every shell type economizer is to be provided with a means of indicating the internal pressure and to be located so that the pressure can be easily read from a position from which the pressure may be controlled.

2.9.2.3 Every shell type economizer is to be provided with removable lagging at the circumference of the tube end plates to enable ultrasonic examination of the tube plate to shell connection.

2.9.3 Feed water

2.9.3.1 Every economizer is to be provided with arrangements for pre-heating and de-aeration, addition of water treatment or

combination thereof to control the quality of feed water to within the manufacturer's recommendations.

2.9.4 Operating instructions

2.9.4.1 The manufacturer is to provide operating instructions for each economizer and is to include reference to:

- Feed water treatment and sampling arrangements.
- Operating temperatures – exhaust gas and feed water temperatures.
- Operating pressure.
- Inspection and cleaning procedures.
- Records of maintenance and inspection.
- The need to maintain adequate water flow through the economizer under all operating conditions.
- Periodical operational checks of the safety devices to be carried out by the operating personnel and to be documented accordingly.
- Procedures for using the exhaust gas economizer in the dry condition.
- Procedures for maintenance and overhaul of safety valves.

Section 3

Fittings and Mountings

3.1 General

3.1.1 All valves over 38 [mm] diameter are to be fitted with outside screws, and the covers are to be secured by bolts or studs. All valves are to be arranged to shut with a right-hand (clockwise rotation) motion of the wheels.

3.1.2 Construction and arrangement of valves and cocks are to be such that it can be seen without difficulty whether they are open or shut, preferably by fitting a suitable indicator.

3.1.3 Where boiler mountings are secured by studs, the studs are to have a full thread holding in the plate for a length of at least one diameter. If the stud hole penetrates the whole thickness of the plate, the stud is to be screwed right through the plate and is to be fitted with a nut inside the boiler. Where bolts are used for securing mountings, they are to be screwed right through the plate with their heads inside the boiler.

3.1.4 Safety valve chests and other boiler and superheater mountings subject to pressures exceeding 10.3 bar or to steam temperatures exceeding 218°C, and boiler blow-down fittings, are to be made of steel or other approved material.

3.1.5 Adequate arrangements are to be provided for draining and venting the separate parts of each pressure vessel.

3.2 Safety valves

3.2.1 For boilers and steam generators

3.2.1.1 Boilers and steam generators are to be fitted with not less than two safety valves, each having a minimum internal diameter of 25 [mm], but those having a total heating surface of less than 50 [m^2] may have one valve not less than 50 [mm] diameter.

3.2.1.2 The valves, spindles, springs and compression screws are to be so encased and locked or sealed that the safety valves and pilot valves after setting to the working pressure, cannot be tampered with or overloaded in service. The spring casing of superheater safety valves should be ventilated, or other arrangements provided to protect the springs from excessive temperature.

3.2.1.3 Valves are to be so designed that in the event of fracture of springs they cannot lift out of their seats.

3.2.1.4 Easing gear is to be provided for lifting the safety valves and is to be operable by mechanical means at a safe position from the boiler or engine room platforms.

3.2.1.5 Safety valves are to be made with working parts having adequate clearances to ensure complete freedom of movement.

3.2.1.6 Valve seats are to be effectively secured in position. Any adjusting devices which control discharge capacity are to be positively secured so that the adjustment will not be affected when the safety valves are dismantled at surveys.

3.2.1.7 All the safety valves of each boiler and steam generator may be fitted in one chest, which is to be separate from any other valve chest and is to be connected directly to the shell by a strong and stiff neck, the passage through which is to be of cross-sectional area not less than the aggregate area of the safety valves in the chest in case of full lift valves, and one half of that area in case of other valves.

3.2.1.8 Each safety valve chest is to be drained by a pipe fitted to the lowest part and led with a downward gradient to the bilges or to a tank, clear of the boilers. No valves or cocks are to be fitted to these drain pipes. It is recommended that the bore of the drain pipes be not less than 19 [mm].

3.2.1.9

a) Where a shell type economizer is capable of being isolated from the steam plant system, it is to be provided with at least one safety valve and when it has a total heating surface of 50 [m^2] or more, it is to be provided with at least two safety valves.

b) To avoid the accumulation of condensate on the outlet side of safety valves, the discharge pipes and/or safety valve housings are to be fitted with drainage arrangements from the lowest part and led with a downward gradient to the bilges or to a tank, clear of the economizer, where it will not pose threat to either personnel or machinery.

3.2.1.10 Full details of the proposed arrangements to satisfy 3.2.1.9(a) to 3.2.1.9(b) are to be submitted for approval.

3.2.1.11 In case of watertube boilers, each saturated steam drum and each superheater are to be provided with at least one safety valve.

3.2.1.12 When a boiler is fitted with an integral superheater without any intervening stop valve, the safety valve(s) on the superheater may be considered as boiler safety valve(s). The safety valves are to be so proportioned and positioned that when relieving, sufficient steam is forced through the superheater to prevent damage to the heater.

Where a superheater, reheater or economizer is fitted with a valve between one of these and the boiler, the unit is to have appropriate safety valves. Such safety valves are not to be regarded as safety valves for the boiler.

3.2.1.13 Where it is impracticable to attach safety valves directly to the superheater, the valves are to be located as near as possible thereto and fitted to a branch piece connected to the superheater outlet pipe.

3.2.1.14 In high temperature installations the drains from safety valves are to be led to a tank or other place where high temperature steam can be safely discharged.

3.2.1.15 The designed discharge capacities of the safety valves on each boiler and steam generators are to be found from the following formulae :

Saturated steam safety valves

$$E = \frac{AC(p + 1.03)}{98.1}$$

Superheated steam safety valves

$$E = \frac{AC(p + 1.03)}{98.1}\sqrt{\frac{v_s}{v_h}}$$

where,

E = the maker's specified peak load evaporation, in [kg/hour] (including all evaporation from waterwalls, integral, or steaming economizers and other heating surfaces in direct communication with the boiler). In no case is the designed evaporation to be based on less than 29 [kg/m^2] hour of heating surface for fired boiler and 14.5 [kg/m^2] hour for exhaust gas heated boilers;

A = for ordinary, high lift or improved high lift safety valves, the aggregate area, in [mm^2], of

the orifices through the seatings of the valves, neglecting the area of guides and other obstructions;

= for full lift safety valves, the net aggregate area, in [mm^2], through the seats after deducting the area of the guides or other obstructions when fully lifted;

C = 4.8 for valves of ordinary type, having a minimum lift of D/24;

= 7.2 for valves of high lift type, having a minimum lift of D/16;

= 9.6 for valves of improved high lift type having a minimum lift of D/12;

= 19.2 for valves of full lift type having a minimum lift of D/4;

D = bore of valve seat [mm];

p = design pressure, in bar;

= specific volume of saturated steam [m^3/kg];

V_h = specific volume of superheated steam [m^3/kg].

3.2.1.16 When the discharge capacity of a safety valve of approved design has been established by type tests, carried out in the presence of the Surveyors or by an independent authority recognized by IRS, on valves representative of the range of sizes and pressures intended for marine application, consideration will be given to the use of a constant higher than C=19.2, based on 90 per cent of the measured capacity up to a maximum of C = 45 for full lift safety valves.

3.2.1.17 Where boilers are not fitted with superheater, the safety valves are to be set to open at a pressure of not more than 3 per cent above the approved design pressure, and in no case at a pressure higher than :

a) the design pressure of the steam piping; or

b) the least sum of the design pressure of the machinery connected to the boiler and the pressure drop in the piping between this machinery and the boiler.

3.2.1.18 Where boilers are fitted with superheaters, the safety valves on the superheaters are to be set to a pressure not higher than :

a) the design pressure of the steam piping; or

b) the least sum of the design pressure of the machinery connected to the boiler and the pressure drop in the piping between this machinery and the boiler.

The safety valves on the boiler drum are to be set to a pressure not less than the superheater valve setting plus 0.35 bar plus the pressure drop through the superheater, when the boiler stop valves are closed and the superheater safety valves are relieving at their rated capacity. In no case, however, are the safety valves to be set to a pressure higher than 3 per cent above the design pressure of the boiler.

3.2.1.19 Tests for accumulation of pressure are to be carried out. The boiler pressure is not to rise more than 10 per cent above the design pressure, when the boiler stop valves are closed under full firing conditions. The duration of the accumulation test is to be 15 minutes for smoke-tube boilers and 7 minutes for water-tube boilers. During this test, no more feed water is to be supplied than is necessary to maintain a safe working water level.

3.2.1.20 For ordinary, high lift and improved high lift type valves, the cross-sectional area of the waste steam pipe and passages leading to it is to be at least 10 per cent greater than the aggregate area of the safety valves as used in the formulae in 3.2.1.15. For full lift and other approved valves of high discharge capacity, the cross-sectional area of the waste steam pipe and passages is to be not less than 0.1C times the aggregate valve area.

3.2.1.21 The cross-sectional area of the main waste steam pipe is to be not less than the combined cross-sectional areas of the branch waste steam pipes leading thereto from the boiler safety valves. In case of water tube boilers, each boiler should have a separate waste steam system to atmosphere.

3.2.1.22 Waste steam pipes are to be led to the atmosphere and are to be adequately supported and provided with suitable expansion joints, bends or other means to relieve the safety valve chests of undue loading.

3.2.1.23 The scantlings of waste steam pipes and silencers are to be suitable for the maximum pressure to which the pipes may be

subjected in service, and in any case not less than 10.0 bar.

3.2.1.24 Silencers fitted to waste steam pipes are to be so designed that the clear area through the baffle plates is not less than that required for pipes.

3.2.1.25 The safety valves of each exhaust gas heated economizer/and each exhaust gas heated boiler which may be used as an economizer are to be provided with entirely separate waste steam pipes.

3.2.1.26 External drains and exhaust steam vents to atmosphere are not to be led to waste steam pipes.

3.2.1.27 It is recommended that a scale trap and means for cleaning be provided at the base of each waste steam pipe.

3.2.1.28 In installations operating with a high degree of superheat, consideration is to be given to the high temperatures which waste steam pipes, silencers and surrounding spaces will attain when the superheater safety valves are blowing during accumulation tests and in service. Adequate protection against heat effects is to be provided to Surveyor's satisfaction.

3.2.1.29 Waste steam pipes are to be led well clear of electric cables and any parts or structures sensitive to heat or likely to distort, the pipes are to be insulated where necessary.

3.2.2 For pressure vessels other than boilers and steam generators

3.2.2.1 Each pressure vessel system or each pressure vessel which can be isolated, is to be provided with arrangements to prevent overpressure.

3.2.2.2 Pressure vessels intended to operate completely filled with liquid are to have a liquid relief valve unless otherwise protected against overpressure.

3.2.2.3 Where a pressure vessel is fitted with heating coils, and fracture in the coils may increase the normal pressure of fluid in the pressure vessel, the relieving capacity of the safety device is to be sufficient to take into account the fracture of one tube.

3.2.2.4 The total capacity of the safety valves, fitted to any pressure vessel or system of pressure vessels, is to be sufficient to discharge the maximum quantity of fluid (liquid or gaseous) that can be generated or supplied without causing a rise in the pressure of more than 10 per cent above the design pressure.

3.2.2.5 The safety valves are to be set to open at a pressure of not more than 3 per cent above the design pressure.

3.2.2.6 The use of bursting discs or a combination of bursting discs and safety valves instead of safety valves is subject to special consideration in each case.

3.2.2.7 The discharge from safety valves is to be led to a place where no hazard will be created by the contents being discharged.

3.2.2.8 Where a gas is used for fire extinguishing in the machinery spaces, the discharge from safety valves or fusion plugs on air receivers is to be led to open deck outside machinery spaces, alternatively, the quantity of gas for fire fighting purposes is to be increased to such an extent that the efficiency of the fire extinguishing installation is not affected.

3.3 Stop valves

3.3.1 Boilers and steam generators

3.3.1.1 One main stop valve is to be fitted to each boiler and located as near the boiler as practicable. There are to be as few auxiliary stop valves as possible so as to avoid piercing the boiler shell than is absolutely necessary.

3.3.1.2 Where two or more boilers are connected together :

a) the steam connections for each boiler are to be provided with two stop valves with a drain connection between them. The valve nearest to the boiler is to be a non-return valve;

b) essential services are to be capable of being supplied from at least two boilers.

3.3.2 Pressure vessels other than boilers and steam generators

3.3.2.1 Each pressure vessel or system is to be fitted with a stop valve situated as close as possible to the shell.

3.4 Water level indicators

3.4.1 Every boiler and steam-heated steam generator is to be fitted with at least two independent means of indicating the water level in it, one of which is to be a gauge glass. The other means is to be either an additional gauge glass or an approved equivalent device.

3.4.2 Where a steam and water drum exceeding 4 [m] in length is fitted athwartships, two gauge glasses are to be fitted in suitable positions, one near each end of the drum.

3.4.3 The water gauges are to be readily accessible and placed so that the water level is clearly visible. The lowest visible part of the glass of the water gauge is to be situated at the lowest safe working water level.

a) In the case of water-tube boilers, the water gauge glasses are to be located so that water is just showing when the water level in the steam drum is just above the top row of tubes when the boiler is cold (generally about 25 [mm] above).

b) In water-tube boilers, the tubes of which are not entirely drowned when cold, the water gauge glasses are to be placed, to the Surveyor's satisfaction, in the positions which have been found by experience to indicate satisfactorily that the water content is sufficient for safety when the boiler is worked under all service conditions.

c) The level of the highest part of the effective heating surfaces, e.g. combustion chamber top of a horizontal boiler and the furnace crown of a vertical boiler, is to be clearly marked in a position adjacent to the water gauge glass.

3.4.4 The length of the water gauge glasses is to be sufficient for verifying the water levels in case of alarm and oil supply cut-off.

3.4.5 The cocks of all water gauges are to be operable from positions free from danger in the event of the glass breaking.

3.4.6 If the water gauges are not fitted directly to the shell of the boiler, but to stand pillars or columns, it is desirable that these pillars or columns should be bolted directly to the shell of the boiler. If they are connected to the boiler by means of pipes, the pipes are to be fitted with terminal cocks, not valves, secured direct to the boiler shell.

a) For boilers exceeding 3 [m] in diameter, the pillars are to be not less than 63 mm, and the connecting pipes not less than 38 [mm] internal diameter. For boilers exceeding 2.3 [m] but not exceeding 3 [m] in diameter, the pillars are to be not less than 50 [mm] and the pipes not less than 32 [mm] internal diameter.

b) The upper ends of the connecting pipes are to be so arranged that there is no pocket or bend where an accumulation of water from the condensation of the steam can lodge. They should not pass through the uptake if they can be otherwise arranged. If, however, this condition cannot be complied with, they may pass through it by means of a passage at least 50 [mm] clear of the pipe all round, open for ventilation.

3.5 Low water level fuel shut-off and alarm

3.5.1 Each fired boiler is to be fitted with a system of water level detection which is to be independent of any other mounting on the boiler and which will operate audible and visible alarms and shut-off automatically the fuel supply to the burners when the water level falls to a predetermined low level.

3.6 Feed check valves

3.6.1 Each main boiler or auxiliary boiler for essential services and each steam-heated steam generator is to have two independent feed pipes; each feed pipe is to be provided with two feed check valves. Boiler heated exclusively by exhaust gases may have only one feed pipe and with one feed check valve.

3.6.2 The feed check valves are to be attached, wherever practicable, direct to the boiler, but where the arrangements necessitate the use of standpipes between the boiler and the check valves, these pipes are to be of steel or other approved material. For boiler feed water systems, See Ch.3, Sec.6.

3.6.3 In boilers, where economizer forms an integral part of the boiler, and where the arrangements necessitate the use of a common inlet pipe on the economizer for both main and auxiliary feed systems, this pipe is to be as short as practicable, and the arrangement of check valves is to be such that either feed line can be effectively isolated without interruption of the feed water supply to the boiler.

3.6.4 The feed check valves are to be fitted with efficient gearing, whereby they can be satisfactorily worked from the stokehold floor, or other convenient position.

3.6.5 Standpipes on boiler, for feed inlet, are to be designed with an internal pipe to prevent direct contact between the feed pipe and the boiler shell or end plates with the object of minimizing thermal stresses in these plates. Similar arrangements are to be provided for desuperheater and other connections, where significant temperature difference occur in service.

3.7 Pressure gauges

3.7.1 Each boiler and superheater is to be provided with a steam-pressure gauge.

3.7.2 The pressure gauges are to be placed where they are easily read. The highest permissible working pressure is to be marked off on pressure gauge in red.

3.8 Blow-down and scum valves

3.8.1 Each boiler is to be fitted with at least one blow-down valve secured to the lower part of the boiler.

3.8.2 Where it is not practicable to attach the blow-down valve direct to water-tube boilers, the valve may be placed immediately outside the boiler casing with a steel pipe of substantial thickness fitted between the boiler and valve. The pipe and valve are to be suitably supported and any pipe which may be exposed to direct heat from the furnace is to be adequately protected.

3.8.3 The blow-down valve and its connections to the sea need not be more than 38 [mm], and is to be not less than 19 [mm] internal diameter. For cylindrical boilers the size of the valve may be generally 0.0085 times the diameter of the boiler.

3.8.4 Blow-down valves and scum valves (where the latter are fitted) of two or more boiler may be connected to one common discharge, but where thus arranged there are to be screw-down non- return valves fitted for each boiler to prevent the possibility of the contents of one boiler passing to another.

3.8.5 The blow-down cock or valve on the ship's side is to be fitted in a readily accessible position, above the level of the floor plates, and is to be arranged such that it can be readily seen whether it is open or shut. The cock handle is not to be removable unless the cock is shut, and if a valve is fitted, the wheel is to be fixed to the spindle.

3.9 Salinometer valve or cock

3.9.1 Each boiler is to be provided with a salinometer valve or cock secured direct to the boiler in a convenient position. The valve or cock is not to be on the water gauge standpipe.

Section 4

Hydraulic Tests

4.1 Boilers (fired and exhaust gas heated), economizers, superheaters, reheaters, steam receivers, steam heated generators and similar vessels

4.1.1 General

4.1.1.1 Boilers and pressure vessels, together with their components are to withstand the following hydraulic tests without any sign of weakness or defect.

4.1.1.2 Having regard to the variation in the types and design of boilers, the hydraulic test may be carried out by either of the methods indicated below:

a) Boilers are to be tested on completion to a pressure 1.5 times the approved design pressure; or

b) Where construction permits, all components of the boiler are to be tested on completion of the work including heat treatment to 1.5 times the design pressure. In the case of components such as drums or headers, which are to be drilled for tube holes, the test may be

made before drilling the tube holes, but is to be after the attachment of standpipes, stubs and similar fittings and also after heat treatment has been carried out. Where all the components have been tested as above, each completed boiler after assembly is to be tested to 1.25 times the design pressure.

4.1.2 Mountings

4.1.2.1 All boiler mountings are to be subjected to a hydraulic test of twice the approved design pressure with the exception of feed check valves and other mountings connected to the main feed system which are to be tested to 2.5 times the approved boiler design pressure, or twice the maximum pressure which can be developed in the feed line in normal service, whichever is greater.

4.2 Other pressure vessels

4.2.1 General

4.2.1.1 Pressure vessels are to be tested on completion to a pressure, p_t, determined by the following formula, without showing signs of weakness or defect :-

$$p_t = 1.3 \frac{\sigma_{50}}{\sigma T} \frac{t}{t - 0.75} p$$

but in no case is to exceed 1.5 $\frac{t}{t - 0.75} p$

where,

p_t = test pressure, in bar

p = design pressure, in bar

t = nominal thickness of shell as indicated on the plan [mm]

σ_{50} = allowable stress at 50°C [N/mm^2]

σT = allowable stress at design temperature [N/mm^2].

4.2.2 Mountings

4.2.2.1 Mountings are to be subjected to a hydraulic test of twice the approved design pressure.

Section 1

General

1.1 Scope

1.1.1 The requirements of this Chapter apply to the design and construction of steering gear.

1.1.2 Whilst the requirements of this Chapter are considered to meet the relevant regulations of the Safety of Life at Sea 1974 and applicable amendments, attention should be given to any relevant statutory requirements of the National Authority of the country in which the ship is to be registered.

1.1.3 Consideration will be given to other cases, or to other arrangements which are equivalent to those required by the Rules.

1.2 Definitions

1.2.1 **Steering System** means ship's directional control system, including main steering gear, auxiliary steering gear, steering gear control system and rudder, if any.

1.2.2 **Steering gear control systems** means the equipment by which orders are transmitted from the navigating bridge to the steering gear power units. Steering gear control systems comprise transmitters, receivers, hydraulic control pumps and their associated motors, motor controllers, piping and cables. Steering gear control system is also understood to cover "the equipment required to control the steering gear power actuating system".

1.2.3 **Main steering gear** means the machinery, rudder actuator(s), the steering gear power units, if any, and ancillary equipment and the means of applying torque to the rudder stock (e.g. tiller or quadrant) necessary for effecting movement of the rudder for the purpose of steering the ship under normal service conditions.

1.2.4 **Steering gear power unit** means :

a) in the case of electric steering gear, an electric motor and its associated electrical equipment;

b) in the case of electrohydraulic steering gear, an electric motor and its associated electrical equipment and connected pump;

c) in the case of other hydraulic steering gear, a driving engine and connected pump.

IR1.2.4 For the purposes of non-traditional steering arrangements such as azimuthing propellers, waterjets, etc, the above definitions may be applied as appropriate. The steering gear power unit relates to the equipment for changing the direction of thrust and does not include those for generating the thrust.

1.2.5 **Auxiliary steering gear** means the equipment other than any part of the main steering gear necessary to steer the ship in the event of failure of the main steering gear but not including the tiller, quadrant or components serving the same purpose.

1.2.6 **Power actuating system** means the hydraulic equipment provided for supplying power to turn the rudder stock, comprising a steering gear power unit or units, together with associated pipes and fittings, and a rudder actuator. The power actuating systems may share common mechanical components, i.e. tiller, quadrant and rudder stock, or components serving the same purpose.

1.2.7 **Maximum ahead service speed** means the greatest speed which the ship is designed to maintain in service at sea at her deepest seagoing draught.

1.2.8 **Rudder actuator** means the compo-nent(s) which converts directly hydraulic pressure into mechanical action to move the rudder.

1.2.9 **Maximum working pressure** means the expected pressure in the system when steering gear is operated to comply with 2.1.2(b).

1.2.10 **Declared steering angle limits** in the case of non-traditional steering arrangements such as azimuthing propellers, waterjets, etc. are the operational limits in terms of maximum steering angle, or equivalent, according to manufacturers guidelines for safe operation, also taking into account the vessel’s speed or propeller torque/speed or other limitation. The "declared steering angle limits" are to be declared by the directional control system manufacturer for each ship specific non-traditional steering mean. Ship's manoeuvrability tests, such as those in the standards for ship maneuverability (Resolution MSC.137(76)) are to be carried out with steering angles not exceeding the declared steering angle limits.

1.2.11 **Hydraulic locking** means all situations where two hydraulic systems (usually identical) oppose each other in such a way that it may lead to loss of steering. It can either be caused by pressure in the two hydraulic systems working against each other or by hydraulic “by-pass” meaning that the systems puncture each other and cause pressure drop on both sides or make it impossible to build up pressure.

1.3 Installation

1.3.1 The steering gear is to be secured to the seating by fitted bolts, and suitable chocking arrangements are to be provided. The seating is to be of substantial construction.

1.4 Steering gear compartment

1.4.1 The steering gear compartment is to be :

a) Readily accessible and, as far as practicable separated from machinery spaces;

b) Provided with suitable arrangements to ensure working access to steering gear machinery and controls. These arrangements are to include handrails and gratings or other non-slip surfaces to ensure suitable working conditions in the event of hydraulic fluid leakage.

1.5 Plans

1.5.1 Before starting construction, all relevant plans and specifications are to be submitted for approval in triplicate.

1.5.2 These plans should give details of scantlings and materials of the steering gear together with proposed rated torque and all relief valve settings.

1.6 Materials

1.6.1 All the steering gear components the rudder stock and/or components of other steering arrangements for directional control are to be of sound and reliable construction to the Surveyor's satisfaction of IRS.

1.6.2 All components transmitting mechanical forces to the rudder stock are to be tested according to the requirements of Pt.2.

1.6.3 Ram; cylinders; pressure housing of rotary vane type actuators; hydraulic power piping; valves; flanges and fittings; and all steering gear components transmitting mechanical forces to the rudder stock (such as tillers, quadrants, or similar components) are to be of steel or other approved ductile material, duly tested in accordance with the requirements of Pt.2. In general, such material is not to have an elongation of less than 12 per cent nor a tensile strength in excess of 650 [N/mm^2]. The use of ductile (nodular) iron castings will be acceptable provided the material has an elongation of not less than 12 per cent.

1.7 Rudder, rudder stock, vanes, tiller and quadrant

1.7.1 For the requirements regarding rudder, rudder stock, See Pt.3, Ch.14.

1.7.2 All components transmitting mechanical forces to the rudder stock are to have a strength of at least equivalent to the rudder stock in way of the tiller. The resultant equivalent stress, σ_e, caused by the transmission of rudder torque, Qr, in tillers, vanes and other power transmitting components is not to exceed 118/k [N/mm^2], i.e.

$$\sigma_e = \sqrt{\sigma^2 + 3\tau^2} \leq 118/k \ \ [\mathrm{N/mm^2}]$$

where,

σ_e = The combined equivalent stress, [N/mm^2]

σ = The bending stress, [N/mm^2]

τ= The torsional shear stress, [N/mm^2]

k = Material factor for the component under consideration as defined in Pt.3, Ch.14, Sec.1;

Q_r = The rudder torque calculated as per Pt.3, Ch.14, Sec.3.2 [N-m].

1.7.3 The section modulus 'Z' [cm^3] and the sectional area 'A' [cm^2] of the tiller arms is not to be less than the following:

$$Z = 0.012\, Q_r \left(1 - \frac{x}{R}\right) k \ [\mathrm{cm^3}]$$

$$A = 2.0 \frac{Q_r}{R} \ k \times 10^{-4} \ [\mathrm{cm^2}]$$

where,

R = The distance [m] from the point of application of the effort on the tiller to the centre of rudder stock; and

x = The distance [m] from the section under consideration to the centre of the rudder stock.

1.7.4 The boss may be fitted on the rudder stock by shrinking with/without key or may be of the split type. The ratio between the mean of outer and inner diameters of the boss is to be not less than 1.75 and the height of the boss is not to be less than the inner diameter of the boss.

1.7.5 Co-efficient of friction for shrink fitting is to be taken as specified in Pt.3, Ch.14, Sec.6.3.

1.7.6 In case of split type boss, the total number of joining bolts is to be at least 4. The distance of the centre of the bolts from the centre of the rudder stock is generally to be 1.15du and the thickness of the coupling flange is to be at least 1.1 times the required bolt diameter. The thickness of shim to be fitted between two halves before machining is to be 0.0015du. The diameter of the coupling bolt, d_b is to be not less than :

$$d_b = 0.60 \frac{du\sqrt{k}}{\sqrt{(nks)}} \ [\mathrm{mm}]$$

where,

du = The rudder stock diameter [mm] in way of the tiller calculated in accordance with Pt.3, Ch.14, Sec.5;

n = Total number of joining bolts.

k = Material factor for the bolts.

ks = Material factor for the rudder stock material.

1.7.7 The dimensions of the key are to comply with the requirements of Pt.3, Ch.14, Sec.6.2.

1.7.8 Where higher tensile bolts are used on bolted tillers and quadrants, the yield and ultimate tensile stresses of the bolt material are to be stated on the plans submitted for approval, together with full details of the methods to be adopted to obtain the required setting-up stress. Where patent nuts or systems are used, the manufacturer's instructions for assembly should be adhered to.

1.7.9 In bow rudders having a vertical locking pin operated from the deck above, positive means are to be provided to ensure that the pin can be lowered only when the rudder is exactly central. In addition, an indicator is to be fitted at the deck to show when the rudder is exactly central.

1.8 Mechanical steering gear

1.8.1 Steel-wire rope, chain and other mechanical systems, when these are used for rudder stock diameters of 120 [mm] and less but excluding allowance for strengthening in ice, will be specially considered. In general, the breaking strength of rods/chains etc. is not to be less than:

$$\text{Breaking strength} = 6\frac{Qr}{R}\ \text{N}$$

Where R is defined in 1.7.3.

Section 2

Performance

2.1 Requirements for traditional type of steering gears

2.1.1 Unless the main steering gear comprises of two or more identical power units, in accordance with 2.1.4 or 8.1.1, every ship is to be provided with a main steering gear and an auxiliary steering gear in accordance with the requirements of the Rules. The main steering gear and the auxiliary steering gear are to be so arranged that the failure of one of them will not render the other one inoperative.

The rudder stock diameters mentioned in 2.1.2c), 2.1.3c) and 6.1.1 are to be taken as having been calculated for mild steel with yield strength of 235 [N/mm^2].

2.1.2 The main steering gear and rudder stock are to be :

a) Of adequate strength and capable of steering the ship at maximum ahead speed which is to be demonstrated in accordance with 7.2;

b) Capable of putting the rudder over from 35° on one side to 35° on the other side with the ship at its deepest seagoing draught and running ahead at maximum ahead service speed and under the same conditions, from 35° on either side to 30° on the other side in not more than 28 seconds;
where it is impractical to demonstrate compliance with this requirement during sea trials with the ship at its deepest seagoing draught and running ahead at the speed corresponding to the number of maximum continuous revolutions of the main engine and maximum design pitch, ships regardless of date of construction may demonstrate compliance with this requirement by one of the following methods:

1 during sea trials the ship is at even keel and the rudder fully submerged whilst running ahead at the speed corresponding to the number of maximum continuous revolutions of the main engine and maximum design pitch or

2 where full rudder immersion during sea trials cannot be achieved, an appropriate ahead speed to be calculated using the submerged rudder blade area in the proposed sea trial loading condition. The calculated ahead speed is to result in a force and torque applied to the main steering gear which is at least as great as if it was being tested with the ship at its deepest seagoing draught and running ahead at the speed corresponding to the number of maximum continuous revolutions of the main engine and maximum design pitch or

3 the rudder force and torque at the sea trial loading condition have been reliably predicted and extrapolated to the full load condition. The speed of the ship is to correspond to the number of maximum continuous revolutions of the main engine and maximum design pitch of the propeller.

c) Operated by power where necessary to meet the requirements of (b) and in any case when the Rules, excluding strengthening for navigation in ice, require a rudder stock over 120 [mm] diameter in way of the tiller (See 2.1.1); and

d) So designed that they will not be damaged at maximum astern speed; however, this design requirement need not be proved by trials at maximum astern speed and maximum rudder angle.

IR 2.1.2.1 In case of 2.1.2 b).2, it is to be ensured that the equivalent stress in the rudder stock due to bending and torque is not to exceed the acceptance limits given in Pt 3, Ch 14, Sec 5.

2.1.3 The auxiliary steering gear is to be :

a) Of adequate strength and capable of steering the ship at navigable speed and of being brought as fast as possible into action in an emergency:

b) Capable of putting the rudder over from 15 on one side to 15 on the other side in not more than 60 seconds with the ship at its deepest seagoing draught and running ahead at one half of the maximum ahead service speed or 7 knots, whichever is the greater;
Where it is impractical to demonstrate compliance with this requirement during sea trials with the ship at its deepest seagoing draught and running ahead at one half of the speed corresponding to the number of maximum continuous revolutions of the main engine and maximum design pitch or 7 [knots], whichever is greater, ships regardless of date of construction, including those constructed before 1 January 2009, may demonstrate compliance with this requirement by one of the following methods:

1 during sea trials the ship is at even keel and the rudder fully submerged whilst running ahead at one half of the speed corresponding to the number of maximum continuous revolutions of the main engine and maximum design pitch or 7 [knots], whichever is greater; or

2 where full rudder immersion during sea trials cannot be achieved, an appropriate ahead speed is to be calculated using the submerged rudder blade area in the proposed sea trial loading condition. The calculated ahead speed is to result in a force and torque applied to the auxiliary steering gear which is at least as great as if it was being tested with the ship at its deepest seagoing draught and running ahead at one half of the speed corresponding to the number of maximum continuous revolutions of the main engine and maximum design pitch or 7 [knots], whichever is greater; or

3 the rudder force and torque at the sea trial loading condition have been reliably predicted and extrapolated to the full load condition; and

c) Operated by power where necessary to meet the requirements of (b) and in any case when the Rules, excluding strengthening for navigation in ice, require a rudder stock over 230 [mm] diameter in way of the tiller. (See 2.1.1).

IR 2.1.3.1 In case of 2.1.3 b).2, it is to be ensured that the equivalent stress in the rudder stock due to bending and torque is not to exceed the acceptance limits given in Pt 3, Ch 14, Sec 5.

2.1.4 Where the main steering gear comprises two or more identical power units, an auxiliary steering gear need not be fitted, provided that :

a) In a passenger ship, the main steering gear is capable of operating the rudder as required by 2.1.2 (b) while any one of the power units is out of operation;

b) In a cargo ship, the main steering gear is capable of operating the rudder as required by 2.1.2 (b) while operating with all power units;

c) The main steering gear is arranged so that after a single failure in its piping system or in one of the power units the defect can be isolated so that steering capability is regained.

2.1.5 Main and auxiliary steering gear power units are to be:

a) Arranged to re-start automatically when power is restored after a power failure;

b) Capable of being brought into operation from a position on the navigating bridge. In the event of a power failure to any one of the steering gear power units, an audible and visual alarm is to be given on the navigating bridge;

c) Arranged so that transfer between units can be readily effected.

2.1.6 Steering gear, other than of the hydraulic type, will be accepted provided the standards are considered equivalent to the requirements of this Section.

2.1.7 Manually operated gears are only acceptable when the operation does not require an effort exceeding 16 [kgf] under normal conditions.

2.2 Requirements for non-traditional (azimuthing propellers, waterjets, etc.) type of steering gears:

2.2.1 For a ship fitted with a single steering-propulsion unit, the requirement in 2.1.1 is considered satisfied if the steering gear is provided with two or more identical power actuating systems and is in compliance with 2.2.4. A detailed risk assessment is to be submitted in order to demonstrate that in the case of any single failure in the steering gear, control system and power supply is maintained.

For a ship fitted with multiple steering - propulsion units , such as but not limited to azimuthing propulsors or water jet propulsion systems each of the steering-propulsion units is to be provided with a main steering gear and an auxiliary steering gear or with two or more identical power actuating systems in compliance with 2.2.5. The main steering gear and the auxiliary steering gear are to be so arranged that the failure of one of them will not render the other one inoperative.

2.2.2 The main steering arrangements for ship directional control are to be:

a) of adequate strength and capable of steering the ship at maximum ahead speed which is to be demonstrated in accordance with 7.2 (Also refer Ch.4, Sec.9);

b) capable of changing direction of the steering- propulsion unit from one side to the other at declared steering angle limits at an average turning speed of not less than 2.3°/s with the ship running ahead at maximum ahead service speed;

c) for all ships, operated by power; and

d) so designed that they will not be damaged at maximum astern speed (Also refer Ch.4, Sec.9), this design requirement need not be proved by trials at maximum astern speed and declared steering angle limits.

Ship maneuverability tests, such as according to Resolution MSC.137(76) on Standards for ship maneuverability, are to be carried out with steering angles not exceeding the declared steering angle limits.

2.2.3 The auxiliary steering arrangements for ship directional control are to be:

a) of adequate strength and capable of steering the ship at navigable speed and of being brought speedily into action in an emergency:

b) capable of changing direction of the ship's directional control system from one side to the other at declared steering angle limits at an average turning speed, of not less than 0.5°/s; with the ship running ahead at one half of the maximum ahead service speed or 7 knots, whichever is the greater; and

c) for all ships, operated by power where necessary to meet the requirements of 2.2.3.b and in any ship having propulsive power of more than 2,500 kW per thruster unit.

Ship maneuverability tests, such as according to Resolution MSC.137(76) on Standards for ship maneuverability, are to be carried out with steering angles not exceeding the declared steering angle limits.

2.2.4 For a ship fitted with a single steering-propulsion unit where the main steering gear comprises two or more identical power units and two or more identical steering actuators, an auxiliary steering gear need not be fitted, provided that the steering gear:

a) in a passenger ship, is capable of satisfying the requirements in 2.2.2 while any one of the power units is out of operation;

b) in a cargo ship, is capable of satisfying the requirements in 2.2.2 while operating with all power units; and

c) is arranged so that after a single failure in its piping system or in one of the power units, steering capability can be maintained or speedily regained.

2.2.5 For a ship fitted with multiple steering-propulsion units, where each main steering system comprises two or more identical power actuating systems, an auxiliary steering gear need not be fitted, provided that each steering gear :

a) in a passenger ship, is capable of satisfying the requirements in 2.2.2 while any one of the steering gear power actuating systems is out of operation;

b) in a cargo ship, is capable of satisfying the requirements in 2.2.2 while operating with all steering gear power actuating systems;

c) is arranged so that after a single failure in its piping or in one of the power actuating systems, steering capability can be maintained or speedily regained

The above capacity requirements apply regardless whether the steering systems are arranged with dedicated power units.

2.2.6 Main and auxiliary steering gear power units are to be:

a) Arranged to re-start automatically when power is restored after a power failure;

b) Capable of being brought into operation from a position on the navigating bridge. In the event of a power failure to any one of the steering gear power units, an audible and visual alarm is to be given on the navigating bridge;

c) Arranged so that transfer between units can be readily effected.

2.3 Other requirements

2.3.1 Where the steering gear is so arranged that more than one power system can be simultaneously operated, the risk of hydraulic locking caused by a single failure is to be considered.

2.3.2 A means of communication is to be provided between the navigating bridge and the steering gear compartment.

2.3.3 Power-operated steering gears are to be provided with positive arrangements, such as limit switches, for stopping the gear before the rudder stops are reached. These arrangements are to be synchronized with the gear itself and not with the steering gear control.

Section 3

Construction and Design

3.1 General

3.1.1 Rudder actuators other than those covered by 8.3 and Sec.9 are to be designed in accordance with the relevant requirement of Ch.5 for Class 1 pressure vessels (notwithstanding any exemptions for hydraulic cylinders).

3.1.2 Accumulators, if fitted, are to comply with the requirements of Ch.5.

3.1.3 The welding details and welding procedures are to be approved. All welded joints within the pressure boundary of a rudder actuator or connecting parts transmitting mechanical loads are to be full penetration type or of equivalent strength.

3.1.4 The construction is to be such as to minimize local concentration of stress.

3.1.5 The design pressure for calculations to determine the scantlings of piping and other steering gear components subjected to internal hydraulic pressure is to be at least 1.25 times the maximum working pressure to be expected under the operational conditions specified in 2.1.2 (b) taking into account any pressure which may exist in the lower pressure side of the system. Fatigue criteria may be applied for the design of piping and components, taking into account pulsating pressures due to dynamic loads (See Sec.9).

3.1.6 The permissible primary general membrane stress is not to exceed the lower of the following values

$$\frac{\sigma B}{A} \text{ or } \frac{\sigma y}{B}$$

where,

σB = specified minimum tensile strength of material at ambient temperature

σY = specified minimum yield stress or 0.2 per cent proof stress of the material, at ambient temperature

A and B are given by the following table :

	Wrought Steel	**Cast Steel**	**Nodular Cast Iron**
A	3.5	4	5
B	1.7	2	3

3.2 Components

3.2.1 Special consideration is to be given to the suitability of any essential component which is not duplicated. Any such essential component is to, where appropriate, utilize anti-friction bearings such as ball bearings, roller bearings or sleeve bearings which are to be permanently lubricated or provided with lubrication fittings.

3.2.2 All steering gear components transmitting mechanical forces to the rudder stock, which are not protected against overload by structural rudder stops or mechanical buffers, are to have a strength at least equivalent to that of the rudder stock in way of the tiller.

3.2.3 Oil seals between non-moving parts, forming part of the external pressure boundary, should be of the metal type or of an equivalent type.

3.2.4 Oil seals between moving parts, forming part of the external pressure boundary, are to be duplicated, so that the failure of one seal does not render the actuator inoperative. Alternative arrangements providing equivalent protection against leakage may be accepted.

3.2.5 Piping, joints, valves, flanges and other fittings are to comply with the requirements of Ch.2 for Class I piping systems components. The design pressure is to be in accordance with 3.1.5.

3.2.6 Hydraulic power operated steering gears are to be provided with the following :-

a) Arrangements to maintain the cleanliness of the hydraulic fluid taking into consideration the type and design of the hydraulic system;

b) A fixed storage tank having sufficient capacity to recharge at least one power actuating system including the reservoir, where the main steering gear is required to be power operated. The storage tank is to be permanently connected by piping in such a manner that the hydraulic systems can be readily recharged from a position within the steering gear compartment and provided with a contents gauge.

3.3 Valve and relief valve arrangement

3.3.1 For all vessels with non-duplicated actuators, isolating valves are to be fitted at the connection of pipes to the actuators, and are to be directly fitted to the actuator. Arrangements for bleeding air from the hydraulic system are to be provided, where necessary.

3.3.2 Relief valves are to be fitted to any part of the hydraulic system which can be isolated and in which pressure can be generated from the power source or from external forces. The setting of the relief valves is not to exceed the design pressure. The valves are to be of adequate size and so arranged as to avoid an undue rise in pressure above the design pressure.

3.3.3 Relief valves, for protecting any part of the hydraulic system which can be isolated, required by 3.3.2 are to comply with the following:

a) The setting pressure is not to be less than 1.25 times the maximum working pressure.

b) The minimum discharge capacity of the relief valve(s) is not to be less than 110 per cent of the total capacity of the pumps which can deliver through it (them). Under such conditions the rise in pressure is not to exceed 10 per cent of the setting pressure. In this regard, due consideration is to be given to extreme foreseen ambient conditions in respect of oil viscosity.

3.4 Flexible hoses

3.4.1 Hose assemblies approved by IRS may be installed between two points where flexibility is required but are not subjected to torsional deflection (twisting) under normal operating conditions. In general, the hose should be limited to the length necessary to provide for flexibility and for proper operation of machinery. (See also Ch.2).

3.4.2 Hoses should be high pressure hydraulic hoses according to recognized standards and suitable for the fluids, pressures, temperatures and ambient conditions in question.

3.4.3 Burst pressure of hoses is not to be less than four times the design pressure.

Section 4

Steering Control Systems

4.1 General

4.1.1 Steering gear control is to be provided:

a) For the main steering gear, both on the navigating bridge and in the steering gear compartment;

b) Where the main steering gear is arranged according to 2.1.4, by two independent control systems, both operable from the navigating bridge. This does not require duplication of the steering wheel or steering lever. Where the control system consists of a hydraulic telemotor, a second independent system need not be fitted, except in a tanker, chemical tanker or gas carrier of 10,000 tons gross and upwards;

c) For the auxiliary steering gear, in the steering gear compartment and, if power operated, it is to be also operable from the navigating bridge and is to be independent of the control system for the main steering gear;

d) Where the steering gear is so arranged that more than one control system can be simultaneously operated, the risk of hydraulic locking caused by a single failure is to be considered.

4.1.2 Any main and auxiliary steering gear control system operable from the navigating bridge is to comply with the following:

a) Means are to be provided in the steering gear compartment for disconnecting any

control system operable from the navigating bridge from the steering gear it serves;

b) The system is to be capable of being brought into operation from a position on the navigating bridge.

4.1.3 The angular position of the rudder is to :

a) If the main steering gear is power operated, be indicated on the navigating bridge. The rudder angle indication is to be independent of the steering gear control system.

b) Be recognizable in the steering gear compartment.

4.1.4 Appropriate operating instructions with a block diagram showing the change-over procedures for steering gear control systems and steering gear actuating systems are to be permanently displayed in the wheelhouse and in the steering gear compartment.

4.1.5 Where the system failure alarms for hydraulic lock (See Ch.7) are provided, appropriate instructions are to be placed on the navigating bridge to shut down the system at fault.

IR4.2 Mechanical, hydraulic and electrical independency and failure detection and response of steering control systems

IR4.2.1 Two independent steering gear control systems are to be provided and so arranged that a mechanical, hydraulic or electrical failure in one of them will not render the other one inoperative.

IR4.2.2 The term “steering gear control system” as defined in 1.2.2 is to be understood as to cover “the equipment required to control the steering gear power actuating system”.

IR4.2.3 Separation of control systems and components

IR4.2.3.1 General

Wires, terminals and the components for duplicated steering gear control systems installed in units, control boxes, switchboards or bridge consoles are to be separated as far as practicable. Where physical separation is not practicable, separation may be achieved by means of a fire retardant plate.

IR4.2.3.2 Steering wheel or steering lever

All electric components of the steering gear control systems are to be duplicated. This does not require duplication of the steering wheel or steering lever.

IR4.2.3.3 Steering mode selector switch

If a joint steering mode selector switch (uniaxial switch) is employed for both steering gear control systems, the connections for the circuits of the control systems are to be divided accordingly and separated from each other by an isolating plate or by air gap.

IR4.2.3.4 Follow-up amplifier

In the case of double follow-up control, the amplifiers are to be designed and fed so as to be electrically and mechanically separated. In the case of non follow-up control and follow-up control, it is to be ensured that the follow-up amplifiers are protected selectively

IR4.2.3.5 Additional control systems

Control circuits for additional control systems, e.g. steering lever or autopilot are to be designed for all pole disconnection.

IR4.2.3.6 Feed-back units and limit switches

The feed-back units and limit switches, if any, for the steering gear control systems are to be separated electrically and mechanically connected to the rudder stock or actuator separately.

IR4.2.3.7 Hydraulic control components

Hydraulic system components in the power actuating or hydraulic servo systems controlling the power systems of the steering gear (e.g. solenoid valves, magnetic valves) are to be considered as part of the steering gear control system and are to be duplicated and separated.

Hydraulic system components in the steering gear control system that are part of a power unit may be regarded as being duplicated and separated when there are two or more separate power units provided and the piping to each power unit can be isolated.

4.2.4 Failure detection and response of all types of steering gear control systems

4.2.4.1 Failure detection

4.2.4.1.1 The most probable failures that may cause reduced or erroneous system performance are to be automatically detected and at least the following failure scenarios are to be considered:

i) Power supply failure

ii) Loop failures in closed loop systems, both command and feedback loops (normally short circuit, broken connections and earth faults)

iii) Earth fault on AC and DC circuits

iv) Data Communication Errors

v) Programmable system failures (hardware and software failures)

vi) Deviation between rudder order and feedback*****.

Note ***** - Deviation alarm is to be initiated if the rudder's actual position does not reach the set point within acceptable time limits for the closed loop control systems (e.g. follow up control and autopilot). Deviation alarm may be caused by mechanical, hydraulic or electrical failures.

All failures detected are to initiate an audible and visual alarm on the navigation bridge.

4.2.4.1.2 System response upon failure

.1 The failures (as defined but not limited to those in 4.2.4.1.1) likely to cause uncontrolled movements of rudder are to be clearly identified. In the event of detection of such failure, the rudder is to stop in the current position without manual intervention or, is to return to the mid ship/ neutral position. For mechanical failures such as sticking valves and failure of static components (pipes, cylinders), the system response without manual intervention is not mandatory, and the operator can follow instructions on the signboard in case of such failures, in accordance with 4.2.4.1.2.2.

Note: For hydraulic locking failure the following are also to be complied with:

(i) Where hydraulic locking, caused by a single failure, may lead to loss of steering, an audible and visual alarm, which identifies the failed system, is to be provided on the navigating bridge.

(ii) This alarm is to be activated whenever:

- position of the variable displacement pump control system does not correspond with the given order; or

- incorrect position of 3-way full flow valve or similar in constant delivery pump system is detected.

.2 Where applicable, following standard signboard is to be fitted at a suitable place on steering control post on the bridge or incorporated into operating instruction on board:

CAUTION

IN SOME CIRCUMSTANCES WHEN 2 POWER UNITS ARE RUNNING SIMULTANEOUSLY THE RUDDER MAY NOT RESPOND TO HELM. IF THIS HAPPENS STOP EACH PUMP IN TURN UNTIL CONTROL IS REGAINED.

The above signboard is related to steering gears provided with two identical power units intended for simultaneous operation, and normally provided with either their own control systems or two separate (partly or mutually) control systems which are/ may be operated simultaneously.

Section 5

Electric Power Circuits, Electric Control Circuits, Monitoring and Alarms

5.1 Electric power circuits

5.1.1 Short circuit protection, an overload alarm and in the case of polyphase circuits, an alarm to indicate single phasing is to be provided for each main and auxiliary motor circuit. Protective devices are to operate at not less than twice the full load current of the motor or circuit protected and are to allow excess current to pass during the normal accelerating period of the motors.

5.1.2 Circuits obtaining their power supply via an electronic converter, e.g. for speed control and which are limited to full load current for continuous rating are exempt from the requirement to provide protection against excess current of magnitude as given in 5.1.1. The overload alarm is to be set to a value for which the electronic converter is designed considering the most severe condition of operation.

5.1.3 Indicators for running indication of each main and auxiliary motor are to be installed on the navigating bridge and at a suitable main machinery control position.

5.1.4 Each electric or electrohydraulic steering gear comprising one or more power units is to be served by at least two exclusive circuits fed directly from the main switchboard; however, one of the circuits may be supplied through the emergency switchboard. An auxiliary electric or electrohydraulic steering gear may be connected to one of the circuits supplying the main steering gear. The circuits supplying an electric or electrohydraulic steering gear are to have adequate rating for supplying all motors which can be simultaneously connected to them and may be required to operate simultaneously.

IR5.1.4 For a ship fitted with multiple steering systems, the above requirements are to be applied to each of the steering systems.

5.1.5 The circuits, required by 5.1.4, are to be separated throughout their length as widely as is practicable.

5.1.6 In ships of less than 1600 tons gross, if an auxiliary steering gear is not electrically powered or is powered by an electric motor primarily intended for other services, the main steering gear may be fed by one circuit from the main switchboard. Consideration would be given to other protective arrangements than described in 5.1.1, for such a motor primarily intended for other services.

5.2 Electric control circuits

5.2.1 Electric control systems are to be independent and separated as far as is practicable throughout their length.

5.2.2 Each main and auxiliary electric control system which is operable from the navigating bridge is to comply with the following:-

a) It is to be served with electric power by a separate circuit supplied from the associated steering gear power circuit, from a point within the steering gear compartment, or directly from the same section of the switchboard busbars, main or emergency, to which the associated steering gear power circuit is connected.

b) Each separate circuit is to be provided with short circuit protection only.

5.3 Monitoring and alarms

5.3.1 All alarms associated with steering gear faults are to be indicated on the navigating bridge and in accordance with the alarm system specified in Ch.7, Table 1.9.1. The alarms are to be both audible and visual.

Section 6

Emergency Power

6.1 General

6.1.1 Where the rudder stock is required to be over 230 [mm] diameter in way of the tiller (See 2.1.1), excluding strengthening for navigation in ice, an alternative power supply, sufficient at least to supply the steering gear power unit which complies with the requirements of 2.1.3 and also its associated control system and the rudder angle indicator, is to be provided automatically, within 45 seconds, either from the emergency source of electrical power or from an independent source of power located in the steering gear compartment. This independent source of power is to be used only for this purpose.

IR 6.1.1 In the case of non-traditional steering arrangements such as azimuthing propellers, waterjets, etc where the propulsion power exceeds 2,500kW per thruster unit, an alternative power supply, sufficient at least to supply the steering arrangements which complies with the requirements of clause 2.1.3.b and also its associated control system and the steering gear response indicator, are to be provided automatically, within 45s, either from the emergency source of electrical power or from an independent source of power located in the steering gear compartment. This independent source of power is to be used only for this purpose.
The above requirement is relevant for the steering-propulsion units having a certain proven steering capability attained due to vessel speed regardless of availability of propulsion power.

6.1.2 In every ship of 10,000 tons gross and upwards, the alternative power supply is to have a capacity for at least 30 minutes of continuous operation and in any other ship for at least 10 minutes.

6.1.3 Where the alternative power source is a generator, or an engine driven pump, starting arrangements are to comply with the requirements relating to the starting arrangements of the emergency generators.

Section 7

Testing and Trials

7.1 Testing

7.1.1 The requirements of the Rules relating to the testing of Class 1 pressure vessels, piping, and related fittings including hydraulic testing apply.

7.1.2 After installation on board the vessel the steering gear is to be subjected to the required hydrostatic and running tests.

7.1.3 Each type of power unit pump is to be subjected to a type test. The type test is to be for a duration of not less than 100 hours, the test arrangements are to be such that the pump may run in idling conditions, and at maximum delivery capacity at maximum working pressure. During the test, idling periods are to be alternated with periods at maximum delivery capacity at maximum working pressure. The passage from one condition to another should occur at least as quickly as on board. During the whole test no abnormal heating, excessive vibration or other irregularities are permitted. After the test, the pump is to be opened out and inspected. Type tests may be waived for a power unit which has been proven to be reliable in marine service.

7.2 Trials

7.2.1 The steering gear is to be tried out on the trial trip in order to demonstrate to the Surveyor's satisfaction that the requirements of the Rules have been met. The trial is to include the operation of the following :-

i) The steering gear; including demonstration of the performances required by 2.1.2 (b) and 2.1.3 (b). In order to demonstrate this ability, the trials may be conducted in accordance with Section 6.1.5.1 of ISO 19019:2005 “Sea-going

vessels and marine technology – Instructions for planning, carrying out and reporting sea trials".

The above is to be to the satisfaction of IRS.

ii) The steering gear power units, including transfer between steering gear power units;

iii) The isolation of one power actuating system, checking the time for regaining steering capability;

iv) The hydraulic fluid recharging system;

v) The emergency power supply required by 6.1.1;

vi) The steering gear controls, including transfer of control and local control;

vii) The means of communication between the steering gear compartment and wheelhouse, also the engine room, if applicable;

viii) The alarm and indicators;

ix) Where the steering gear is designed to avoid hydraulic locking, this feature is to be demonstrated.

Test of items (iv), (vii), (viii) and (ix) may be effected at the dockside.

7.2.2 On all occasions when steering gear trials are conducted with the vessel not at the summer load waterline the loading condition can be accepted on the conditions that either:

i) the rudder is fully submerged (at zero speed waterline) and the vessel is in an acceptable trim condition.

or

ii) the rudder torque at the trial loading condition have been reliably predicted (based on the system pressure measurement) and extrapolated to the summer load waterline condition using the following method to predict the equivalent torque and actuator pressure at the summer load waterline:

$$Q_F = Q_T\ \alpha$$

$$\alpha = 1.25\ \left(\frac{A_F}{A_T}\right)\left(\frac{V_F}{V_T}\right)^2$$

Where:

α = extrapolation factor

Q_F = rudder stock moment for the deepest service draught and design speed condition

Q_T = rudder stock moment for the trial condition

A_F = total immersed projected area of the moveable part of the rudder at summer load waterline

A_T = total immersed projected area of the moveable part of the rudder in the trail condition

V_F = contractual design speed of the vessel corresponding to the maximum continuous revolutions of the [main engine] at the. summer load waterline (also see 7.2.3)

V_T = measured speed of the vessel (considering current) in the trial condition.

Where the rudder actuator system pressure is shown to have a linear relationship to the rudder stock torque the above equation can be taken as:

$$P_F = P_T\ \alpha$$

Where:

P_F = estimated steering actuator hydraulic pressure at summer load waterline.

P_T = maximum measured actuator hydraulic pressure in the trial condition.

Where constant volume fixed displacement pumps are utilized then the regulations can be deemed satisfied if the estimated steering actuator hydraulic pressure at the deepest draught is less than the specified maximum working pressure of the rudder actuator. Where a variable delivery pump is utilized, pump data should be supplied and interpreted to estimate the delivered flow rate corresponding to the summer load waterline in order to calculate the

steering time and allow it to be compared to the required time.

Where A_T is greater than $0.95A_F$ there is no need for extrapolation methods to be applied.

iii) Alternatively the designer or builder may use computational fluid dynamic (CFD) studies or experimental investigations to predict the rudder stock moment at the summer load waterline condition and design speed. These calculations or experimental investigations are to be to the satisfaction of IRS.

7.2.3 In any case for the main steering gear trial, the speed of the ship corresponding to the number of maximum continuous revolution of main engine and maximum design pitch applies.

Section 8

Additional Requirements

8.1 For tankers, chemical tankers or gas carriers of 10,000 tons gross and upwards and every ship of 70,000 tons gross and upwards

8.1.1 The main steering gear is to comprise two or more identical power units complying with the provisions of 2.1.4.

8.2 For tankers, chemical tankers or gas carriers of 10,000 tons gross and upwards

8.2.1 Subject to 8.3, the following are to be complied with :

a) The main steering gear is to be so arranged that in the event of loss of steering capability due to a single failure in any part of one of the power actuating systems of the main steering gear, excluding the tiller, quadrant or components serving the same purpose, or seizure of rudder actuators, steering capability is to be regained in not more than 45 seconds after the loss of one power actuating system.

b) The main steering gear is to comprise either;

   i) two independent and separate power actuating systems, each capable of meeting the requirements of 2.1.2 (b); or

   ii) at least two identical power actuating systems which, acting simultaneously in normal operation are capable of meeting the requirements of 2.1.2(b). Where necessary to comply with these requirements, inter- connection of hydraulic power actuating systems is to be provided. Loss of hydraulic fluid from one system is to be capable of being detected and the defective system automatically isolated so that the other actuating system or systems remain fully operational.

c) Steering gears other than of the hydraulic type are to achieve equivalent standards.

8.3 For tankers, chemical tankers or gas carriers of 10,000 tons gross and upwards but of less than 100,000 tonnes deadweight

8.3.1 Solutions other than those set out in 8.2.1 which need not apply the single failure criterion to the rudder actuator or actuators, may be permitted provided that an equivalent safety standard is achieved and that:

a) Following loss of steering capability due to a single failure of any part of the piping system or in one of the power units, steering capability is regained within 45 seconds; and

b) Where the steering gear includes only a single rudder actuator special consideration is given to stress analysis for the design including fatigue analysis and fracture mechanics analysis, as appropriate, the material used, the installation of sealing arrangements and the testing and inspection and provision of effective maintenance. In consideration of the foregoing, regard will be given to the "GUIDELINES" in Sec.9.

8.3.2 Manufacturers of steering gear who intend their product to, comply with the requirements of the Sec.9 are to submit full details when plans are forwarded for approval.

Section 9

Guidelines for the Acceptance of Non-duplicated Rudder Actuators for Tanker, Chemical Tankers or Gas Carriers of 10,000 tons gross and upwards but of less than 100,000 tonnes Deadweight

9.1 Materials

9.1.1 Parts subject to internal hydraulic pressure or transmitting mechanical forces to the rudder-stock are to be made of duly tested ductile materials complying with recognized standards. Materials for pressure retaining components are to be in accordance with recognized pressure vessel standards. These materials are not to have an elongation less than 12 per cent nor a tensile strength in excess of 650 [N/mm^2].

9.2 Design

9.2.1 **Design pressure** The design pressure should be assumed to be at least equal to the greater of the following :-

a) 1.25 times the maximum working pressure to be expected under the operating conditions required in 2.1.2(b).

b) The relief valves(s) setting.

9.2.2 **Analysis** In order to analyse the design the following are required :

a) The manufacturers of rudder actuators should submit detailed calculations showing the suitability of the design for the intended service.

b) A detailed stress analysis of the pressure retaining parts of the actuator should be carried out to determine the stresses at the design pressure.

c) Where considered necessary because of the design complexity or manufacturing procedures, a fatigue analysis and fracture mechanics analysis may be required. In connection with these analyses, all foreseen dynamic loads should be taken into account. Experimental stress analysis may be required in addition to, or in lieu of, theoretical calculations depending upon the complexity of the design.

9.2.3 **Dynamic loads for fatigue and fracture mechanics analysis** The assumptions for dynamic loading for fatigue and fracture mechanics analysis where required by 3.1.5, 8.3 and 9.2.2 are to be submitted for appraisal. Both the cases of high cycle and cumulative fatigue are to be considered.

9.2.4 **Allowable stresses** For the purpose of determining the general scantlings of parts of rudder actuators subject to internal hydraulic pressure the allowable stresses should not exceed:

$$\sigma_m \leq f$$

$$\sigma_p \leq 1.5\, f$$

$$\sigma_b \leq 1.5\, f$$

$$\sigma_p + \sigma_b \leq 1.5\, f$$

$$\sigma_m + \sigma_b \leq 1.5\, f$$

where,

σ_m = equivalent primary general membrane stress

σ_p = equivalent primary local membrane stress

σ_b = equivalent primary bending stress

f = the lesser of $\frac{\sigma B}{A}$ or $\frac{\sigma Y}{B}$

σB = specified minimum tensile strength of material at ambient temperature

σY = specified minimum yield stress or 0.2 percent proof stress of material at ambient temperature

A and B are as follows :

	Wrought Steel	**Cast Steel**	**Nodular Cast Iron**
A	4	4.6	5.8
B	2	2.3	3.5

9.2.5 **Burst test** Pressure retaining parts not requiring fatigue analysis and fracture mechanics analysis may be accepted on the basis of a certified burst test and the detailed stress analysis required by 9.2.2 need not be provided. The minimum bursting pressure should be calculated as follows :-

$$P_b = P\,A\,\frac{\sigma B_a}{\sigma B}$$

where,

P_b = minimum bursting pressure

P = design pressure as defined in 9.2.1

A = as defined in 9.2.4

σB_a = actual tensile strength

σB = tensile strength as defined in 9.2.4.

9.3 Construction details

9.3.1 General The construction should be such as to minimize local concentration of stress.

9.3.2 Welds

a) The welding details and welding procedures should be approved.

b) All welded joints within the pressure boundary of a rudder actuator or connection parts transmitting mechanical loads should be full penetration type or of equivalent strength.

9.3.3 Oil seals Oil seals forming part of the external boundary are to comply with 3.2.3 and 3.2.4.

9.3.4 Isolating valves Isolating valves are to be fitted at the connection of the pipes to the actuator, and should be directly mounted on the actuator.

9.3.5 Relief valves Relief valves for protecting the rudder actuator against over-pressure as required in 3.3.2 are to comply with the following:

a) The setting pressure is not to be less than 1.25 times the maximum working pressure expected under operating conditions required by 2.1.2(b).

b) The minimum discharge capacity of the relief valve(s) is to be not less than 110 per cent of the total capacity of all pumps which provide power for the actuator. Under such conditions the rise in pressure should not exceed 10 per cent of the setting pressure. In this regard due consideration should be given to extreme foreseen ambient conditions in respect of oil viscosity.

9.4 Non-destructive testing

9.4.1 The rudder actuator should be subjected to suitable and complete non-destructive testing to detect both surface flaws and volumetric flaws. The procedure and acceptance criteria for non-destructive testing should be in accordance with requirements of recognized standards. If found necessary, fracture mechanics analysis may be used for determining maximum allowable flaw size.

9.5 Testing

9.5.1 Tests, including hydrostatic test, of all pressure parts at 1.5 times the design pressure should be carried out.

9.5.2 When installed on board the ship, the rudder actuator should be subjected to a hydrostatic test and a running test.

Section 1

General

1.1 Scope

1.1.1 The requirements of this Chapter are in general to be complied with for all machinery plants where instrumentation is required according to other Chapters of the Rules. In addition, the requirements apply to the following, when installed :-

a) remote control systems for propulsion machinery, controllable pitch propeller, and steering gear;

b) safety systems for propulsion plants and electric power generating plants;

c) instrumentation equipment of boiler plants.

d) Safety systems for emergency diesel engines.

1.1.2 For vessels intended to operate with unattended machinery spaces, refer to Pt.5.

1.1.3 Alarm systems are to satisfy the environmental requirements of IRS Classification Notes "Type Approval of Electrical Equipment used for Control, Protection, Safety and Internal Communication in Marine Environment".

1.2 Remote control systems capability

1.2.1 When it is desired to fit a centralized control system having one or more control locations and embodying various degrees of automatic and remote control of the propulsion plant or associated ship's service systems, the control and monitoring systems are to be designed, assembled and installed in accordance with the requirements given in Section 5, to assure operation as effective as could be obtained with the same systems arranged for manual control and monitoring by watchkeeping personnel.

1.3 Plans and particulars

1.3.1 Plans and specifications for the control systems, are to be submitted, for approval and are to at least include the following information:

a) machinery arrangement plans showing locations control in relation to controlled units;

b) arrangements and details of control consoles including front views, installation arrangements together with schematic diagrams for all power, control and

monitoring systems including their functions;

c) kind and size of all electrical cables and wiring associated with the control systems including voltage rating, service voltage and currents together with overload and short circuit protection;

d) functional block diagrams of all control and monitoring systems;

e) schematic plans of hydraulic and pneumatic control systems together with all inter-connections, piping sizes and materials including working pressures, relief valve settings, reducing valves, filters, compressors and their type and manufacturers;

f) description of all alarm and emergency tripping arrangements, functional sketches or description of all special valves, actuators, sensors and relays;

g) schematic plans and supporting data of fire-protection and extinguishing systems, including fire-detection and alarm systems, bilge high level alarms;

h) control system fault analysis, test program for testing controls, monitoring and alarm systems;

i) Where computer based systems are used for essential services and are integrated with other computer based systems, the failure analysis is to be carried out and should include networks and associated network components (routers, switches etc.)

j) A network plan clearly identifying all the network components for each on board operational technology (OT) network, including location of each network device, details of IT network where the IT and OT Networks are interconnected;

k) documents/plans indicated at Section 7.2 for integrated systems.

1.4 Operational guidance manual

1.4.1 An operational guidance manual is to be provided on board the vessel for reference and is to contain the necessary system technical information and give operating instructions for normal and emergency operations.

1.5 Location of controls

1.5.1 Ship motion and anticipated structural vibrations are to be considered when selecting the locations of main and associated secondary control locations.

1.5.2 The control locations are to be well ventilated and air conditioning is to be provided for the control consoles when required by the operational characteristics of the components within the consoles. There is to be an alarm for failure of the console integral air conditioning.

1.5.3 Enclosed main control location located within the machinery spaces are to have two means of access located as remote from each other as practicable.

1.5.4 The leading of pipes in the vicinity of control console is to be avoided as far as possible. When such leads are necessary, care is to be taken to fit no flanges or joints over or near the console unless provision is made to prevent any leakage from injuring the equipment.

1.5.5 Glass in a control room located within or adjacent to the machinery space is to be of the shatter-resistant type.

1.5.6 When the main control for the propulsion plant is to be situated in a location remote from the propulsion machinery space, details of special arrangements are to be submitted to show that the operation of the propulsion plant would be as effective as with the main control located within or adjacent to the machinery space.

1.6 Main control location

1.6.1 Controls

1.6.1.1 The main control location is to provide control of the propulsion plant and associated ship's service system including starting, stopping, and for change over of vital pumps and motors, and is to provide effective means for monitoring temperatures, pressures, the electrical system, fluid and gas flows, liquid levels and other variables which are essential for the propulsion plant operation.

1.6.1.2 Effective means are to be provided for monitoring and controlling direction of rotation or propeller pitch and speed of propeller for the safe operation of the plant from standby

condition at departure through normal operation to "finished with engines" at the end of the voyage.

1.6.1.3 The main control location is to be fitted with alarms and emergency trips as required together with indicators and is to have means for the assessment of the operational status of all machinery and systems vital to the propulsion of the vessel. Control functions from the console may be designed for either 'remote manual' or 'automatic control'.

1.6.2 Independent manual control

1.6.2.1 Means are to be provided for independent manual control, at or near the machinery concerned, in the event of failure of a particular control in the centralized control system. Necessary instrumentation is to be provided so that satisfactory operation of the machinery under independent manual control can be exercised for lengthy periods. Independent manual control of propulsion machinery is to be demonstrated during the tests/trials to the satisfaction of the Surveyors. This is to include demonstration of independent manual control through the full maneuvering range and transfer from automatic control.

1.6.3 Order of control-location command

1.6.3.1 When the propulsion machinery is arranged to be controlled from two or more locations, the main control location is to have means for transferring control from a secondary location to the main location at all times and blocking any unauthorized control from any secondary location. Consideration will be given to special cases where it may be necessary for a secondary control location to have command over control transfers between control locations.

1.6.4 Control transfer

1.6.4.1 Transfer of control from one location to another, except as required by 1.6.3.1, is to be possible only with acknowledgement by the receiving locations. The main control location and the secondary control location are to have an indicator showing which location is in control.

1.7 Secondary control locations

1.7.1 In general, secondary control locations for the control of propulsion machinery from the bridge or other locations on board are to be kept as simple as possible and provided with only those indicators and controls necessary for the effective control of speed and direction of the propulsion engines, and of the controllable-pitch propeller where fitted, for normal operation.

1.7.2 Precautions are to be taken to ensure that the engine is not normally operated in a barred speed range.

1.7.3 If the control system automatically shuts down the main propulsion engine for any reason, this is to be alarmed at the main control location and each secondary control location. Restoration of normal operating conditions is to be possible only after manual reset. Automatic restarting is not to be possible.

1.8 Control console construction

1.8.1 Control consoles are to be preferably self-supported with the sides and backs suitably protected. Where necessary, protection is to be provided for consoles which might be subject to damage by leaks or falling objects.

1.9 Instrumentation

1.9.1 Main control location

1.9.1.1 Instrumentation and alarms at the main control location are to provide all information necessary for monitoring the operation of the propulsion, electrical and emergency systems, generally in accordance with Table 1.9.1.

1.9.2 Secondary control location

1.9.2.1 Instrumentation and alarms for the bridge control locations and other secondary control locations are to be generally in accordance with Table 1.9.2.

1.10 Displays, indications and alarms

1.10.1 The alarms and displays required by Table 1.9.1 and Table 1.9.2 for essential services are to be readily distinguishable from other alarms (e.g. fire alarm) and are to be grouped functionally in so far as practicable. Alarms are to have individual visual presentation with preferably a common audible signal.

1.10.2 In general, alarms and displays not required by Table 1.9.1 and Table 1.9.2 or not concerned with the management of the

propulsion machinery (non- essential alarms) are to be grouped separately from the essential alarms. Audible signals for non-essential alarms, if provided, are to be of a character distinct from that for essential alarms.

1.10.3 The number of colours used to indicate status of plant operation is to be kept to a minimum. A uniform code is to be used so that like colours indicate like functions or status of operation in the controlled plant or system.

1.10.4 Alarm systems are to be designed so that they cannot remain deactivated when the monitoring system has returned to the normal running condition. Alarm systems are to provide both audible and visual alarm upon each fault condition. Alarms, due to fault condition in machinery, are to remain active until acknowledged and if arrangements are made to mute audible alarms they are not to extinguish visual alarms. Acknowledgement of visual alarms is to be clearly indicated. Alarms are to be of the self-monitoring type so that a circuit failure will cause an alarm condition and are to have provisions for testing all audible and visual alarms and indicating lamps.

1.10.5 Machinery, safety and control system faults are to be indicated at the relevant control locations to advise duty personnel of a fault condition. The presence of unrectified faults is to be clearly indicated at all times.

1.10.6 Where the alarms are displayed as group alarms provision is to be made to identify individual alarms at the main control location (if fitted) or alternatively at subsidiary control locations.

1.10.7 Acknowledgement of alarms at positions outside a machinery space is not to silence the audible alarm or extinguish the visual alarm in that machinery space.

1.10.8 If an alarm has been acknowledged and a second fault occurs prior to the first being rectified, audible and visual alarms are again to operate. Where alarms are displayed at a local panel adjacent to the machinery and with arrangements to provide a group or common fault alarm at the main control room alarm display then the occurrence of a second fault prior to the first alarm being rectified need only be displayed at the local panel, however, the group alarm is to be re-initiated. Unacknowledged alarms on monitors are to be distinguished by either flashing text or a flashing marker adjacent to the text. A change of colour will not in itself be sufficient to distinguish between acknowledged and unacknowledged alarms.

1.10.9 For the detection of transient faults which are subsequently self-correcting, alarms are required to lock in until accepted.

1.10.10 The alarm system is to be arranged with automatic changeover to a standby power supply in the event of a failure of the normal power supply. Where an alarm system could be adversely affected by an interruption in power supply, changeover to the standby power supply is to be achieved without a break.

1.10.11 Failure of any power supply to the alarm system is to operate an audible and visual alarm at the main control location.

1.10.12 The alarm system is to be capable of being tested during normal machinery operation.

1.10.13 The alarm system is to be designed as far as practicable to function independently of control and safety systems such that a failure or malfunction in these systems will not prevent the alarm system from operating.

1.10.14 Disconnection or manual overriding of any part of the alarm system should be clearly indicated.

1.10.15 When alarm systems are provided with means to adjust their set point, the arrangements are to be such that the final settings can be readily identified.

1.10.16 Where monitors are provided at the location in control and if fitted, in the duty engineer's accommodation, they are to provide immediate display of new alarm information regardless of the information display page currently selected. This may be achieved by provision of a dedicated alarm monitor, a dedicated area of screen for alarms or other suitable means.

1.10.17 Alarms are to be displayed in the order in which they occur. Alarms requiring shutdown or slowdown action are to be given visual prominence.

1.11 Safety systems

1.11.1 Where safety systems are provided, the requirements of Pt.5, Ch.22, 2.5.2 to 2.5.8 are to be complied with.

1.11.2 Where arrangements are provided for over-riding a safety system, they are to be such that in-advertent operation is prevented. Visual indication is to be given at the relevant control location(s) when a safety over-ride is operated. The consequences of over-riding a safety system are to be established and documented.

1.11.3 Monitoring and safety systems for DF or GF engines are to be provided in accordance with the requirements of Ch. 4, Sec. 4, 4.14.4.8 in addition to those given in this Section.

Table 1.9.1 : Displays, indications and alarms for main control location				
	System	**Remote Display**	**Alarm activation**	**Remarks**
Main boilers				
1	Main steam superheater outlet	Temperature Pressure	High	-
2	Fuel oil to burners	Pressure Viscosity (temperature)	Low High (low)	-
3	Master fuel oil cut-off valve	-	Closed	-
4	Atomizing medium	Pressure	Outside limits	-
5	Forced draft	Pressure (water column)	Failure	-
6	Water level	Level	High, low Low-low	-
7	Feed pump discharge	Pressure		-

15	Fire main	Pressure	-	-
16	Bilge pump	Running	-	-
17	Bilge level	-	High	-
18	Clutch air or oil pressure	-	Low	-

Table 1.9.1 : (Contd.)

Notes:

1 Individual alarms are required where separate lubricating oil systems (e.g. for camshaft, rocker arms, turbocharger, etc.) are installed. For turbochargers with an integrated self-contained oil lubrication system such alarm is not required.

2 Where separate lubricating oil systems are installed, individual level alarms are required for the tanks.

3 Where one common cooling space without individual stop valves is employed for all cylinder jackets, one temperature alarm for the common cooling water outlet will be approved.

4 Only applicable for cross-head type engines.

5 High-level alarm is required only if suitable overflow arrangements are not provided.

6 Both the displays and alarms are not required if automatic temperature control is not necessary. Low temperature alarm may be replaced by an alarm for water detection in the charging air duct.

7 Not required for distillate fuels.

8 Alarm for slow speed engines (under 300 RPM) and medium speed engines above 4000 bhp.

9 Not required for attached cooling pumps.

10 Not required for engines with bore 300 [mm], or under.

11 Alarms required for steering gear need to be fitted only on the bridge.

12 The rudder angle indication is to be on the navigation bridge and independent of the steering gear control system.

13 Steering gear motors running indicators are to be fitted both on the bridge and main control location.

14 Each tank is to be monitored.

15 Where more than one system (either power or control) can be operated simultaneously each system is to be monitored and the system at fault is to be identified.

16 If engine power is $\geq$ 2250 [kW] or cylinder bore > 300 [mm], following is to be provided:

- Oil mist detection arrangements or engine bearing temperature monitors or equivalent devices.
- Slow down with alarm for low speed diesel engines
- Shut down with alarm for medium and high speed engines.
- IRS may permit overriding of auto shut off or slow down arrangements, provided consequences of overriding auto shut off or slow down are established and documented.
- For the purpose of this requirement :-
    - Low speed engines means diesel engines having a rated speed of less than 300 rpm
    - Medium speed engines means diesel engines having a rated speed of 300 rpm and above, but less than 1400 rpm.
    - High Speed engines means diesel engines having a rated speed of 1400 rpm and above

Table 1.9.2 : Displays, indications and alarms for secondary control location

	System	Display	Alarm	Remarks
1	Control location	In command	-	-
2	Propeller speed and direction	Ahead, astern, RPM	-	-
3	Propeller pitch	Pitch	-	-
4	Starting air pressure	-	Low	-
5	Propulsion unit	-	Abnormal	-
6	Remote control power	-	Failure	-
7	Shaft roll over	-	Stopped	-
8	Bilge level	-	High	-

Section 2

Control - System Characteristics

2.1 Power supply

2.1.1 The control systems are to be served by two feeders from the main switchboard. One of the feeders may be from the emergency switchboard, if provided. Transfer may be by manual or automatic switch installed in or adjacent to the control console. The feeder from the transfer switch to the control console may be through a single cable. These feeders are not to supply power for any other machinery.

2.1.2 The feeders supplying power to the control console are to be provided with short-circuit protection at the main switchboard and emergency switchboards, if provided. Where circuits within the control consoles are protected by fuses or circuit breakers, the control-system protection is to be subdivided and arranged so that failure of one set of fuses or circuit breakers will not cause maloperation or failure of another circuit or system and it is to be possible to isolate the defective system.

2.1.3 The power for monitoring, alarms and emergency action is to be supplied automatically from an emergency source upon failure of ship's service power supply. An audio / visual alarm is to be provided at the main control location to indicate failure of power supply.

2.1.4 Cables and console wiring for control and monitoring are to be of the flame-retarding type and are to be stranded except that solid conductors may be used in low energy circuits, where they are properly supported and not subject to undue vibration or movements.

2.1.5 Conductors for monitoring circuits which carry low-level or information-level signals are to be installed in such a manner or provided with shields so as to minimize the introduction of spurious signals from outside sources. Wiring within consoles is to be arranged to provide maximum accessibility and protection from steam, water or oil piping.

2.2 Electrical and electronic devices

2.2.1 All electrical and electronic devices are to be suitable for use in marine atmosphere, resistant to corrosion, not affected by shipboard vibration and motion and are to be capable of performing their intended functions at compartment ambient temperature. Electrical and electronic devices are to be applied on the basis of 50°C ambient when located in machinery spaces or 40°C ambient when located in other spaces, including those cases when the component is located in an airconditioned console.

2.2.2 Semiconductor devices are to be selected on the basis of expected shipboard ambient air-temperature ranges of 0°C-50°C for interior compartments and 0°C-60°C inside of consoles. Silicon and selenium semiconductor devices are to be used in

preference to germanium which may be used, where its characteristics are favoured for a circuit provided care is taken to ensure satisfactory operation under shipboard conditions.

2.2.3 Steady-state voltage variations of 10 per cent and frequency variations of ± 5 per cent from the nominal console feeder rating are not to affect the intended functioning of the electrically operated control and monitoring devices. Where close tolerances on voltage and frequency are required, special regulated supplies are to be provided. Voltage transients are not to cause any dangerous malfunctioning or damage to the control and monitoring devices and the control equipment is to be fitted with transient- voltage suppressors.

2.2.4 The design and arrangement of all devices is to provide ready accessibility to parts requiring inspection, adjustment or periodic replacement. Where devices are parts of sub-circuits assembled in physically-identical modular units for easy mounting on and removal from the console, suitable arrangements such as matched plug-in modules with coded plugs are to be provided to facilitate correct replacement of modules in the console.

2.2.5 Built-in circuitry is to be provided for use in the testing of module functions.

2.2.6 Consideration is to be given to minimize, as far as practicable, the probability that failure of any one component or device in the control circuitry will cause unsafe operation of the plant.

2.2.7 Control levers or wheels are to be readily identifiable as to function and position and are to be arranged for a logical sequence of operations. Suitable interlocks are to be provided to prevent incorrect operation.

2.2.8 When logic circuits are used for sequential start-up or for operating individual plant, components, indicators are to be provided at the control console to show the successful completion of the sequence of operations by the logic circuit and start-up and operation of the component. If some particular step is not carried out during the sequence, the sequence is to stop at this point. Manual override is to be fitted in vital functions to permit control in case of failure of a logical circuit.

2.2.9 Electrically-powered actuators for the execution of control commands are to be suitable for shipboard use, and have working and other parts which would not be damaged or rendered ineffective by corrosion. The windings are to be treated to resist oil and water and the enclosures are to be suitable for the location. The ratings of coils is to be based on ambient air temperature of 50°C when located in the machinery spaces and 40°C when located outside such spaces. The power supply for electrical actuators is to be from the same source as the power to the control systems.

2.3 Hydraulic controls

2.3.1 Hydraulic pumps, actuators, motors and accessories are to be suitable for the intended duty, compatible with the working fluid and are to be designed to operate safely at full-power conditions. In general, the hydraulic fluid is to be non-flammable or have a flash point above 157°C.

2.3.2 All control piping is to be readily accessible and supported so as to protect the piping and associated accessories from mechanical damage, vibration and shock. The control piping is to be suitably marked to indicate the character of its service.

2.3.3 The hydraulic pumps are to be fitted in duplicate and have pressure relief protection on the discharge side. The pump suctions are to be from a reservoir of sufficient capacity to contain all the fluid when drained from the system, maintain the fluid level at an effective working height and allow air and foreign matter to separate out. The pump suctions are to be sized and positioned to prevent cavitation or starvation of a pump. A duplex filter which can be cleaned without interrupting the oil supply is to be fitted on the discharge side of the pumps.

2.4 Pneumatic controls

2.4.1 Air compressors, actuators, motors and accessories are to be suitable for the intended duty and have working and other parts which will not be damaged or rendered ineffective by corrosion.

2.4.2 All control piping is to be readily accessible and supported so as to protect the piping and associated accessories from mechanical damage, vibration and shock. The

control piping is to be suitably marked to indicate the character of its service.

2.4.3 Compressed air for pneumatic control is to be available from at least two air compressors. The starting air system may be used as a source of control air. The air pressure to the pneumatic control system is to be automatically maintained at the level required for the operation of the installation and low air pressure is to set off an alarm at the main control location. Means are to be provided in the delivery from the compressors to assure clean, dry and oil-free air to the pneumatic controls.

2.5 Ship motion effects

2.5.1 All control, actuating, monitoring and alarm devices are to be able to operate successfully when inclined at an angle of 30° in any direction from the vertical and when subjected to vibratory frequencies of 2 to 80 Hz, in conjunction with peak to peak amplitudes of 2 [mm] for frequencies 2 to 13.2 Hz and an acceleration of 0.7 g for frequencies of 13.2 to 80 Hz. Care is to be taken to ensure that mounting arrangements for the components will not amplify shipboard vibrations.

2.6 Bridge control for main propulsion machinery

2.6.1 Where a bridge control system for main propulsion machinery is to be fitted, the requirements of 2.6.2 to 2.6.8 are to be complied with.

2.6.2 Means are to be provided to ensure satisfactory control of propulsion from the bridge in both the ahead and astern directions.

2.6.3 Instrumentation to indicate the following is to be fitted on the bridge:

a) Propeller speed.
b) Direction of rotation of propeller for a fixed pitch, propeller or pitch position for controllable pitch propeller.
c) Clutch position where applicable.
d) Shaft brake position where applicable.
e) Engine speed.

2.6.4 The propeller speed, direction of rotation and, if applicable, the propeller pitch are to be controlled from the bridge under all normal sea going and manoeuvring conditions.

2.6.5 Remote control of the propulsion machinery is to be from one control location at any one time. See also 1.6.3. Main propulsion control units on the navigating bridge may be interconnected. Means are to be provided at the main machinery control location to ensure smooth transfer of control between the bridge and machinery control locations.

2.6.6 Means of control, independent of the bridge control system, are to be provided on the bridge to enable the propulsion machinery to be stopped in an emergency.

2.6.7 Audible and visual alarms are to operate on the bridge and in the locations required by Pt.5, Ch.22 if any power supply to the bridge control system fails. Where practicable the preset speed and direction of thrust are to be maintained until corrective action is taken.

2.6.8 At least two means of communication are to be provided between the bridge and the main control location in the machinery space. One of these means may be the bridge control system; the other is to be independent of the main electrical power supply. See also Pt.4, Ch.1, Sec.2, Cl. 2.5.

2.7 Valve control system

2.7.1 Where bilge, ballast, oil fuel transfer and sea valves for engine services are operated by remote or automatic control, the requirements of 2.7.2 to 2.7.5 are to be satisfied.

2.7.2 Failure of actuator power is not to permit a valve to move to an unsafe condition.

2.7.3 Positive indication is to be provided at the remote control location for the service to show the actual valve position or alternatively that the valve is fully open or closed.

2.7.4 Equipment located in places which may be flooded is to be capable of operating when submerged.

2.7.5 A secondary means of operating the valves, which may be by local manual control, is to be provided.

2.7.6 For requirements applicable to closing appliances on scuppers and sanitary discharges, see Pt.3, Ch.13.

Section 3

Requirements for various Machinery Installations

3.1 Boilers

3.1.1 General

3.1.1.1 Where a boiler-control system is fitted for the purpose of automatically controlling the combustion, feed water and firing functions, the arrangements are to be capable of automatically and safely satisfying the steam requirements demanded from the boiler under normal evaporation between minimum and maximum firing rates and be able to maintain complete and stable combustion at the minimum rate of firing or during any sudden change in steam demand.

3.1.1.2 To prevent a build-up of excessive boiler steam which might occur when all burners are in service and burners are at the minimum firing rate, one of the following arrangements or equivalent is to be provided:-

a) Burners sequencing, which may require automatic control of one or more, but not necessarily all, burners in the boiler;

b) an automatic steam dump system, unloading to a condenser of adequate size.
For long-term operation at low loads, the excess burner capacity may be secured.

3.1.2 Fuel oil system

3.1.2.1 A master fuel oil cut-off valve is to be provided in the fuel system to each boiler. The valve is to be automatically closed upon flame failure of all burners in the boiler or upon action of the low-water alarm or upon loss of forced draft. The closing of the master fuel oil valve is to be alarmed at the main control location. Before any attempt at restarting after a complete flame out, manual intervention is to be initiated to determine the cause of flame failure and to reset the master fuel-oil valve.

3.1.2.2 The oil burners are to be so arranged that they cannot be withdrawn unless oil supply to the burners is cut off.

3.1.3 Combustion-control safety

3.1.3.1 Each burner is to be fitted with a flame scanner designed to automatically shut off the fuel oil supply to the burner in the event of flame failure. The flame failure shut off is to be capable of shutting off the oil supply to the burner within 6 seconds following flame failure. In the case of the failure of the flame scanner, the fuel to the burner is to be shut off automatically. On flame failure of all burners in boilers fitted with an automatic ignition system, the control system is to go to the automatic boiler purge condition.

3.1.3.2 Where boilers are fitted with an automatic ignition system, a timed boiler purge with all air registers open is required prior to ignition of the initial burner. The boiler purge may be initiated manually or automatically. The purge time is to be based on a minimum of four air changes of the combustion chamber and furnace passes. It is to be proven that the forced draft fan is operating and the air registers and dampers are open before the purge time commences.

3.1.3.3 Means provided to by-pass the flame-scanner control system temporarily during a trial- for ignition period is to be limited to 15 seconds from the time the fuel reaches the burners. Except for this trial- for-ignition period there is to be no means provided to by-pass one or more of the burner flame scanner systems unless the boiler is being manually fired.

3.1.3.4 Where boilers are fitted with an automatic ignition system, and where residual fuel oil is used, means are to be provided for lighting off the burners with igniters lighting properly heated residual fuel oil. Alternatively, the burners may be lighted off with a light oil used as a pilot to ignite residual fuel oil. If all burners experience a flame failure, the initial burner is to be brought back in to automatic service only in the low-firing position. To avoid the possibility of false indication due to the failure of the flame scanner in the 'flame-on' mode, the initial light-off burner is to be fitted with dual scanners or a scanner of the self checking type.

3.1.3.5 Off-limit conditions of burner primary-air pressure or atomizing- steam pressure are to be alarmed at the main control location.

3.1.4 Boiler alarms and indications

3.1.4.1 Action of the automatic fuel oil or burner shut-off arrangement is to be indicated by audible and visual alarms. Means are to be provided to silence the audible alarms without canceling the visual indicator. Alarm systems are to be designed so that the alarm cannot remain silenced when the monitored system has returned to normal running condition.

3.1.4.2 Each boiler is to be fitted with one high-water level alarm and two independent low water-level sensors and alarms. The low-low water-level alarm is to close the master fuel oil cut- off for the boiler, and is to be set to operate when the water level falls to a minimum safe level, but at a level not lower than that visible in the gauge glass. Water-level sensors are to be so located as to minimize the effect of roll and pitch or they are to be provided with a short- time delay (approximately 5 seconds) to prevent trip-out due to transients or to the vessel's motion.

3.1.4.3 The alarms for forced-draft failure and for low-water level are to be installed in association with limiting controls which are to prevent start-up and cause shut-down when unsafe firing conditions exist. Manual resetting of the control system is to be required before the boiler can be restarted.

3.1.4.4 The operation status of the boiler is to be indicated at the boiler by conventional instruments, gauges, lights or other devices to show the functional condition of fuel, air, feed-water and steam circuits of boiler. Monitoring instruments are also to be provided at the main control location.

3.1.5 Logic sequence for boiler controls

3.1.5.1 Where automatically started boilers are installed, they are to be provided with a programmed control to assure a safe cycle of operation upon initial starting and cycling between temperature and pressure limits.

3.1.5.2 The programmed control is to be designed to cycle the boiler in accordance with a predetermined sequence and, in addition to the automatic boiler purge required by 3.1.3.2, is to include the following:-

a) Ignition (spark coming on) is to precede the opening of the fuel valve;

b) Where it is necessary to cut burners in and out to handle the load on the boiler and the controls are provided to modulate the air-fuel ratio, the automatic boiler purge period is to start with the modulating control in the high firing position and the ignition is not to be turned on until the modulating control has returned to the low-firing position.

3.1.5.3 Means are to be provided for independent manual control at the boiler in the event of failure of the automatic control and sufficient conventional instrumentation is to be provided so that satisfactory operation of the boiler under independent manual control can be exercised for lengthy periods of time.

3.2 Propulsion machinery

3.2.1 General

3.2.1.1 The fitting of centralized automatic controls for propulsion engines and turbines is not to impair the effectiveness of the safety and speed control devices required by the applicable parts of Ch.4.

3.2.1.2 Plant or engine response to throttle control demands is to be tested during trials and after final adjustment to demonstrate that no part of the plant or engine is jeopardized by the rate at which the throttle is moved from one extreme position to the other. Overriding of the remote throttle control is to be possible only from the main control location.

3.2.1.3 The emergency tripping of propulsion machinery is to be possible at the main control location and at the machine site.

3.2.2 Steam turbines

3.2.2.1 The astern guardian valve is to open automatically as a result of a throttle trip or a maneuvering signal, such as the actuation of a specific switch or by movement of the throttle control in the maneuvering range. An alarm is to indicate any failure of the guardian valve to open.

3.2.2.2 If scoop circulation is provided for the main condenser, the main circulating pump is to be automatically started as required for satisfactory operation of the propulsion machinery.

3.2.2.3 In the event of low lubricating-oil pressure there is to be an automatic changeover to the standby lubricating-oil pump(s). The governor is to be arranged to shut off the steam to the ahead turbines upon failure of the lubricating-oil system.

3.2.2.4 Alarms at the main control location are to indicate low vacuum in the condenser, excessive bearing temperature and low lubricating-oil pressure. Remote throttle control-system power failure indication is to be provided at the main control and secondary control locations. An alarm is to be provided at the main control and secondary control locations to indicate that the propeller shaft has been stopped too long on a standby or stop maneuver.

3.2.3 Gas turbines

3.2.3.1 Automatic control arrangements for gas turbine modules are to be provided to regulate the quantity of fuel flowing to the burners during starting, over the operating power range and when stopping the gas turbine, in a controlled manner and with in the safe operating envelope of the gas turbine. The arrangement is to have provision to collect, condition and transmit both primary and secondary surveillance signals to the local and remote operating locations.

3.2.3.2 The control system is to be provided with control functions at the component level to allow direct manual control of the fuel flow and engine shut down in the event of failure of the electrical power supplies or a critical failure of the engine control system.

3.2.3.3 Each gas turbine module is to be provided control unit comprising of minimum instrumentation necessary for monitoring, control and surveillance for safe operation both local and remote positions with facility for transfer of control authority through a suitable selector switch.

The alarms and automatic shut down devices to be provided are as indicated in Pt.4, Ch.4, Table 3.13.1.

3.2.4 Diesel engines

3.2.4.1 In the event of the lubricating oil pressure dropping to a preset level, there is to be an automatic changeover to a standby lubricating oil pump or a reduction in main engine speed to a predetermined level. In the event of a loss of lubricating oil pressure engines are to stop automatically.

3.2.4.2 Engine alarms are to be in accordance with Table 1.9.1 and Table 1.9.2.

3.2.4.3 Precautions are to be taken to ensure that it is not possible to continuously run the main engine in a barred speed range.

3.3 Emergency internal combustion engines

3.3.1 These requirements apply to I.C. engines, which use distillate marine fuels covered by ISO 8217:2017, required to be immediately available in an emergency and capable of being controlled remotely or automatically operated. Information is to be submitted alongwith instructions to test alarm and safety shutdown systems demonstrating compliance with the requirements.

3.3.2 Alarms and safeguards are to be fitted in accordance with Table 3.3.2.

3.3.3 The safety shutdown and alarm systems are to be designed to ‘fail safe’. The characteristics of the ‘fail safe’ operation are to be evaluated on the basis not only of the system and its associated machinery, but also the complete installation, as well as the ship.

3.3.4 Regardless of the engine output, if shutdowns additional to those specified in Table 3.3.2 are provided except for the overspeed shutdown, they are to be automatically overridden when the engine is in automatic or remote control mode during navigation.

3.3.5 The alarm system is to function in accordance with Pt.5, Ch.22, with additional requirements that grouped alarms are to be arranged on the bridge. (See Pt.5, Ch.22, Cl.2.4.14).

3.3.6 In addition to the fuel oil control from outside the space, a local means of engine shutdown is to be provided.

3.3.7 Local indications of at least those parameters listed in Table 3.3.2 are to be provided within the same space as the I.C. engines and are to remain operational in the event of failure of the alarm and safety shutdown systems.

Table 3.3.2 : Alarms and safeguards

Parameter	Alarm activation(Y/N)	Shutdown with alarm(Y/N)
Fuel oil leakage from high pressure pipes (fuel injection pipes and common rails)	Y	N
Lubricating oil temperature[1]	Y, Alarm for high value	N
Lubricating oil pressure	Y, Alarm for low value	N
Activation of oil mist detection arrangements (or activation of the temperature monitoring systems or equivalent devices of : - the engine main and crank bearing oil outlet; or - the engine main and crank bearing)[2]	Y	N
Pressure or flow of cooling water[1]	Y, Alarm for low value	N
Temperature of cooling water (or cooling air)	Y, Alarm for high value	N
Overspeed activated[1]		Y

Note
1 : For engines having a power of or more than 220 kW.

2 : For engines having a power of more than 2250 kW or a cylinder bore of more than 300 [mm].

Section 4

Tests and Trials

4.1 Individual components

4.1.1 The manufacturers of control systems are to certify that the mechanical, electrical, and solid-state components utilized have been satisfactorily tested individually or by acceptable lot sampling to establish their suitability for the intended service including their exposure to the following conditions :-

a) shipboard ambient conditions, See Ch.1, Sec.1;

b) ship motion and vibration as per 2.5;

c) temperature range as per 2.2;

d) voltage and frequency tolerances as per 2.2;

e) pressure tests as per 4.1.2 and 4.2.

4.1.2 Hydraulic and pneumatic piping is to be subjected to pressure tests at 1.5 times the relief-device settings using the service fluid in hydraulic systems and dry air or dry inert gas for pneumatic systems as the testing media. Means are to be provided for the automatic removal of moisture from the piping before delivery to the pneumatic control system.

4.1.3 All electrical control and monitoring circuits are to be checked and proven free of unintentional grounds and short circuits, defective electrical or electronic elements.

4.2 Shop testing

4.2.1 Upon completion of the control consoles or sections or component assemblies of such consoles, the manufacturer is to carry out tests in the presence of the Surveyor to

demonstrate the satisfactory performance of all controls, instruments and alarms. The tests are to simulate all control and alarm functions given in the operational manual as far as practicable. The tests are to demonstrate satisfactory performance under the following conditions :

a) tests to be carried out at rated power supply at prevailing ambient air conditions;

b) loss of power to be simulated;

c) the voltage of the electrical supply to be varied plus or minus 10 per cent and where alternating current is used, the frequency is to be varied simultaneously to plus or minus 5 per cent. The controls are to function satisfactorily during these variations without faults. Where the components selected have been tested individually and are certified to function satisfactorily during these power variations, retesting of final assemblies will not be required;

d) all electrical circuits supplying power to servo-motors and actuators rated over 100 volts are to be subjected to dielectric-strength tests as required by Ch.8;

e) vibration tests required by 2.5 may be conducted in shops other than the plant of manufacture. When equipment is not energized during the test it is to perform satisfactorily after the vibration test;

f) variation of hydraulic or pneumatic system pressure $\pm$ 20 per cent of normal operating pressure, except that relief valve pressure need not be exceeded. The system is to operate satisfactorily at the relief valve pressure setting.

4.3 Trials on board

4.3.1 Upon completion of the installation, complete performance tests of all systems are to be carried out during dock trials and sea trials to demonstrate that the system will perform successfully during standby, maneuvering, steady conditions, and during transfer of controls.

4.3.2 A copy of the record of the trials is to be submitted for information. It is recommended that a copy of the record of the trials be kept on board for reference purposes for future adjustments/testing etc. The record should include details of all adjustments, calibrations, method of simulating failures and expected results due to these simulations. The record should be kept up to date at all times.

Section 5

Machinery Operated from a Centralised Control Station – ‘CCS’ Notation

5.1 General requirements

5.1.1 Where it is proposed to install control, alarm and safety systems to the following equipment, applicable features contained in Section 2 and Section 3 are to be incorporated in the system design.

- Propulsion machinery including essential auxiliaries;
- Electric power generating plant;
- Controllable pitch propellers;
- Oil fuel transfer and storage systems;
- Air compressors;
- Steam generating plant (boilers and their auxiliary equipment).

5.1.2 The arrangements are to be such that corrective actions can be taken at the control location in the event of machinery faults, e.g. stopping of machinery, starting of standby machinery, adjustments of operating parameters, etc. These actions may be effected by either remote manual or automatic control.

5.1.3 The controls, alarms and safeguards required by this chapter and Pt.5, Ch.22, as applicable, are to be provided at the control location. A fire detection system satisfying the requirements of Pt.5, Ch.22, Sec.2.13 is, also to be provided.

5.1.4 Additional requirements for controls, alarms and safeguards are given in 5.2.

5.2 Centralised control station for machinery

5.2.1 A centralized control station is to be provided at some suitable location, which satisfies the requirements of 5.2.2 to 5.2.7.

5.2.2 A system of alarm displays and controls is to be provided which readily ensures identification of faults in the machinery and satisfactory supervision and related equipment. The alarm and control systems are to satisfy the requirements of Section 1 and Section 2 as applicable.

5.2.3 Indication of all essential parameters necessary for the safe and effective operation of the machinery is to be provided, e.g. temperatures, pressures, tank levels, speeds, powers etc.

5.2.4 Indication of the operational status of running and standby machinery is to be provided.

5.2.5 At the centralized control station, means of communication with the bridge area, the accommodation for engineering personnel and if necessary, the machinery space are to be provided.

5.2.6 In addition to the communication required by 5.2.5, a second means of communication is to be provided between the bridge and the centralized control station. One of these means is to be independent of the main electrical power supply.

5.2.7 Arrangements are to be provided in the centralised control station so that the normal supply of electrical power may be restored in the event of failure.

Section 6

Computer Based Systems

6.1 Scope

6.1.1 These requirements apply to design, construction, commissioning and maintenance of computer-based systems where they depend on software for the proper achievement of their functions. These requirements apply to systems which provide control, alarm, monitoring, safety, or internal vessel communication functions that are subject to classification.

6.1.2 The requirements given in this section do not apply to navigation, radio communication systems and loading instruments/ stability computer.

6.1.3 Vessels complying with the requirements in IRS “Guidelines on Maritime Cyber Safety” will be assigned the following optional additional Class Notations:

a) **CyS-I** – Informed Cyber Safety. This notation is assigned where the organisation assesses the issues related to cyber safety, cyber risks and have documented policies. The organization implements minimum cyber safety practices.

b) **CyS-II** – Advanced Cyber Safety. This notation is assigned where the cyber safety policies and procedures are reviewed periodically for continual improvement. The organisation implements advanced cyber safety practices.

6.1.4 Ships and units complying with the requirements in Section 7 will be assigned additional class notation **CyS-E** (i.e. Essential Cyber Safety).

6.2 Definitions and abbreviations (for the purpose of this Section)

6.2.1 Stakeholders

6.2.1.1 **Owner**: The organization or person which orders the vessel in the construction phase or the organization which owns or manages the vessel in service.

6.2.1.2 **Systems Integrator**: A single organization or a person coordinating interaction between suppliers of systems and sub-systems on all stages of life cycle of computer-based systems in order to integrate them into a verified vessel-wide system of systems and to provide proper operation and maintenance of the computer-based systems. During the design and delivery phase, the Shipyard is the default systems integrator, during operations phase, the Owner is the default systems integrator.

6.2.1.3 **Supplier**: A generic term used for any organization or person that is a contracted or a subcontracted provider of services, system components, or software.

6.2.1.4 **System supplier:** An organization or person that is contracted or a subcontracted provider of system components or software under the coordination of the Systems integrator.

6.2.1.5 **Service supplier:** A person or company, not employed by IRS, who at the request of an equipment manufacturer, shipyard, vessel's owner or other client acts in connection with inspection work and provides services for a ship or an offshore unit such as measurements, tests or maintenance of safety systems and equipment, the results of which are used by Surveyors in making decisions affecting classification or statutory certification and services

6.2.2 Objects

6.2.2.1 The hierarchy and relationships of a typical computer based system are shown in Fig. 6.2.2.1.

6.2.2.2 **Vessel** means a ship or offshore unit where the computer-based system is to be installed.

6.2.2.3 **System** means a combination of components, equipment and logic which has a defined purpose, functionality and performance. In the context of this Section, a specific system is delivered by one system supplier.

6.2.2.4 **Sub-system** means an identifiable part of a system, which may perform a specific function or set of functions.

6.2.2.5 **Programmable Device** means a physical component where software is installed.

6.2.2.6 **Software component**means a module is a standalone piece of code that provides specific and closely coupled functionality.

6.2.2.7 **Computer-based system (CBS):** A programmable electronic device, or interoperable set of programmable electronic devices, organized to achieve one or more specified purposes such as collection, processing, maintenance, use, sharing, dissemination, or disposition of information. CBSs onboard include Information Technology (IT) and Operational Technology (OT) systems. A CBS may be a combination of subsystems connected via network. Onboard CBSs may be connected directly or via public means of communications (e.g. Internet) to ashore CBSs, other vessels' CBSs and/or other facilities.

6.2.2.8 **Software master files:** The computer-files that constitute the original source of the software. For custom-made software this may be readable source-code files, and for Commercial off-the-shelf (COTS) software it may be different forms of binary files.

6.2.2.9 **Simulation test:** Monitoring, control, or safety system testing where the equipment under control is partly or fully replaced with simulation tools, or where parts of the communication network and lines are replaced with simulation tools.

6.2.2.10 **Parameterization:** To configure and tune system and software functionality by changing parameters. It does not usually require computer programming and is normally done by the system supplier or a service provider, not the operator or end-user.

6.2.2.11 **Failure mode description:** A document describing the effects due to failures in the system, not failures in the equipment supported by the system. The following aspects are to be covered:

- list of failures which are subject to assessment, with
- description of the system response to each of the above failures
- comments to the consequence of each of these failures

6.2.2.12 **Black-box test methods:** Verification of the functionality, performance, and robustness of a system, sub-system or component by only manipulating the inputs and observing the outputs. This does not require any knowledge of the system's inner workings and focuses only on the observable

behaviour of the system/ component under test in order to achieve the desired level of verification.

6.2.3 Abbreviations

6.2.3.1 Abbreviations used in this Section:

Cat I, Cat II and Cat III are category one, category two and category three systems respectively, as defined in Table 6.3.1

COTS : Commercial off-the-shelf
FAT : Factory acceptance test
FMEA : Failure mode and effect analysis
IT : Information technology
OT : Operational technology
PMS : Planned maintenance system
SAT : System acceptance test
SOST : System of systems test
SSLS : Ship software logging system

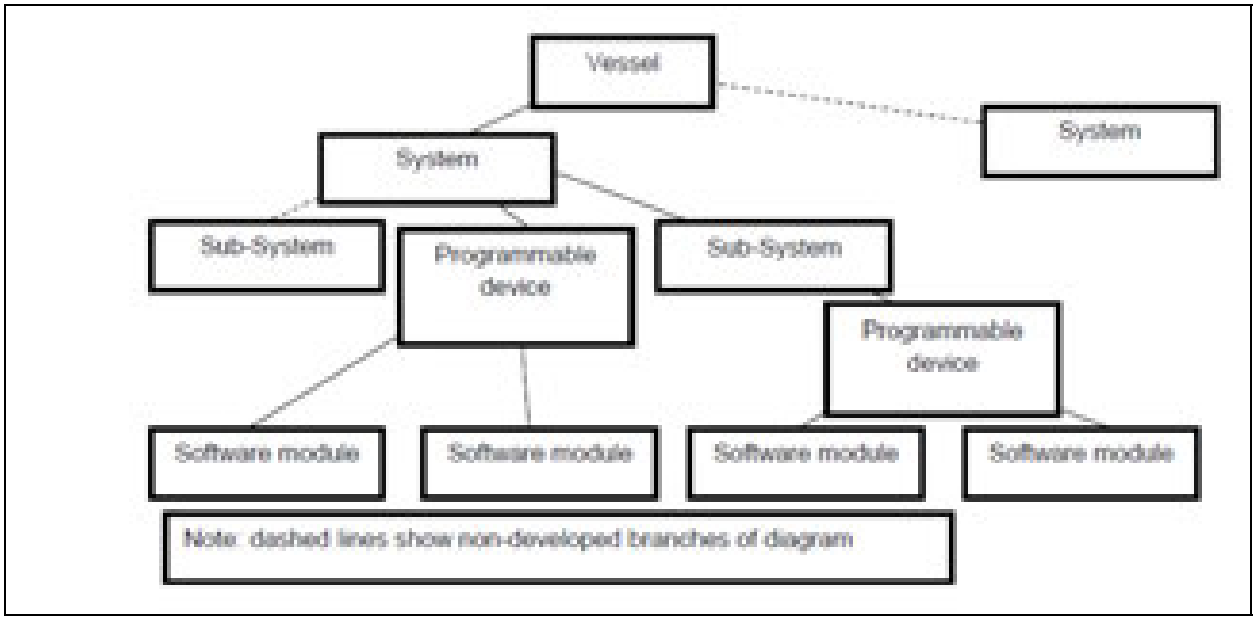

Fig 6.2.2.1 : Illustrative System Hierarchy

6.3 System Categories

6.3.1 The categorization of a system in the context of this Section is based on the potential severity of consequences if the system serving the function fails as shown in Table 6.3.1

Table 6.3.1 : System Categories

Category	Failure Effects	Typical System Functionality
I	Those systems, failure of which will not lead to dangerous situations for human safety, safety of the vessel and/or threat to the environment.	- Monitoring, informational and administrative functions
II	Those systems, failure of which could eventually lead to dangerous situations for human safety, safety of the vessel and/or threat to the environment	- Vessel alarm, monitoring and control functions which are necessary to maintain the vessel in its normal operational and habitable conditions
III	Those systems, failure of which could immediately lead to dangerous or catastrophic for human safety, safety of the vessel and/or threat to the environment.	- Control functions for maintaining the vessel's propulsion and steering - Safety functions

6.3.2 Scope of Classification

6.3.2.1 Category I systems are normally not subject to verification by IRS, as failure of these systems are not to lead to dangerous situations. However, information pertinent to category I systems is to be provided upon request to determine the correct category or ensure that they do not influence the operation of systems in category II and category III.

6.3.3 System category examples

6.3.3.1 The category of a system is to be evaluated in the context of the specific vessel in question; thus, the categorization of a system may vary from one vessel to the next. The examples of categories given below are for guidance only. For determining the categorization of systems for a specific vessel, 6.4.3.2 may be referred.

6.3.3.2 Examples of category I systems: Fuel monitoring system, maintenance support system, diagnostics and troubleshooting system, closed circuit television, cabin security, entertainment system, fish detection system.

6.3.3.3 Examples of category II systems: Fuel oil treatment system, alarm and monitoring and safety systems for propulsion and auxiliary machinery, Inert gas system, control, monitoring and safety system for cargo containment system.

6.3.3.4 Examples of category III systems: Propulsion control system, steering gear control system, electric power system (including power management system), dynamic positioning system (IMO classes 2 and 3).

Note: The examples listed above are not exhaustive.

6.4 Requirements for development and certification of computer-based systems

6.4.1 General requirements

6.4.1.1 Life cycle approach with appropriate standards

.1 A global top to bottom approach is to be undertaken in the design and development of both hardware and software the integration in sub-systems, systems, and spanning the complete system lifecycle. This approach is to be accomplished according to standards as listed in this sub-section or other national/ international standards. This requirement will be verified as a part of the quality management system verification described in 6.4.1.2.

6.4.1.2 Quality management System

.1 Systems integrators and system suppliers are to undertake development of computer-based systems for category II and category III, complying with a recognized quality standard such as ISO 9001; also incorporating principles of ISO 90003. The quality management system may be verified by two alternative means:

- IRS confirming that the quality management system is certified as compliant to the recognized standard by an organization with accreditation under a national accreditation scheme.

- IRS confirming compliance to a standard through a specific assessment of quality management system. The documentation requirements will be defined per case.

.2 The quality management system is to have a minimum of the following topics, applicable for both category II and category III systems, as shown in Table 6.4.1.2

Table 6.4.1.2: Quality Management System			
Area		**Role**	
Sr. No.	**Topic**	**System supplier**	**Systems integrator**
1	Responsibilities and competency of the staff	X	X
2	The complete lifecycle of delivered software and of associated hardware	X	X
3	Specific procedure for unique identification of a computer-based system, it's components and versions.	X	
4	Creation and update of the vessel's system architecture		X
5	Organization set in place for acquisition of software and related hardware from suppliers	X	X
6	Organization set in place for software code writing and verification	X	
7	Organization set in place for system validation before integration in the vessel	X	
8	Specific procedure for conducting and approving of systems at FAT and SAT	X	X
9	Creation and update of system documentation	X	
10	Specific procedure for software modification and installation on board the vessel, including interactions with shipyard and owner	X	X
11	Specific procedures for verification of software code	X	
12	Procedures for integrating systems with other systems and testing of the system of systems for the vessel	X	X
13	Procedures for managing changes to software and configurations before FAT	X	
14	Procedures for managing and documenting changes to software and configurations after FAT	X	X
15	Checkpoints for the organization's own follow-up of adherence to the quality management system	X	X

6.4.2 **Requirements for the system supplier:**

6.4.2.1 Define and follow a quality plan

.1 The system supplier is to document that the quality management system is applied for the design, construction, delivery, and maintenance of the specific system to be delivered. All applicable items described in 6.4.1.2 (for the system supplier role) are to be demonstrated to exist and being followed, as relevant and applicable.

.2 For verification of the above requirements for category II and III, a quality plan is to be available during survey (FAT) or submitted for information upon request. For category I items, no documentation is required.

6.4.2.2 Unique identification of systems and software

.1 A method for unique identification of a system, its different software components and different revisions of the same software component is to be applied. The method is to be applied throughout the lifecycle of the system and the software.

.2 The system is to provide means to identify its name, version, identifier, and manufacturer. It is recommended that the system can automatically report the status of its software to a ship software logging system (SSLS) as specified in the international standard ISO 24060.The documentation of the method is typically a part of the quality management system as indicated in 6.4.1.2.

.3 Application of the identification system will be verified by the Surveyor as a part of the FAT (see 6.4.2.7) and SAT (see 6.4.3.5) for category II and III. This verification is not required for category I.

6.4.2.3 System description

.1 The system's specification and design are to be documented in a system description. In addition to serving as a specification for the detailed design and implementation, the purpose of the system description is to document that the entire system-delivery is according to the specifications and in compliance with applicable rule requirements. The system description is to contain information of the following:

- Purpose and main functions, including any safety aspects
- System category as defined
- Key performance characteristics
- Compliance with the technical requirements and Rules
- User interfaces/mimics
- Communication and Interface aspects
  - Identification and description of interfaces to other vessel systems
- Hardware-arrangement related aspects:
  - Network-architecture/topology, including all network components like switches, routers, gateways, firewalls etc.
  - Internal structure with regards to all interfaces and hardware nodes in the system (e.g., operator stations, displays, computers, programmable devices, sensors, actuators, I/O modules etc.)
  - I/O allocation (mapping of field devices to channel, communication link, hardware unit, logic function)
  - Power supply arrangement
  - Failure mode description

Note: The information listed above is collectively referred to as 'system description' in this Section. It may however be divided into several different documents and models.

.2 For verification of the above requirements for category I, the system description documentation is to be submitted for information, upon request. For category II and III, the system description documentation is to be submitted for approval.

6.4.2.4 Environmental compliance of hardware components

.1 Evidence of environmental type testing according to IRS *Classification Note "Type Approval of Electrical Equipment used for Control, Monitoring, Alarm and Protection Systems for Use in Ships"* regarding hardware elements included in the system and sub-systems are to be submitted to IRS.

.2 The above verification is not mandatory for category I systems. Reference to type approval certificate or other evidence of type testing is to be submitted for information, upon request. For category II and III, reference to type approval certificate or other evidence of type testing is to be submitted for information.

6.4.2.5 Software code creation, parameterization, and testing

.1 The software created, modified, or configured for a particular project is to have the quality assurance activities assessed according to the selected standard(s) as indicated in 6.4.2.1. The quality assurance activities are to be performed on several levels of the software structure and include both custom-made software and configured components (e.g., software libraries) as appropriate. The following aspects of the software are to be verified, as a minimum, based on black-box methods:

- Correctness, completeness and consistency of any parameterization and configuration of software components
- Intended functionality
- Intended robustness

.2 For components in systems of category II and III, the scope, purpose, and results of all performed reviews, analyses, tests, and verification activities are to be documented in test reports.

Note: Some of the methods utilized in this activity are referred to as "software unit test" or "developer test" and may also include verification methods like code-reviews and static- or dynamic code analysis.

.3 Software test reports for category II and III systems, are to be submitted for information, upon request. No documentation is required for category I systems.

6.4.2.6 Internal system testing before FAT

.1 The system is to be tested as far as practicable before the FAT. The main purpose of the system test is for the system supplier to verify that the entire system delivery is according to the specifications, approved documentation and in compliance with applicable requirements. Further, the system supplier can verify that the system is completed and ready for the FAT. The testing is to verify the following aspects of the system:

- Functionality
- Effect of faults and failures (including diagnostic functions, detection, alerts response)
- Performance
- Integration between software and hardware components
- Human-machine interfaces
- Interface to other systems

.2 Faults are to be simulated as realistically as possible to demonstrate appropriate system fault detection and system response. Some of the testing may be performed by utilizing simulators and replica hardware. The test environment is to be documented, including a description of any simulators, emulators, test-stubs (programs that simulate behaviour of software components or modules), test-management tools, or other tools affecting the test environment and its limitations. Test cases and test results are to be documented in test programs and test reports respectively.

.3 Internal system test report is to be made available during FAT or submitted for information, upon request for category II and III systems. No documentation is required for category I systems.

6.4.2.7 Factory acceptance testing (FAT) before installation on board

.1 The main purpose of the FAT is to demonstrate that the system is completed and compliant with applicable Rule requirements. The FAT test program is to cover test items from the internal system test indicated in 6.3.1.3.6.

.2 Network testing is to be carried out for category II and III systems to verify the network resilience requirements, as follows:

- A single failure in data link is not to cause loss of vessel functions of category III. Any effect of such failures is to meet the principle of fail-to-safe for the vessel function(s) being served.
- For vessel-functions of category II and III, any loss of functionality in the remote-control system is to be compensated by local/ manual means.
- The data link is to have means to prevent or cope with excessive communication rates.
- Data links are to be self-checking, detecting failures or performance issues on the link itself and data communication failures on nodes connected to the link.
- Detected failures are to initiate an alarm.

If agreed by all stakeholders, the network testing may be performed as part of the system test onboard the vessel.

.3 The FATs are to be performed with the project specific software operating on the actual hardware components to be installed on board, with necessary means for simulation of functions and failure responses, however other solutions such as replica hardware or simulated hardware (emulators) may be agreed with IRS. For each test case, it is to be noted if the test passed or failed, and the test results are to be documented in a test report. The test report is also to contain a list of the software (including software versions) that were installed in the system when the test was executed.

Note: For complex systems there may be a large difference in scope between the “Internal system testing before FAT” activity and the FAT, while for some systems the scope may be identical.

.4 FATs are not required for category I systems. For category II and III systems, the FAT program is to be approved by IRS before the test is executed. The FAT execution is to be witnessed by the Surveyor and the report is to be submitted for information. Additional FAT documentation including user manuals and internal system report is to be made available during FAT or submitted upon request for information.

6.4.2.8 Secure and controlled software installation on the vessel

.1 The initial installation and subsequent updates of the software components of the system are to be carried out according to a management of change procedure which has

been agreed between the system supplier and the systems integrator. The management of change procedure is to comply with the requirements in 6.7.

.2 The management of change procedure is to be submitted for Category II and III systems, upon request, for information. Cyber security measures are to be incorporated as specified in Sections 7 & 8.

6.4.2.9 Summary of documentation to be submitted

.1 The summary of documentation to be submitted by the system supplier is listed in Table 6.4.2.9

Table 6 4.2.9: Documentation to be submitted by the system supplier

Item		System category		
Clause reference	**Document**	**Cat I**	**Cat II**	**Cat III**
6.4.2.1	Quality plan	-	FI on req.	FI on req.
6.4.2.3	System description	FI on req.	AP	AP
6.4.2.4	Environmental compliance	FI on req.	FI	FI
6.4.2.5	Software test reports	-	FI on req.	FI on req.
6.4.2.6	System test reports	-	FI on req.	FI on req.
6.4.2.7	FAT program	-	AP	AP
6.4.2.7	FAT report	-	FI	FI
6.4.2.7	Additional FAT docs. (e.g., user manual, etc.)	-	FI on req.	FI on req.
6.4.2.8	Management of change procedure	-	FI on req.	FI on req.

Note:

AP: Approval
FI: For Information
"- ": No requirement
On req.: Upon request by IRS

6.4.3 **Requirements for the systems integrator**

For the purpose of this Section, the Shipyard is considered as the 'systems integrator' in the development and delivery phase unless another organization or person is appointed by the Shipyard.

6.4.3.1 Quality plan

.1 The systems integrator is to document that a quality management system is applied for the installation, integration, completion, and maintenance of the systems to be installed on board. All applicable items indicated in 6.4.1.2 (for the systems integrator role) are to be demonstrated to exist and being followed, as relevant.

.2 The quality plan is to be made available during survey (at SAT/ SOST) or upon request, submitted for information, for category II and III systems.

6.4.3.2 Categorization of the system

.1 For each system being delivered to a particular vessel, it is to be decided which category the system falls under based on the failure effects of the system as specified in 6.3. The category for a specific system is to be conveyed to the relevant system supplier. IRS may decide that a risk-assessment is needed to verify the proper system category.

.2 The categorization for the different systems (category I, II and III) is to be documented and submitted for approval, upon request.

6.4.3.3 Risk assessment of the system

.1 When requested by IRS, risk assessment of a specific system in the context of a specific vessel is to be performed and documented in order to determine the applicable category for the system.

Note: Standards such as *IEC/ ISO 31010 "Risk Management – Risk Assessment techniques"* may be applied in order to determine method of risk assessment.

.2 The risk assessment report is to be submitted for approval for Category I, II and III systems, upon request.

6.4.3.4 Vessel's system-architecture

.1 The system of systems (SoS) is to be specified and documented. This architecture specification provides the basis for categorization and development of different integrated systems by allocating functionality to the individual systems and by identifying the main interfaces between the systems. The SoS is also to serve as a basis for the testing of the integrated systems on the vessel level as indicated in 6.4.3.6. The vessel's system architecture, is to at least to contain a description of the following:

- Overview of the total systems architecture (the system of systems)
- Each system's purpose and main functionality
- Communication and interface aspects between different systems

.2 The vessel's system architecture is to be submitted for information, upon request, for category I, II and III systems.

Note: Sec. 7.6.2.1 may be referred for inclusion of security zones and conduits, as applicable, in the architecture diagram.

6.4.3.5 System acceptance test (SAT) onboard the vessel

.1 The main purpose of the system acceptance test (SAT) is to verify the system functionality, after installation and integration with the applicable machinery/electrical/process systems on board including possible interfaces with other control and monitoring systems.

.2 For each test-case it is to be noted if the test passed or failed, and the test-results are to be documented in a test report. The test report is also to contain a list of the software (including software versions) that were installed in the system when the test was executed.

.3 For Category II and III systems, the SAT program is to be submitted for approval before the test is executed. The SAT execution is to be witnessed by the Surveyor and the report is to be submitted for information.

6.4.3.6 Testing of integrated systems (System of systems test - SOST)

.1 Integration tests are to be conducted after installation and integration of the different systems in its final environment on board. The purpose of the tests is to verify the functionality of the complete installation (system of systems) including all interfaces and inter-dependencies in compliance with requirements and specifications.
The testing is to at least verify the following aspects of the system of systems:

- The overall functionality of the interacting systems as a whole
- Failure response between systems
- Performance
- Human-machine interfaces
- Interfaces between the different systems

Note: For complex systems there may be a large difference in scope between the "System acceptance test (SAT) onboard the vessel" activity and the SOST, while for some systems the scope may be overlapping or identical. It is possible to combine the two activities into one when the test scope is similar.

.2 For Category II and III systems, the SOST program is to be submitted for approval before the test is executed. The SOST execution is to be witnessed by the Surveyor and SOST report is to be submitted for information.

6.4.3.7 Change management

.1 The systems integrator is to follow procedures for management of change to the system as indicated in 6.7.

.2 The management of change procedure is to be submitted for information, upon request, for category II and III systems.

6.4.3.8 Summary of documentation to be submitted

.1 The summary of documentation to be submitted by the system integrator is listed in Table 6.4.3.8.

Table 6.4.3.8: Documentation to be submitted by the system integrator

Item		System category		
Clause reference	**Document**	**Cat I**	**Cat II**	**Cat III**
6.4.3.1	Quality plan	-	FI on req.	FI on req.
6.4.3.2	List of system categorizations	AP on req.	AP on req.	AP on req.
6.4.3.3	Risk assessment report	AP on req.	AP on req.	AP on req.
6.4.3.4	Vessel's system architecture	FI on req.	FI on req.	FI on req.
6.4.3.5	SAT program	-	AP	AP
6.4.3.5	SAT report	-	FI	FI
6.4.3.6	SOST program	-	AP	AP
6.4.3.6	SOST report	-	FI	FI
6.4.3.7	Change management procedure for software	-	FI on req.	FI on req.

Note:

AP: Approval
FI: For Information
"- ": No requirement
On req.: Upon request by IRS

6.4.4 Summary of activities

6.4.4.1 The summarized list of activities such as test witnessing and survey related to computer-based systems is given in Table 6.4.4.

Table 6.4.4 : Summary of test witnessing and survey					
Item		**Responsible role**	**System category**		
Clause reference	**Activity**		**Cat I**	**Cat II**	**Cat III**
6.4.2.7	FAT witnessing	System supplier	-	X	X
6.4.3.5	SAT witnessing	System integrator	-	X	X
6.4.3.6	SOST witnessing	System integrator	-	X	X
6.7.12	Verification of changes	System integrator	-	X	X
Note: **"X":** Witnessing required. **"-":** Witnessing Not required					

6.5 Approval of system and components

6.5.1 System certification

6.5.1.1 Computer-based systems that are essential to accomplish vessel functions of category II or category III as defined in 6.3 are to be delivered with a vessel-specific certificate. The objective of the vessel-specific system certification is to confirm that design and manufacturing of the system has been completed and that the system complies with applicable Rules. Vessel-specific system certification consist of two main activities:

- Assessment of vessel-specific documentation indicated in 6.4.2 and 6.7.
- Survey and testing of the system to be delivered to the vessel mentioned in 6.4.2.7.

Alternative Certification Scheme (ACS) may be accepted provided that the requirements are met, and that the system is provided with a vessel-specific certificate.

6.5.2 Type approval of computer-based systems

6.5.2.1 Computer-based systems that are routinely manufactured and include standardized software functions may be type approved in accordance with IRS guidelines on *Certification of Software for Computer Based Control Systems*. Hardware is to be documented according to the requirements indicated in 6.4.2.4.

The type approval consists of two main verification activities:

- Assessment of type-specific documentation
- Survey and testing of the standardized functions

Type approval will normally not exempt vessel specific system certification since vessel-specific functions, parameter configurations and installation elements require vessel specific verification and certification.

6.6 Maintenance of computer-based systems

6.6.1 Requirements for the Vessel Owner

6.6.1.1 Responsibilities

.1 In the context of this Section, the vessel Owner is considered to be the systems integrator in the operations phase unless another organization or person is appointed by the Owner.

.2 IRS is to be informed by the Owner, in a timely manner about the appointed systems integrator, who is responsible for implementing any changes to the systems in conjunction with the system supplier(s).

6.6.2 Requirements for the Systems Integrator

6.6.2.1 Change management

.1 The systems integrator is to ensure that necessary procedures for software and

hardware change management exist on board, and that any software modifications/ upgrades are performed according to the procedure(s) specified in 6.7.

.2 Changes to computer-based systems in the operational phase are to be recorded. The records are to contain information about the relevant software versions and other relevant information as indicated in 6.7.11.

.3 The above would be verified by IRS for Category II and III systems, in accordance with the requirements specified in 6.7.12.

6.6.3 Requirements for the System Supplier

6.6.3.1 Change management

.1 The system supplier is to follow procedures for maintenance of the system including procedures for management of change as specified in 6.7.

.2 The above would be verified by IRS for Category II and III systems, in accordance with the requirements specified in 6.7.12.

6.6.3.2 Testing of changes before installation onboard

.1 The system supplier is to make sure that the planned changes to a system have passed relevant in-house tests before the change is made to systems on board.

.2 The above would be verified by IRS for Category II and III systems, in accordance with the requirements specified in 6.7.12.

6.7 Management of change

6.7.1 General

.1 Requirements for the management of change throughout the lifecycle of a computer-based system are specified in this sub-section. Different procedures for the management of change may be defined for specific phases in a system's lifecycle as the different phases typically involve different stakeholders. Requirements for verification by IRS are specified in 6.7.12.

6.7.2 Documented change management procedures

.1 The organization in question is to have defined and documented change management procedures applicable for the computer-based system in question covering both hardware and software. After FAT, the system supplier is to manage all changes to the system in accordance with the procedure. Examples could be qualification of new versions of acquired software, new hardware, modified control logic, changes to configurable parameters, etc.

.2 The procedure(s) are to at least describe the activities listed in 6.7.3 through 6.7.11. The outcome of the impact analysis in 6.7.8 will determine to what extent the activities in 6.7.3 to 6.7.12 are to be performed. Change records (6.7.11) are always to be produced.

6.7.3 Agreement between relevant stakeholders

.1 The management of change process is to be coordinated and agreed between the relevant stakeholders along the different stages of the lifecycle of the computer-based system.

Note:
Typically, the management of change addresses at least three different stages:

- Development and internal verification before FAT; involving the system supplier and sub-suppliers.
- From FAT to handover of the vessel to the owner; involving the system supplier, the systems integrator, IRS, and the owner.
- In operation; involving the system supplier, service suppliers, the owner, and IRS.

6.7.4 Change Management of Approved Software

.1 If changes are required to a system after it has been approved by applicable stakeholders (typically the systems integrator and IRS at FAT) the modifications are to follow defined change management procedures.

6.7.5 Unique identification of system and software versions

.1 The system supplier is to make sure that each system and software version is uniquely identifiable as indicated in 6.4.2.2.

6.7.6 Handling of software master files

.1 There are to be defined mechanisms for handling of the files that constitute the master-

files for a software component. Personnel authorities are to be clearly defined along with the tools and mechanisms used to ensure the integrity of the master files.

6.7.7 Backup and restoration of onboard software

.1 It is to be clearly defined how to perform backup and restoration of the software components of a computer-based system onboard the vessel.

6.7.8 Impact analysis

.1 Before a change to the system is made, an impact analysis is to be performed in order to:

- Determine the criticality of the change.
- Determine the impact on existing documentation.
- Determine the needed verification and test activities.
- Determine the need to inform other stakeholders about the change.
- Determine the need to obtain approval from other stakeholders (e.g., IRS and or Owner) before the change is made.

6.7.9 Roll-back in case of failed software changes

.1 When maintenance includes installation of new versions of the software in the system, it is to be possible to perform a rollback of the software to the previously installed version with the purpose of returning the system to a known, stable state. Roll-backs are to be documented and analyzed to find and eliminate the root cause.

6.7.10 Verification and validation of system changes

.1 Modifications are to be verified before being installed onboard.

.2 After installation, the modification(s) are to be verified onboard according to a documented verification program containing:

- Verification that the new functionalities and/or improvements have had the intended effect.
- Regression test to verify that the modification has not had any negative effects on functionality or capabilities that was not expected to be affected

6.7.11 Change records

.1 Changes to systems and software are to be documented in change records to allow for visibility and traceability of the changes. The change records are to contain at least the following items:

- The purpose for a change
- A description of the changes and modifications
- The main conclusions from the impact analysis, as in 6.7.8.
- The identity and version of any new system or software version(s), as in 6.7.5.
- Test reports or tests summaries, as in 6.7.10.

.2 Documentation of the changes to software may be recorded in the planned maintenance system (PMS), in a software registry or equivalent.

6.7.12 Verification of change management

6.7.12.1 In operation (vessel in service) phase

.1 The verification regarding the management of change in operation will be generally performed during the annual survey of the vessel. Procedures for management of change and relevant change records, as in 6.7.11 are to be made available at the time of survey for verification by the Surveyor.

.2 In cases where the change requires prior approval of IRS, the relevant procedures and documentation for the subject change may be verified at that time.

6.7.12.2 During new construction

.1 The verification of management of change in the new construction phase is to be divided into two phases; Procedures are to be verified as a part of the verification of the quality management system (6.4.1.2), while project specific implementation of the procedures is to be verified during FAT (6.4.2.7), SAT (6.4.3.5) and SOST (6.4.3.6).

6.8 Technical requirements for computer-based systems

6.8.1. Compliance with the requirements in this sub-section is to be documented in the design documentation, as indicated in 6.4.2.3 and verified through the verification activities as detailed .

6.8.2 Reporting of system and software identification and version

6.8.2.1 System identification

The system is to provide means to identify its name, version, and manufacturer. It is recommended that the system should automatically report the status of its software to a ship software logging system (SSLS) as specified in the international standard ISO 24060.

6.8.3 Data links

6.8.3.1 General Requirements for Category II and III systems

.1 Loss of a data link is to be specifically addressed in risk assessment analysis/ Failure Mode and Effect Analysis (FMEA).

..2 A single failure in data link is not to cause loss of vessel-functions of category III. Any effect of such failure is to comply with the principle of fail-to-safe for the vessel-function(s) being served.

.3 For vessel-functions of category II and III, any loss of functionality in the remote-control system is to be compensated for by local/ manual means.

.4 The data link is to have means to prevent or cope with excessive communication rates..

.5 Data link is to be self-checking, detecting failures on the link itself and data communication failures on nodes connected to the link. Detected failures are to initiate an alarm.

.6 The network cables are to be installed to prevent EMI effects from power cables.

.7 Network cables are to be designed and tested as per National/ International Standards.

.8 Network components are to be suitable for the intended area of operation onboard.

Guidance note: The network devices (Hubs, routers, switches etc.) are to be installed in protective cases unless the ingress protection of the device meets the requirements. The protective cases are to be designed for the ambient environment and ease of operation and maintenance of the device.

6.8.3.2 Specific requirements for wireless data links

.1 Category III systems are not to use wireless data links unless specifically considered by IRS on the basis of an engineering analysis carried out in accordance with an International or National Standard acceptable to IRS.

.2 Other categories of systems may use wireless data links with the following requirements

a) Recognized international wireless communication system protocols are to be employed, incorporating:

- *Message integrity*. Fault prevention, detection, diagnosis, and correction so that the received message is not corrupted or altered when compared to the transmitted message.

- *Configuration and device authentication*. Shall only permit connection of devices that are included in the system design.

- *Message encryption*. Protection of the confidentiality and or criticality of the data content.

- *Security management*. Protection of network assets, prevention of unauthorized access to network assets.

b) The internal wireless system within the vessel is to comply with the radio frequency and power level requirements of International Telecommunication Union and flag state requirements. Consideration should be given to system operation in the event of port state and local regulations that pertain to the use of radio-frequency transmission prohibiting the operation of a wireless data communication link due to frequency and power level restrictions.

c) For wireless data communication equipment, tests during harbour and sea trials are to be conducted to demonstrate that radio-

frequency transmission does not cause failure of any equipment and does not itself-fail as a result of electromagnetic interference during expected operating conditions.

6.8.4 Verification of technical requirements

6.8.4.1 The implementation of the technical requirements specified in 6.8 will be verified as part of documentation review of the system description in 6.4.2.3, by the Surveyor during FAT in 6.4.2.7 and SAT in 6.4.3.5

6.9 Performance Management Systems

6.9.1 The requirements in this sub-section are applicable to vessels, which may be installed with additional sensors, and/ or computer based systems, for performance monitoring and analysis.

6.9.2 A performance management system is a monitoring system for a function that is supplementary or additional to those required by the Rules and, is installed to provide operational or decision support. The support provided by the performance management system may either be guidance or recommendations. Examples of such systems could be fuel optimization, vessel performance monitoring systems, condition monitoring, and similar other systems.

6.9.3 In general, performance management systems are arranged as follows:

a) with dedicated operator stations and servers, in which case the loss of hardware will not affect the functions required to be operable as per Rules; or

b) without dedicated input/ output signals, but utilizing data through interface with communication links.

6.9.4 The hardware and associated software are to meet relevant requirements specified in the Rules.

6.9.5 When the performance management system is integrated with multiple control systems, they are to be arranged to meet the requirements of Integrated Systems (Refer Section 7) and are to have sufficient redundancy and/ or segregation, so as to prevent loss of the control of essential functions upon a single failure.

6.9.6 A failure in a performance management system, including the interfaces and communication network, is not to propagate to the interfaced control, monitoring and safety systems.

6.9.7 Cyber risk is to be evaluated and performance management systems are to be protected against cyber incidents.

6.9.8 Plans for the proposed systems including the effect of loss of such systems when they are interfaced with control, monitoring and safety systems are to be submitted for review.

6.9.9 The scope of approval and certification requirements are to be agreed for each vessel for all such additional systems, including testing at manufacturer works and on-board.

Section 7

Cyber Resilience of Ships

7.1 Scope

7.1.1 This Section provides a minimum set of requirements for cyber resilience of ships.

7.1.2 The requirements in this Section are applicable to the following:

- Passenger ships (including passenger high-speed craft) engaged in international voyages
- Cargo ships of 500 GT and upwards engaged in international voyages
- High speed craft of 500 GT and upwards engaged in international voyages
- Mobile offshore drilling units of 500 GT and upwards
- Self-propelled mobile offshore units engaged in construction (i.e. wind turbine installation maintenance and repair, crane units, drilling tenders, accommodation, etc.)

7.1.3 The requirements in this Section may be used as guidance for the following:

- Ships of war and troopships
- Cargo ships less than 500 GT
- Vessels not propelled by mechanical means
- Wooden ships of primitive build
- Passenger yachts (passengers not more than 12)
- Pleasure yachts not engaged in trade
- Fishing vessels
- Site specific offshore installations (i.e. FPSOs, FSUs, etc.)

7.1.4 Ships and units complying with the requirements in this Section will be assigned additional class notation **CyS-E.**

7.1.5 Minimum requirements for cyber resilience of on-board systems and equipment are specified in Section 8.

7.2 Application

Requirements of this Section are applicable to:

a) Operational Technology (OT) systems onboard ships, i.e. those Computer Based Systems (CBSs) using data to control or monitor physical processes that can be vulnerable to cyber incidents and, if compromised, could lead to dangerous situations for human safety, safety of the vessel and/or threat to the environment.

In particular, the CBSs used for the operation of the following ship functions and systems, if present onboard, are to be considered:

- Propulsion
- Steering
- Anchoring and mooring
- Electrical power generation and distribution
- Fire detection and extinguishing systems
- Bilge and ballast systems, loading computer
- Watertight integrity and flooding detection
- Lighting (e.g. emergency lighting, low locations, navigation lights, etc.)
- Any other safety system(s) whose disruption or functional impairment may pose risks to ship operations (e.g. emergency shutdown system, cargo safety system, pressure vessel safety system, gas detection system, etc.)

In addition, the requirements are also applicable to the following systems:

- Navigational systems required by Statutory Regulations

- Internal and external communication systems required by the Rules and Statutory Regulations

For navigation and radiocommunication systems, the application of IEC 61162-460 or other equivalent standards in lieu of the required security capabilities in section 8.4 may be accepted by IRS, on the condition that requirements in section 6 are complied with.

b) Any Internet Protocol (IP)-based communication interface from CBSs to other systems. Examples of such systems are, including but not limited to, the following:

- passenger or visitor servicing and management systems
- passenger-facing networks
- administrative networks
- crew welfare systems
- any other systems connected to OT systems, either permanently or temporarily (e.g. during maintenance).

The cyber incidents considered in this Section are events resulting from any offensive manoeuvers that target OT systems onboard ships as defined in section 7.4.

7.3 System Category

System categories are defined in Section 6 based on the consequences of a system failure to human safety, safety of the vessel and/or threat to the environment.

7.4. Definitions

7.4.1 Definition and abbreviations (for the purpose of this Section):

Attack Surface: The set of all possible points where an unauthorized user can access a system, cause an effect on or extract data from. The attack surface comprises two categories: digital and physical. The digital attack surface encompasses all the hardware and software that connect to an organization's network. These include applications, code, ports, servers and websites. The physical attack surface comprises all endpoint devices that an attacker can gain physical access to, such as desktop computers, hard drives, laptops, mobile phones, removable drives and carelessly discarded hardware.

Authentication: Provision of assurance that a claimed characteristic of an entity is correct.

Compensating countermeasure: An alternate solution to a countermeasure employed in lieu of or in addition to inherent security capabilities to satisfy one or more security requirements.

Computer Based System (CBS): A programmable electronic device, or interoperable set of programmable electronic devices, organized to achieve one or more specified purposes such as collection, processing, maintenance, use, sharing, dissemination, or disposition of information. CBSs onboard include IT and OT systems. A CBS may be a combination of sub-systems connected via network. Onboard CBSs may be connected directly or via public means of communications (e.g. Internet) to ashore CBSs, other vessels' CBSs and/or other facilities.

Cyber incident: An event resulting from any offensive manoeuver, either intentional or unintentional, that targets or affects one or more CBS onboard, which actually or potentially results in adverse consequences to an onboard system, network and computer or the information that they process, store or transmit, and which may require a response action to mitigate the consequences. Cyber incidents include unauthorized access, misuse, modification, destruction or improper disclosure of the information generated, archived or used in onboard CBS or transported in the networks connecting such systems. Cyber incidents do not include system failures.

Cyber resilience: The capability to reduce the occurrence and mitigating the effects of cyber incidents arising from the disruption or impairment of operational technology (OT) used for the safe operation of a ship, which potentially lead to dangerous situations for human safety, safety of the vessel and/or threat to the environment.

Essential services: Services for propulsion and steering, and safety of the ship. Essential services comprise "Primary Essential Services" and "Secondary Essential Services": Primary Essential Services are those services which need to be in continuous operation to

maintain propulsion and steering; Secondary Essential Services are those services which need not necessarily be in continuous operation to maintain propulsion and steering but which are necessary for maintaining the vessel's safety.

Information Technology (IT): Devices, software and associated networking focusing on the use of data as information, as opposed to Operational Technology (OT).

Integrated system: A system combining a number of interacting sub-systems and/or equipment organized to achieve one or more specified purposes.

Logical network segment: The same as "Network segment", but where two or more logical network segments share the same physical components.

Network: A connection between two or more computers for the purpose of communicating data electronically by means of agreed communication protocols.

Network segment: In the context of this UR, a network segment is an OSI layer-2 Ethernet segment (a broadcast domain).

Note: Network address plan is prefixed by IP addresses and the network mask. Communication between network segments is only possible by the use of routing service at network layer (OSI Layer 3).

Operational Technology (OT): Devices, sensors, software and associated networking that monitor and control onboard systems. Operational technology systems may be thought of as focusing on the use of data to control or monitor physical processes.

Physical network segment: The same as "Network segment", but where physical components are not shared by other network segments.

Protocol: A common set of rules and signals that computers on the network use to communicate. Protocols allow data communication, network management and security. Onboard networks usually implement protocols based on TCP/IP stacks or various fieldbuses.

Security zone: A collection of CBSs in the scope of applicability of this Section that meet the same security requirements. Each zone consists of a single interface or a group of interfaces, to which an access control policy is applied.

Untrusted network: Any network outside the scope of applicability of this Section.

7.4.2 In the context of this Section, the roles and responsibilities of the following are further elaborated as given below:

Shipowner/ Company: The owner of the ship or any other organization or person, such as the manager, agent or bareboat charterer, who has assumed responsibility for operation of the ship from the shipowner and who on assuming such responsibilities has agreed to take over all the attendant duties and responsibilities. The shipowner could be the Shipyard or systems integrator during initial construction. After vessel delivery, the shipowner may delegate some responsibilities to the vessel management company.

Supplier: A manufacturer or provider of hardware and/or software products, system components or equipment (hardware or software) comprising of the application, embedded devices, network devices, host devices etc. working together as system or a subsystem. The supplier is responsible for providing programmable devices, sub-systems or systems to the systems integrator.

Systems Integrator: The specific person or organization responsible for the integration of systems and products provided by suppliers into the system invoked by the requirements in the ship specifications and for providing the integrated system. The systems integrator may also be responsible for integration of systems in the ship. Until vessel delivery, this role is to be performed by the Shipyard unless an alternative organization is specifically contracted/assigned this responsibility.

7.5. Goals and Functional Elements

7.5.1 Primary goal

The primary goal is to support safe and secure shipping, which is operationally resilient to cyber risks. To support safe and secure shipping resilient to cyber risk, the following sub-goals for the management of cyber risk are defined in the five functional elements listed in section 7.5.2 below.

7.5.2 Sub-goals per functional element

.1 *Identify*: Develop an organizational understanding to manage cybersecurity risk to onboard systems, people, assets, data, and capabilities.

.2 *Protect*: Develop and implement appropriate safeguards to protect the ship against cyber incidents and maximize continuity of shipping operations.

.3 *Detect*: Develop and implement appropriate measures to detect and identify the occurrence of a cyber incident onboard.

.4 *Respond*: Develop and implement appropriate measures and activities to take action regarding a detected cyber incident onboard.

.5 *Recover*: Develop and implement appropriate measures and activities to restore any capabilities or services necessary for shipping operations that were impaired due to a cyber incident.

These sub-goals and relevant functional elements are to be concurrent and considered as parts of a single comprehensive risk management framework.

7.5.3 Organization of requirements

The requirements in this Section are organized according to a goal-based approach. Functional/ technical requirements are given for the achievement of specific sub-goals of each functional element (as indicated in 7.5.2). A summary of actions to be carried out and documentation to be made available is also indicated for each phase of the ship's life and relevant stakeholders participating in such phase.

7.6 Requirements

This sub-section contains the requirements to be satisfied in order to achieve the primary goal defined in 7.5.1, organized according to the five functional elements identified in 7.5.2.

The requirements are to be complied with by stakeholders involved in the design, building and operation of the ship. Among them, the following stakeholders are identified (see also section 7.4 for definitions):

- Shipowner/ Company
- Systems integrator
- Supplier
- IRS

Whilst the above requirements may be fulfilled by any of these stakeholders, for the purposes of this Section, responsibility to fulfil them will lie with the stakeholder who has contracted with IRS.

7.6.1 Identify

The requirements for the 'Identify' functional element are aimed at identifying on one side, the CBSs onboard, their interdependencies and the relevant information flows; on the other side, the key resources involved in their management, operation and governance, their roles, and responsibilities.

7.6.1.1 Vessel asset inventory

.1 Requirement

An inventory of hardware and software (including application programs, operating systems, if any, firmware and other software components) of the CBSs in the scope of applicability of this Section and of the networks connecting such systems to each other and to other CBSs onboard or ashore are to be provided and kept up to date during the entire life of the ship.

.2 Requirement details

The vessel asset inventory is to include at least the CBSs indicated in section 7.2, if present onboard.

The inventory is to be kept updated during the entire life of the ship. Software and hardware modifications potentially introducing new vulnerabilities or modifying functional dependencies or connections among systems are to be recorded in the inventory.

If confidential information is included in the inventory (e.g. IP addresses, protocols, port numbers), special measures are to be adopted to limit access to such information only to authorized people.

a) Hardware

For all hardware devices in the scope of applicability of this Section, the vessel asset

inventory is to include at least the information in section 8.3.1.1. In addition, the vessel asset inventory may specify system category and security zone associated with the CBS.

b) Software

For all software in the scope of applicability of this Section (e.g., application program, operating system, firmware), the vessel asset inventory is to include at least the information in section 8.3.1.1.

The software of the CBSs in the scope of applicability of this Section is to be maintained and updated in accordance with the shipowner's process for management of software maintenance and update policy in the Ship cyber security and resilience program.

.3 Demonstration of compliance

a) Design phase

The systems integrator is to submit vessel asset inventory to IRS (ref. section 7.7.1.3).

The vessel asset inventory is to incorporate the asset inventories of all individual CBSs falling under the scope of this Section. Any equipment in the scope of this Section delivered by the systems integrator is also to be included in the vessel asset inventory.

b) Construction phase

The systems integrator is to keep the vessel asset inventory updated.

c) Commissioning phase

The systems integrator is to submit Ship cyber resilience test procedure (ref. section 7.7.2.1) and demonstrate to IRS that:

- Vessel asset inventory is updated and completed at delivery
- CBSs in the scope of applicability of this Section are correctly represented in the vessel asset inventory
- Software of the CBSs in the scope of applicability of this Section have been kept updated, e.g. by vulnerability scanning or by checking the software versions of CBSs while switched on.

d) Operation phase

The shipowner is to (in the Ship cyber security and resilience program) describe the process of management of change (MoC) for the CBSs in the scope of applicability of this Section, addressing at least the following requirements:

- Management of change (section 7.7.2.3)
- Hardware and software modifications (section 7.6.1.1.2)

The shipowner is to (in the Ship cyber security and resilience program) also describe the management of software updates, addressing at least the following requirements:

- Vulnerabilities and cyber risks (section 7.6.1.1.2)
- Security patching (section 7.6.2.6.2 a))

Other requirements for periodical surveys are indicated in Part 1, Chapter 2, Section 25 of the Rules.

7.6.2 Protect

The requirements for the ‘Protect’ functional element are aimed at the development and implementation of appropriate safeguards supporting the ability to limit or contain the impact of a potential incident.

7.6.2.1 Security Zones and Network Segmentation

.1 Requirement

All CBSs in the scope of applicability of this Section are to be grouped into security zones with well-defined security policies and security capabilities. Security zones are either to be isolated (i.e. air gapped) or connected to other security zones or networks by means providing control of data communicated between the zones (e.g. firewalls/routers, simplex serial links, TCP/IP diodes, dry contacts, etc.)

Only explicitly allowed traffic is to traverse a security zone boundary.

.2 Requirement details

A security zone may contain multiple CBSs and networks, all of which are to comply with applicable security requirements given in this Section and Section 8.

The network(s) of a security zone are to be logically or physically segmented from other zones or networks. See also 7.6.2.6.2.

CBSs providing required safety functions are to be grouped into separate security zones and are to be physically segmented from other security zones.

Navigational and communication systems are not to be in same security zone as machinery or cargo systems. If navigation and/or radiocommunication systems are approved in accordance with other equivalent standard(s) (see section 7.2), these systems should be in a dedicated security zone.

Wireless devices are to be in dedicated security zones. See also 7.6.2.5.

Systems, networks or CBSs outside the scope of applicability of this Section are considered untrusted networks and are to be physically segmented from security zones required by this Section. Alternatively, it is accepted that such systems are part of a security zone if these OT-systems meet the same requirements as demanded by the zone.

It is to be possible to isolate a security zone without affecting the primary functionality of the CBSs in the zone, see also section 7.6.4.3.

.3 Demonstration of compliance

a) Design phase

The systems integrator is to submit Zones and conduit diagram and the Cyber security design description (see 7.7.1.1 and 7.7.1.2).

The Zones and conduit diagram is to illustrate the CBSs in the scope of applicability of this Section, how they are grouped into security zones, and include the following information:

- Clear indication of the security zones
- Simplified illustration of each CBS in scope of applicability of this Section, and indication of the security zone in which the CBS is allocated, and indication of physical location of the CBS/equipment.
- Reference to the approved version of the CBS system topology diagrams provided by the suppliers (section 8.3.1.2)
- Illustration of network communication between systems in a security zone
- Illustration of any network communication between systems in different security zones (conduits).
- Illustration of any communication between systems in a security zone and untrusted networks (conduits).

The systems integrator is to include the following information in the Cyber security design description:

- A short description of the CBSs allocated to the security zone. It is to be possible to identify each CBS in the Zones and conduit diagram.
- Network communication between CBSs in the same security zone. The description is to include the purpose and characteristics (i.e. protocols and data flows) of the communication.
- Network communication between CBSs in different security zones. The description is to include the purpose and characteristics (i.e. protocols and data flows) of the communication. The description is also to include zone boundary devices and specify the traffic that is permitted to traverse the zone boundary (e.g. firewall rules).
- Any communication between CBSs in security zones and untrusted networks. The description is to include discrete signals, serial communication, and the purpose and characteristics (i.e. protocols and data flows) of IP-based network communication. The description is also to include zone boundary devices and specify the traffic that is permitted to traverse the zone boundary (e.g. firewall rules).

b) Construction phase

The systems integrator is to keep the Zones and conduit diagram updated.

c) Commissioning phase

The systems integrator is to submit Ship cyber resilience test procedure (ref. section 7.7.2.1) and demonstrate to IRS that:

- the security zones on board are implemented in accordance with the approved documents (i.e. zones and conduit diagram, cyber security design description, asset inventory, and relevant documents provided by the supplier). This may be done by e.g., inspection of the physical installation, network scanning and/or other methods providing the Surveyor assurance that the installed equipment is grouped in security zones according to the approved design.

- security zone boundaries allow only the traffic that has been documented in the approved Cyber security description. This may be done by e.g., evaluation of firewall rules or port scanning.

d) Operation phase

The shipowner is to (in the Ship cyber security and resilience program) describe the management of security zone boundary devices (e.g., firewalls), addressing at least the following requirements:

- Principle of Least Functionality (section 7.6.2.2.1)

- Explicitly allowed traffic (section 7.6.2.1.1)

- Protection against denial of service (DoS) events (section 7.6.2.2.1)

- Inspection of security audit records (section 7.6.3.1.2)

Other requirements for periodical surveys are indicated in Part 1, Chapter 2, Section 25 of the Rules.

7.6.2.2 Network protection safeguards

.1 Requirements

Security zones are to be protected by firewalls or equivalent means as specified in section 7.6.2.1.

The networks are also to be protected against the occurrence of excessive data flow rate and other events which could impair the quality of service of network resources.

The CBSs in scope of this Section are to be implemented in accordance with the principle of Least Functionality, i.e. configured to provide only essential capabilities and to prohibit or restrict the use of non-essential functions, where unnecessary functions, ports, protocols and services are disabled or otherwise prohibited.

.2 Requirement details

The design of the network is to include means to meet the intended data flow through the network and minimize the risk of denial of service (DoS) and network storm/high rate of traffic. Estimation of data flow rate is to at least consider the capacity of network, data speed requirement for intended application and data format.

.3 Demonstration of compliance

a) Commissioning phase

The systems integrator is to submit Ship cyber resilience test procedure (ref. section 7.7.2.1) and demonstrate the following to IRS:

- Test denial of service (DoS) attacks targeting zone boundary protection devices, as applicable.

- Test denial of service (DoS) to ensure protection against excessive data flow rate, originating from inside each network segment. Such denial of service (DoS) tests are to cover flooding of network (i.e., attempt to consume the available capacity on the network segment), and application layer attack (i.e., attempt to consume the processing capacity of selected endpoints in the network)

- Test e.g. by analytic evaluation and port scanning that unnecessary functions, ports, protocols and services in the CBSs have been removed or prohibited in accordance with hardening guidelines provided by the suppliers. See section 8.5.7 and 8.6.3.4.7.

The second and third tests may be omitted if performed during the certification of CBSs in accordance with section 7.7.2.1.

b) Operation phase

Requirements for periodical surveys are indicated in Part 1, Chapter 2, Section 25 of the Rules.

7.6.2.3 Antivirus, antimalware, antispam and other protections from malicious code

.1 Requirements

CBSs in the scope of applicability of this Section are to be protected against malicious code such as viruses, worms, trojan horses, spyware, etc.

.2 Requirement details

Malware protection is to be implemented on CBSs in the scope of applicability of this Section. On CBSs having an operating system for which industrial-standard anti-virus and anti-malware software is available and maintained up-to-date, anti-virus and/or anti-malware software are to be installed, maintained and regularly updated, unless the installation of such software impairs the ability of CBS to provide the functionality and level of service required (e.g. for Cat.II and Cat.III CBSs performing real-time tasks).
On CBSs where anti-virus and anti-malware software cannot be installed, malware protection is to be implemented in the form of operational procedures, physical safeguards, or according to manufacturer's recommendations.

.3 Demonstration of compliance

a) Design phase

The systems integrator is to include the following information in the Cyber security design description:

- For each CBS, summary of the approved mechanisms provided by the supplier for protection against malicious code or unauthorized software.

- For CBSs with anti-malware software, information about how to keep the software updated.

- Any operational conditions or necessary physical safeguards to be implemented in the shipowner's management system.

b) Construction phase

The systems integrator is to ensure that malware protection is kept updated during the construction phase.

c) Commissioning phase

The systems integrator is to submit Ship cyber resilience test procedure (ref. section 7.7.2.1) and demonstrate the following to IRS:

Approved anti-malware software or other compensating countermeasures are effective (test e.g., with a trustworthy anti-malware test file).

The above tests may be omitted if performed during the certification of CBSs in accordance with section 7.7.2.1.

d) Operation phase

The shipowner is to (in the Ship cyber security and resilience program) describe the management of malware protection, addressing at least the following requirements:

- Maintenance/update (section 7.6.2.3.2)

- Operational procedures, physical safeguards (section 7.6.2.3.2)

- Use of mobile, portable, removable media (section 7.6.2.4.2.4 and 7.6.2.7.2)

- Access control (section 7.6.2.4)

Other requirements for periodical surveys are indicated in Part 1, Chapter 2, Section 25 of the Rules.

7.6.2.4 Access control

.1 Requirements

CBSs and networks in the scope of applicability of this Section are to provide physical and/ or logical/ digital measures to selectively limit the ability and means to communicate with or otherwise interact with the system itself, to use system resources to handle information, to gain knowledge of the information the system contains or to control system components and functions. Such measures are to be such as not to hamper the ability of authorized personnel to access CBS for their level of access according to the least privilege principle.

.2 Requirement details

Access to CBSs and networks in the scope of applicability of this Section and all information stored on such systems is only to be allowed to authorized personnel, based on their need to access the information as a part of their responsibilities or their intended functionality.

.1 Physical access control

CBSs of Cat.II and Cat.III are to generally be located in rooms that can normally be locked or in controlled space to prevent unauthorized access or are to be installed in lockable cabinets or consoles. Such locations or lockable cabinets/ consoles are to be however easy to access for the crew and various stakeholders who need to access CBSs for installation, integration, operation, maintenance, repair, replacement, disposal etc. so as not to hamper effective and efficient operation of the ship.

.2 Physical access control for visitors

Visitors such as authorities, technicians, agents, port and terminal officials, and shipowner representatives are to be restricted regarding access to CBSs onboard whilst on board, e.g. by allowing access under supervision.

.3 Physical access control of network access points

Access points to onboard networks connecting Cat.II and/or Cat.III CBSs are to be physically and/or logically blocked except when connection occurs under supervision or according to documented procedures, e.g. for maintenance.

Independent computers isolated from all onboard networks, or other networks, such as dedicated guest access networks, or networks dedicated to passenger recreational activities, are to be used in case of occasional connection requested by a visitor (e.g. for printing documents).

.4 Removable media controls

A policy for the use of removable media devices is to be established, with procedures to check removable media for malware and/or validate legitimate software by digital signatures and watermarks and scan prior to permitting the uploading of files onto a ship's system or downloading data from the ship's system. See also 7.6.2.7.

.5 Management of credentials

CBSs and relevant information are to be protected with file system, network, application, or database specific Access Control Lists (ACL). Accounts for onboard and onshore personnel are to be left active only for a limited period according to the role and responsibility of the account holder and are to be removed when no longer needed.

Note: CBSs are to identify and authenticate human users as per item No.1 in Table 8.4.1 of Section 8. In other words, it is not necessary to "uniquely" identify and authenticate all human users.

Onboard CBSs are to be provided with appropriate access control that complies with the policy of their Security Zone but does not adversely affect their primary purpose. CBSs which require strong access control may need to be secured using a strong encryption key or multi-factor authentication.

Administrator privileges are to be managed in accordance with the policy for access control, allowing only authorized and appropriately trained personnel full access to the CBS, who as part of their role in the company or onboard need to log on to systems using these privileges.

.6 Least privilege principle

Any human user allowed to access CBS and networks in the scope of applicability of this Section is to have only the bare minimum privileges necessary to perform its function.

The default configuration for all new account privileges is to be set as low as possible. Wherever possible, raised privileges are to be restricted only to moments when they are needed, e.g. using only expiring privileges and one-time-use credentials. Accumulation of privileges over time are to be avoided, e.g. by regular auditing of user accounts.

7.6.2.4.3 Demonstration of compliance

a) Design phase

The systems integrator is to include the following information in the Cyber security design description:

- Location and physical access controls for the CBSs. Devices providing Human Machine Interface (HMI) for operators needing immediate access need not enforce user identification and authentication provided they are located in an area with physical access control. Such devices are to be specified.

b) Construction phase

The systems integrator is to prevent unauthorized access to the CBSs during the construction phase.

c) Commissioning phase

The systems integrator is to submit Ship cyber resilience test procedure (ref. section 7.7.2.1) and demonstrate the following to IRS:

- Components of the CBSs are located in areas or enclosures where physical access can be controlled to authorized personnel.

- User accounts are configured according to the principles of segregation of duties and least privilege and that temporary accounts have been removed (may be omitted based on certification of CBSs in accordance with section 7.7.2.1)

d) Operation phase

The shipowner is to (in the Ship cyber security and resilience program) describe the management of logical and physical access, addressing at least the following requirements:

- Physical access control (section 7.6.2.4.2.1)

- Physical access control for visitors (section 7.6.2.4.2.2)

- Physical access control of network access points (section 7.6.2.4.2.3)

- Management of credentials (section 7.6.2.4.2.5)

- Least privilege policy (section 7.6.2.4.2.6)

The shipowner is also to (in the Ship cyber security and resilience program) describe the management of confidential information, addressing at least the following requirements:

- Confidential information (see section 7.6.1.1.2)

- Information allowed to authorized personnel (see section 7.6.2.4.2)

- Information transmitted on the wireless network (see section 7.6.2.5.2)

Other requirements for periodical surveys are indicated in Part 1, Chapter 2, Section 25 of the Rules.

7.6.2.5 Wireless communication

.1 Requirements

Wireless communication networks in the scope of this Section are to be designed, implemented and maintained to ensure that:

- Cyber incidents will not propagate to other control systems

- Only authorized human users will gain access to the wireless network

- Only authorized processes and devices will be allowed to communicate on the wireless network

- Information in transit on the wireless network cannot be manipulated or disclosed

.2 Requirement details

Cryptographic mechanisms such as encryption algorithms and key lengths in accordance with industry standards and best practices are to be applied to ensure integrity and confidentiality of the information transmitted on the wireless network.

Devices on the wireless network are to only communicate on the wireless network (i.e. they are not to be “dual-homed”)

Wireless networks are to be designed as separate segments in accordance with 7.6.2.1 and protected as per 7.6.2.2.

Wireless access points and other devices in the network are to be installed and configured such that access to the network can be controlled.

The network device or system utilizing wireless communication is to provide capability to identify and authenticate all users (humans, software processes or devices) engaged in that communication.

7.6.2.5.3 Demonstration of compliance

a) Design phase

The systems integrator is to include the following information in the Cyber security design description:

- Description of wireless networks in the scope of applicability of this Section and how these are implemented as separate security zones.
- The description is to include zone boundary devices and specify the traffic that is permitted to traverse the zone boundary (e.g. firewall rules)

b) Construction phase

The systems integrator is to prevent unauthorized access to the wireless networks during the construction phase.

c) Commissioning phase

The systems integrator is to submit Ship cyber resilience test procedure (ref. section 7.7.2.1) and demonstrate the following to IRS:

- Only authorized devices can access the wireless network.
- Secure wireless communication protocol is used as per approved documentation by the respective supplier (demonstrate e.g. by use of a network protocol analyzer tool).

The above tests may be omitted if performed during the certification of CBSs as per section 7.7.2.1.

d) Operation phase

Requirements for periodical surveys are covered in Part 1, Chapter 2 of the Rules.

7.6.2.6 Remote access control and communication with untrusted networks

.1 Requirements

CBSs in scope of this Section are to be protected against unauthorized access and other cyber threats from untrusted networks.

.2 Requirement details

User manual is to be submitted for control of remote access to onboard IT and OT systems. Clear guidelines are to identify roles and permissions with functions.

For CBSs in the scope of applicability of this Section, no IP address is to be exposed to untrusted networks.

Communication with or via untrusted networks requires secure connections (e.g. tunnels) with endpoint authentication, protection of integrity and authentication and encryption at network or transport layer. Confidentiality is to be ensured for information that is subject to read authorization.

a) Design phase

CBSs in the scope of applicability of this Section are to:

- have the capability to terminate a connection from the onboard connection endpoint. Any remote access is not to be possible until explicitly accepted by a responsible role on board.
- be capable of managing interruptions during remote sessions so as not to compromise the safe functionality of OT systems or the integrity and availability of data used by OT systems.

- provide a logging function to record all remote access events and retain for a period of time sufficient for offline review of remote connections, e.g. after detection of a cyber incident.

b) Additional requirements for remote maintenance

When remote access is used for maintenance, the following requirements are to be complied with in addition to those in 7.6.2.6.2 a):

- Documentation is to be provided to show how they connect and integrate with the shore side.

- Security patches and software updates are to be tested and evaluated before they are installed to ensure they are effective and do not result in side effects or cyber events that cannot be tolerated. A confirmation report from the software supplier towards above is to be obtained, prior to undertaking remote update.

- Suppliers are to provide plans for and make security updates available to the shipowner, see Sections 8.5.2, 8.5.3 and 8.5.4.

- At any time, during remote maintenance activities, authorized personnel are to have the possibility to interrupt and abort the activity and roll back to a previous safe configuration of the CBS and systems involved.

- Multi-factor authentication is required for any access by human users to CBS's in scope from an untrusted network.

- After a configurable number of failed remote access attempts, the next attempt is to be blocked for a predetermined length of time.

- If the connection to the remote maintenance location is disrupted for some reason, access to the system is to be terminated by an automatic logout function.

7.6.2.6.3 Demonstration of compliance

a) Design phase

The systems integrator is to include the following information in the Cyber security design description:

- Identification of each CBS in the scope of applicability of this Section that can be remotely accessed or that otherwise communicates through the security zone boundary with untrusted networks.

- For each CBS, a description of compliance with requirements in 7.9.6.2, as applicable

b) Construction phase

The systems integrator is to ensure that any communication with untrusted networks is only temporarily enabled and used in accordance with the requirements of this section.

c) Commissioning phase

The systems integrator is to submit Ship cyber resilience test procedure (ref. section 7.7.2.1) and demonstrate the following to IRS:

- Communication with untrusted networks is secured in accordance with 8.4.2 and that the communication protocols cannot be negotiated to a less secure version (demonstrate e.g., by use of a network protocol analyzer tool).

- Remote access requires multifactor authentication of the remote user.

- A limit of unsuccessful login attempts is implemented, and that a notification message is provided for the remote user before session is established.

- Remote connections must be explicitly accepted by responsible personnel on board.

- Remote sessions can be manually terminated by personnel on board or that the session will automatically terminate after a period of inactivity.

- Remote sessions are logged (see section 8.4.1 item 13).

- Instructions or procedures are provided by the respective product suppliers (see section 8.3.1.3).

d) Operation phase

The shipowner is to describe the management of remote access and communication with/via untrusted networks, in the Ship cyber security and resilience program addressing at least the following requirements:

- User's manual (section 7.6.2.6.2)
- Roles and permissions (section 7.6.2.6.2)
- Patches and updates (section 7.6.2.6.2 b))
- Confirmation prior to undertaking remote software update (section 7.6.2.6.2 b))
- Interrupt, abort, roll back (section 7.6.2.6.2 b))

Other requirements for periodical surveys are indicated in Part 1, Chapter 2, Section 25 of the Rules.

7.6.2.7 Use of Mobile and Portable Devices

.1 Requirements

The use of mobile and portable devices in CBSs in the scope of applicability of this Section are to be limited to only necessary activities and be controlled in accordance with section 8.4.1 item 10. For any CBS that cannot fully meet these requirements, the interface ports are to be physically blocked.

.2 Requirement details

Mobile and portable devices are to only be used by authorized personnel. Only authorized devices may be connected to the CBSs. All use of such devices is to be in accordance with the shipowner's policy for use of mobile and portable devices, taking into account the risk of introducing malware in the CBS.

7.6.2.7.3 Demonstration of compliance

a) Design phase

The systems integrator is to include the following information in the Cyber security design description:

- Any CBSs in the scope of applicability that do not meet the requirements in section 8.4.1 item 10, are to have protection of interface ports by physical means such as port blockers.

b) Construction phase

The systems integrator is to ensure that use of physical interface ports in the CBSs is controlled in accordance with section 8.4.1 item 10, and that any use of such devices follows procedures to prevent malware from being introduced in the CBS.

c) Commissioning phase

The systems integrator is to submit Ship cyber resilience test procedure (ref. section 7.7.2.1) and demonstrate to IRS that capabilities to control use of mobile and portable devices are implemented correctly. The following countermeasures are to be demonstrated as relevant:

- Use of mobile and portable devices is restricted to authorized users
- Interface ports can only be used by specific device types
- Files cannot be transferred to the system from such devices
- Files on such devices will not be automatically executed (by disabling autorun)
- Network access is limited to specific MAC or IP addresses
- Unused interface ports are disabled
- Unused interface ports are physically blocked

d) Operation phase

The shipowner is to describe the management of mobile and portable devices, in the Ship cyber security and resilience program addressing at least the following requirements:

- Policy and procedures (section 7.6.2.4.2.4)
- Physical block of interface ports (section 7.6.2.7.1)
- Use by authorized personnel (section 7.6.2.7.2)

- Connect only authorized devices (section 7.6.2.7.2)

- Consider risk of introducing malware (section 7.6.2.7.2)

Other requirements for periodical surveys are indicated in Part 1, Chapter 2, Section 25 of the Rules.

7.6.3 Detect

The requirements for the Detect functional element are aimed at the development and implementation of appropriate means supporting the ability to reveal and recognize anomalous activity on CBSs and networks onboard and identify cyber incidents.

7.6.3.1 Network operation monitoring

.1 Requirements

Networks in scope of this Section are to be continuously monitored, and alarms are to be generated if malfunctions or reduced/degraded capacity occurs.

.2 Requirement details

Measures to monitor networks in the scope of applicability of this Section are to have the following capabilities:

- Monitoring and protection against excessive traffic

- Monitoring of network connections

- Monitoring and recording of device management activities

- Protection against connection of unauthorized devices

- Generate alarm if utilization of the network's bandwidth exceeds a threshold specified as abnormal by the supplier. See section 6.8.3.1.

Intrusion detection systems (IDS) may be implemented, subject to the following:

- The IDS are to be qualified by the supplier of the respective CBS

- The IDS are to be passive and not activate protection functions that may affect the performance of the CBS

- Relevant personnel should be trained and qualified for using the IDS

7.6.3.1.3 Demonstration of compliance

a) Commissioning phase

The systems integrator is to specify in the Ship cyber resilience test procedure and demonstrate to IRS the network monitoring and protection mechanisms in the CBSs.

- Test that disconnected network connections will activate alarm and that the event is recorded.

- Test that abnormally high network traffic is detected, and that alarm and audit record is generated. This test may be carried on together with the test in section 7.6.4.4.3 b).

- Demonstrate that the CBS will respond in a safe manner to network storm scenarios, considering both unicast and broadcast messages (see also 7.6.4.2.3)

- Demonstrate generation of audit records (logging of security-related events)

- If Intrusion detection systems are implemented, demonstrate that this is passive and will not activate protection functions that may affect intended operation of the CBSs.

The above tests may be omitted if performed during the certification of CBSs as per section 7.7.2.1.

Any Intrusion detection systems in the CBSs in scope of applicability to be implemented will be subject to verification by IRS. Relevant documentation is to be submitted for approval, and survey/tests are to be carried out on board.

b) Operation phase

The shipowner is to describe the management activities to detect anomalies in the CBSs and networks, in the Ship cyber security and resilience program addressing at least the following requirements:

- Reveal and recognize anomalous activity (section 7.6.3)

- Inspection of security audit records (section 7.6.3.1.2)

- Instructions or procedures to detect incidents (section 7.6.4.1.1)

The above activities may be addressed together with incident response in section 7.6.4.1.

Other requirements for periodical surveys are indicated in Part 1, Chapter 2, Section 25 of the Rules.

7.6.3.2 Verification and diagnostic functions of CBS and networks

.1 Requirements

CBSs and networks in the scope of applicability of this Section are to be capable of checking performance and functionality of security functions required by this Section. Diagnostic functions are to provide adequate information on CBSs integrity and status for the use of the intended user and means for maintaining their functionality for a safe operation of the ship.

.2 Requirement details

CBSs and networks' diagnostics functionality are to be available to verify the intended operation of all required security functions during test and maintenance phases of the ship.

7.6.3.2.3 Demonstration of compliance

a) Commissioning phase

The systems integrator is to submit Ship cyber resilience test procedure (ref. section 7.7.2.1) and demonstrate to IRS the effectiveness of the procedures for verification of security functions provided by the suppliers.

The above tests may be omitted if performed during the certification of CBSs as per section 7.7.2.1.

b) Operation phase

The shipowner is to describe the management activities to verify correct operation of the security functions in the CBSs and networks, in the Ship cyber security and resilience program, addressing at least the following requirements:

- Test and maintenance periods (section 7.6.3.2.2)

- Periodic maintenance

Other requirements for periodical surveys are indicated in Part 1, Chapter 2, Section 25 of the Rules.

7.6.4 Respond

The requirements for the Respond functional element are aimed at the development and implementation of appropriate means supporting the ability to minimize the impact of cyber incidents, containing the extension of possible impairment of CBSs and networks onboard.

7.6.4.1 Incident response plan

.1 Requirements

An incident response plan is to be developed by the shipowner covering relevant contingencies and specifying how to react to cyber security incidents. The Incident response plan is to contain documentation of a predetermined set of instructions or procedures to detect, respond to, and limit consequences of incidents against CBSs in the scope of applicability of this Section.

.2 Requirement details

The various stakeholders involved in the design and construction phases of the ship are to provide information to the shipowner for the preparation of the Incident Response Plan to be placed onboard at the first annual Survey. The Incident Response Plan is to be kept up-to-date (e.g. upon maintenance) during the operational life of the ship.

The Incident response plan is to provide procedures to respond to detected cyber incidents on networks by notifying the proper authority, reporting needed evidence of the incidents and taking timely corrective actions, to limit the cyber incident impact to the network segment of origin.

The incident response plan is to, as a minimum, include the following information:

- Breakpoints for the isolation of compromised systems

- A description of alarms and indicators signalling detected ongoing cyber

events or abnormal symptoms caused by cyber events

- A description of expected major consequences related to cyber incidents

- Response options, prioritizing those which do not rely on either shut down or transfer to independent or local control, if any

- Independent and local control information for operating independently from the system that failed due to the cyber incident, as applicable

The incident response plan is to be kept in hard copy in the event of complete loss of electronic devices enabling access to it.

7.6.4.1.3 Demonstration of compliance

a) Design phase

The systems integrator is to include the following information in the cyber security design description:

- References to information provided by the suppliers (see section 8.3.1.8) that may be applied by the shipowner to establish plans for incident response.

b) Operation phase

The shipowner is to describe incident response plans to in the Ship cyber security and resilience program. The plans are to cover the CBSs in scope of applicability of this Section and are to address at least the following requirements:

- Description of who, when and how to respond to cyber incidents in accordance with requirements of section 7.6.4.1

- Procedures or instructions for local/manual control in accordance with requirements in section 7.6.4.2

- Procedures or instructions for isolation of security zones in accordance with requirements in section 7.6.4.3

- Description of expected behaviour of the CBSs in the event of cyber incidents in accordance with requirements in section 7.6.4.4.

Other requirements for periodical surveys are indicated in Part 1, Chapter 2, Section 25 of the Rules.

7.6.4.2 Local, independent and/or manual operation

.1 Requirements

Any CBS needed for local backup control as required by SOLAS II-1 Regulation 31 are to be independent of the primary control system. This also includes the necessary Human Machine Interface (HMI) for effective local operation.

.2 Requirement details

The CBS for local control and monitoring are to be self-contained and not depend on communication with other CBS for its intended operation.

If communication to the remote-control system or other CBS's is arranged by networks, segmentation and protection safeguards as described in 7.6.2.1 and 7.6.2.2 are to be implemented. This implies that the local control and monitoring system is to be considered a separate security zone. Notwithstanding the above, special considerations can be given to CBSs with different concepts on case-by-case basis

The CBS for local control and monitoring are to otherwise comply with requirements in this Section.

7.6.4.2.3 Demonstration of compliance

a) Design phase

The systems integrator is to include the following information in the Cyber security design description:

- Description of how the local controls specified in SOLAS II-1 Reg.31 are protected from cyber incidents in any connected remote or automatic control systems.

b) Commissioning phase

The systems integrator is to submit Ship cyber resilience test procedure (ref. section 7.7.2.1)

and demonstrate to IRS that the required local controls in the scope of applicability of this Section needed for safety of the ship can be operated independently of any remote or automatic control systems. The tests are to be carried out by disconnecting all networks from the local control system to other systems/devices.

The above tests may be omitted if performed during the certification of CBSs as per section 7.7.2.1.

c) Operation phase

Requirements for periodical surveys are indicated in Part 1, Chapter 2, Section 25 of the Rules.

7.6.4.3 Network isolation

.1 Requirements

It is to be possible to terminate network-based communication to or from a security zone.

.2 Requirement details

Where the Incident Response Plan indicates network isolation as an action to be carried out, it is to be possible to isolate security zones according to the indicated procedure, e.g. by operating a physical On/Off switch on the network device or similar actions such as disconnecting a cable to the router/firewall. There are to be available instructions and clear marking on the device that allows the personnel to isolate the network in an efficient manner.

Individual system's data dependencies that may affect function and correct operation, including safety, are to be identified, clearly showing where systems must have compensations for data or functional inputs if isolated during a contingency.

7.6.4.3.3 Demonstration of compliance

a) Design phase

The systems integrator is to include the following information in the Cyber security design description:

- specification of how to isolate each security zone from other zones or networks. The effects of such isolation are also to be described, demonstrating that the CBSs in a security zone do not rely on data transmitted by IP-networks from other zones or networks.

b) Commissioning phase

The systems integrator is to submit Ship cyber resilience test procedure (ref. section 7.7.2.1) and demonstrate to IRS by disconnecting all networks traversing security zone boundaries, that the CBSs in the security zone will maintain adequate operational functionality without network communication with other security zones or networks.

The above tests may be omitted if performed during the certification of CBSs as per section 7.7.2.1.

c) Operation phase

Requirements for periodical surveys are indicated in Part 1, Chapter 2, Section 25 of the Rules.

7.6.4.4 Fallback to a minimal risk condition

.1 Requirements

In the event of a cyber incident impairing the ability of a CBS or network in the scope of applicability of this Section to provide its intended service, the affected system or network is to fall back to a minimal risk condition, i.e. bring itself in a stable, stopped condition to reduce the risk of possible safety issues.

.2 Requirement details

As soon as a cyber incident affecting the CBS or network is detected, compromising the system's ability to provide the intended service as required, the system is to fall back to a condition in which a reasonably safe state can be achieved. Fall-back actions may include:

- bringing the system to a complete stop or other safe state;
- disengaging the system;
- transferring control to another system or human operator;
- other compensating actions.

Fall-back to minimum risk conditions is to occur in a time frame adequate to keep the ship in a safe condition.

The ability of a system to fall back to a minimal risk condition is to be considered from the design phase by the supplier and the systems integrator.

7.6.4.4.3 Demonstration of compliance

a) Design phase

The systems integrator is to include the following information in the Cyber security design description:

- Specification of safe state for the control functions in the CBSs in the scope of applicability of this Section.

b) Commissioning phase

The systems integrator is to submit Ship cyber resilience test procedure (ref. section 7.7.2.1) and demonstrate to IRS that CBSs in the scope of applicability of this section respond to cyber incidents in a safe manner (as per section 7.6.4.4.3 a), e.g. by maintaining its outputs to essential services and allowing operators to carry out control and monitoring functions by alternative means. The tests are to at least include denial of service (DoS) attacks and may be done together with related test in section 7.6.3.1.3 a).

The above tests may be omitted if performed during the certification of CBSs as per section 7.7.2.1.

c) Operation phase

Requirements for periodical surveys are indicated in Part 1, Chapter 2, Section 25 of the Rules.

7.6.5 Recover

The requirements for the Recover functional element are aimed at the development and implementation of appropriate means supporting the ability to restore CBSs and networks onboard affected by cyber incidents.

7.6.5.1 Recovery plan

.1 Requirements

A recovery plan is to be made by the shipowner to support restoring CBSs under the scope of applicability of this Section to an operational state after a disruption or failure caused by a cyber incident. Details of where assistance is available and by whom are to be part of the recovery plan.

.2 Requirement details

The various stakeholders involved in the design and construction phases of the ship are to provide information to the ship owner for the preparation of the recovery plan to be placed onboard at the first annual Survey. The recovery plan is to be kept up-to-date (e.g. upon maintenance) during the operational life of the ship.

Recovery plans are to be easily understandable by the crew and external personnel and include essential instructions and procedures to ensure the recovery of a failed system and how to get external assistance if the support from ashore is necessary. In addition, software recovery medium or tools essential for recovery on board are to be available.

When developing recovery plans, the various systems and subsystems involved are to be specified.

The following recovery objectives are also to be specified:

- System recovery: methods and procedures to recover communication capabilities are to be specified in terms of Recovery Time Objective (RTO). This is defined as the time required to recover the required communication links and processing capabilities.

- Data recovery: methods and procedures to recover data necessary to restore safe state of OT systems and safe ship operation are to be specified in terms of Recovery Point Objective (RPO). This is defined as the longest period of time for which an absence of data can be tolerated.

Once the recovery objectives are defined, a list of potential cyber incidents is to be created, and the recovery procedure developed and described. Recovery plans are to include, or refer to the following information;

- Instructions and procedures for restoring the failed system without disrupting the operation from the redundant, independent or local operation.

- Processes and procedures for the backup and secure storage of information.

- Complete and up-to-date logical network diagram.

- The list of personnel responsible for restoring the failed system.

- Communication procedure and list of personnel to contact for external technical support including system support vendors, network administrators, etc.

- Current configuration information for all components.

The operation and navigation of the ship is to be prioritized in the plan in order to help ensure the safety of onboard personnel.

Recovery plans in hard copy onboard and ashore are to be available to personnel responsible for cyber security and who are tasked with assisting in cyber incidents.

7.6.5.1.3 Demonstration of compliance

a) Design phase

The systems integrator is to include the following information in the Cyber security design description:

- references to information provided by the suppliers (see section 8.3.1.8) that may be applied by the shipowner to establish plans to recover from cyber incidents.

b) Commissioning phase

The systems integrator is to submit Ship cyber resilience test procedure (ref. section 7.7.2.1) and demonstrate to IRS the effectiveness of the procedures and instructions provided by the suppliers to respond to cyber incidents as specified in section 7.6.5.2 and 7.6.5.3.

The above tests may be omitted if performed during the certification of CBSs as per section 7.7.2.1.

c) Operation phase

The shipowner is to describe incident recovery plans in the Ship cyber security and resilience program. The plans are to cover the CBSs in scope of applicability of this Section and are to address at least the following requirements:

- Description of who, when and how to restore and recover from cyber incidents in accordance with requirements in section 7.6.5.1

- Policy for backup addressing frequency, maintenance and testing of the backups, considering acceptable downtime, availability of alternative means for control, vendor support arrangements and criticality of the CBSs in accordance with requirements in section 7.6.5.2.

- Reference to user manuals or procedures for backup, shutdown, reset, restore and restart of the CBSs in accordance with requirements in section 7.6.5.2 and 7.6.5.3.

Other requirements for periodical surveys are indicated in Part 1, Chapter 2, Section 25 of the Rules.

7.6.5.2 Backup and restore capability

.1 Requirements

CBSs and networks in the scope of applicability of this Section are to have the capability to support back-up and restore in a timely, complete and safe manner. Backups are to be regularly maintained and tested.

.2 Requirement details

a) Restore capability

CBSs in the scope of applicability of this Section are to have backup and restore capabilities to enable the ship to safely regain navigational and operational state after a cyber incident.

Data is to be restorable from a secure copy or image.

Information and backup facilities are to be sufficient to recover from a cyber incident.

b) Backup

CBSs and networks in the scope of applicability of this Section are to provide backup for data. The use of offline backups is also to be considered to improve tolerance

against ransomware and worms affecting online backup appliances.

Backup plans are to be developed, including scope, mode and frequency, storage medium and retention period.

7.6.5.2.3 Demonstration of compliance

a) Commissioning phase

The systems integrator is to submit Ship cyber resilience test procedure (ref. section 7.7.2.1) and demonstrate to IRS the procedures and instructions for backup and restore provided by the suppliers for CBSs in the scope of applicability of this Section.

The above tests may be omitted if performed during the certification of CBSs as per section 7.7.2.1.

b) Operation phase

Requirements for periodical surveys are indicated in Part 1, Chapter 2, Section 25 of the Rules.

7.6.5.3 Controlled shutdown, reset, roll-back and restart

.1 Requirements

CBS and networks in the scope of applicability of this Section are to be capable of controlled shutdown, reset to an initial state, roll-back to a safe state and restart from a power-off condition in such state, in order to allow fast and safe recovery from a possible impairment due to a cyber incident.

Suitable documentation on how to execute the above-mentioned operations is to be available to onboard personnel.

.2 Requirement details

CBS and networks in the scope of applicability of this Section are to be capable of:

- controlled shutdown allowing other connected systems to commit/rollback pending transactions, terminating processes, closing connections, etc. leaving the entire integrated system in a safe, consistent and known state.

- resetting themselves, instructing the system to go through the process of shutting down, clear memory and reset devices to their initialized state.

- rolling back to a previous configuration and/or state, to restore system integrity and consistency.

- restarting and reloading a fresh image of all the software and data (e.g. after a rollback operation) from a read-only source. Restart time is to be compatible with the system's intended service and are to not bring other connected systems, or the integrated system it is part of, to an inconsistent or unsafe state.

Documentation is to be available to onboard personnel on how to execute the above-mentioned operations in case of a system affected by a cyber incident.

7.6.5.3.3 Demonstration of compliance

a) Design phase

The systems integrator is to include the following information in the Cyber security design description:

- references to product manuals or procedures describing how to safely shut down, reset, restore and restart the CBSs in the scope of applicability of this Section.

b) Commissioning phase

The systems integrator is to submit Ship cyber resilience test procedure (ref. section 7.7.2.1) and demonstrate to IRS that manuals or procedures are established for shutdown, reset and restore of the CBSs in the scope of applicability of this Section. These manuals/procedures are to be provided to the shipowner.

The above tests may be omitted if performed during the certification of CBSs as per section 7.7.2.1.

c) Operation phase

Requirements for periodical surveys are indicated in Part 1, Chapter 2, Section 25 of the Rules.

7.7 Compliance with the Requirements

Evaluation of compliance with requirements in this Section is to be carried out by the Surveyor by assessment of documentation and survey in the relevant phases as specified in the following subsections.

Documentation to be submitted by suppliers to IRS is specified in Section 8. The approved versions of this documentation are also to be provided by the suppliers to the systems integrator as specified in section 8.6.2

Documents to be provided by the systems integrator are listed in section 7.7.1 and 7.7.2.

Documents to be provided by the shipowner are listed in section 7.7.3.

Upon delivery of the ship, the systems integrator is to provide the following documentation to the shipowner:

- Documentation of the CBSs provided by the suppliers (see section 8.6.2)

- Documentation produced by the systems integrator (see sections 7.7.1 and 7.7.2)

Appendix I and Appendix II may be referred for a summary of the documents.

7.7.1 During design and construction phases

The supplier is to demonstrate compliance to IRS by following the certification process specified in section 8.6.

During the design and construction phases, modifications to the design are to be carried out in accordance with the management of change (MoC) requirements in Section 6.
The systems integrator is to demonstrate compliance by submitting documents, as specified in the following subsections to IRS for assessment:

.1 Zones and conduit diagram

The content of this document is specified in section 7.6.2.1.3 a).

.2 Cyber security design description (CSDD)

The content of this document is specified in subsections “Design phase” for each requirement in section 7.6.

.3 Vessel asset inventory

The content of this document is specified in section 7.6.1.1.

.4 Risk assessment for the exclusion of CBSs

The content of this document is specified in section 7.8.

.5 Description of compensating countermeasures

If any CBS in the scope of applicability of this Section has been approved with compensating countermeasures in lieu of a requirement in Section 8, this document is to specify the respective CBS, the security capability that is lacking, as well as provide a detailed description of the compensating countermeasures. See also Section 8.3.1.3 requiring that the supplier describes such compensating countermeasures in the system documentation.

7.7.2 Upon ship commissioning

Before final commissioning of the ship, the systems integrator is to:

a) Submit updated design documentation to IRS (as-built versions of the documents in section 7.7.1)

b) Submit Ship cyber resilience test procedure to IRS describing how to demonstrate compliance with this Section by testing and/or analytic evaluation.

c) Carry out testing, witnessed by the Surveyor, in accordance with the approved Ship cyber resilience test procedure.

7.7.2.1 Ship cyber resilience test procedure

The content of this document is specified for the commissioning phase in each subsection “Demonstration of compliance” in section 7.6.

For each CBS, the required inherent security capabilities and configuration thereof are verified and tested in the certification process of each CBS (see Section 8). Testing of such security functions may be omitted if specified in the respective subsection "Commissioning phase", on the condition that these security

functions have been successfully tested during the certification of the CBS as per Section 8.

Nevertheless, all tests are to be included in the Ship cyber resilience test procedure and the decision to omit tests will be taken by IRS. Tests may generally not be omitted if findings/comments are carried over from the certification process to the commissioning phase, if the respective requirements have been met by compensating countermeasures, or due to other reasons such as modifications of the CBS after the certification process.

The Ship cyber resilience test procedure is also to specify how to test any compensating countermeasures described in Section 7.7.1.5.

The Ship cyber resilience test procedure is to include means to update status and record findings during the testing, and specify the following information:

- Necessary test setup (i.e. to ensure the test can be repeated with the same expected result)
- Test equipment
- Initial condition(s)
- Test methodology, detailed test steps
- Expected results and acceptance criteria

Before submitting the Ship cyber resilience test procedure to IRS, the systems integrator is to verify that the information is updated and placed under change management; that it is aligned with the latest configurations of CBSs and networks connecting such systems together onboard the ship and to other CBSs not onboard (e.g., ashore); and that the tests documented are sufficiently detailed as to allow verification of the installation and operation of measures adopted for the fulfilment of relevant requirements on the final configuration of CBSs and networks onboard.
The systems integrator is to document verification tests or assessments of security controls and measures in the fully integrated ship, maintaining change management for configurations, and noting in the documented test results where safety conditions may be affected by specific circumstances or failures addressed in the Ship cyber resilience test procedure.

The testing is to be carried out on board in accordance with the approved Ship cyber resilience test procedure after other commissioning activities for the CBSs are completed. IRS may request execution of additional tests.

7.7.3 During the operational life of the ship

After the ship has been delivered to the shipowner, the shipowner is to manage technical and organizational security countermeasures by establishing and implementing processes as specified in this Section.

Modifications to the CBSs in scope of applicability of this Section are to be carried out in accordance with the management of change (MoC) requirements in Section 6. This includes keeping documentation of the CBSs up to date.

The shipowner, with the support of suppliers, is to keep the Ship cyber resilience test procedure up to date and aligned with the CBSs onboard the ship and the networks connecting such systems to each other and to other CBSs not onboard (e.g. ashore). The shipowner is to update the Ship cyber resilience test procedure considering the changes occurred on CBSs and networks onboard, possible emerging risks related to such changes, new threats, new vulnerabilities and other possible changes in the ship's operational environment.

The shipowner is to prepare and implement operational procedures, provide periodic training and carry out drills for the onboard personnel and other concerned personnel ashore to familiarize them with the CBSs onboard the ship and the networks connecting such systems to each other and to other CBSs not onboard (e.g. ashore), and to properly manage the measures adopted for the fulfilment of requirements.

The shipowner, with the support of supplier, is to keep the measures adopted for the fulfilment of requirements up to date, e.g. by periodic maintenance of hardware and software of CBSs onboard the ship and the networks connecting such systems.

The shipowner is to retain onboard a copy of results of execution of tests and an updated Ship cyber resilience test procedure and make them available to the Surveyor.

The shipowner is to submit a Ship cyber security and resilience program to IRS for approval, documenting management of cyber security and cyber resilience of the CBSs, as relevant and applicable, well in advance of the first annual survey,

The Ship cyber security and resilience program is to include policies, procedures, plans and/or other information documenting the processes/ activities specified in subsections “demonstration of compliance” in this Section.

The shipowner is to demonstrate compliance by presenting records or other documented evidence of implementation of the processes described in the approved Ship cyber security and resilience program.

Change of vessel management company will require a new verification of the Ship cyber security and resilience program.

Other requirements for periodical surveys are specified in Part 1, Chapter 2, Section 25 of the Rules.

7.8 Risk assessment for exclusion of CBS from the application of requirements

7.8.1 Requirements

A risk assessment is to be carried out in case any of the CBSs falling under the scope of applicability of this Section is excluded from the application of relevant requirements. The risk assessment is to provide evidence of the acceptable risk level associated with the excluded CBSs.

7.8.2 Rationale

Exclusion of a CBS falling under the scope of applicability of this Section from the application of relevant requirements needs to be duly justified and documented. Such exclusion will be accepted by IRS only if evidence is given that the risk level associated to the operation of the CBS is under an acceptable threshold by means of specific risk assessment.

The risk assessment is to be based on available knowledge bases and experience on similar designs, if any, considering the CBS category, connectivity and the functional requirements and specifications of the ship and of the CBS. Cyber threat information from internal and external sources may be used to gain a better understanding of the likelihood and impact of cybersecurity events.

7.8.3 Requirement details

Risk assessment document is to be made and kept up to date by the System integrator during the design and building phase considering possible variations of the original design and newly discovered threats and/or vulnerabilities not known from the beginning.

During the operational life of the ship, the shipowner is to update the risk assessment considering the constant changes in the cyber scenario and new weaknesses identified in CBS onboard in a process of continuous improvement. Should new risks be identified, the shipowner is to update existing or implement new risk mitigation measures.

Should the changes in the cyber scenario be such as to elevate the risk level associated to the CBS under examination above the acceptable risk threshold, the shipowner is to inform IRS and submit the updated risk assessment for evaluation.

The envisaged operational environments for the CBS under examination are to be analyzed in the risk assessment to discern the likelihood of cyber incidents and the impact they could have on the human safety, the safety of the vessel or the marine environment, taking into account the category of the CBS. The attack surface is to be analyzed, taking into account the connectivity of the CBS, possible interfaces for portable devices, logical access restrictions, etc.

Emerging risks related to the specific configuration of the CBS under examination are also to be identified. In the risk assessment, the following elements are to be considered:

- Asset vulnerabilities;
- Threats, both internal and external;
- Potential impacts of cyber incidents affecting the asset on human safety, safety of the vessel and/or threat to the environment;
- Possible effects related to integration of systems, or interfaces among systems, including systems not onboard (e.g. if remote access to onboard systems is provided).

7.8.4 Acceptance criteria

Exclusion of a CBS falling under the scope of applicability of this Section from the application of relevant requirements will be accepted by IRS only if assurance is given that the operation of the CBS has no impact on the safety of operations regarding cyber risk. The said exclusion may be accepted for a CBS which does not fully meet the additional criteria listed below but is provided with a rational explanation together with evidence and is found satisfactory by IRS. IRS may also require submittal of additional documents to consider the said exclusion.

The following criteria are to be met to exclude a system from the scope of applicability of this Section:

a) The CBS is to be isolated (i.e, have no IP-network connections to other systems or networks)

b) The CBS is to have no accessible physical interface ports. Unused interfaces are to be logically disabled. It is not to be possible to connect unauthorized devices to the CBS

c) The CBS is to be located in areas to which physical access is controlled

d) The CBS is not to be an integrated control system serving multiple ship functions as specified in the scope of applicability of this Section (see section 7.1).

The following additional criteria should be considered for the evaluation of risk level acceptability:

a. The CBS should not serve ship functions of category III

b. Known vulnerabilities, threats, potential impacts deriving from a cyber incident affecting the CBS have been duly considered in the risk assessment

c. The attack surface for the CBS is minimized, having considered its complexity, connectivity, physical and logical access points, including wireless access points

Appendix I – Summary of actions and documents

Legend:

Submit	The stakeholder is to submit the document to IRS for verification and approval of compliance with requirements in this Section
Maintain	The stakeholder is to keep the document updated in accordance with procedure for management of change (MoC). Updated document and change management records are to be submitted to IRS as per Section 6.
Demonstrate	The stakeholder is to demonstrate compliance to IRS in accordance with the approved document.

Section 8

Cyber resilience of on-board systems and equipment

8.1 General

8.1.1 Introduction

.1 This Section specifies minimum requirements for cyber resilience of on-board systems and equipment.

.2 This Section does not cover environmental performance for the system hardware and the functionality of the software.

.3 In addition to the requirements of this Section, the following are to be applied:

- Classification Note: *Type Approval of Electrical Equipment used for Control, Monitoring, Alarm and Protection Systems for Use in Ships*, for environmental performance for the system hardware.

- Section 6 for safety of equipment for the functionality of the software.

.4 For navigation and radiocommunication systems, the application of IEC 61162-460 or other equivalent standards in lieu of the required security capabilities in Section 8.4 may be accepted by IRS, on the condition that requirements in Section 6 are complied with.

8.1.2 Scope of application

8.1.2.1 The requirements in this Section are applicable to the following:

- Passenger ships (including passenger high-speed craft) engaged in international voyages

- Cargo ships of 500 GT and upwards engaged in international voyages

- High speed craft of 500 GT and upwards engaged in international voyages

- Mobile offshore drilling units of 500 GT and upwards

- Self-propelled mobile offshore units engaged in construction (i.e. wind turbine installation maintenance and repair, crane units, drilling tenders, accommodation, etc.)

8.1.2.2 The requirements in this Section may be used as guidance for the following:

- Ships of war and troopships

- Cargo ships less than 500 GT

- Vessels not propelled by mechanical means

- Wooden ships of primitive build

- Passenger yachts (passengers not more than 12)

- Pleasure yachts not engaged in trade

- Fishing vessels

- Site specific offshore installations (i.e. FPSOs, FSUs, etc.)

8.1.3 Definitions & Abbreviations

Definition and abbreviations (for the purpose of this Section):

Attack surface: The set of all possible points where an unauthorized user can access a system, cause an effect on or extract data from. The attack surface comprises two categories: digital and physical. The digital attack surface encompasses all the hardware and software that connect to an organization’s network. These include applications, code, ports, servers and websites. The physical attack surface comprises all endpoint devices that an attacker can gain physical access to, such as desktop computers, hard drives, laptops, mobile phones, removable drives and carelessly discarded hardware.

Authentication: Provision of assurance that a claimed characteristic of an identity is correct.

Compensating countermeasure: An alternate solution to a countermeasure employed in lieu of or in addition to inherent

security capabilities to satisfy one or more security requirements.

Computer Based System (CBS): A programmable electronic device, or interoperable set of programmable electronic devices, organized to achieve one or more specified purposes such as collection, processing, maintenance, use, sharing, dissemination, or disposition of information. CBS on-board include IT and OT systems. A CBS may be a combination of subsystems connected via network. On-board CBS may be connected directly or via public means of communications (e.g. Internet) to ashore CBSs, other vessels' CBS and/or other facilities.

Computer Network: A connection between two or more computers for the purpose of communicating data electronically by means of agreed communication protocols.

Control: Means of managing risk, including policies, procedures, guidelines, practices or organizational structures, which can be administrative, technical, management, or legal in nature.

Cyber incident: An event resulting from any offensive cyber manoeuvre, either intentional or unintentional, that targets or affects one or more CBS onboard, which actually or potentially results in adverse consequences to an onboard system, network and computer or the information that they process, store or transmit, and which may require a response action to mitigate the consequences. Cyber incidents include unauthorized access, misuse, modification, destruction or improper disclosure of the information generated, archived or used in onboard CBS or transported into the networks connecting such systems. Cyber incidents do not include system failures.

Cyber resilience: The capability to reduce the occurrence and mitigating the effects of incidents arising from the disruption or impairment of operational technology (OT) used for the safe operation of a ship, which potentially lead to dangerous situations for human safety, safety of the vessel and/or threat to the environment.

Defence in depth: Information Security strategy integrating people, technology, and operations capabilities to establish variable barriers across multiple layers and missions of the organization.

Essential Systems: Computer Based System contributing to the provision of services essential for propulsion and steering, and safety of the ship. Essential services comprise "Primary Essential Services" and "Secondary Essential Services": Primary Essential Services are those services which need to be in continuous operation to maintain propulsion and steering; Secondary Essential Services are those services which need not necessarily be in continuous operation to maintain propulsion and steering but which are necessary for maintaining the vessel's safety.

Firewall: A logical or physical barrier that monitors and controls incoming and outgoing network traffic controlled via predefined rules.

Firmware: Software embedded in electronic devices that provide control, monitoring and data manipulation of engineered products and systems. These are normally self-contained and not accessible to user manipulation.

Hardening: Hardening is the practice of reducing a system's vulnerability by reducing its attack surface.

Information Technology (IT): Devices, software and associated networking focusing on the use of data as information, as opposed to Operational Technology (OT).

Integrated system: A system combining a number of interacting sub-systems and/or equipment organized to achieve one or more specified purposes.

Network switch (Switch): A device that connects devices together on a computer network, by using packet switching to receive, process and forward data to the destination device.

Offensive cyber manoeuvre: Actions that result in denial, degradation, disruption, destruction, or manipulation of OT or IT systems.

Operational technology (OT): Devices, sensors, software and associated networking that monitor and control onboard systems. Operational technology systems may be thought of as focusing on the use of data to control or monitor physical processes.

OT system: Computer based systems, which provide control, alarm, monitoring, safety or internal communication functions**.**

Patches: Software designed to update installed software or supporting data to address security vulnerabilities and other bugs or improve operating systems or applications.

Protocols: A common set of rules and signals that computers on the network use to communicate. Protocols allow to perform data communication, network management and security. Onboard networks usually implement protocols based on TCP/IP stacks or various field buses.

Recovery: Develop and implement the appropriate activities to maintain plans for resilience and to restore any capabilities or services that were impaired due to a cyber security event. The Recovery function support s timely return to normal operations to reduce the impact from a cyber security event.

Supplier: A manufacturer or provider of hardware and/or software products, system components or equipment (hardware or software) comprising of the application, embedded devices, network devices, host devices etc. working together as system or a subsystem. The Supplier is responsible for providing programmable devices, sub-systems or systems to the System Integrator.

System: Combination of interacting programmable devices and/or sub-systems organized to achieve one or more specified purposes.

System Categories (I, II, III): System categories based on their effects on system functionality, which are defined in Section 6.

System Integrator: The specific person or organization responsible for the integration of systems and products provided by suppliers into the system invoked by the requirements in the ship specifications and for providing the integrated system. The system integrator may also be responsible for integration of systems in the ship. Until vessel delivery, this role shall be taken by the Shipyard unless an alternative organization is specifically contracted/assigned this responsibility.

Untrusted network: Any network outside the scope of applicability of this Section.

8.2 Security Philosophy

8.2.1 Systems and Equipment

8.2.1.1 A System can consist of group of hardware and software enabling safe, secure and reliable operation of a process. Typical example could be Engine control system, DP system, etc.

8.2.1.2 Equipment may be one of the following:

- Network devices (i.e. routers, managed switches)
- Security devices (i.e. firewall, Intrusion Detection System)
- Computers (i.e. workstation, servers)
- Automation devices (i.e. Programmable Logic Controllers)
- Virtual machine cloud-hosted

8.2.2 Cyber Resilience

The cyber resilience requirements in section 8.4 will be applicable for all systems in scope of Section 7 as applicable. Additional requirements related to interface with untrusted networks will only apply for systems where such connectivity is designed.

8.2.3 Essential Systems Availability

8.2.3.1 Security measures for Essential systems are not to adversely affect the availability of systems.

8.2.3.2 Implementation of security measures is not to cause loss of safety functions, loss of control functions, loss of monitoring functions or loss of other functions which could result in health, safety and environmental consequences.

8.2.3.3 The system is to be adequately designed to allow the ship to continue its mission critical operations in a manner that ensures the confidentiality, integrity, and availability of the data necessary for safety of the vessel, its systems, personnel and cargo.

8.2.4 Compensating Countermeasures

8.2.4.1 Compensating countermeasures may be employed in lieu of or in addition to inherent security capabilities to satisfy one or more security requirements.

Compensating countermeasure(s) are to meet the intent and rigor of the original stated requirement considering the referenced standards as well as the differences between

each requirement and the related items in the standards, and follow the principles specified in section 8.3.1.3.

8.3 Documentation

8.3.1 CBS Documentation

The following documents are to be submitted to IRS for review and approval in accordance with the requirements in this Section. See also section 8.6.2.

8.3.1.1 CBS asset inventory

The CBS asset inventory is to include the information as follows:

- List of hardware components (e.g., host devices, embedded devices, network devices)Name
- Brand/manufacturer
- Model/type
- Short description of functionality/purpose
- Physical interfaces (e.g., network, serial)
- Name/type of system software (e.g., operating system, firmware)
- Version and patch level of system software
- Supported communication protocols

List of software components (e.g., application software, utility software)

- The hardware component where it is installed
- Brand/manufacturer
- Model/type
- Short description of functionality/purpose
- Version of software

8.3.1.2 Topology diagrams

The physical topology diagram is to illustrate the physical architecture of the system. It is to be possible to identify the hardware components in the CBS asset inventory. The diagram is to illustrate the following:

- All endpoints and network devices, including identification of redundant units
- Communication cables (networks, serial links), including communication with I/O units
- Communication cables to other networks or systems

The logical topology diagram is to illustrate the data flow between components in the system. The diagram is to illustrate the following:

- Communication endpoints (e.g. workstations, controllers, servers)
- Network devices (switches, routers, firewalls)
- Physical and virtual computers
- Physical and virtual communication paths
- Communication protocols

One combined topology diagram may be acceptable if all requested information can be clearly illustrated.

8.3.1.3 Description of security capabilities

This document is to describe how the CBS with its hardware and software components meets the required security capabilities in section 8.4.1.

Any network interfaces to other CBSs in the scope of applicability of Section 7 are to be described. The description is to include destination CBS, data flows, and communication protocols. If the System integrator has allocated the destination CBS to another security zone, components providing protection of the security zone boundary (see Section 7.6.2.2.1) are to be described in detail if delivered as part of the CBS.

Any network interfaces to other systems or networks outside the scope of applicability of Section 7 (untrusted networks) are to be described. The description is to specify compliance with the additional security capabilities in section 8.4.2, and include relevant procedures or instructions for the crew. Components providing protection of the security zone boundary (see section 7.6.2.2.1) are to be described in detail if delivered as part of the CBS.

A separate chapter is to be designated for each requirement. All hardware and software components in the system are to be addressed in the description, as relevant.

If any requirement is not fully met, this is to be specified in the description, and compensating countermeasures are to be proposed. The compensating countermeasures should:

- Protect against the same threats as the original requirement
- Provide an equal level of protection as the original requirement
- Not be a security control that is required by other requirements in this Section
- Not introduce higher security risk

Any supporting documents (e.g. OEM information) necessary to verify compliance with the requirements are to be referenced in the description and submitted.

8.3.1.4 Test procedure of security capabilities

This document is to describe how to demonstrate by testing that the system complies with the requirements in section 8.4.1 and 8.4.2, including any compensating countermeasures. Demonstration of compliance by analytic evaluation may be specially considered. The procedure is to include a separate chapter for each applicable requirement and describe:

- Necessary test setup (i.e. to ensure the test can be repeated with the same expected result)
- Test equipment
- Initial condition(s)
- Test methodology, detailed test steps
- Expected results and acceptance criteria

The procedure is also to include means to update test results and record findings during the testing.

8.3.1.5 Security configuration guidelines

This document is to describe recommended configuration settings of the security capabilities and specify default values. The objective is to ensure the security capabilities are implemented in accordance with Section 7 and any specifications by the System integrator (e.g. user accounts, authorization, password policies, safe state of machinery, firewall rules, etc.)

The document is to serve as basis for verification of item no. 29 in section 8.4.1.

8.3.1.6 Secure development lifecycle documents

This documentation is to be submitted to IRS upon request and is to describe the supplier's processes and controls in accordance with requirements for secure development lifecycle in section 8.5. Software updates and patching are to be described. The document is a preparatory document for survey as per section 8.6.3.4.

8.3.1.7 Plans for maintenance and verification of the CBS

This document is to be submitted to IRS upon request and is to include procedures for security-related maintenance and testing of the system. The document is to include instructions for how the user can verify correct operation of the system's security functions as required by item no.19 in section 8.4.1.

8.3.1.8 Information supporting the owner’s incident response and recovery plan

This document is to be submitted to IRS upon request and is to include procedures or instructions allowing the user to accomplish the following:

- Local independent control (see sec. 7.6.4.2)
- Network isolation (see sec. 7.6.4.3)
- Forensics by use of audit records (see sec. 8.4.1 item no.13)
- Deterministic output (see sec. 7.6.4.4 and sec. 8.4.1 item no. 20)
- Backup (see sec. 8.4.1 item no. 26)
- Restore (see sec. 8.4.1 item no. 27)
- Controlled shutdown, reset, roll-back and restart (see sec. 7.6.5.3)

8.3.1.9 Management of change plan

This document is to be submitted to IRS upon request. This procedure is not specific for cyber security and is also required by Section 6.

8.3.1.10 Test reports

CBSs with Type approval certificate covering the security capabilities of this Section may be

exempted from survey by IRS. However, test reports signed by the supplier are to be submitted to IRS, demonstrating that the supplier has completed design, construction, testing, configuration, and hardening as would otherwise be verified by IRS in survey (section 8.6.3).

8.4 System Requirements

This subsection specifies the required security capabilities for CBSs in the scope specified in section 8.1.1.

The requirements in this subsection are based on certain selected requirements in IEC 62443-3-3. To determine the full content, rationale and relevant guidance for each requirement, the subject standard may be referred.

8.4.1 Required security capabilities

Security capabilities required for CBSs in the scope specified in Section 8.1.1 are indicated in Table 8.4.1

Table 8.4.1 : Required security capabilities for all CBSs

Item No	Objective	Requirements
Protect against casual or coincidental access by unauthenticated entities		
1	Human user identification and authentication	The CBS is to identify and authenticate all human users who can access the system directly or through interfaces (Ref. IEC 62443-3-3/SR 1.1)
2	Account management	The CBS is to provide the capability to support the management of all accounts by authorized users, including adding, activating, modifying, disabling and removing account (Ref. IEC 62443-3-3/SR 1.3)
3	Identifier management	The CBS is to provide the capability to support the management of identifiers by user, group and role. (Ref. IEC 62443-3-3/SR 1.4)
4	Authenticator management	The CBS is to provide the capability to: - Initialize authenticator content - Change all default authenticators upon control system installation - Change/refresh all authenticators - Protect all authenticators from unauthorized disclosure and modification when stored and transmitted. (Ref. IEC 62443-3-3/SR 1.5)
5	Wireless access management	The CBS is to provide the capability to identify and authenticate all users (humans, software processes or devices) engaged in wireless communication (Ref. IEC 62443-3-3/SR 1.6)
6	Strength of password-based authentication	The CBS is to provide the capability to enforce configurable password strength based on minimum length and variety of character types. (Ref. IEC 62443-3-3/SR 1.7)
7	Authenticator feedback	The CBS is to obscure feedback during the authentication process. (Ref. IEC 62443-3-3/SR 1.10)
Protect against casual or coincidental misuse		
8	Authorization enforcement	On all interfaces, human users are to be assigned authorizations in accordance with the principles of segregation of duties and least privilege. (Ref. IEC 62443-3-3/SR 2.1)
9	Wireless use control	The CBS is to provide the capability to authorize, monitor and enforce usage restrictions for wireless connectivity to the system according to commonly accepted security industry practices (Ref. IEC 62443-3-3/SR 2.2)

10	Use control for portable and mobile devices	When the CBS supports use of portable and mobile devices, the system is to include the capability to a) Limit the use of portable and mobile devices only to those permitted by design b) Restrict code and data transfer to/from portable and mobile devices Note: Port limits / blockers (and silicone) could be accepted for a specific system (Ref. IEC 62443-3-3/SR 2.3)
11	Mobile code	The CBS is to control the use of mobile code such as java scripts, ActiveX and PDF. (Ref. IEC 62443-3-3/SR 2.4)
12	Session lock	The CBS is to be able to prevent further access after a configurable time of inactivity or following activation of manual session lock. (Ref. IEC 62443-3-3/SR 2.5)
13	Auditable events	The CBS is to generate audit records relevant to security for at least the following events: access control, operating system events, backup and restore events, configuration changes, loss of communication. (Ref. IEC 62443-3-3/SR 2.8)
14	Audit storage capacity	The CBS is to provide the capability to allocate audit record storage capacity according to commonly recognized recommendations for log management. Auditing mechanisms shall be implemented to reduce the likelihood of such capacity being exceeded. (Ref. IEC 62443-3-3/SR 2.9)
15	Response to audit processing failures	The CBS is to provide the capability to prevent loss of essential services and functions in the event of an audit processing failure. (Ref. IEC 62443-3-3/SR 2.10)
16	Timestamps	The CBS is to timestamp audit records. (Ref. IEC 62443-3-3/SR 2.11)
Protect the integrity of the CBS against casual or coincidental manipulation		
17	Communication integrity	The CBS is to protect the integrity of transmitted information. Note: Cryptographic mechanisms are to be employed for wireless networks. (Ref. IEC 62443-3-3/SR 3.1)
18	Malicious code protection	The CBS is to provide capability to implement suitable protection measures to prevent, detect and mitigate the effects due to malicious code or unauthorized software. It is to have the feature for updating the protection mechanisms (Ref. IEC 62443-3-3/SR 3.2)
19	Security functionality verification	The CBS is to provide the capability to support verification of the intended operation of security functions and report when anomalies occur during maintenance (Ref. IEC 62443-3-3/SR 3.3)
20	Deterministic output	The CBS is to provide the capability to set outputs to a predetermined state if normal operation cannot be maintained as a result of an attack. The predetermined state could be: - Unpowered state, - Last-known value, or - Fixed value (Ref. IEC 62443-3-3/SR 3.6)
Prevent the unauthorized disclosure of information via eavesdropping or casual exposure		
21	Information confidentiality	The CBS is to provide the capability to protect the confidentiality of information for which explicit read authorization is supported, whether at rest or in transit. Note: For wireless network, cryptographic mechanisms shall be employed to protect confidentiality of all information in transit. (Ref. IEC 62443-3-3/SR 4.1)

22	Use of cryptography	If cryptography is used, the CBS is to use cryptographic algorithms, key sizes and mechanisms according to commonly accepted security industry practices and recommendations. (Ref. IEC 62443-3-3/SR 4.3)
Monitor the operation of the CBS and respond to incidents		
23	Audit log accessibility	The CBS is to provide the capability for accessing audit logs on read only basis by authorized humans and/or tools. (Ref. IEC 62443-3-3/SR 6.1)
Ensure that the control system operates reliably under normal production conditions		
24	Denial of service protection	The CBS is to provide the minimum capability to maintain essential functions during DoS events. Note: It is acceptable that the CBS may operate in a degraded mode upon DoS events, but it is not to fail in a manner which may cause hazardous situations. Overload-based DoS events should be considered, i.e. where the networks capacity is attempted flooded, and where the resources of a computer is attempted consumed. (Ref. IEC 62443-3-3/SR 7.1)
25	Resource management	The CBS is to provide the capability to limit the use of resources by security functions to prevent resource exhaustion. (Ref. IEC 62443-3-3/SR 7.2)
26	System backup	The identity and location of critical files and the ability to conduct backups of user-level and system-level information (including system state information) is to be supported by the CBS without affecting normal operations (Ref. IEC 62443-3-3/SR 7.3)
27	System recovery and reconstitution	The CBS is to provide the capability to be recovered and reconstituted to a known secure state after a disruption or failure. (Ref. IEC 62443-3-3/SR 7.4)
28	Alternative power source	The CBS is to provide the capability to switch to and from an alternative power source without affecting the existing security state or a documented degraded mode. (Ref. IEC 62443-3-3/SR 7.5)
29	Network and security configuration settings	The CBS traffic is to provide the capability to be configured according to recommended network and security configurations as described in guidelines provided by the supplier. The CBS is to provide an interface to the currently deployed network and security configuration settings. (Ref. IEC 62443-3-3/SR 7.6)
30	Least Functionality	The installation, the availability and the access rights of the following are to be limited to the strict needs of the functions provided by the CBS: - operating systems software components, processes and services - network services, ports, protocols, routes and hosts accesses and any software (Ref. IEC 62443-3-3/SR 7.7)

8.4.2 Additional security capabilities

The following additional security capabilities are required for CBSs with network communication to untrusted networks (i.e. interface to any networks outside the scope of Section 7).

CBSs with communication traversing the boundaries of security zones are also to meet requirements for network segmentation and zone boundary protection in section 7.6.2.1 and 7.6.2.2.

Table 8.4.2: Additional security capabilities for CBSs with network communication to untrusted networks		
Item No	**Objective**	**Requirements**
31	Multifactor authentication for human users	Multifactor authentication is required for human users when accessing the CBS from or via an untrusted network. (Ref. IEC 62443-3-3/SR 1.1, RE 2)
32	Software process and device identification and authentication	The CBS is to identify and authenticate software processes and devices (Ref. IEC 62443-3-3/SR 1.2)
33	Unsuccessful login attempts	The CBS is to enforce a limit of consecutive invalid login attempts from untrusted networks during a specified time period. (Ref. IEC 62443-3-3/SR 1.11)
34	System use notification	The CBS is to provide the capability to display a system use notification message before authenticating. The system use notification message is to be configurable by authorized personnel. (Ref. IEC 62443-3-3/SR 1.12)
35	Access via Untrusted Networks	Any access to the CBS from or via untrusted networks is to be monitored and controlled. (Ref. IEC 62443-3-3/SR 1.13)
36	Explicit access request approval	The CBS is to deny access from or via untrusted networks unless explicitly approved by authorized personnel on board. (Ref. IEC 62443-3-3/SR 1.13, RE1)
37	Remote session termination	The CBS is to provide the capability to terminate a remote session either automatically after a configurable time period of inactivity or manually by the user who initiated the session. (Ref. IEC 62443-3-3/SR 2.6)
38	Cryptographic integrity protection	The CBS is to employ cryptographic mechanisms to recognize changes to information during communication with or via untrusted networks. (Ref. IEC 62443-3-3/SR 3.1, RE1)
39	Input validation	The CBS is to validate the syntax, length and content of any input data via untrusted networks that is used as process control input or input that directly impacts the action of the CBS. (Ref. IEC 62443-3-3/SR 3.5)
40	Session integrity	The CBS is to protect the integrity of sessions. Invalid session IDs are to be rejected. (Ref. IEC 62443-3-3/SR 3.8)
41	Invalidation of session IDs after session termination	The system is to invalidate session IDs upon user logout or other session termination (including browser sessions). (Ref. IEC 62443-3-3/SR 3.8, RE1)

8.5 Secure Development Lifecycle Requirements

A Secure Development Lifecycle (SDLC) broadly addressing security aspects in following stages is to be followed for the development of systems or equipment

- Requirement analysis phase
- Design phase
- Implementation phase
- Verification phase
- Release phase
- Maintenance Phase
- End of life phase

A document is to be developed that records how the security aspects have been addressed in above phases and is to at a minimum integrate controlled processes as set out in 8.5.1 to 8.5.7. The subject document is required to be submitted to IRS for review and approval.

8.5.1 (Ref. IEC 62443-4-1/SM-8) The manufacturer is to have procedural and technical controls in place to protect private keys used for code signing, if applicable, from unauthorized access or modification.

8.5.2 (Ref. IEC 62443-4-1/SUM-2) A process is to be employed to ensure that documentation about product security updates is made available to users (which could be through establishing a cyber security point of contact or periodic publication which can be accessed by the user) that includes but is not limited to:

a) The product version number(s) to which the security patch applies;

b) Instructions on how to apply approved patches manually and via an automated process;

c) Description of any impacts that applying the patch to the product can have, including reboot;

d) Instructions on how to verify that an approved patch has been applied; and

e) Risks of not applying the patch and mediations that can be used for patches that are not approved or deployed by the asset owner.

8.5.3 (Ref. IEC 62443-4-1/SUM-3) A process is to be employed to ensure that documentation about dependent component or operating system security updates is available to users that includes but is not limited to:

a) Stating whether the product is compatible with the dependent component or operating system security update;

8.5.4 (Ref. IEC 62443-4-1/SUM-4) A process is to be employed to ensure that security updates for all supported products and product versions are made available to product users in a manner that facilitates verification that the security patch is authentic.

Note: The manufacturer is to have QA process to test the updates before releasing.

8.5.5 (Ref. IEC 62443-4-1/SG-1) A process is to exist to create product documentation that describes the security defence in depth strategy for the product to support installation, operation and maintenance that includes:

a) Security capabilities implemented by the product and their role in the defence in depth strategy;

b) Threats addressed by the defence in depth strategy; and

c) Product user mitigation strategies for known security risks associated with the product, including risks associated with legacy code.

8.5.6 (Ref. IEC 62443-4-1/SG-2) A process is to be employed to create product user documentation that describes the security defence in depth measures expected to be provided by the external environment in which the product is to be used.

8.5.7 (Ref. IEC 62443-4-1/SG-3) A process is to be employed to create product user documentation that includes guidelines for hardening the product when installing and maintaining the product. The guidelines shall include, but are not limited to, instructions, rationale and recommendations for the following:

a) Integration of the product, including third-party components, with its product security context

b) Integration of the product's application programming interfaces/protocols with user applications;

c) Applying and maintaining the product's defence in depth strategy

d) Configuration and use of security options/capabilities in support of local security policies, and for each security option/capability:

   i. its contribution to the product's defence in depth strategy

   ii. descriptions of configurable and default values that include how each affects security along with any

potential impact each has on work practices; and

iii. setting/changing/deleting its value;

e) Instructions and recommendations for the use of all security-related tools and utilities that support administration, monitoring, incident handling and evaluation of the security of the product;

f) Instructions and recommendations for periodic security maintenance activities;

g) Instructions for reporting security incidents for the product to the supplier;

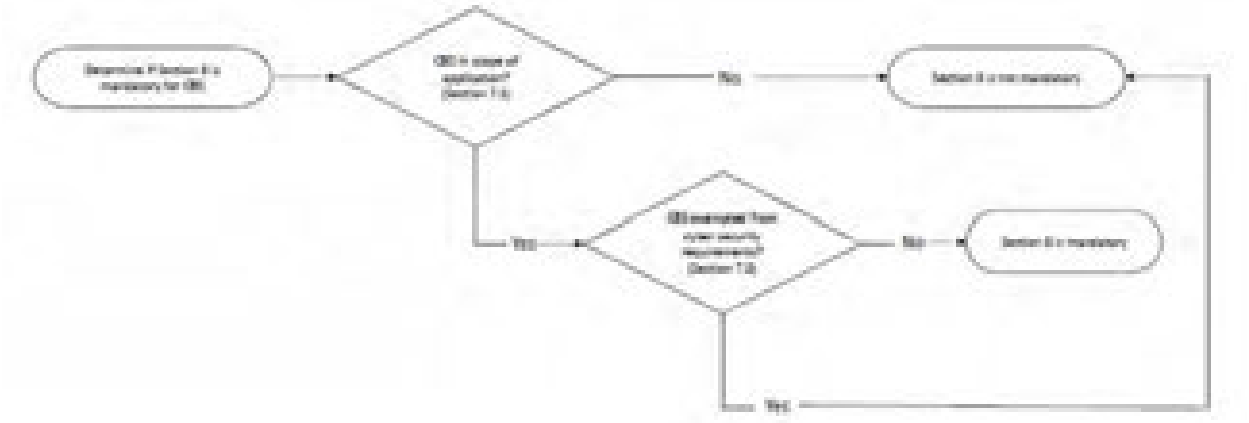
h) Description of the security best practices for maintenance and administration of the product.

8.6 Demonstration of compliance

8.6.1 Introduction

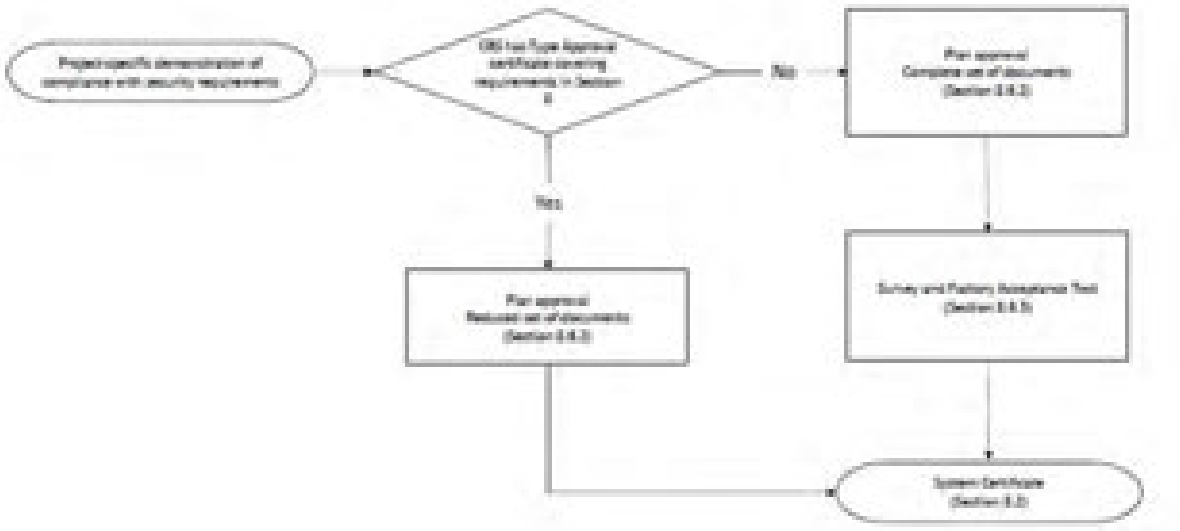
Suppliers are to determine if this section is mandatory for the CBS in cooperation with the System integrator.

Figure 1



Compliance with security requirements is to be demonstrated as indicated in Figure 2. This classification process is ship-specific and shall result in a System certificate.

Figure 2



Type approval is voluntary and applies for CBSs that are standard and routinely manufactured. See Section 6 for definition of System certification and Type approval. In cases where the manufacturer is desirous of type approval, the requirements in IRS Classification Notes: *Type Approval of Cyber Secured Control System Components* are to be complied with.

The process in Figure 1 and Figure 2 applies also if other equivalent standards are applied for navigation and radiocommunication equipment (see section 1.3). In such case:

- the process in Figure 1 illustrates if the equivalent standard is mandatory (in lieu of Section 8)
- the process in Figure 2 illustrates that the certification process is lessened if the CBS has been type approved in accordance with the equivalent standard.

8.6.2 Plan approval

Plan approval is assessment of documents of a CBS intended for a specific vessel. The documents in section 8.3 are required to be submitted by the supplier.

If the CBS holds a valid Type approval certificate covering the requirements of this Section, subject to approval by IRS, the supplier may submit a reduced set of vessel-specific documents to IRS (see Appendix I).

The approved version of the documents is to be included in the delivery of the CBS to the system integrator.

8.6.3 Survey and factory acceptance test

Survey and factory acceptance testing (FAT) is a vessel-specific verification activity required for CBSs that do not hold a valid Type approval certificate covering the requirements of this Section.

The objective of the survey and FAT is to demonstrate by testing and/or analytic evaluation that the CBS complies with applicable requirements in this Section. The survey and FAT is to be carried out at the supplier's premises or at other works having the adequate apparatus for testing and inspection.

After completed plan approval and survey/FAT, IRS will issue a System certificate that is to accompany the CBS upon delivery to the system integrator.

The following subsections specify the survey and FAT activities.

8.6.3.1 General survey items

The supplier is to demonstrate that design, construction, and internal testing has been completed.

It is also to be demonstrated that the system to be delivered is correctly represented by the approved documentation. This is to be done by inspecting the system and comparing the components and arrangement/architecture with the asset inventory (section 8.3.1.1) and the topology diagrams (section 8.3.1.2).

8.6.3.2 Test of security capabilities

The supplier is to test the required security capabilities on the system to be delivered. The tests are to be carried out in accordance with the approved test procedure in section 8.3.1.4 and be witnessed/accepted by the Surveyor.

The tests are to provide the Surveyor with reasonable assurance that all requirements are met. This implies that testing of identical components is normally not required.

8.6.3.3 Correct configuration of security capabilities

The supplier is to test/ demonstrate for the Surveyor that security settings in the system's components have been configured in accordance with the configuration guidelines in section 8.3.1.5. This demonstration may be carried out in conjunction with testing of the security capabilities.

The security settings are to be documented in a report, e.g. a ship-specific instance of the configuration guidelines.

8.6.3.4 Secure development lifecycle

The supplier is to, in accordance with documentation in section 8.3.1.6, demonstrate compliance with requirements for secure development lifecycle in section 8.5.

8.6.3.4.1 Controls for private keys (Ref. IEC 62443-4-1/SM-8)

This requirement applies if the system includes software that is digitally signed for the purpose of enabling the user to verify its authenticity.

The supplier is to present management system documentation substantiating that policies, procedures and technical controls are in place to protect generation, storage and use of private keys used for code signing from unauthorized access.

The policies and procedures are to address roles, responsibilities and work processes. The technical controls are to include e.g. physical access restrictions and cryptographic hardware (e.g. Hardware security module) for storage of the private key.

8.6.3.4.2 Security update documentation (Ref. IEC 62443-4-1/SUM-2)

The supplier is to present management system documentation substantiating that a process is established in the organization to ensure security updates are informed to the users. The information to the users is to include the items listed in section 8.5.2.

8.6.3.4.3 Dependent component security update documentation (Ref. IEC 62443-4-1/SUM-3)

The supplier is to present management system documentation, as required by section 8.5.3, substantiating that a process is established in the organization to ensure users are informed whether the system is compatible with updated versions of acquired software in the system (new versions/patches of operating system or firmware). The information is to address how to manage risks related to not applying the updated acquired software.

8.6.3.4.4 Security update delivery (Ref. IEC 62443-4-1/SUM-4)

The supplier is to present management system documentation, as required by section 8.5.4, substantiating that a process is established in the organization ensuring that system security updates are made available to users, and describing how the user may verify the authenticity of the updated software.

8.6.3.4.5 Product defence in depth (Ref. IEC 62443-4-1/SG-1)

The supplier is to present management system documentation, as required by section 8.5.5, substantiating that a process is established in the organization to document a strategy for defence-in-depth measures to mitigate security threats to software in the CBS during installation, maintenance and operation.

Examples of threats could be installation of unauthorized software, weaknesses in the patching process, tampering with software in the operational phase of the ship.

8.6.3.4.6 Defence in depth measures expected in the environment (Ref. IEC 62443-4-1/SG-2)

The supplier is to present management system documentation, as required by section 8.5.6, substantiating that a process is established in the organization to document defence-in-depth measures expected to be provided by the external environment, such as physical arrangement, policies and procedures.

8.6.3.4.7 Security hardening guidelines (Ref. IEC 62443-4-1/SG-3)

The supplier is to present management system documentation, as required by section 8.5.7, substantiating that a process is established in the organization to ensure that hardening guidelines are produced for the system.

The guidelines are to specify how to reduce vulnerabilities in the system by removal/prohibiting /disabling of unnecessary software, accounts, services, etc.

Appendix I

The following table summarizes documents to be submitted by the supplier to IRS.

Document	Requirements	IRS
CBS asset inventory (sec. 8.3.1.1)	To be incorporated in vessel asset inventory (E26 sec.7.6.1.1)	Approve [1) 2)]
Topology diagrams (sec. 8.3.1.2)	Enabling System integrator to design security zones and conduits (E26 sec.7.6.2.1)	Approve [1) 2)]
Description of security capabilities (sec. 8.3.1.3)	Required security capabilities (sec. 8.4.1)	Approve [1)]
	Additional security capabilities, if applicable (sec. 8.4.2)	
Test procedure for security capabilities (sec. 8.3.1.4)	Required security capabilities (sec. 8.4.1)	Approve [1)]
	Additional security capabilities, if applicable (sec. 8.4.2)	
Security configuration guidelines (sec. 8.3.1.5)	Network and security configuration settings (sec. 8.4.1 item 29)	Info [1)]
Secure development lifecycle (sec. 8.3.1.6)	SDLC requirements (sec. 8.5)	Approve [1)]
Plans for maintenance and verification (sec. 8.3.1.7)	Security functionality verification (sec. 8.4.1 item 19)	Info [1)]
Information supporting incident response and recovery plans (sec. 8.3.1.8)	Auditable events (sec. 8.4.1 item 13)	Info [1)]
	Deterministic output (sec. 8.4.1 item 20)	Info [1)]
	System backup (sec. 8.4.1 item 26)	Info [1)]
	System recovery and reconstitution (sec. 8.4.1 item 27)	Info [1)]
Management of change plan (sec. 8.3.1.9)	Management of change process (sec. 6)	Info [1)]
Test reports (sec. 8.3.1.10)	Configuration of security capabilities and hardening (sec. 8.3.1.5 and sec. 8.5.7)	Info [2)]
Note 1: Required for CBS without type approved security capabilities Note 2: Required for CBS with type approved security capabilities

Section 1

General Requirements

1.1 Scope

1.1.1 The requirements of this Chapter are applicable to both direct current and alternating current installations unless specifically stated otherwise.

1.1.2 The requirements of this Chapter apply to all ships. Consideration will be given to arrangements or details of equipment which comply with other National or International standards in so far as they are not less effective and reliable.

The arrangements for vessels intended for restricted services or for special services will be specially considered.

1.1.3 Whilst these requirements are considered to meet those of the "International Convention for the Safety of Life at Sea, 1974, including amendments", attention should also be given to any relevant statutory requirements of the National Authority of the country in which the ship is to be registered.

1.1.4 In addition to the requirements of this Chapter, vessels using batteries as the main and/ or additional source of power for propulsion are also to be in accordance with IRS '*Guidelines on Battery Powered Vessels*'.

Requirements for approval of Lithium-ion battery systems to be used in battery powered vessels or hybrid vessels are specified in IRS Classification Note "*Approval of Lithium-ion Battery Systems"*.

1.2 Definitions

1.2.1 **Normal operational and habitable condition** is condition under which the ship as

a whole, the machinery, services, means and aids ensuring propulsion, ability to steer, safe navigation, fire and flooding safety, internal and external communications and signals, means of escape and emergency boat winches, as well as designed comfortable conditions of habitability are in working order and functioning normally.

1.2.2 **Emergency condition** is a condition under which any services needed for normal operational and habitable conditions are not in a working order due to the failure of the main source of electrical power.

1.2.3 **Main source of electrical power** is a source intended to supply electrical power to the main switchboard for distribution to all services necessary for maintaining the ship in normal operational and habitable conditions.

1.2.4 **Main generating station** is the space in which the main source of electrical power is situated.

1.2.5 **Main switchboard** is a switchboard which is directly supplied by the main source of electrical power and is intended to distribute electrical energy to ship's services.

1.2.6 **Emergency switchboard** is a switchboard which in the event of failure of the main electrical power supply system is directly supplied by the emergency source of electrical power or transitional source of emergency power and is intended to distribute electrical energy to the emergency services.

1.2.7 **Emergency source of electrical power** is a source of electrical power, intended to supply the emergency switchboard in the event of failure of the supply from the main source of electrical power.

1.3 Surveys

1.3.1 Electrical propelling machinery and associated equipment together with auxiliary services for the safety of the ship are to be installed in accordance with the relevant requirements of this Chapter, surveyed and have tests witnessed by the Surveyors.

1.3.2 All generators, motors and transformers of 100 [kW] and over, intended for essential services, are to be surveyed during test and if appropriate also during manufacturing.

Where an alternative survey scheme has been approved by IRS as per Ch.1, Sec.4, the attendance of the Surveyor during manufacturing may not be necessary.

1.3.3 All electric propelling machinery including switchgear, control gear, converting equipment, cables, main and auxiliary generators, motors and exciters are to be surveyed by the Surveyors during manufacture and testing.

1.3.4 For refrigerated cargo installations having HY class notation, motors are to be tested and certificates furnished by the manufacturers. Motors of 100 [kW] or over are to be surveyed by the Surveyors during manufacture and testing.

1.4 Plans

1.4.1 The following plans and details for electrical installations including propulsion equipment, if fitted, and auxiliary machinery are to be submitted in triplicate for approval:

a) Schematic diagram of the electrical system including information such as cable sizes, type of insulation, normal working currents, line drop of voltages and details of protection devices together with rating and interrupting capacity of circuit breakers and fuses;

b) Calculations of prospective short circuit current of main busbars and secondary side of transformers (Additionally load schedule is to be submitted for information);

c) Construction details, sectional views, type, rating, make of rotating machines rated at 100 [kW] and above, where welding is to be applied to shafts of machines and plans showing the construction;

d) The arrangement plans and circuit diagrams of switchgear and controlgear giving details of isolating, protective and control devices, details of bus bars, cable sizes, type of insulation and normal working currents in the circuits. Additional details such as mechanical stresses on the bus bars by short circuit, bus bar supporting arrangements, verification of protective devices;

e) General diagrams of emergency circuits, control and alarms for essential services and internal communications together with details of sources of supply, cable sizes and types of insulation and any other

information required for assessment of such circuits;

f) Plans for generators, motors and seatings together with diagrams of control gears, cables and circuits for electric propulsion equipment, if fitted. A harmonic distortion calculation report, indicating distortion levels at MSB and power distribution centers is to be submitted for review for all vessels with electric propulsion and for vessels fitted with harmonic filters. Key diagram and explanation of the system are to be submitted;

g) Plans of electric slip couplings, if fitted, showing details of construction and scantlings together with diagrams of control gear and other electrical components;

h) For tankers and similar vessels, a general arrangement of the ship showing hazardous spaces and the location of the electrical equipment in such spaces. A schedule of safe type electrical equipment located in hazardous spaces giving details of the type of equipment fitted, the certifying authority and copies of the certificates. Where the prescriptive requirements within SOLAS and related codes (IBC, IGC) and the standards published by the International Electro-technical Commission, IEC, such as but not limited to IEC 60092-502, are not aligned, the prescriptive requirements in SOLAS and Codes take precedence and are to be applied.

1.4.2 Additional information may be required for vessels engaged in special services or of a novel design.

1.5 Essential and other services

1.5.1 Essential services

1.5.1.1 Essential services are divided into following types of services:

a) "Primary Essential Services" and

b) "Secondary Essential Services".

Definitions and examples of such services are given in 1.5.1.2 and 1.5.1.3.

1.5.1.2 Primary Essential Services

Primary Essential Services are those services which need to be in continuous operation to maintain propulsion and steering. Examples of equipment for primary essential services are as follows:

- Steering gears
- Pumps for controllable pitch propellers
- Scavenging air blower, fuel oil supply pumps, fuel valve cooling pumps, lubricating oil pumps and cooling water pumps for main and auxiliary engines and turbines necessary for propulsion
- Forced draught fans, feed water pumps, water circulating pumps, vacuum pumps and condensate pumps for steam plants on steam turbine ships, and also for auxiliary boilers on ships where steam is used for equipment supplying primary essential services
- Oil burning installations for steam plants on steam turbine ships and for auxiliary boilers where steam is used for equipment supplying primary essential services
- Azimuth thrusters which are the sole means for propulsion/steering and associated lubricating oil pumps, cooling water pumps
- Electrical equipment for electric propulsion plant with lubricating oil pumps and cooling water pumps
- Electric generators and associated power sources supplying the above mentioned equipment
- Hydraulic pumps supplying the above mentioned equipment
- Viscosity control equipment for heavy fuel oil
- Control, monitoring and safety devices/systems of equipment for primary essential services.

1.5.1.3 Secondary Essential Services

Secondary Essential Services are those services which need not necessarily be in continuous operation to maintain propulsion and steering but which are necessary for maintaining the vessel's safety. Example of equipment for secondary essential services are as follows:

- Windlass
- Fuel oil transfer pumps and fuel oil treatment equipment
- Lubricating oil transfer pumps and lubrication oil treatment equipment
- Pre-heaters for heavy fuel oil
- Starting air and control air compressors
- Bilge, ballast and heeling pumps
- Fire pumps and other fire extinguishing medium pumps

- Ventilating fans for engine and boiler rooms
- Services considered necessary to maintain dangerous spaces in a safe condition
- Navigation lights, aids and signals
- Internal safety communication equipment
- Fire detection and alarm system
- Lighting system
- Electrical equipment for watertight closing appliances
- Electric generators and associated power sources supplying the above equipment
- Hydraulic pumps supplying the above equipment
- Control, monitoring and safety systems for cargo containment systems
- Control, monitoring and safety devices / systems of equipment for secondary essential services.
- Equipment used for cooling and maintaining lesser ambient temperature (refer Ch.1, 1.7.4)

1.5.2 Services such as following are considered necessary for minimum comfortable conditions of habitability :

- cooking;
- heating;
- domestic refrigeration;
- mechanical ventilation;
- sanitary and fresh water;
- electric generators and associated power sources supplying the above mentioned equipment.

1.5.3 Services such as following, which are in addition to 1.5.1 and 1.5.2, are considered necessary to maintain the ship in a normal seagoing operational and habitable condition :

- cargo handling and cargo gear equipment;
- hotel services, other than those required for habitable conditions;
- thrusters, other than those for dynamic positioning.

1.6 Ambient reference conditions

1.6.1 For details regarding ambient reference conditions, See Ch.1.

1.7 Vibrations, accelerations

1.7.1 Electrical equipment is to be constructed to withstand when subjected to following :

vibrations within the frequency range 5 - 50 Hz and with vibration velocity amplitude 20 [mm/sec].

peak accelerations caused by the ship's movements in waves - $\pm$ 0.6 g for vessels of length exceeding 90 [m] and $\pm$ 1 g for other vessels.

1.7.2 All connections for current-carrying parts and earthing connections are to be fixed so that they cannot loosen by vibrations. This also applies to fixing of mechanical parts when found necessary.

1.8 Voltage and frequency variations

1.8.1 All electrical appliances supplied from the main or emergency systems are to be so designed and manufactured that they are capable of operating satisfactorily under the normally occurring variations in voltage and frequency. Unless otherwise stated in national or international standards, provided the variations comply with as stated below, all equipment are to operate satisfactorily with the variations from its rated value as shown in the following Tables 1.8.1 to 1.8.3.

a) For alternating current components; voltage and frequency variations shown in Table 1.8.1 are to be assumed.

b) For direct current components supplied by d.c. generators or converted by rectifiers, voltage variations shown in Table 1.8.2 are to be assumed.

c) For direct current components supplied by electrical batteries, voltage variations shown in Table 1.8.3 are to be assumed.

Table 1.8.1 : Voltage and frequency variations for a.c. distribution systems		
Quantity in operation	**Permanent variations**	**Transient variations**
Frequency	± 5%	± 10% (recovery time 5 seconds)
Voltage	+ 6% - 10%	± 20% (recovery time 1.5 seconds)

Table 1.8.2 : Voltage variations for d.c. distribution systems	
Parameters	**Variations**
Voltage tolerance (continuous)	±10%
Voltage cyclic variation deviation	5%
Voltage ripple (a.c., r.m.s., over steady d.c. voltage)	10%

Table 1.8.3 : Voltage variations for battery systems	
Systems	**Variations**
Components connected to the battery during charging (see Note)	+30%, -25%
Components not connected to the battery during charging	+20%, -25%
Note : Different voltage variations as determined by the charging / discharging characteristics, including ripple voltage from the charging device, may be considered.	

1.8.2 Any special system, e.g. electronic circuits, whose function cannot operate satisfactorily within the limits given in 1.8.1 are not be supplied directly from the system but by alternative means, e.g. through stabilized supply.

1.8.3 Contactors and similar electro-magnetic devices are not to drop out at or above 85 per cent rated voltage.

1.9 Location and construction

1.9.1 Electrical equipment is to be placed in accessible and adequately lighted spaces clear of flammable material and heat sources such as boilers, heated tanks etc. The spaces should be well ventilated, free from accumulations of flammable dusts, vapours or gases and acid fumes. The equipment should not be exposed to risk of mechanical injury or damage from water, excessive moisture, steam, oil or any other dangerous fluid. Where necessarily exposed to such hazards, the equipment is to be suitably constructed or enclosed.

1.9.2 Live parts are to be efficiently shielded from any accidental contact.

1.9.3 All electrical apparatus and equipment is to be constructed and installed so as to avoid injury or electrical shock when handled or touched in the course of normal operation.

1.9.4 Insulating materials and insulated windings are to be resistant to tracking, moisture, sea air, oil vapour and any other similar conditions, unless special precautions are taken to protect them.

1.9.5 Equipment is not to remain alive through the control circuits and/or pilot lamps when switched off by the control switch. This does not apply to synchronising switches and/or plugs.

1.9.6 The operation of all electrical equipment and the lubrication arrangements are to be efficient under such conditions of vibration and shock as arise in normal practice.

1.9.7 All nuts and bolts/screws used to connect or secure current- carrying parts and working

parts are to be effectively locked, to prevent them from working loose due to vibration.

1.9.8 Generators, motors, conductors and generally any electrical equipment producing an external magnetic field are to be placed at such distance from the magnetic compass or any other equipment likely to be affected by such magnetic field or are to be so screened that the interfering external magnetic field is negligible (deviation less than 0.5°), even when circuits are switched on and off.

1.9.9 Where electric power is used for propulsion, the equipment is to be so arranged that it will operate satisfactorily in the event of partial flooding by bilge water above the tank top up to the floor plate level. See also Ch.3, Sec.2.

1.10 Design and construction

1.10.1 Design, construction and installation of electrical propelling machinery and associated equipment together with auxiliary services essential for the safety of ship are to be done in accordance with the relevant requirements of this Chapter and are to be surveyed and tested by the Surveyors.

1.10.2 Design and installation of other equipment is to be such as to ensure minimising the risk of fire due to its failure. As a minimum, it should comply with a National or International Standard, revised where necessary for ambient conditions.

1.10.3 Subject to inspection and testing by the Surveyors, compliance with the recommendations of the International Electrical Commission (IEC) publication 92 : "Electro-technical Installation in Ships" or equivalent national standards, may be accepted as meeting the requirements of this Chapter.

1.10.4 Where the Rules require electrical equipment to be of a 'safe type', such equipment is to be certified for the gases/vapours involved. The construction and type testing is to be in accordance with IEC publication 79 : "Electrical Apparatus for Explosive Gas Atmospheres", or an equivalent national standard.

1.11 Voltages

1.11.1 Standard voltages as recommended by IEC for shipboard installations, will in general be accepted subject to the following limits :

a) For power and the heating equipment, permanently installed and connected to fixed wiring, except for space heaters (radiators) in accommodation spaces - 1000V;

b) For lighting (including signal lamps), space heaters in accommodation spaces, socket-outlets, portable appliances and other consumers supplied by flexible cables and for communication and instrumentation equipment - 250V.

1.11.2 The requirements of 1.11.1 may be waived for the following applications :

a) For permanently installed power and heating equipment, where connection by flexible cable is essential because of the application (e.g. for movable cranes and other hoisting gear), a maximum of 1000V is acceptable,

b) For portable appliances, which are not hand-held during operation (e.g. welding transformers, refrigerated containers), a maximum of 1000V with connection by flexible cable and socket outlet, which is interlocked with a switch. At each such socket outlet a precautionary warning is to be permanently and prominently displayed indicating the nature and voltage of the electric supply and the specific purpose for which the socket outlet is intended. Such arrangements may be installed for applications in 1.11.2(a) also,

c) For instrumentation and control equipment which are part of power and heating installations (e.g. pressure or temperature switches for start/stop of motors), a maximum of 1000V, provided that all components are constructed for this voltage. The wider choice available of such components suitable for a voltage upto 250V is not to be overlooked,

d) Internal circuits of radio, television and navigation equipment or the external transmission circuits of radio and radar equipment. These may be however subject to statutory regulations.

1.11.3 Installations with higher voltages than specified above may be accepted for special purposes (e.g. cold cathode discharge lamps, for large auxiliary machinery and for propulsion machinery) after special consideration, in each case, and subject to the provisions of Sec.13 of this Chapter.

1.12 Electrical equipment for use in explosive gas atmospheres

1.12.1 Where the Rules require electrical equipment to be of a "safe type", such equipment is to be certified for the gases/vapours involved. The equipment should conform to IEC publication 79, "Electrical Apparatus for Explosive Gas Atmospheres", or an equivalent national standard.

1.12.2 Certified safe type equipment includes the following types of protection :

Intrinsically safe Ex "i"

Increased safety Ex "e"

Flameproof Ex "d"

Pressurized enclosure Ex "p"

1.12.3 Further, lighting fittings of the air driven type with pressurized enclosures are considered to be a "safe type" of lighting fitting.

1.12.4 When "safe type" equipment is permitted in hazardous zones or spaces all switches and protective devices are to interrupt all lines or phases and, where practicable, are to be located in a non-hazardous zone or space unless specifically permitted otherwise. Appropriate labels of non-inflammable material are to be permanently affixed to such equipment, switches and protective devices for identification purposes.

1.13 Enclosures

1.13.1 The enclosure types given in Table 1.13.1 are required as a minimum.

Table 1.13.1 : Enclosure types in relation to location
(N : Normally not accepted for installation in this location)

Location	Switchboards	Control gear and motor starters	Rotating machines	Transformers and rectifiers	Lighting fittings	Heating appliances	Socket outlets	Accessories such as switches connection boxes
Engine and boiler rooms								
above the floor	IP 22	IP 22	IP 22	IP 22	IP 22	IP 22	IP 44	IP 44

1.13.2 *Installation of electrical and electronic equipment in engine rooms protected by fixed water-based local application fire-fighting systems (FWBLAFFS)*

Definitions:

Protected space:

- A machinery space where a FWBLAFFS is installed.

Protected areas:

- Areas within a protected space which is required to be protected by FWBLAFFS.

Adjacent areas:

- Areas, other than protected areas, exposed to direct spray.

- Areas, other than those defined above, where water may extend. See also Fig.1.13.2.

Electrical and electronic equipment enclosures located within areas protected by FWBLAFFS and those within adjacent areas exposed to direct spray are to have a degree of protection not less than IP44, except where evidence of suitability is submitted to and approved by IRS.

The electrical and electronic equipment within adjacent areas not exposed to direct spray may have a lower degree of protection provided evidence of suitability for use in these areas is submitted taking into account :

a) the design and equipment layout,
b) position of inlet ventilation openings and
c) cooling airflow for the equipment.

Note :

1. Additional precautions may be required to be taken in respect of:

    a) tracking as the result of water entering the equipment.

    b) Potential damage as the result of residual salts from sea water systems.

    c) High voltage installations.

    d) Personnel protection against electric shock

2. Also refer to requirements indicated in Pt.6, Ch.3, Sec.4, Cl. 4.5.6.

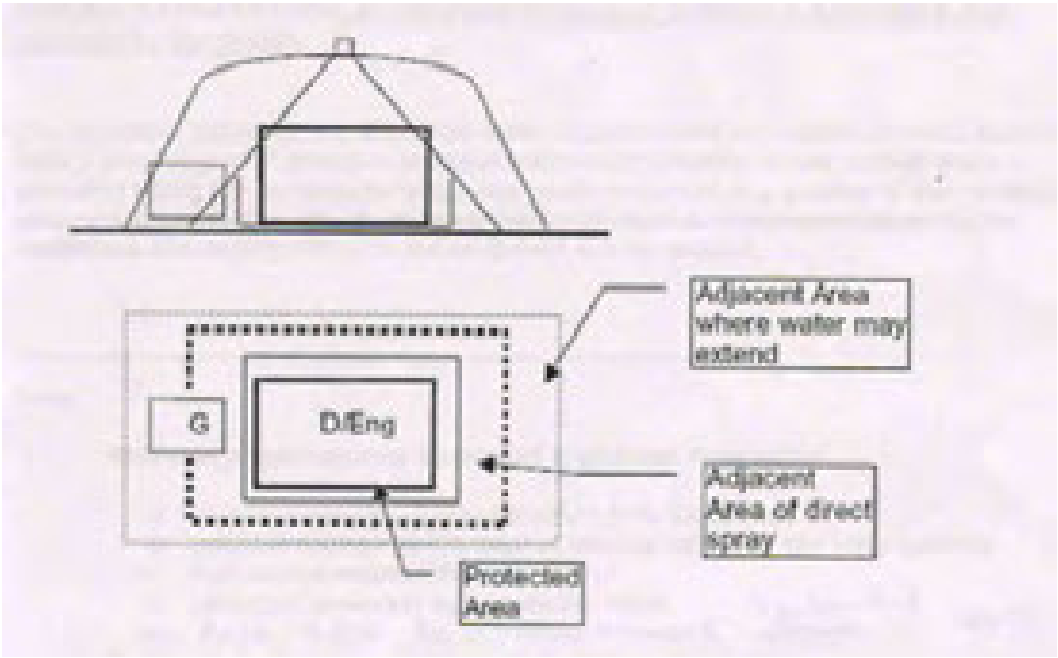

Fig. 1.13.2

1.14 Creepage and clearance

1.14.1 Distance between live parts and between live parts and earthed metal, whether across surfaces or in air, are to be adequate for the working voltages considering the nature of the insulating material and the transient over voltages developed by switch and fault conditions.

1.14.2 For bare busbars the minimum clearance distances in Table 1.14.1 are to be observed. Where necessary these distances are to be increased to allow for the electromagnetic forces involved.

Table 1.14.1 : Minimum clearances between bare busbars

Voltage between phases or poles	Minimum clearance to earth		Minimum clearance between phases or poles	
	In air [mm]	In oil [mm]	In air [mm]	In oil [mm]
660 or less	16	-	19	-
2200	38	-	38	-
3300	51	13	51	10
6600	63	19	89	25

1.15 Earthing of non-current carrying parts

1.15.1 Except where exempted by 1.15.2, all non-current carrying exposed metal parts of electrical equipment and cables are to be earthed.

1.15.2 The following parts may be exempted from the requirements of 1.15.1:

a) lamp-caps, where suitably shrouded;

b) shades, reflectors and guards supported on lamp holders or light fittings constructed of, or shrouded in, non-conducting material;

c) metal parts on, or screws in or through, non-conducting materials, which are separated by such material from current-carrying parts and from earthed non-current carrying parts in such a way that in normal use they cannot become live or come into contact with earthed parts;

d) apparatus which is constructed in accordance with the principle of double insulation;

e) bearing housings which are insulated in order to prevent circulation of current in the bearings;

f) clips for fluorescent lamps;

g) cable clips and short lengths of pipes for cable protection;

h) apparatus supplied at a voltage not exceeding 55 V direct current or 55 V, root mean square, between conductors, or between any conductor and earth in a circuit isolated from the supply. Auto transformers are not to be used for the purpose of achieving the alternating current voltage;

i) apparatus or parts of apparatus which although not shrouded in insulating material is nevertheless otherwise so guarded that it cannot be touched and cannot come in contact with exposed metal.

1.15.3 Metal coverings of cables are to be effectively earthed at both ends of the cable. In final sub-circuits, other than those installed in hazardous zones or spaces, earthing at the supply end only will be considered adequate. Single point earthing may be accepted for instrumentation cables, or cables for intrinsically safe circuits, if desirable for technical reasons.

1.15.4 The electrical continuity of all metal coverings of cables throughout the length of the cable, particularly at joints and trappings, is to be ensured.

1.15.5 Metal parts of portable appliances, other than current-carrying parts and parts exempted by 1.15.2 are to be earthed by means of an earth continuity conductor in the flexible cable or cord through the associated plug and socket outlet.

1.15.6 Earthing conductors are to be of copper or other corrosion-resistant material and be securely installed and protected where necessary against damage and also, where necessary, against electrolytic corrosion. Connections are to be so secured that they cannot work loose under vibration.

1.15.7 The nominal cross-section areas of copper earthing conductors are, in general to be equal to the cross-section of the current-carrying conductor upto 16 [mm^2]. Above this figure they are to be equal to at least half the cross-section of the current-carrying conductor with a minimum of 16 [mm^2]. Every other earthing conductor is to have a conductance not less than that specified for an equivalent copper earthing conductor.

1.15.8 The connection of the earthing conductors to the hull of the ship are to be made in accessible locations to permit their ready examination and to enable their disconnection for testing of insulation. They are to be secured by a screw or stud of diameter not less than 6 [mm] which is to be used for this purpose only. Bright metallic surfaces at the contact areas are to be ensured immediately before the nut or screw is tightened and where necessary, the joint is to be protected against electrolytic corrosion. The connection is to remain unpainted.

1.16 Bonding for the control of static electricity

1.16.1 Bonding straps for the control of static electricity are required for cargo tanks, process plant and piping systems, for flammable products and solids liable to release flammable gas and/or combustible dust, which are not permanently connected to the hull of the ship either directly or via their bolted or welded supports and where the resistance between them and the hull exceeds 1MΩ.

1.16.2 Where bonding straps are required for the control of static electricity, they are to be robust, that is, having a cross-sectional area of about 10 [mm^2] and are to comply with 1.15.6 and 1.15.8.

1.17 Operation under fire conditions

1.17.1 Electrical services required to be operable under fire conditions are as follows:

- Control and power systems to power-operated fire doors and their status indication.
- Control and power systems to power-operated watertight doors and their status indication.
- Emergency fire pump.
- Emergency lighting.
- Fire and general alarms.
- Fire detection systems.
- Fire-extinguishing systems and fire-extinguishing media release alarms.
- Low location lighting, see Pt.6, Ch.4, Sec.2.
- Public address systems.
- Remote emergency stop/shutdown arrangements for systems which may support the propagation of fire and/or explosion.

1.17.2 Where cables for services as described in 1.17.1 including their power supplies, pass through high fire risk areas and in addition for passenger ships, main vertical fire zones, other than those which they serve, they are to be so arranged that a fire in any of these areas or zones does not affect the operation of the service in any other area or zone (refer 1.17.3 for requirements for emergency fire pump). This may be achieved by either of the following measures:

a) Cables of a fire resistant type and complying with

i) IEC 60331-1:2018 for overall diameter greater than 20 [mm] and

ii) IEC 60331-21:1999 and AMD 1:2009 or IEC 60331-2:2018 for overall diameter less than or equal to 20 [mm]

are installed and run continuously within the high fire risk area to keep the fire integrity. See Fig.1.17.2.

b) By running cables in two loops or distributing cables radially as widely apart as practicable and so arranged that in the event of damage by fire atleast one of loops or radial distributions remains operational.

Systems that are self monitoring, fail safe or duplicated with cable runs as widely separated as is practicable may be exempted.

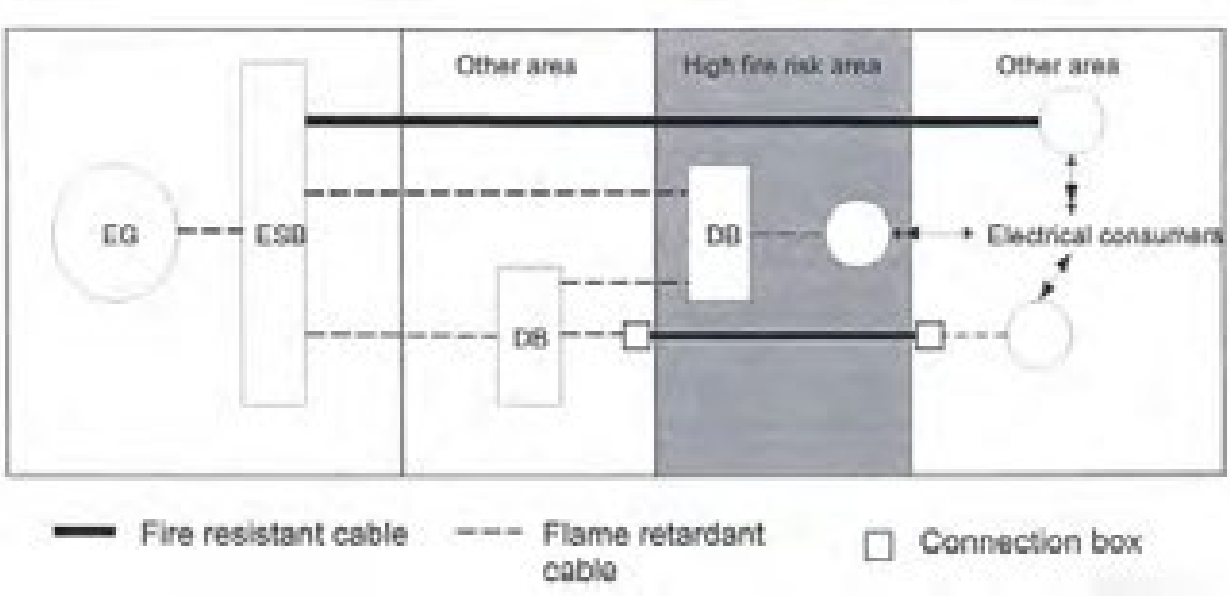

Fig.1.17.2 : The running of fire resistant type cables

1.17.3 The electrical cables to the emergency fire pump are not to pass through the machinery spaces containing the main fire pumps and their source(s) of power and prime mover(s). They are to be of a fire resistant type, in accordance with 1.17.2 (a), where they pass through other high fire risk areas.

1.17.4 “High fire risk areas” are defined as follows:

i) Machinery spaces as defined by Pt.6, Ch.1, 3.30, except spaces having little or no fire risk as defined in Pt 6, Ch 3, 3.2.2.3.2.2 (10) (including interpretations of table 9.3 to 9.8 given in MSC/Circ.1120 as amended by MSC.1/ Circ. 1436 and MSC.1/ Circ. 1510).

ii) Spaces containing fuel treatment equipment and other highly flammable substances.

iii) Galley and pantries containing cooking appliances.

iv) Laundry with drying equipment.

v) Spaces as defined by paragraphs (8), (12) and (14) of Part 6, Chapter 3, Cl.3.2.2.3.2 for ships carrying more than 36 passengers.

1.18 Additions and alterations

1.18.1 Additions or alterations (temporary or permanent) to the approved load of the existing electrical installations are not to be made unless it has been ascertained that the current carrying capacity and condition of the existing installation are adequate for the proposed modification.

1.18.2 Plans for the proposed modifications are to be submitted for approval and the additions or alterations are to be carried out under the inspection and to the satisfaction of the Surveyors.

Section 2

System Design

2.1 General

2.1.1 Electrical installations are to be such that:

- all electrical auxiliary services necessary for maintaining the ship in normal operational and habitable conditions are ensured without recourse to the emergency source of electrical power;

- electrical services essential for safety are ensured under various emergency conditions; and

- the safety of passengers, crew and ship from electrical hazards is ensured.

2.2 Supply and distribution systems

2.2.1 The following systems of generation and distribution as detailed in Table 2.2.1 are acceptable.

2.2.2 Systems of generation and distribution, other than those specified above, will, upon application, be given special consideration.

2.3 Voltage and frequency variations

2.3.1 For installations supplied by generators, the voltage on the main switchboard's bus-bars is to be kept between 97.5 and 102.5 per cent of the installation's nominal voltage under all steady load conditions.

2.3.2 For D.C. installations supplied by batteries, consideration is to be given to the supply voltage variation between the battery's full-charged and minimum-charged voltages. For battery installations with "float charge", the maximum charging voltage is to be considered.

2.3.3 The transient voltage variations on the main switchboard's bus-bars by the maximum power and current variations which can occur (except under fault conditions), are not to exceed - 15% and + 20% of the nominal voltage.

2.3.4 The voltage drop in each consumer circuit, by full load on this circuit, is not to exceed 6% of the nominal voltage, measured from the main switchboard's bus-bars to the consumer. For battery circuits with supply voltage less than 50 Volts, 10% voltage drop may be accepted.

2.3.5 The frequency variations on AC installations are to be kept within the following limits :

- 95 - 105 per cent of rated frequency under steady load conditions; and

- 90 - 110 per cent of rated frequency under transient load conditions.

Table 2.2.1 : Systems of generation and distribution

Description	Tankers intended for the carriage in bulk of oil, liquefied gases and other hazardous liquids having a flashpoint not exceeding 60°C (closed cup test)	Other vessels
d.c. two wire insulated system (See Note 1)	Acceptable	Acceptable
a.c., single-phase, two wire insulated system (See Note 1)	Acceptable	Acceptable
a.c., three-phase, three wire insulated system (See Note 2)	Acceptable	Acceptable
a.c. or d.c. earthed systems	Normally not acceptable (See Note 3)	Acceptable
a.c. three-phase, four wire system with neutral earthed but without hull return	Not acceptable	Acceptable upto 1000V
Hull return system of distribution (a.c. or d.c.)	Normally not acceptable (See Notes 4 and 5)	Normally not acceptable (See Notes 4 and 5)

Note 1 : None of the poles/phases is earthed (see also para 2.4).

Note 2 : Neutral is not earthed.

Note 3 : This may be acceptable for -

a) Power supplied control circuits and instrumentation circuits, where technical or safety reasons require connection to earth, provided the current in the hull is limited to not more than 5 amps in both normal and fault conditions.

b) Earthed intrinsically safe circuits.

c) Limited and locally earthed systems, provided that any possible resulting current does not flow directly through any of the dangerous spaces.

d) Alternating current power networks of 1000 Volts root mean square (line to line) and over, provided that any possible resulting current does not flow directly through any of the dangerous spaces.

e) The electrical systems shall be specially considered for existing vessels built before 1st October, 1994.

Note 4 : This may be acceptable for -

a) Impressed current cathodic protection systems.

b) Limited and locally earthed systems, such as starting and ignition systems of internal combustion engines, provided that any possible resulting current does not flow directly through any of the dangerous spaces.

c) Insulation level monitoring devices, provided the circulation current does not exceed 30 mA under the most unfavourable conditions.

Note 5 : All final sub-circuits, i.e. all circuits fitted after the last protective device are to be of two insulated wires the hull return being achieved by connecting to the hull, one of the busbars of the distribution board from which wires originate.

2.4 Earth indication

2.4.1 Every insulated distribution system is to be provided with a device or devices to continuously monitor the values of electrical insulation to earth and to give an audible or visual indication in case of abnormally low insulated values.

2.5 Number, arrangement and capacity of generators

2.5.1 The number and capacity of generators are to be such that with any one generator not in operation, the capacity of the remaining generators is to be sufficient for :

- supplying all essential and other services mentioned under 1.5.1 and 1.5.2 of this chapter which can be expected to be in use simultaneously, at full power on the propulsion plant, and including the maximum load which can be expected to occur on the lighting installation; and

- to have sufficient reserve capacity for starting the largest electric motor on board, without the transient voltage and frequency variations exceeding the values specified in 2.3.

2.5.2 For a duplicated essential or important consumer with only one unit driven electrically, it is not expected that electrically driven auxiliary would be used with one generator out of action. Similarly the loads due to side/bow thrusters are not to be taken in to account while calculating the electric load with one generator out of action unless necessitated by additional class notation regarding Dynamic Positioning.

2.5.3 The arrangement of the generators is to be such that the requirements of 2.5.1 would be met regardless of the speed and direction of the propulsion machinery or shafting.

2.5.4 In addition, the generating sets are to be such as to ensure that with any one generator or its primary source of power out of operation, the remaining generating sets are to be capable of providing the electrical services necessary to start the main propulsion plant from a dead ship condition. The emergency source of power may be used for the purpose of starting from a dead ship condition if its capability alone or combined with that of any other source of electrical power is sufficient to provide at the same time those services required to be supplied by 2.8.

2.5.5 Where the main source of electrical power is essential for the propulsion and steering of the ship, the system is to be arranged such that the electrical supply to equipment necessary for propulsion, steering and safety of the ship is maintained or immediately restored in case of loss of any one generator in service.

2.5.6 Requirement in 2.5.5 to be fulfilled by the following measures:

a) Where the electrical power is normally supplied by more than one generator set simultaneously in parallel operation, provision of protection, including automatic disconnection of sufficient non-essential services and if necessary services those provided for habitability, should be made to ensure that, in case of loss of any of these generating sets, the remaining ones are kept in operation to permit propulsion and steering and to ensure safety.

b) Where the electrical power is normally supplied by one generator provision shall be made, upon loss of power, for automatic starting and connecting to the main switchboard of stand-by generator(s) of sufficient capacity with automatic restarting of the essential auxiliaries, in sequential operation if required. Starting and connection to the main switchboard of the stand-by generator is to be preferably within 30 seconds, but in any case not more than 45 seconds, after loss of power. Where prime movers with longer starting time are to be used, the starting and connection time are subject to special approval.

c) Load shedding or other equivalent arrangements should be provided to protect the generators against sustained overload.

i) The load shedding is to be automatic.

ii) Primary essential services mentioned in 1.5.1.2 are not to be included in any load shedding.

iii) The secondary essential services mentioned in 1.5.1.3 may be included in load shedding provided:

a) Following systems, required for safety, are not disrupted:
- lighting systems,
- navigation lights, aids and signals,

- internal safety communication equipment,
- fire detection and alarm systems
- electrical equipment for watertight closing appliances.

b) Immediate availability of following services, required for safety, is not affected when the power supply is restored to normal operating conditions:
- fire pumps and other extinguishing medium pumps,
- bilge pumps,
- ventilating fans for engine and boiler rooms.

iv) The services for habitable conditions mentioned in 1.5.2 may be included in load shedding.

2.5.7 For vessels with electric propulsion system, under normal sea-going conditions, the number and capacity of generators is to be such that with any one generator not in operation, the capacity of remaining generator/s is to be sufficient for supplying all essential and other services mentioned at 1.5.1 and 1.5.2 of this Chapter, which can be expected to be used simultaneously, at speed of 7 knots or half the design speed, whichever is lesser.

2.6 Prime movers for generators

2.6.1 Each generator required according to 2.5 is normally to be driven by a separate auxiliary prime mover. If such prime mover for a generator also is used for driving other auxiliary machinery, it is to have sufficient capacity for the total load, or the machinery arrangement is to be such that the generator and the other auxiliary machinery can not be used simultaneously.

If the other auxiliary machinery is connected to the prime mover in such a way that it is possible to overload the prime mover, an interlocking or other effective means for preventing such overloading is to be arranged.

2.6.2 When generators driven by reciprocating steam engines or steam turbines are used, and the operation of the boiler(s) depends on electric power supply, then there is to be at least one generator driven by an auxiliary oil engine or gas turbine to enable the boiler plant to be started.

2.6.3 Generators and generator systems, having the ship's main propulsion machinery as their prime mover, may be accepted as part of the ships main source of electrical power, provided:

a) They are capable of operating under all weather conditions during sailing and during manoeuvring, also when the vessel is stopped, within the limits of voltage and frequency variations as specified in 2.3;

b) Their rated capacity is safeguarded during all operations given above and is such that in the event of any other one of the generators failing, the services given in 1.5.1 and 1.5.2 are maintained;

c) The short circuit current of the generator / generator system is sufficient to trip the generator / generator system circuit-breaker taking into account the selectivity of the protective devices for the distribution system.

d) Protection is to be arranged in order to safeguard the generator / generator system in case of a short-circuit in the main bus bar. The generator / generator system is to be suitable for further use after fault clearance.

e) It is to be possible to disconnect the generator from the propulsion system by a separate clutch.

f) Starting of stand-by generating sets is to be in accordance with 2.5.6b).

2.6.4 Generators and generator systems, having the ship's propulsion machinery as their prime mover but not forming part of the ship's main source of electrical power as specified in 2.6.3a) may be accepted whilst the ship is at sea to supply electrical services required for normal operational and habitable conditions provided :

a) There are sufficient and adequately rated additional generators fitted, which constitute the main source of electrical power, meeting the requirements as specified in 2.5.3.

b) Means are provided to automatically start one or more of the generators, constituting the main source of electrical power as per 2.5.3 or 2.5.6b), upon the frequency

variations exceeding ± 10 of the limits as specified in 2.3 and the voltage variations exceeding the limits as specified in 2.3.

c) The short circuit current of the generator and/or generator system is sufficient to trip the generator/generator system circuit-breaker taking into account the selectivity of the protective devices for the distribution system.

d) Where considered appropriate, load shedding arrangements are fitted to meet the requirements of 2.5.6c).

e) On ships having remote control of the ship's propulsion machinery from the navigating bridge means are provided, or procedures be in place, so as to ensure that supplies to essential services are maintained during manoeuvring conditions in order to avoid a blackout situation.

2.7 Number and capacity of transformers or power convertors

2.7.1 Where essential and other services mentioned under 1.5.1 and 1.5.2 of this chapter are supplied, by transformers or power convertors, the number and rating of transformers or power convertors are to be sufficient to ensure the operation of essential services and important consumers even when any one transformer or power convertor is out of action.

2.7.2 With any one transformer or power convertor out of action, the remaining transformer(s) or power convertor(s) should be adequate for starting the largest essential and important electric motor, without the transient voltage and frequency variations exceeding the limits specified in 2.3.

2.7.3 Each transformer or power convertor fitted in accordance with these requirement is to be installed as a separate unit, with a separate enclosure.

2.7.4 Each transformer is to be served by separate circuits on the primary and secondary sides. Auto transformers used for motor starting are excluded.

2.8 Emergency source of power

2.8.1 A self-contained emergency source of electrical power is to be provided in all ships.

2.8.2 The emergency source of electrical power and associated transforming equipment, if any, transitional source of emergency power, emergency switchboard and emergency lighting switchboard are to be located above the uppermost continuous deck and are to be readily accessible from the open deck. They are not to be located forward of the collision bulkhead.

2.8.3 The location of the emergency source of electrical power and associated transforming equipment, if any, the transitional source of emergency power, the emergency switchboard and the emergency electric lighting switchboards in relation to the main source of electrical power, associated transforming equipment, if any, and the main switchboard are to be such as to ensure to the satisfaction of IRS that a fire or other casualty in spaces containing the main source of electrical power, associated transforming equipment, if any, and the main switchboard or in any machinery space of category A will not interfere with the supply, control and distribution of emergency electrical power. As far as practicable, the space containing the emergency source of electrical power, associated transforming equipment, if any, the transitional source of emergency electrical power and the emergency switchboard is not to be continuous to the boundaries of machinery spaces of category A or those spaces containing the main source of electrical power, associated transforming equipment, if any, or the main switchboard. Requirements for ventilation of emergency generator rooms are given in 2.8.10.

2.8.4 Provided that suitable measures are taken for safeguarding independent emergency operation under all circumstances, the emergency generator may be used exceptionally, and for short periods, to supply non-emergency circuits.

Exceptionally, whilst the vessel is at sea, is understood to mean conditions such as:

- blackout situation
- dead-ship situation
- routine use for testing
- short-term parallel operation with the main source of electrical power for the purpose of load transfer.

Unless instructed otherwise by the Administration the emergency generator may be used during lay time in port for the supply of the ship mains, provided the requirements of 2.8.4.1 and 2.8.4.2 below are complied with.

2.8.4.1 Requirements

a) To prevent the generator or its prime mover from getting overloaded when used in port, arrangements are to be provided to shed sufficient non-emergency loads to ensure its continued safe operation.

b) The prime mover is to be arranged with fuel oil filters and lubrication oil filters, monitoring equipment and protection devices as required for the prime mover for main power generation and for unattended operation.

c) The fuel oil supply tank to the prime mover is to be provided with a low level alarm, arranged at a level ensuring sufficient fuel oil capacity for the emergency services for the period of time as required by 2.8.8 and 2.8.9 of this section.

d) The prime mover is to be designed and built for continuous operation and should be subjected to a planned maintenance scheme ensuring that it is always available and capable of fulfilling its role in the event of an emergency at sea.

e) Fire detectors are to be installed in the location where the emergency generator set and emergency switchboard are installed.

f) Means are to be provided to readily change over to emergency mode from harbour mode.

g) Control, monitoring and supply circuits, for the purpose of the use of the emergency generator in port are to be so arranged and protected that any electrical fault will not influence the operation of the main and emergency services.

h) When necessary for safe operation, the emergency switchboard is to be fitted with switches to isolate the circuits.

2.8.4.2 Operation

Instructions* are to be provided on board to ensure that when the vessel is under way all control devices (e.g. valves, switches) are in a correct position for the independent emergency operation of the emergency generator set and emergency switchboard.

* These instructions are also to contain information on required fuel oil tank level, position of harbour/sea mode switch if fitted, ventilation openings etc.

2.8.5 The emergency generator and other means needed to restore the propulsion are to have a capacity such that the necessary propulsion starting energy is available within 30 minutes of blackout/dead ship condition. For the purpose of this requirement "Blackout" is to be understood to mean a "dead ship" condition. Emergency generator stored starting energy is not to be directly used for starting the propulsion plant, the main source of electrical power and/or other essential auxiliaries (emergency generator excluded). The requirement of propulsion starting energy being available within 30 minutes would remain applicable even when there is no emergency generator installed.

For steam ships, the 30 minutes time limit is the time from blackout / dead ship condition to lighting of the first boiler.

2.8.6 Use of emergency generator during lay time in port for the supply of the ship mains as stated in para 2.8.4 will be specially considered on submission of details of safeguards to ensure its continued availability for its intended emergency duties.

2.8.7 Starting arrangements for emergency generating sets

2.8.7.1 Emergency generating sets are to be capable of being readily started in their cold condition at a temperature of 0°C. If this is impracticable, or if lower temperatures are likely to be encountered, provision acceptable to IRS is to be made for the maintenance of heating arrangements, to ensure ready starting of the generating sets.

2.8.7.2 Each emergency generating set arranged to be automatically started is to be equipped with starting devices approved by IRS with a stored energy capability of at least three

consecutive starts. A second source of energy is to be provided for an additional three starts within 30 minutes unless manual starting can be demonstrated to be effective.

2.8.7.3 The stored energy is to be maintained at all time, as follows:

a) electrical and hydraulic starting systems are to be maintained from the emergency switchboard;

b) compressed air starting systems may be maintained by the main or auxiliary compressed air receivers through a suitable non-return valve or by an emergency air compressor which, if electrically driven, is supplied from the emergency switchboard;

c) all of these starting, charging and energy storing devices are to be located in the emergency generator space; these devices are not to be used for any purpose other than the operation of the emergency generating set. This does not preclude the supply to the air receiver of the emergency generating set from the main or auxiliary compressed air system through the non-return valve fitted in the emergency generator space.

2.8.7.4 Where automatic starting is not required, manual starting is permissible, such as manual cranking, inertia starters, manually charged hydraulic accumulators, or powder charge cartridges, where they can be demonstrated as being effective.

2.8.7.5 When manual starting is not practicable, the requirements of 2.8.7.2 and 2.8.7.3 are to be complied with except that starting may be manually initiated.

2.8.8 Passenger ships

2.8.8.1 The electrical power available is to be sufficient to supply all those services that are essential for safety in an emergency, due regard being paid to such services as may have to be operated simultaneously. The emergency source of electrical power is to be capable, having regard to starting currents and the transitory nature of certain loads, of supplying simultaneously at least the following services for the periods specified herein, if they depend upon an electrical source for their operation:

a) For a period of 36 hours, emergency lighting:

i) at every embarkation station on deck and over sides;

ii) in alleyways, stairways and exits giving access to the muster and embarkation stations;

iii) in all service and accommodation alleyways, stairways and exits, personnel lift cars;

iv) in the machinery spaces and main generating stations including their control positions;

v) in all control stations, machinery control rooms, and at each main and emergency switchboard;

vi) at all stowage positions for firemen's outfits;

vii) at the steering gear; and

viii) at the fire pump, the sprinkler pump and the emergency bilge pump referred to in 2.8.8.1(d) and at the starting position of their motors.

b) For a period of 36 hours

i) the navigation lights and other lights required by the International Regulations for Preventing Collisions at Sea in force; and

ii) on ships constructed on or after 1 February 1995, the VHF radio installation; and if applicable

- the MF radio installation;
- the ship earth station; and
- the MF/HF radio installations.

c) For a period of 36 hours; unless such services have an independent supply for the period of 36 hours from an accumulator battery suitably located for use in an emergency:

i) all internal communication equipment required in an emergency which is generally;

- The means of communication which is provided between the navigating

bridge and the steering gear compartment.

- The means of communication which is provided between the navigating bridge and the position in the machinery space or control room from which the engines are normally controlled.

- The means of communication which is provided between the bridge and the radio telegraph or radio telephone stations.

- The means of communication which is provided between the officer of the watch and the person responsible for closing any watertight door which is not capable of being closed from a central control station.

- The public address system or other effective means of communication which is provided throughout the accommodation, public and service spaces.

- The means of communication which is provided between the navigating bridge and the main fire control station.

ii) the shipborne navigational equipment, where such provision is unreasonable or impracticable IRS may waive this requirement for ships of less than 5,000 tons gross tonnage;

iii) the fire detection and fire alarm system, and the fire door holding and release system; and

iv) for intermittent operation of the daylight signaling lamp, the ship's whistle, the manual fire alarms and all internal signals that are required in an emergency.

d) For a period of 36 hours:

i) one of the fire pumps required by Pt.6, Ch.3, Sec.4, Cl.4.2.2.2 and 4.2.2.3;

ii) the automatic sprinkler pump, if any; and

iii) the emergency bilge pump and all the equipment essential for the operation of electrically powered remote controlled bilge valves.

e) For the period of time required by Ch.6, Sec.6, the steering gear if required to be so supplied.

f) For a period of half an hour:

i) any watertight doors which are required to be power operated together with their indicators and warning signals. Sequential operation of the doors may be permitted provided all doors can be closed in 60 seconds;

ii) the emergency arrangements to bring the lift cars to deck level for the escape of persons. The passenger lift cars may be brought to deck level sequentially in an emergency.

g) In a ship engaged regularly on voyages of short duration, IRS if satisfied that an adequate standard of safety would be attained may accept a lesser period than the 36 hour period specified in 2.8.8.1(a) to 2.8.8.1(e) but not less than 12 hours.

2.8.8.2 The emergency source of electrical power may be either a generator or an accumulator battery, which is to comply with the following:

a) Where the emergency source of electrical power is a generator, it is to be:

i) driven by a suitable prime-mover with an independent supply of fuel having a flashpoint (closed cup test) of not less than 43°C;

ii) started automatically upon failure of the electrical supply from the main source of electrical power and is to be automatically connected to the emergency switchboard; those services referred to in 2.8.8.3 are then to be transferred automatically to the emergency generating set. The automatic starting system and the characteristic of the prime-mover are to be such as to permit the emergency generator to carry its full rated load as quickly as is safe and practicable, subject to a maximum of 45 seconds; unless a second independent means of starting the emergency generating set is provided, the single source of stored

energy is to be protected to preclude its complete depletion by the automatic starting system; and

iii) provided with a transitional source of emergency electrical power according to 2.8.8.3.

b) Where the emergency source of electrical power is an accumulator battery, it is to be capable of:

i) carrying the emergency electrical load without recharging while maintaining the voltage of the battery throughout the discharge period within 12 per cent above or below its nominal voltage;

ii) automatically connecting to the emergency switchboard in the event of failure of the main source of electrical power; and

iii) immediately supplying at least those services specified in 2.8.8.3.

2.8.8.3 The transitional source of emergency electrical power required by 2.8.8.2(a)(iii) is to consist of an accumulator battery suitably located for use in an emergency which is to operate without recharging while maintaining the voltage of the battery throughout the discharge period within 12 per cent above or below its nominal voltage and be of sufficient capacity and so arranged as to supply automatically in the event of failure of either the main or emergency source of electrical power at least the following services, if they depend upon an electrical source for their operation:

a) For half an hour:

i) the lighting required by paragraphs 2.8.8.1(a) and 2.8.8.1(b)(i);

ii) Services required by paragraphs 2.8.8.1(c) (i, iii and iv) unless such services have an independent supply for the period specified from an accumulator battery suitably located for use in an emergency.

b) Power to close the watertight doors but not necessarily all of them simultaneously, unless an independent temporary source of stored energy is provided. Power to the control, indication and alarm circuits as required for half an hour.

2.8.8.4 Where the emergency and/or transitional emergency loads are supplied from a battery via an electronic converter or inverter the maximum permitted voltage variations are to be taken as those on the load side of the converter or inverter.

The above mentioned voltage variants are not to exceed the following limits, as applicable:

a) Where the system on the load side of the converter or inverter is d.c. : limits as given in 2.8.8.3.

b) Where the system on the load side of the converter or inverter is a.c. : limits as given in 1.8.1.

2.8.8.5 The emergency switchboard is to be installed as near as is practicable to the emergency source of electrical power.

2.8.8.6 Where the emergency source of electrical power is a generator, the emergency switchboard is to be located in the same space unless the operation of the emergency switchboard would thereby be impaired.

2.8.8.7 No accumulator battery fitted in accordance with this Section is to be installed in the same space as the emergency switchboard. An indicator is to be mounted in a suitable place on the main switchboard or in the machinery control room to indicate when the batteries constituting either the emergency source of electrical power or the transitional source of emergency electrical power referred to in paragraph 2.8.8.2(b) or 2.8.8.3 are being discharged.

2.8.8.8 The emergency switchboard is to be supplied during normal operation from the main switchboard by an interconnector feeder which is to be adequately protected at the main switchboard against overload and short circuit and which is to be disconnected automatically at the emergency switchboard upon failure of the main source of electrical power. Where the system is arranged for feedback operation, the interconnector feeder is also to be protected at the emergency switchboard at least against short circuit.

2.8.8.9 In order to ensure ready availability of the emergency source of electrical power, arrangements are to be made where necessary to disconnect automatically non-emergency circuits from the emergency switchboard to ensure that power will be available to the emergency circuits.

2.8.8.10 The emergency generator and its prime-mover and any emergency accumulator battery is to be so designed and arranged as to ensure that they will function at full rated power when the ship is upright and when inclined at any angle of list up to 22.5° or when inclined up to 10° either in the fore or aft direction, or is in any combination of angles within those limits.

2.8.8.11 Provision is to be made for the periodic testing of the complete emergency system and is to include the testing of automatic starting arrangements.

2.8.9 Cargo ships

2.8.9.1 The electrical power available is to be sufficient to supply all those services that are essential for safety in an emergency, due regard being paid to such services as may have to be operated simultaneously. The emergency source of electrical power is to be capable, having regard to starting currents and the transitory nature of certain loads, of supplying simultaneously at least the following services for the periods specified herein, if they depend upon an electrical source for their operation:

a) For a period of 3 hours, emergency lighting at every muster and embarkation station and over sides;

b) For a period of 18 hours, emergency lighting:

i) in all service and accommodation alleyways, stairways and exits, personnel lift cars and personnel lift trunks;

ii) in the machinery spaces and main generating stations including their control positions;

iii) in all control stations, machinery control rooms, and at each main and emergency switchboard;

iv) at all stowage positions for firemen's outfits;

v) at the steering gear;

vi) at the fire pump referred to in 2.8.9.2, at the sprinkler pump, if any, and at the emergency bilge pump, if any, and at the starting positions of their motors; and

vii) in all cargo pump-rooms of tankers.

c) For a period of 18 hours

i) the navigation lights and other lights required by the International Regulations for Preventing Collisions at Sea in force; and

ii) on ships constructed on or after 1 February 1995, the VHF radio installation; and if applicable

- the MF radio installation;
- the ship earth station; and
- the MF/HF radio installations.

d) For a period of 18 hours; unless such services have an independent supply for the period of 18 hours from an accumulator battery suitably located for use in an emergency:

i) all internal communication equipment as required in an emergency which is generally as indicated in 2.8.8.1 c) i);

ii) the shipborne navigational equipment, where such provision is unreasonable or impracticable IRS may waive this requirement for ships of less than 5,000 tons gross tonnage;

iii) the fire detection and fire alarm system; and

iv) intermittent operation of the daylight signaling lamp, the ship's whistle, the manual fire alarms, and all internal signals that are required in an emergency.

2.8.9.2 For period of 18 hours one of the fire pumps required by Pt.6, Ch.3, if dependent upon the emergency generator for its source of power.

2.8.9.3 For the period of time required by Ch.6, Sec.6, the steering gear where it is required to be so supplied.

2.8.9.4 In a ship engaged regularly in voyages of short duration, IRS if satisfied that an adequate standard of safety would be attained may accept a lesser period than the 18 hour period specified in paragraphs 2.8.9.1(b) to 2.8.9.1(d) and 2.8.9.2 but not less than 12 hours.

2.8.9.5 The emergency source of electrical power may be either a generator or an accumulator battery, which is to comply with the following:

a) Where the emergency source of electrical power is a generator, it is to be:

i) driven by a suitable prime-mover with an independent supply of fuel, having a flashpoint (closed cup test) of not less than 43°C;

ii) started automatically upon failure of the main source of electrical power supply unless a transitional source of emergency electrical power in accordance with 2.8.9.5(a)(iii) is provided; where the emergency generator is automatically started, it is to be automatically connected to the emergency switchboard; those services referred to in 2.8.9.6 are then to be connected automatically to the emergency generator; and unless a second independent means of starting the emergency generator is provided the single source of stored energy is to be protected to preclude its complete depletion by the automatic starting system; and

iii) provided with a transitional source of emergency electrical power as specified in 2.8.9.6 unless an emergency generator is provided capable both of supplying the services mentioned in 2.8.9.6 and of being automatically started and supplying the required load as quickly as is safe and practicable subject to a maximum of 45 seconds.

b) Where the emergency source of electrical power is an accumulator battery it is to be capable of:

i) carrying the emergency electrical load without recharging while maintaining the voltage of the battery throughout the discharge period within 12 per cent above or below its nominal voltage;

ii) automatically connecting to the emergency switchboard in the event of failure of the main source of electrical power; and

iii) immediately supplying at least those services specified in 2.8.9.6.

2.8.9.6 The transitional source of emergency electrical power where required by 2.8.9.5(a) is to consist of an accumulator battery suitably located for use in an emergency which is to operate without recharging while maintaining the voltage of the battery throughout the discharge period within 12 per cent above or below its nominal voltage and be of sufficient capacity and is to be so arranged as to supply automatically in the event of failure of either the main or the emergency source of electrical power for half an hour at least the following services if they depend upon an electrical source for their operation:

a) the lighting required by 2.8.9.1(a) to 2.8.9.1(c). For this transitional phase, the required emergency electric lighting, in respect of the machinery space and accommodation and service spaces may be provided by permanently fixed, individual, automatically charged, relay operated accumulator lamps; and

b) all services required by 2.8.9.1(d) (i, iii and iv) unless such services have an independent supply for the period specified from an accumulator battery suitably located for use in an emergency.

2.8.9.7 Where the emergency and/or transitional emergency loads are supplied from a battery via an electronic converter or inverter the maximum permitted voltage variations are to be taken as those on the load side of the converter or inverter.

The above mentioned voltage variants are not to exceed the following limits, as applicable:

a) Where the system on the load side of the converter or inverter is d.c. : limits as given in 2.8.9.6.

Where the system on the load side of the converter or inverter is a.c. : limits as given in 1.8.1.

2.8.9.8 The emergency switchboard is to be installed as near as is practicable to the emergency source of electrical power.

2.8.9.9 Where the emergency source of electrical power is a generator, the emergency switchboard is to be located in the same space unless the operation of the emergency switchboard would thereby be impaired.

2.8.9.10 No accumulator battery fitted in accordance with this Section is to be installed in the same space as the emergency switchboard. An indicator is to be mounted in a suitable place on the main switchboard or in the machinery control room to indicate when the batteries constituting either the emergency source of electrical power or the transitional source of electrical power referred to in paragraph 2.8.9.5(b) or 2.8.9.6 are being discharged.

2.8.9.11 The emergency switchboard is to be supplied during normal operation from the main switchboard by an interconnector feeder which is to be adequately protected at the main switchboard against overload and short circuit and which is to be disconnected automatically at the emergency switchboard upon failure of the main source of electrical power. Where the system is arranged for feedback operation, the interconnector feeder is also to be protected at the emergency switchboard at least against short circuit.

2.8.9.12 In order to ensure ready availability of the emergency source of electrical power, arrangements are to be made where necessary to disconnect automatically non-emergency circuits from the emergency switchboard to ensure that electrical power will be available automatically to the emergency circuits.

2.8.9.13 The emergency generator and its prime-mover and any emergency accumulator battery is to be so designed and arranged as to ensure that they will function at full rated power when the ship is upright and when inclined at any angle of list up to 22.5° or when inclined up to 10° either in the fore or aft direction, or is in any combination of angles within those limits. Also refer to Part 4, Chapter 1, Table 1.7.1.

2.8.9.14 Provision is to be made for the periodic testing of the complete emergency system and is to include the testing of automatic starting arrangements.

2.8.10 Ventilation of emergency generator rooms

2.8.10.1 The following requirements apply to closable ventilation louvers and ventilator closing appliances serving emergency generator rooms, where fitted:

a) Ventilation louvers and closing appliances may either be hand-operated or power-operated (hydraulic / pneumatic / electric) and are to be operable under a fire condition;

b) Hand-operated ventilation louvers and closing appliances are to be kept open during normal operation of the vessel. Corresponding instruction plates are to be provided at the location where hand-operation is provided;

c) Power-operated ventilation louvers and closing appliances are to be of a fail-to-open type. Closed power operated ventilation louvers and closing appliances are acceptable during normal operation of the vessel. Power-operated ventilation louvers and closing appliances are to open automatically whenever the emergency generator is starting / in operation;

d) It is to be possible to close ventilation openings by a manual operation from a clearly marked safe position outside the space where the closing operation can be easily confirmed. The louver status (open / closed) is to be indicated at this position. Such closing is not to be possible from any other remote position.

2.9 Requirements for uninterrupted power system (UPS) units as alternative and/or transitional source of power

2.9.1 Scope

These requirements to UPS units, as defined in IEC 62040-3:2011, apply when providing an alternative power supply or transitional power supply to services as defined in 2.8.8 and 2.8.9.

A UPS unit complying with these requirements may provide an alternative power supply as an accumulator battery in terms of being an independent power supply for services defined in 2.8.8.1c) and 2.8.9.1d).

2.9.2 Definitions

Uninterruptible Power System (UPS) – combination of converters, switches and energy storage means, for example batteries, constituting a power system for maintaining continuity of load power in case of input power failure (IEC 62040-3:2011).

Off-line UPS unit – a UPS unit where under normal operation the output load is powered from the bypass line (mains) and only transferred to the inverter if the bypass supply

fails or goes outside preset limits. This transition will invariably result in a brief (typically 2 to 10 milli-seconds) break in the load supply.

Line interactive UPS unit – an off-line UPS unit where the bypass line switches to stored energy power when the input power goes outside the preset voltage and frequency limits.

On-line UPS unit – a UPS unit where under normal operation the output load is powered from the inverter and will therefore continue to operate without break in the event of the supply input failing or going outside preset limits.

2.9.3 Design and construction

a) UPS units are to be constructed in accordance with IEC 62040-1:2017, IEC 62040-2:2016, IEC 62040-3:2011, IEC 62040-4:2013 and/or IEC 62040-5:2016, as applicable, or an acceptable and relevant national or international standard.

b) The operation of the UPS is not to depend upon external services.

c) The type of UPS unit employed, whether off-line, line interactive or on-line, is to be appropriate to the power supply requirements of the connected load equipment.

d) An external bypass is to be provided.

e) The UPS unit is to be monitored and audible and visual alarm is to be given in a normally attended location for –

- Power supply failure (voltage and frequency) to the connected load,
- Earth fault,
- Operation of battery protective device,
- When the battery is being discharged, and
- When the bypass is in operation for on-line UPS units.

2.9.4 Location

a) The UPS unit is to be suitably located for use in an emergency.

b) UPS units utilizing valve regulated sealed batteries may be located in compartments with normal electrical equipment, provided the ventilation arrangements are in accordance with the requirements to IEC 62040-1:2017, IEC 62040-2:2016, IEC 62040-3:2011, IEC 62040-4:2013 and/or IEC 62040-5:2016, as applicable, or an acceptable and relevant national or international standard.

2.9.5 Performance

a) The output power is to be maintained for the duration required for the connected equipment as stated in 2.8.8 and 2.8.9.

b) No additional circuits are to be connected to the UPS unit without verification that the UPS unit has adequate capacity. The UPS battery capacity is, at all times, to be capable of supplying the designated loads for the time specified in the regulations.

c) On restoration of the input power, the rating of the charge unit shall be sufficient to recharge the batteries while maintaining the output supply to the load equipment.

2.9.6 Testing and survey

a) UPS units of 50 kVA and over are to be surveyed during manufacturing and testing.

b) Appropriate testing is to be carried out to demonstrate that the UPS unit is suitable for its intended environment. This is expected to include as a minimum the following tests:

- Functionality, including operation of alarms;
- Temperature rise;
- Ventilation rate
- Battery capacity.

c) Where the supply is to be maintained without a break following a power input failure, this is to be verified after installation by an appropriate test.

2.10 Essential services

2.10.1 Where essential services are duplicated, they are to be served by individual circuits separated throughout their length as widely as is practicable and without the use of common feeders, protective devices or control circuits.

2.11 Diversity factor

2.11.1 Circuits supplying two or more final sub-circuits are to be rated in accordance with the total connected load subject, where justified, to the application of a diversity factor. Where spare ways (feeders) are provided on a section

or distribution board, an allowance for future increase of load is to be added to the total connected load before application of any diversity factor.

2.11.2 The diversity factor may be applied when calculating cable size and when calculating the rating of switchgear and fusegear.

2.11.3 The Diversity factors are not applicable to supply cables to distribution switchboards for lighting and heating.

2.11.4 The calculation of the diversity factor is to be submitted along with all relevant data.

2.12 Lighting circuits

2.12.1 Lighting circuits are to be supplied by final sub-circuits, which are separate from those for heating and power. This provision need not be applied to cabin fans and small wardrobe heaters.

2.12.2 A final sub-circuit of rating exceeding 15 A is not to supply more than one point.

2.12.3 A final sub-circuit of rating 15 A or less is not to supply more than the following number of lighting points:-

10 for ……. 24 - 55 V circuits

14 for ……. 110 - 127 V circuits

24 for ……. 220 - 250 V circuits.

This provision is not applicable to final sub-circuits for cornice lighting, panel lighting and electric signs where lampholders are closely grouped; in such cases, the number of points is unrestricted provided the maximum operating current in the sub-circuit does not exceed 10 A.

2.12.4 Lighting for machinery spaces, control stations, work spaces, public spaces, corridors and stairways leading to boat decks should be supplied from at least two final sub-circuits in such a way that failure of any one of the circuits does not leave the spaces in darkness.

2.12.5 For lighting in hazardous areas, switches are to be of the double-pole type and wherever practicable, located in a non-hazardous area. If fitted in hazardous areas, these switches are to be of flameproof type.

2.12.6 Lighting of unattended spaces, such as cargo spaces and coal bunkers, is to be controlled by multi-pole linked switches located outside such spaces. Provision is to be made for the complete isolation of these circuits and locking in the "OFF" position of the means of control.

2.12.7 The arrangement of the main electric lighting system is to be such that a fire or other casualty in spaces containing the main source of electrical power, associated transforming equipment, if any, the main switchboard and the main lighting switchboard, will not render the emergency lighting system inoperative.

2.13 Motor circuits

2.13.1 A separate final sub-circuit is to be provided for every motor required for essential services and for every motor of 1 [kW] or more.

2.13.2 Motors of permanently installed submersible bilge pumps are to be connected to the emergency switchboard, (if fitted).

2.13.3 Cables and their connections to such pumps are to be capable of operating under a head of water equal to their distance below the bulkhead deck. The cables are to be suitable for operation in permanently wet situations, and installed in continuous lengths from above the bulkhead deck to the motor terminals.

2.13.4 Under all circumstances it is to be possible to start the motor of a permanently installed submersible bilge pump from a position above the bulkhead deck.

If an additional starter is provided at the motor, it is to be so arranged as to permit, in all cases, remote starting.

2.14 Motor controls

2.14.1 Every electric motor is to be provided with an efficient means of starting and stopping so placed as to be easily accessible to the person controlling the motor.

2.14.2 Every motor required for essential services and every motor of 0.5 [kW] or more is to be provided with the control apparatus as mentioned in 2.14.4 to 2.14.8.

2.14.3 When motor control gear is being selected, the maximum current of the motor is to be taken as its rated full load current.

2.14.4 Efficient means of isolation are to be provided so that all voltage may be cut off from the motor and any associated apparatus including any automatic circuit breaker.

2.14.5 Where the primary means of isolation (viz. that provided at the switchboard, section board or distribution fuse board) is remote from a motor, one of the following provisions is to be made :

a) An additional means of isolation fitted adjacent to the motor; or

b) Provision made for locking the primary means of isolation in the OFF position; or

c) Provision made so that the fuses in each line can be readily removed and retained by authorized personnel.

2.14.6 Means to prevent the undesired restarting after a stoppage due to low volts or complete loss of volts are to be provided. This does not apply to motors where a dangerous condition might result from the failure to restart automatically e.g. steering gear motor. It is, however, to be ensured that the total starting current of motors having automatic restart will not cause excessive voltage drop or overcurrent on the installation.

2.14.7 Means for automatic disconnection of the supply in the event of excess current due to mechanical overloading of the motor are to be provided. (This does not apply to steering gear motors and thruster motors. Overload alarms are to be provided for these motors. For requirements regarding steering gear motors, See Ch.6).

2.14.8 Where fuses are installed to protect polyphase motor circuits, means are to be provided to protect the motor against unacceptable overload in the case of single phasing.

2.15 Remote stops for ventilation fans and pumps

2.15.1 Ventilating fans for machinery spaces are to be provided with means for stopping them from easily accessible control stations located outside such spaces. (Also refer Pt.6, Ch.2, 2.2.1.2).

2.15.2 Motors driving forced and induced draught fans, independently driven pumps delivering oil to main propulsion machinery for bearing lubrication and piston cooling, oil fuel transfer pumps, oil fuel unit pumps and other similar fuel pumps, fuel and lubricating oil purifiers and their attached pumps are to be fitted with remote controls situated outside the space concerned so that the electrical supply thereto can be disconnected in the event of fire arising in the space in which they are located. (Also refer Ch.3, Cl. 4.11.1) and Pt.6, Ch.2, Sec.2.

2.15.3 Where overboard discharges from cooling water or similar pumps are likely to jeopardize the safe launching of lifeboats or life rafts, under any condition of loading of the ship, then the motors driving these pumps are to be provided with suitably located remote shut-off arrangements.

2.16 Fire detection and extinguishing systems

2.16.1 Electrical equipment used in operating fire detecting systems is to be served by two circuits, one fed from the main power supply system and the other from the emergency power supply system. These feeders are to be connected to an automatic change-over switch installed in the vicinity of the fire detection panel.

2.16.2 Where an electrically driven fire pump is supplied power from the emergency switchboard, the supply cable to such pump is not to pass through the main machinery spaces.

2.17 Lift circuits

2.17.1 Lifts or hoists to be used by passengers and/or crew are to be supplied from the main switchboard, either directly or through a section board, by circuits which do not supply any other appliance.

2.17.2 Cable or cables supplying current to motors of lifts or hoists are not to be incorporated within the flexible trailing cable used in connection with the control and safety devices.

2.18 Heating and cooking equipment

2.18.1 Every heating or cooking appliance is to be controlled as a complete unit by a multi-pole linked switch mounted in the vicinity of the appliance.

2.18.2 In the case of small heaters, for individual cabins or similar small dry accommodation spaces where the floor coverings, bulkheads and ceiling linings are of insulating materials, a single pole switch is acceptable.

2.18.3 Heating arrangements of the exposed element type are not to be used in any location.

2.18.4 Means of cutting off power to the galley except lighting circuits, in the event of a fire, are to be provided outside the galley exits, at positions which will not readily be rendered inaccessible by such a fire.

2.19 Temporary external supply/shore connection

2.19.1 Where arrangements are provided for the supply of electric power from a source on shore or elsewhere, a connection box is to be installed in an easily accessible location in a manner suitable for the convenient reception of flexible cables from the external source. This box should contain a circuit-breaker or isolating switch and fuses and terminals of ample size and suitable shape to facilitate a satisfactory connection. The mechanical stress of the portable cable is to be conveyed directly to the metallic framework and not to electrical connectors. Suitable cables, permanently fixed, are to be provided, connecting the circuit breaker/isolating switch in the connection box to a linked switch and/or circuit breaker at the main switchboard.

2.19.2 For alternating current systems an earthed terminal is to be provided for the reception of three-phase external supplies with earthed neutrals.

2.19.3 The external connection is to be provided with an indicator at the main switchboard in order to show when the cable is energized.

2.19.4 Means are to be provided for checking the polarity (for direct current) or the phase sequence (for three-phase alternating current) of the incoming supply. This device should be connected between the incoming connectors and the interrupting device in the connection box.

2.19.5 A notice is to be provided at the connection box giving complete information on the system of supply and the normal voltage (and frequency for alternating current) of the ship's installed system. Full details of the procedure for effecting the connection are to be given on this notice.

2.19.6 Alternate arrangements for providing a temporary external supply will be specially considered.

2.20 Permanent external supply

2.20.1 Details are to be submitted for consideration in each specific case.

2.21 Protection

2.21.1 General

2.21.1.1 All installations are to be protected against accidental over-currents including short circuits and other electrical faults. The choice, location and characteristics of the protective device are to provide complete and co-ordinated protection to ensure:

a) Elimination of the fault to reduce damage to the system and hazard of fire.

b) Continuity of service so as to maintain, through the discriminative action of the protective devices, the supply to essential and all other services not directly affected by the fault.

2.21.2 Protection against overload

2.21.2.1 Protection against overloads may be provided by circuit-breakers, automatic switches or fuses. The tripping characteristics of these devices are to be appropriate to the system. Fuses rated above 320 A are not to be used for protection against overload, but may be used for short-circuit protection.

2.21.2.2 The rating or appropriate setting of the overload protective device for each circuit should be permanently indicated at the location of the protective device.

2.21.2.3 The overload releases of circuit-breakers for generators and the setting of preferential trip relays are to be adjustable or, if of the non-adjustable type, are to be readily replaceable by others of different values.

2.21.3 Protection against short-circuit

2.21.3.1 Protection against short-circuit currents is to be provided by circuit-breakers or fuses.

2.21.3.2 The breaking capacity of every protective device is to be not less than the maximum value of the short-circuit current which can flow at the point of installation at the instant of contact separation.

2.21.3.3 The making capacity of every circuit-breaker or switch intended to be capable of being closed, if necessary, on short circuit, is to be not less than the maximum value of the short-circuit current at the point of installation. On alternating current this maximum value corresponds to the peak value allowing for maximum asymmetry.

2.21.3.4 Every protective device or contactor not intended for short circuit interruption is to be adequate for the maximum short-circuit current which can occur at the point of installation having regard to the time required for the short circuit to be removed.

2.21.3.5 In the absence of precise data of rotating machines the following short-circuit currents at the machine terminals are to be assumed. The short circuit current is to be the sum of short circuit currents of generators and that of motors;

a) Direct current systems

- Ten times full load current for generators normally connected (including spare),

- Six times full load current for motors simultaneously in service;

b) Alternating current systems.

- Ten times full load current for generators normally connected (including spare) - symmetrical RMS,

- Three times full load current for motors simultaneously in service.

2.21.4 Combined circuit-breakers and fuses

2.21.4.1 The use of a circuit-breaker of breaking capacity less than the prospective short-circuit current at the point of installation is permitted, provided that it is preceded on the generator side by fuses, or by a circuit-breaker having at least the necessary breaking capacity. The generator breakers are not to be used for this purpose.

2.21.4.2 Fused circuit-breakers with fuses connected to the load side may be used where operation of the circuit-breaker and fuses is co-ordinated.

2.21.4.3 The characteristics of the arrangement are to be such that:

a) When the short-circuit current is broken, the circuit-breaker on the load side is not to be damaged and is to be capable of further service,

b) When the circuit-breaker is closed on the short-circuit current, the remainder of the installation is not to be damaged. However, it is admissible that the circuit-breaker on the load side may require servicing after the fault has been cleared.

2.21.5 Protection of circuits

2.21.5.1 Short circuit protection is to be provided in each live pole of a direct current system and in each phase of an alternating current system.

2.21.5.2 Protection against overloads is to be provided as follows:

a) Two-wire direct current or single-phase alternating current system - at least one line or phase,

b) Insulated three-phase alternating current system - at least two phases,

c) Earthed three-phase alternating current system - all three phases.

2.21.5.3 No fuse, non-linked switch or non-linked circuit-breaker is to be inserted in an earthed conductor. Any switch or circuit-breaker fitted is to operate simultaneously in the earthed conductor and the insulated conductors.

2.21.5.4 These requirements do not preclude the provision (for test purposes) of an isolating link to be used only when the other conductors are isolated.

2.21.6 Protection of generators

2.21.6.1 In addition to over-current protection, the provisions of 2.21.6.2 to 2.21.6.7 are to be adhered to as a minimum.

2.21.6.2 For generators not arranged to run in parallel :

- A multi-pole circuit-breaker arranged to open simultaneously all insulated poles or in the case of generators rated at less than 50 [kW] a multi-pole linked switch with a fuse in each insulated pole on the generator side. The fuse rating in such

cases is to be maximum 125 per cent of the generator rated current.

2.21.6.3 For generators arranged to run in parallel:

- A circuit-breaker arranged to open simultaneously all insulated poles. This circuit-breaker is to be provided with :

a) For direct current generators, instantaneous reverse-current protection operating at not more than 15 percent rated current,

b) For alternating current generators :

i) A reverse-power protection, in accordance with characteristics of prime movers is to be set as shown in Table 2.21.6.3

Table 2.21.6.3 Reverse power protection

Prime Mover	Protection setting (as % of full load of generator)	Time delay
Diesel Generator	Between 2 to15%	Between 3 to 10 sec
Turbo Generator	Between 2 to 6 %	

ii) A device for protection against the effects of parallel connection in opposite phase.

2.21.6.4 The reverse-current protection is to be adequate to deal with the reverse-current conditions emanating from the network, e.g. from winches, the reverse-power protection specified for alternating current generators may be replaced by other devices ensuring adequate protection of the prime movers.

2.21.6.5 A fall of 50 per cent in the applied voltage should not render the reverse-current mechanism inoperative, although it may alter the amount of reverse-current required to open the breaker.

2.21.6.6 The following protective gear is also to be provided for direct current generators arranged to operate in parallel :

a) Where an equaliser connection is in use the reverse-current protection is to be provided in the pole opposite to that in which the series winding is connected,

b) For compound generators an equaliser switch for each generator so interlocked that it closes before and opens after the main contacts of the circuit-breaker with which it is associated, or a three-pole circuit-breaker with all poles acting simultaneously.

2.21.6.7 Generator circuit-breakers are normally to be provided with under voltage release.

2.21.7 Protection of essential services

2.21.7.1 Where generators are operated in parallel and essential services are electrically operated, arrangements are to be made to disconnect automatically the excess non-essential load when the generators are overloaded.

2.21.7.2 If required, this load shedding may be carried out in one or more stages according to the overload ability of the generating sets, taking into consideration the relative importance of the loads being thus disconnected.

2.21.7.3 In cargo ships, circuits for cargo refrigeration machinery are to be included in the last group of services to be disconnected.

2.21.8 Protection of feeder circuits

2.21.8.1 Isolation and protection of each main distribution circuit is to be ensured by a multi-pole circuit-breaker, multi-pole fused circuit-breakers or multi-pole switch and fuses. The provisions of 2.21.2, 2.21.3 and 2.21.5 are to be complied with. The protective devices are to allow excess current to pass during the normal accelerating period of motors. Where multi-pole switch and fuses are used, the fuses are generally to be installed between the busbars and the switch.

2.21.8.2 Circuits which supply motors fitted with overload protection may be provided with short-circuit protection only.

2.21.8.3 Motors of rating exceeding 0.5 [kW] and all motors for essential services are to be protected individually against overload and short- circuit. The short-circuit protection can be provided by the same protective device for the

motor and its supply cable. For essential motors which are duplicated, the overload protection may be replaced by an overload alarm, if desired.

2.21.8.4 For motors intended to provide uninterrupted service the protective gear is to have a delay characteristic to enable the motor to start, and to operate on overload before the windings reach an un-acceptably high temperature. The current which the protective device will allow to pass indefinitely is not to exceed 125 per cent of the rated current.

2.21.8.5 For motors for intermittent service the current setting and the delay are to be chosen in relation to the load factor of the motor.

2.21.8.6 Where fuses are used to protect polyphase motor circuits, means are to be provided to protect the motor against unacceptable overloads in the case of single phasing.

2.21.9 Protection of power transformers

2.21.9.1 The primary circuits of power transformers are to be protected against short-circuit by circuit-breakers or fuses. The rating of fuses or the setting for overcurrent releases of circuit breakers is not to exceed 125 per cent of rated primary current.

2.21.9.2 Each of the secondary circuits is to be provided with a multiple isolating switch as shown in Fig.2.21.9.2.

2.21.9.3 When transformers are arranged to operate in parallel, an automatic protective device is to be provided on the secondary circuits. Switches and circuit-breakers are to be capable of withstanding surge currents.

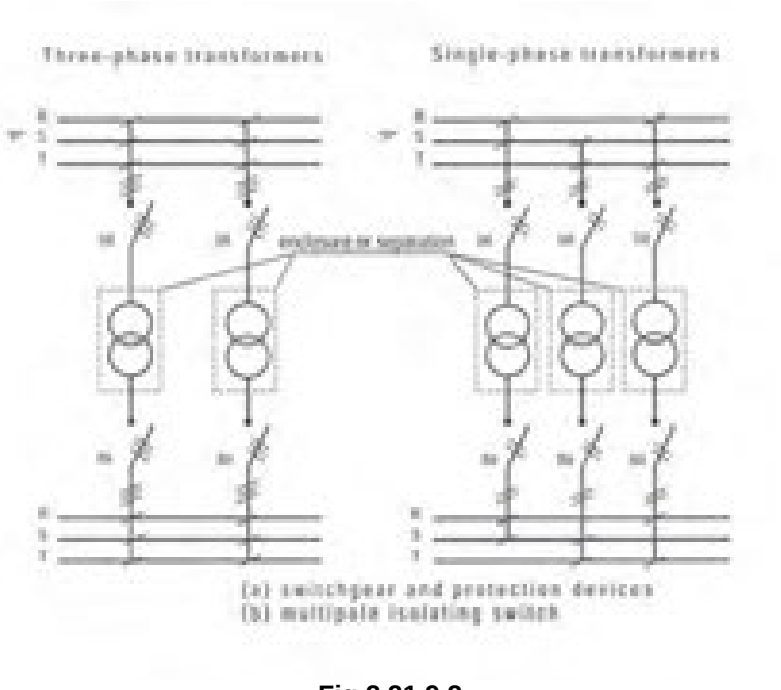

Fig.2.21.9.2

2.21.10 Protection of lighting circuits

2.21.10.1 Lighting circuits are to be provided with overload and short- circuit protection.

2.21.11 Protection of meters, pilot lamps, capacitors, control transformers and control circuits

2.21.11.1 Short circuit protection is to be provided for voltmeters, voltage coils of measuring instruments, earth indicating devices and pilot lamps, control transformers and control circuits together with their connecting leads by means of protective devices fitted to each insulated pole or phase.

2.21.11.2 A pilot lamp installed as an integral part of another item of equipment need not be individually protected, provided it is fitted in the same enclosure. Where a fault in a pilot lamp would jeopardise the supply to essential equipment such lamps are to be individually protected.

2.21.11.3 Where capacitors for suppression of radio interference are fitted to busbars, generators or steering gear, fuses of appropriate size are to be connected in the capacitor circuit.

2.21.12 Protection of batteries

2.21.12.1 Accumulator batteries other than engine starting batteries are to be protected against overload and short circuit by devices, in each insulated pole, placed at a position adjacent to the battery compartment.

2.21.13 Protection of communication circuits

2.21.13.1 Communication circuits other than those supplied from primary batteries are to be protected against overload and short-circuit.

2.21.14 Harmonics

2.21.14.1 **Scope**. The requirements of 2.21.14 to 2.21.18 are applicable to ships where harmonic filters are installed on main bus bars of electrical distribution system, other than those installed for single application frequency drives such as pump motors.

2.21.14.2 The total harmonic distortion (THD) in the voltage waveform of the AC distribution systems is not to exceed 8% and any single order harmonics is not to exceed 5%.

2.21.14.3 Higher values other than those specified in 2.21.14.2 may be accepted provided the distribution equipment and consumers are designed to operate at the higher limits. A harmonic distortion calculation report, indicating distortion levels at MSB and power distribution centers is to be submitted for review for all vessels with electric propulsion and for vessels fitted with harmonic filters. This report is to document the ability of the system and its components to sustain the actual distortion levels. This report is to be made available onboard as a reference for the surveyor at each periodical survey.

2.21.14.4 Total Harmonic Distortion (THD) is a ratio of the rms value of the harmonic content to the rms value of the fundamental frequency, expressed in percent and may be calculated by the expression:

$$THD = \frac{\sqrt{\mathrm{V}_2^2 + \mathrm{V}_3^2 + \mathrm{V}_4^2 + \cdots \mathrm{V}_\mathrm{n}^2}}{\mathrm{V}_1}$$

Where, V_n is the rms voltage of the n^{th} harmonic and n = 1 is the fundamental frequency

2.21.14.5 Equipment producing transient voltage, frequency and current variations are not to cause malfunction of other onboard equipment.

2.21.15 Harmonic Filters

2.21.15.1 If harmonic filter circuits are used in association with semiconductor converter assemblies to reduce the harmonics and transients in the system, they are to be suitably protected against short circuit and overload.

2.21.15.2 The requirements for monitoring harmonic distortion, mitigation of effects and protection arrangements for harmonic filters given in 2.21.16 to 2.21.18 are applicable to ships contracted for construction, on or after 01 July 2017. Existing ships retrofitted with harmonic filters, on or after 01 July 2017 are also to comply with the requirements of 2.21.16 to 2.21.18.

2.21.16 Monitoring of harmonic distortion levels for a ship fitted with harmonic filters

2.21.16.1 The ships are to be fitted with facilities to continuously monitor the levels of harmonic distortion experienced on the main busbar as well as alerting the crew should the level of harmonic distortion exceed the acceptable limits.

2.21.16.2 Where the engine room is provided with automation systems, this reading is to be logged electronically, otherwise it is to be recorded in the engine log book for future inspection by the surveyor.

2.21.17 Mitigation of the effects of harmonic filter failure on a ship's operation

2.21.17.1 Where the electrical distribution system on board a ship includes harmonic filters the system integrator of the distribution system is to show, by calculation, the effect of a failure of a harmonic filter on the level of harmonic distortion experienced.

2.21.17.2 The system integrator of the distribution system is to provide the ship owner with guidance documenting permitted modes of operation of the electrical distribution system while maintaining harmonic distortion levels within acceptable limits during normal operation as well as following the failure of any combination of harmonic filters.

2.21.17.3 The calculation results and validity of the guidance provided are to be verified by the surveyor during sea trials.

2.21.18 Protection arrangements for harmonic filters

2.21.18.1 Arrangements are to be provided to alert the crew in the event of activation of the protection of a harmonic filter circuit.

2.21.18.2 A harmonic filter is to be arranged as a three phase unit with individual protection of each phase. The activation of the protection arrangement in a single phase is to result in automatic disconnection of the complete filter. In addition, a current imbalance detection system is to be installed, independent of the overcurrent protection to alert the crew in case of current imbalance.

2.21.18.3 Individual capacitor elements are to be additionally protected by means such as relief valve or overpressure disconnector in order to protect against damage from rupturing. The additional protection arrangements are to be designed taking into account the type of capacitors used.

Section 3

Cables and Busbar Trunking Systems

3.1 General

3.1.1 The requirements of this Section are applicable to fixed cables on permanent installations. For flexible cables, the requirements apply only as far as applicable.

3.1.2 Cables are to be of a type approved by IRS.

3.1.3 Electric cables for fixed wiring are to be designed, manufactured and tested in accordance with the relevant IEC Publication stated in Table 3.1.1 or an acceptable relevant standard. Cables manufactured and tested to standards other than those specified in Table 3.1.1 may be accepted provided they are in accordance with an acceptable and relevant international or national standard and are of an equivalent or higher safety level than those listed in Table 3.1.1.

Table 3.1.1 : Electric cables

Application	IEC Standard
General constructional and testing requirements	60092-350:2020
Choice and installation of electrical cables	60092-352:2005
Fixed power and control circuits	60092-353:2016
Insulating and sheathing materials for power, control, telecommunication and instrumentation	60092-360:2014
Guidance for selection of cables for telecommunication and data transfer including radio frequency cables.	60092-370:2019
Cables for control and instrumentation circuits 150/250 V (300V)	60092-376:2017

3.1.4 The use of flexible cables on permanent installations is to be limited to applications where flexibility is necessary, and the lengths of such flexible cables are to be kept as short as practicable. Additional requirements may be specified for flexible cable, depending on the applications.

3.1.5 Electric cables complying with IEC Publication 60502 are to have stranded conductors.

3.2 Conductors

3.2.1 High conductivity annealed copper only is to be used.

3.2.2 Where the conductor insulation is composed of vulcanised rubber or of a synthetic rubber liable to contain sulphides, the copper wires are to be tinned or alloy coated and the surface is to be bright. Similarly the copper wires are to be tinned or alloy coated when the insulation is composed of a cambric impregnated with a product other than bitumen, unless an efficient separator is inserted between conductor and insulation.

3.2.3 Conductor composition and stranding is to be selected so that adequate flexibility of the finished cable is assured. Conductors of nominal cross-section 2.5 [mm^2] and less need not be stranded. This requirement does not apply to mineral-insulated cables which have solid conductors.

3.2.4 Cores of multi-core cables are to be readily identifiable.

3.3 Insulating materials

3.3.1 Permitted insulating materials with maximum rated conductor temperatures are given in Table 3.3.1.

3.3.2 Where a rubber or rubber-like material with maximum conductor temperature greater than 60°C is used, it is to be readily identifiable.

3.3.3 Consideration will be given to other insulating materials.

Table 3.3.1 : Insulating materials & maximum rated conductor temperature

Type of insulating compound	Maximum rated conductor temp. °C
Thermoplastics	
Based upon polyvinyl chloride or co-polymer of vinyl chloride and vinyl acetate	60
Based upon polyethylene	60
Elastomeric or thermosettings	
Based upon ethylene propylene rubber or similar (EPM or EPDM)	85
Based upon chemically crosslinked polyethylene	85
Based upon silicon rubber	95
Mineral	95

3.4 Construction

3.4.1 Electric cables are to be at least of a flame-retardant type. Compliance with testing in accordance with IEC 60332-1-2:2004+AMD1:2015 or a test procedure equivalent thereto, will be acceptable.

3.4.2 Exemption from the requirements of 3.4.1 for applications such as radio frequency or digital communication systems, which require the use of particular types of cable, will be subject to special consideration.

3.4.3 Where electric cables are required to be of a 'fire resistant type', they are to comply with the requirements of IEC 60331-1:2018 for cables of greater than 20 [mm] overall diameter, otherwise 60331-21:1999 and AMD 1:2009 or IEC 60331-2:2018.

Notes:

a) Installation methods specified in 3.11 are to be applied.

b) Cables complying with alternative national standards and suitable for use in a marine environment may be considered.

c) Fire resistant type cables are to be easily distinguishable, for e.g. by way of colour code.

d) Following standards may be used for special cables such as electrical data and optical fibre cables:

IEC60331-23:1999 : Electric data cables
IEC60331-25:1999 : Optical fiber cables.

3.4.4 Where electric cables are installed in locations exposed to the weather, in damp and in wet situations, in machinery compartments, refrigerated spaces or exposed to harmful vaporous including oil vapour they are to have the conductor insulating materials enclosed in an impervious sheath of material appropriate to the expected ambient conditions.

3.4.5 Electric cables where it is required that their construction includes metallic sheaths, armouring or braids are to be provided with an overall impervious sheath or other means to protect the metallic elements against corrosion.

3.4.6 Where single core electric cables are used in circuits rated in excess of 20 A and are armoured the armour is to be of a non-magnetic material.

3.4.7 Electric cables are to be constructed such that they are capable of withstanding the mechanical and thermal effects of the maximum short circuit current which can flow in any part of the circuit in which they are installed, taking into consideration not only the time/current characteristics of the circuit protective device but also the peak value of the prospective short circuit current. Where electric cables are to be used in circuits with a maximum short circuit current in excess of 70 kA, evidence is to be submitted for consideration when required demonstrating that the cable construction can withstand the effects of the short circuit current.

3.4.8 All high voltage electric cables are to be readily identified by suitable marking.

3.5 Testing

3.5.1 Routine tests are to include at least

- measurement of electrical resistance of conductors;
- high voltage test;
- insulation resistance measurement; and
- partial discharge tests in case of high voltage cables.

Evidence of successful completion of routine tests is to be provided by the manufacturer for cables supplied to a project.

Note: Routine tests are to be carried out in the presence of the Surveyor for cables intended to be used for electrical propulsion systems, and as required elsewhere by the Rules.

3.5.2 Particular, special and type tests are to be made, when required, in accordance with the requirements of relevant publication or national standard.

3.6 Voltage rating

3.6.1 The rated voltage of any cable is not to be lower than the nominal voltage of the circuit for which it is used. Cables exposed to voltage surges associated with highly inductive circuits, e.g. contactor operating circuits for winches etc., are to be given special consideration.

3.6.2 Electric cables used in unearthed systems are to be suitably rated to withstand the additional stresses imposed on the insulation due to an earth fault.

3.7 Choice of insulating material

3.7.1 The rated operating temperature of the insulating material is to be at least 10°C higher than the maximum ambient temperature liable to be produced in the space where the cable is installed.

3.8 Choice of protective covering

3.8.1 Cables fitted in the following locations are to have an impervious sheath. In permanently wet situations, metallic sheaths are to be used for cables with hydroscopic insulation.

- Decks exposed to weather;
- Bathrooms;
- Refrigerated spaces;
- Machinery spaces; and

- Any other location where water condensation or harmful vapour (e.g. oil vapour) may be present.

3.8.2 All cables are to be of flame-retardant type or fire-resisting type, except that non flame-retardant cables may be accepted for final circuits only in the following cases :

a) Where cables are installed in metallic conduits having internal diameter not exceeding 25 [mm] and provided the conduits are electrically and mechanically continuous.

b) Bare lead sheathed cable having conductor sections not exceeding 4.5 [mm^2].

3.9 Current rating

3.9.1 The highest continuous load carried by a cable is not to exceed its current rating. The diversity factor of the individual loads and the duration of the maximum demand may be allowed for in estimating the maximum continuous load and is to be shown on the plans submitted for approval.

3.9.2 The cross sectional area of the conductors is to be sufficient to ensure that, under short circuit conditions, the maximum rated conductor temperature for short circuit operation is not exceeded, taking in to account the time current characteristics of the circuit protective device and the peak value of the prospective short circuit current.

3.9.3 In assessing the current rating of lighting circuits, every lampholder is to be assessed at the maximum load likely to be connected to it, with a minimum of 60 W, unless the fitting is so connected as to take only a lamp rated at less than 60 W.

Table 3.9.1 : Electric cable current rating, normal operation, based on ambient temp. of 45°C

Nominal cross-section in [mm^2]	Continuous current rating in amperes (based on ambient temp. 45°C)								
	Thermoplastic, PVC, PE			EP rubber and cross linked PE			Silicon rubber or mineral		
	Single core	2 core	3 or 4 core	Single core	2 core	3 or 4 core	Single core	2 core	3 or 4 core
1	8	7	6	16	14	11	20	17	14
1.5	12	10	8	20	17	14	24	20	17
2.5	17	14	12	28	24	20	32	27	22
4	22	19	15	38	32	27	42	36	29
6	29	25	20	48	41	34	55	47	39
10	40	34	28	67	57	47	75	64	53
16	54	46	38	90	77	63	100	85	70
25	71	60	50	120	102	84	135	115	95
35	87	74	61	145	123	102	165	140	116
50	105	89	74	180	153	126	200	175	140
70	135	115	95	225	191	158	255	217	179
95	165	140	116	275	234	193	310	264	217
120	190	162	133	320	272	224	360	306	252
150	220	187	154	365	310	256	410	349	287
185	250	213	175	415	353	291	470	400	329
240	290	247	203	490	417	343	570	485	400
300	335	285	235	560	476	392	660	560	460

3.9.4 Cables supplying winches, cranes, windlasses and capstans are to be suitably rated for their duty. Unless the duty is such as to require a longer time rating, cables for winch or crane motors may be half hour rated on the basis of the half hour [kW] rating of the motors. Cables for windlass and capstan motors are to be not less than one hour rated on the basis of

the one hour [kW] rating of the motor. In all cases the rating is to be subject to the voltage drop being within the specified limits.

3.9.5 The current ratings given in Table 3.9.1 are based on the maximum operating conductor temperatures, given in Table 3.3.1. Where a more precise evaluation of current rating has been carried out based on experimental or calculated data, details may be submitted for approval.

3.10 Correction factors for current rating

3.10.1 Bunching of cables : Where more than six cables belonging to the same circuit are bunched together a correction factor of 0.85 is to be applied.

3.10.2 Ambient temperature : The current ratings in Table 3.9.1 are based on an ambient temperature of 45°C. For other values of ambient temperature the correction factors shown in Table 3.10.1 are to be applied.

3.10.3 Intermittent Service : Where the load is intermittent, the correction factors in Table 3.10.2 may be applied for half hour and one hour ratings. In no case is a shorter rating than one half hour rating to be used, whatever the degree of intermittency.

Table 3.10.1 : Correction factors for temperature

Insulation material	Correction factor for ambient air temperature of °C										
	35	40	45	50	55	60	65	70	75	80	85
PVC, Polyethelene	1.29	1.15	1.00	0.82	-	-	-	-	-	-	-
EPR, XLPE	1.12	1.06	1.00	0.94	0.87	0.79	0.71	0.61	0.5	-	-
Mineral, Silicon rubber	1.10	1.05	1.00	0.95	0.89	0.84	0.77	0.63	0.55	0.45	-

Table 3.10.2 : Correction factors for intermittent rating

Correction factor	Half-hour rating		One-hour rating	
	With metallic sheath [mm^2]	Without metallic sheath [mm^2]	With metallic sheath [mm^2]	Without metallic sheath [mm^2]
1.00	Upto 20	Upto 75	upto 67	upto 230
1.10	21 - 40	76 – 125	68 - 170	231 - 400
1.15	41 - 65	126 – 180	171 - 290	401 - 600
1.20	66 - 95	181 – 250	291 - 430	-
1.25	96 - 130	251 – 320	431 - 600	-
1.30	131 - 170	321 – 400	-	-
1.35	171 - 220	401 – 500	-	-
1.40	221 - 270	-	-	-

3.11 Installation of cables

3.11.1 Cable runs are to be, as far as practicable, straight and accessible and as high as possible above bilges.

3.11.2 The installation of cables across expansion joints in any structure is to be avoided. Where such installation is unavoidable, a loop of cable of length proportional to the expansion of the joint is to be provided. The internal radius of the loop is to be at least twelve times the external diameter of the cable.

3.11.3 Where a duplicate supply is required and provided for any particular service, the two cables are to follow different routes which are separated throughout their length as widely as is practicable, to minimise the probability of simultaneous damage to the two circuits. The provision is also applicable to control circuits.

3.11.4 Generator cables are as far as practicable to be divided between two or more cable runs. These cable runs are to be separated as far apart as practicable.

3.11.5 Cables supplying essential or important consumers are generally not to be installed in rooms where there is an excessive fire hazard such as paint stores, galleys, etc. purifiers, welding-gas bottles etc.

3.11.6 Cables having insulating materials with different maximum-rated conductor temperatures are not to be bunched together, or, where this is not practicable, the cables are to be operated so that no cable reaches temperature higher than that permitted for the lowest temperature-rated cable in the group.

3.11.7 Cables having a protective covering which may damage the covering of other cables are not to be bunched with those of other cables.

3.11.8 The minimum internal radius of cable bends, which are not subjected to movements by expansion when installed, is to be generally in accordance with Table 3.11.1.

3.11.9 Electric cables are not to be coated or painted with materials which may adversely affect their sheath or their fire protection.

3.11.10 Where electric cables are installed in refrigerated spaces they are not to be covered with thermal insulation but may be placed directly on the face of the refrigeration chamber, provided that precautions are taken to prevent the electric cables being used as casual means of suspension.

3.11.11 Cable runs are normally not to include joints. However, if a joint is necessary it is to be carried out with prior approval and with due consideration to methods of splicing that retain the original mechanical and electrical properties of the cable and which ensure that all conductors are adequately secured, insulated and protected from atmospheric action. Terminals and busbars are to be of dimensions adequate for the cable rating.

3.11.12 Where electric cables are installed in bunches, provision is to be made to limit the propagation of fire, which may be achieved by either of the following:

a) Cables which have been tested in accordance with IEC 60332-3-22:2018 Category A or a test procedure for cables installed in bunches equivalent thereto.

b) (Refer to Fig.3.11.12a, b, c and d)

i) Fire stops having at least B0 penetrations fitted as follows:

- Cable entries at the main and emergency switchboard,
- Where cable enter engine control rooms,
- Cable entries at centralized control panels for propulsion machinery and essential auxiliaries,
- At each end of totally enclosed cable trunks, and

ii) In enclosed and semi enclosed spaces, cable runs are to comply with the following:

- to have fire protection coating applied
- to at least 1 metre in every 14 metres
- to entire length of vertical runs or
- Fitted with fire stops having at least B0 penetrations every second deck or approximately 6 metres for vertical runs and at every 14 metres for horizontal runs.

Table 3.11.1 : Minimum internal radii of bends in cables for fixed wiring

Cable construction		Overall diameter of cable	Minimum internal radius of bend (times overall diameter of cable)
Insulation	**Outer covering**		
Thermoplastic and elastomeric 600/1000 V and below	Metal sheathed Armoured and braided	Any	6D
	Other finishes	≤ 25 [mm] > 25 [mm]	4D 6D
Mineral	Hard metal sheathed	Any	6D
Thermoplastic and elastomeric above 600/1000 V			
- single core	Any	Any	20D
- multicore	Any	Any	15D

Note : (All fire stops steel plates 3 mm thk)

Fig.3.11.12a) to d) : Installation of cables

3.12 Mechanical protection of cables

3.12.1 Cables exposed to risk of mechanical damage are to be protected by metal channels or casing or enclosed in steel conduit unless the protective covering (e.g. armour or sheath) is adequate to withstand the possible damage.

3.12.2 Cables, in spaces where there is exceptional risk of mechanical damage (e.g. on weather decks, in cargo hold areas and inside the cargo holds) and also below the floor in engine and boiler rooms, are to be suitably protected, even if armoured, unless the steel structure affords adequate protection.

3.12.3 Metal casings for mechanical protection of cables are to be efficiently protected against corrosion.

3.12.4 Non metallic protective casings and fixings are to be flame retardant in accordance with the requirements of IEC Publication 92-101.

3.12.5 If cable trays/protective casings are made of plastics materials, then they are to comply with the requirements in 3.12.5.1 to 3.12.5.4.

3.12.5.1 They are to be of approved type and are to be supplemented by metallic fixing and straps such that in the event of a fire they, and the cables affixed, are prevented from falling and causing an injury to personnel and/or an obstruction to any escape route. The spacing of their metallic fixing and straps is generally not to exceed 2.0 m.

3.12.5.2 When used on open deck, they are additionally to be protected against ultra-violet light.

3.12.5.3 The load on the plastics cable trays/protective casings is to be within the Safe Working Load (SWL) and the spacing of support, in general, is not to exceed 2 metres.

3.12.5.4 The sum of the total cross-sectional area of the cables, based on their external diameter, is not to exceed 40% of the internal cross-sectional area of the protective casing. This does not apply to a single cable in a protective casing.

Note : Cable trays/protective casings made of plastic materials are to be approved in accordance with the Classification Notes issued by IRS.

3.13 Earthing of metal coverings

3.13.1 Metal coverings of cables are to be effectively earthed at both ends of the cable, except its final sub-circuits, other than those installed in hazardous zones or spaces, earthing at the supply end only will be considered adequate. This does not necessarily apply to instrumentation cables where single point earthing may be desirable for technical reasons.

3.13.2 The electrical continuity of all metal coverings of cables throughout the length of the cable, particularly at joints and tappings, is to be ensured.

3.13.3 The lead sheath of lead-sheathed cables is not to be used as the sole means of earthing the non-current carrying parts of items of equipment.

3.14 Securing of cables

3.14.1 Cables, other than those attached to portable appliances and those installed in pipes, conduits or special casing are to be effectively supported and secured in a manner that prevents damage to their coverings.

3.14.2 Supports and accessories are to be robust and are to be of corrosion-resistant material or suitably corrosion inhibited before erection.

3.14.3 The distance between supports, for horizontal as well as vertical runs of cables, is to be chosen according to the type/size of cable, but generally in accordance with Table 3.14.1.

3.14.4 When electric cables are fixed by means of clips or straps manufactured from a material other than metal the material is to be flame retardant and the fixings are to be supplemented by suitable metal clips or straps at regular intervals, each not exceeding 2 [m].

3.14.5 Single core cables are to be firmly fixed, using supports of strength adequate to withstand forces corresponding to the values of the peak prospective short circuit current.

Table 3.14.1 : Distance between supports			
External diameter of cable			
Exceeding [mm]	**Not exceeding [mm]**	**Non-armoured cables [mm]**	**Armoured cables [mm]**
-	8	200	250
8	13	250	300
13	20	300	350
20	30	350	400
30	-	400	450

3.15 Penetration of bulkheads and decks by cables

3.15.1 Penetration of watertight bulkheads or decks is to be carried out with either individual watertight glands or with packed watertight boxes carrying several cables. In either case, the watertight integrity and strength of the bulkheads and decks are to be maintained. Where cables with polyvinyl chloride insulation are being installed, particular care is to be taken to avoid damage to the sheathing during the fitting of watertight bulkhead glands.

3.15.2 Where fire-resisting or fire-retarding bulkheads or decks are drilled for the passage of cables, all arrangements are to be such that this fire resisting or fire retarding property and strength are not diminished.

3.15.3 Where cables pass through gastight bulkheads or decks separating hazardous zones or spaces, arrangements are to be such that the gastight integrity and strength of the bulkhead or deck are not impaired.

3.15.4 Where cables pass through non-watertight bulkheads or structural steel, the holes are to be bushed, in order to protect the cables, with lead or other approved material which will prevent damage to the cables by abrasion. If the steel is 6 [mm] thick, adequately rounded edges may be accepted as the equivalent of bushing.

3.15.5 Cables passing through decks are to be protected by deck tubes or ducts.

3.15.6 Materials used for glands and bushings are to be such that there is no risk of corrosion.

3.15.7 Where rectangular holes are cut in bulkheads or structural steel the corners are to be adequately rounded.

3.15.8 The distance from cable penetrations to flanges of steam pipes or hot oil pipes is to be not less than 500 [mm].

3.16 Installation of cables in pipes and conduits

3.16.1 Installation of cables in pipes and conduits is to be carried out in such a manner that there is no damage to the cable covering.

3.16.2 Metal conduit systems are to be earthed and are to be mechanically and electrically continuous across joints. Individual short lengths of conduit need not be earthed.

3.16.3 The internal radius of bend of pipes and conduit is to be not less than that laid down for cables, provided that for pipes exceeding 64 [mm] diameter the internal radius of bend is not less than twice the diameter of the pipe.

3.16.4 The drawing-in factor (ratio of the sum of the cross-sectional areas of the cables, based on their external diameter, to the internal cross-section area of the pipe) is not to exceed 0.4.

3.16.5 Expansion joints are to be provided where necessary.

3.16.6 Cable pipes and conduits are to be adequately and effectively protected against corrosion. Where necessary, openings are to be provided at the highest and lowest points to permit air circulation and to prevent accumulation of water.

3.16.7 Cable pipes are to be effectively supported, particularly in areas where they are likely to be subject to heavy vibrations.

3.16.8 Cables in a conduit should belong to the same temperature class.

3.16.9 Where cables are laid in trunks, the trunks are to be so constructed as not to afford passage for fire from one deck or compartment to another.

3.16.10 Cables used for cold cathode luminous discharge lamps are not to be installed in metal conduit unless protected by metal sheath or screen.

3.16.11 Non-metallic ducting or conduit is to be of flame-retardant material. PVC conduit is not to be used in refrigerated spaces or on open decks, unless specially approved.

3.17 Installation of cables in refrigerated spaces

3.17.1 The installation of cables in refrigerated spaces is to be avoided as far as possible.

3.17.2 PVC insulated cables are not to be installed in refrigerated spaces.

3.17.3 Cables installed in refrigerated spaces are to have a watertight or impervious sheath and are to be protected against mechanical damage. If an armoured cable is used, the armour, unless galvanised or of non-corrosive material, is to be protected against corrosion by an additional moisture-resisting covering.

3.17.4 Cables are not to be embedded in or covered by the thermal insulation. They may be fixed to galvanised perforated plates with a space left between the back of the plate and the wall of the room.

3.17.5 Where cables entering a refrigerated space have to pass through the thermal insulation, they are to be installed at right angle to such insulation and are to be protected by a pipe, sealed at each end. Alternatively, the cables may be passed through solid door frames, the necessary holes being sealed at each end.

3.17.6 Precautions are to be taken to prevent the placing of hooks around the cable as a casual means of suspension.

3.17.7 Supporting strips, plating or hangers used for securing the cables are to be galvanised or otherwise protected against corrosion.

3.18 Cables for alternating current

3.18.1 Generally, multi-core cables are to be used in A.C. installations. Where it is necessary to use single-core cables for alternating current circuits rated in excess of 20 A the requirements of 3.18.2 to 3.18.9 are to be complied with.

3.18.2 Cables are to be either non-armoured or armoured with non- magnetic material.

3.18.3 If installed in pipe or conduit, cables belonging to the same circuit are to be installed in the same conduit, unless the conduit or pipe is of non-magnetic material.

3.18.4 Cable clips are to include cables of all phases of a circuit unless the clips are of non-magnetic material.

3.18.5 When installing two, three or four single-core cables forming respectively single-phase circuits, three-phase circuits or three-phase and neutral circuits, the cables are to be in contact with one another, as far as possible. In any case, the distance between the external covering of two adjacent cables is not to be greater than one diameter.

3.18.6 In the case of circuits using two or more parallel connected cables per phase, all cables are to have the same length and cross sectional area.

3.18.7 Where single core cables of rating exceeding 50 A and over 30 [m] in length are used, the phases are to be transposed at regular intervals of approximately 15 [m] in order to obtain the same degree of impedance of circuits.

3.18.8 Where single core cables of rating exceeding 50 A are used, magnetic material is not to be placed between single-core cables of a group. If these cables pass through steel plates, all cables of the same circuit are to pass through the plate or gland so constructed that there is no magnetic material between the cables, and suitable clearance is provided between the cable core and magnetic material. This clearance, wherever practicable, is not to be less than 75 [mm] when the current exceeds 300 A. For currents between 50 A and 300 A the clearance may be proportionately reduced.

3.18.9 If single-core cables of current rating greater than 250 A are run along a steel bulkhead, wherever practicable the cables should be spaced away from the steel.

3.19 Cable ends

3.19.1 The ends of all conductors of cross-sectional area greater than 4 [mm^2] are to be fitted with soldering sockets, compression type sockets or mechanical clamps. Corrosive fluxes are not to be used.

3.19.2 Cables having hygroscopic insulation (e.g. mineral insulated) are to have their ends sealed against ingress of moisture.

3.19.3 Cables with a supplementary insulating belt beneath the protective sheath are to have additional insulation at those points where the insulation of each core makes or may make contact with earthed metal.

3.20 Busbar trunking systems

3.20.1 Where busbar trunking systems are used in place of electric cables, they are to comply with the requirements of 3.20.2 to 3.20.6, in addition to the applicable requirements in Section 3.

3.20.2 The busbar trunking, or enclosure system, is to have a minimum ingress protection of IP54, according to IEC 60529 Degrees of protection provided by enclosures (IP Code).

3.20.3 The internal and external arrangements of the busbar trunking or enclosure system are to ensure that the fire and/or watertight integrity of any structure through which it passes is not impaired.

3.20.4 Where the busbar trunking system is employed for circuits on and below the bulkhead deck, arrangements are to be made to ensure that circuits on other decks are not affected in the event of partial flooding under the normal angles of inclination given in Chapter 1, Table 1.7.1.

3.20.5 Supports and accessories are to be robust and are to be of corrosion-resistant material or suitably corrosion inhibited before erection. The support system is to effectively secure the busbar trunking system to the ship's structure.

3.20.6 When accessories are fixed to the busbar system by means of clips or straps manufactured from a material other than metal, the fixings are to be supplemented by suitable metal clips or straps, such that, in the event of a fire or failure, the accessories are prevented from failing and causing injury to personnel and/or an obstruction to any escape route. Alternatively, the busbar system may be routed away from such areas.

3.21 Watertight Cable transits

3.21.1 Watertight cable transits are to be installed and maintained in accordance with the manufacturer's requirements and in accordance with the requirements of the relevant type approval certification.

3.21.2 A Cable Transit Seal Systems Register is to be provided by the shipbuilder for all watertight cable transits fitted on-board the vessel. For an example of a register see Table 3.21.2. The Register can be in either a hard copy or digitized media. It is to include a marking / identification system, documentation referencing manufacturer manual(s) for each type of cable transit installed, the Type Approval certification for each type of transit system, applicable installation drawings, and a recording of each installed transit documenting the as built condition after final inspection in the shipyard. It is to include sections to record any inspection, modification, repair and maintenance.

3.21.3 During new construction the Register is to be reviewed by the attending Surveyor to confirm it contains a list of the watertight cable transits, applicable cable transit information and sections to maintain in-service maintenance and survey records.

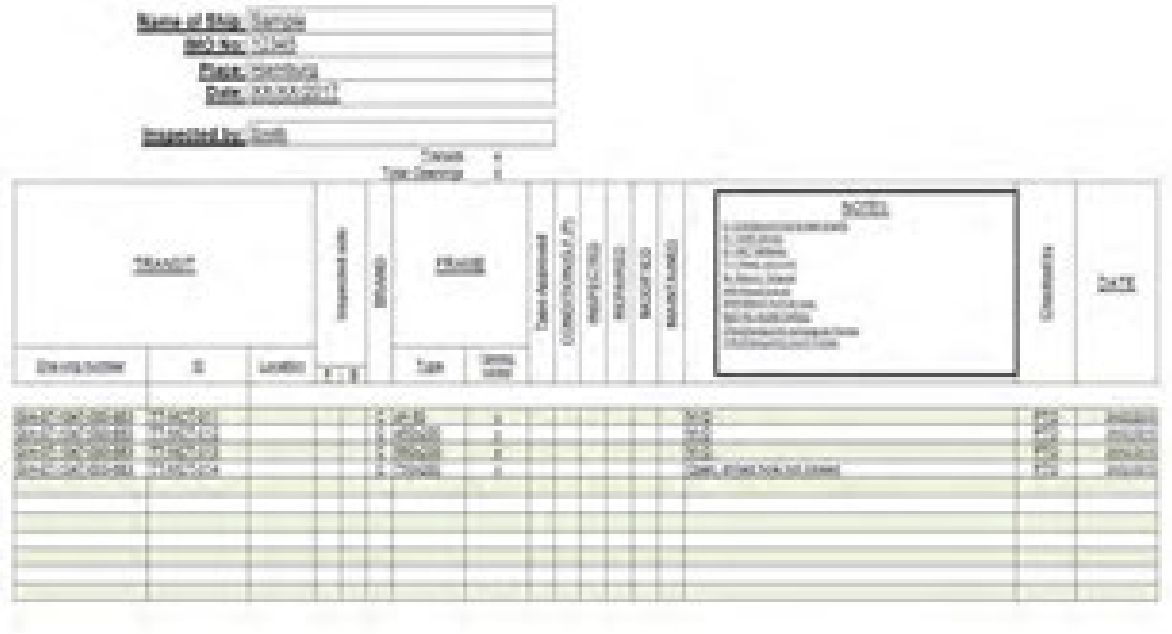
3.21.4 The Register is to be held onboard the vessel.

3.21.5 The owner is to maintain the Register to record any disruption (repair, modification or opening out and closing) to a cable transit or to record the installation of a new cable transit.

3.21.6 At new construction it is to be confirmed by the surveyor that:

- Cable transits have been installed, and where disrupted have been reinstated, in accordance with the manufacturer's requirements and in accordance with the requirements of Type Approval.
- Where specified, appropriate specialized tools have been used.

Table 3.21.2 : Recommended format for Cable Transit Seal System Register



Section 4

Switchgear and Control Gear Assemblies

4.1 Main and emergency switchboards

4.1.1 Location and installation

4.1.1.1 Switchboards are to be installed in accessible and well ventilated dry spaces free from flammable gases and acid fumes.

4.1.1.2 Switchboards are to be secured to a solid foundation and protected against shocks and damage due to leaks and falling objects. They are to be self-supported, or be braced to the bulkhead or the deck above. In case the latter method is used, the means of bracing is to allow normal deflections of the deck without buckling the control cell or assembly structure.

4.1.1.3 Pipes should not be installed directly above or in front of or behind switchboards. If such piping is unavoidable, suitable protection is to be provided in these positions.

4.1.1.4 An adequate, unobstructed working space is to be left in front of switchboards. At the rear, a clearance of at least 0.6 m is to be maintained except that this may be reduced to 0.5 m in way of stiffeners or frames. If switchboards are enclosed at the rear and are fully serviceable from the front, clearance at the rear will not be required unless necessary for cooling.

4.1.1.5 The main switchboard is to be so placed relative to one main generating station that, as far as practicable, the integrity of the normal electrical supply may be affected only by a fire or other casualty in one space. The main switchboard is to be located as close as practicable to the main generating station, within the same machinery space and the same vertical and horizontal A60 fire boundaries. An environmental enclosure for main switchboard, such as may be provided by a machinery

control room situated within the main boundaries of the space, is not to be considered as separating the switchboards from the generators.

4.1.1.6 Where essential services for steering and propulsion are supplied from section boards these and any transformers, converters and similar appliances constituting an essential part of electrical supply system are also to satisfy 4.1.1.5.

4.1.2 Construction of switchboards

4.1.2.1 Switchboards are to have roof with degree of protection IP 22 and are to be of dead front type.

On systems with voltages above 50 V up to and including 1000 V, front and rear dead type switchboards are to be used.

4.1.2.2 All main switchboards are to be guarded by hand rails either made of hardwood or insulated. Where access is provided behind a main switchboard, the handrails on the rear are to be horizontal, and so placed that one cannot accidentally fall into the switchboard. Further, insulated mats or gratings are to be laid on the floor of passage-ways in front of and to the rear of switchboards. Instruments and handles or push buttons for switchgear are to be placed on the front of the switchboard (except for isolating switches, if used). All other parts which require operation, are to be accessible and so placed that the risk of accidental touching of current carrying parts, or accidental making of short-circuits and earthings, is reduced as far as practicable.

4.1.2.3 Section boards (sub-switchboards) and distribution boards are to be enclosed unless they are installed in a cupboard or compartment to which only authorised personnel have access, in which case the cupboard may serve as an enclosure.

4.1.2.4 Framework, panels and doors of switchboards are generally to be of steel or aluminium alloy, and are to be of rigid construction.

4.1.2.5 All parts of the main switchboard are to be accessible for maintenance work.

4.1.2.6 Equipment for each generator and for different distribution systems are to be placed in separate cubicles (panels) or are to be separated from each other by partitions clearly marked with the actual voltages.

4.1.2.7 Doors, behind which equipment requiring operation is placed, are to be hinged. Arrangement is also to be provided to keep the hinged doors open.

4.1.2.8 Cable entrances are generally to be from below or from the side. Cable entries from the top may be accepted provided watertight glands are used.

4.1.2.9 Where the main source of electrical power is essential for propulsion of the ship, the main busbars are to be subdivided into at least two parts which are normally to be connected by circuit breakers (with or without tripping mechanism), disconnecting links or switch by which busbars can be split and reconnected easily and safely. Bolted links (e.g. bolted bus bar sections) are not acceptable. So far is practicable, the connection of generating sets and any other duplicated equipment is to be equally divided among the busbar divisions. Equivalent arrangements to the satisfaction of IRS may be accepted.

4.1.3 Marking and labels

4.1.3.1 All measuring instruments and all apparatus controlling circuits are to be clearly and indelibly marked for identification purposes. An indelible label is to be permanently secured to, or adjacent to, every fuse and every circuit breaker, and marked with particulars of the full load current of the generator or cable which the fuse or circuit-breaker protects. Where inverse time limit and/or reverse current devices are provided in connection with a circuit breaker, the appropriate settings of these devices are to be stated on the lable. The distribution voltage is to be indicated. Labels are to be of flame-retardant material and markings are to correspond with the designations used in the wiring diagrams.

4.1.4 Busbars

4.1.4.1 Busbars and their connections are to be of copper, all connections being so made as to prevent deterioration of the joint by corrosion or oxidation.

4.1.4.2 The sizes of busbars and their connections are to be calculated to ensure that their mean temperature rise does not exceed by more than 45°C from the ambient temperature, when running continuously at the normal rating.

4.1.4.3 Busbars, together with their connections and supports, are to be capable of

withstanding, without detrimental effect, the mechanical stresses which will arise during short-circuits. Further, provision is to be made to allow the busbars to expand without causing any abnormal stress on their supports.

4.1.4.4 Busbars and other bare conductors are to be mounted on non- deteriorating and non-hygroscopic insulating material, maintaining adequate clearance and creepage distance, in accordance with Section 1, to ensure that there is no risk of flash-over under normal service conditions. Where necessary these distances may have to be increased to allow for the electro-magnetic forces involved.

4.1.4.5 Connections from bus-bars and from generator circuit terminals to all circuit breakers and fuses are to be installed "short-circuit proof", i.e. either bare conductors, or insulated conductors or single-core cable without metallic sheath/armour /braid are used and these are mounted on supports of insulating material and with adequate distance between the different poles (phases) and to earthed parts.

4.1.4.6 Horizontally installed bus-bars and bare conductors are to be protected by screens, if they are placed so low that it could be a risk, e.g. by tools falling on them.

4.1.5 Equalizer connections

4.1.5.1 The current rating of equalizer connections and equalizer switches is to be not less than half the rated full load current of the generator.

4.1.5.2 The current rating of equalizer busbars is to be not less than half the rated full load current of the largest generator in the group.

4.1.6 Instruments for direct current generators

4.1.6.1 For generators not arranged to run in parallel, at least one voltmeter and one ammeter are to be provided for each generator.

4.1.6.2 For generators arranged to run in parallel at least one ammeter for each generator and two voltmeters are to be provided. One of these voltmeters is to be permanently connected to the busbars and the other is to be provided with a change-over switch to enable it to be connected to any one generator.

4.1.6.3 For compound wound generators fitted with equalizer connections, the ammeter is to be connected to the pole opposite to that connected to the series winding of the generator.

4.1.7 Instruments for alternating current generators

4.1.7.1 For alternating current generators not arranged to run in parallel, each generator is to be provided with at least one voltmeter, one frequency meter, and one ammeter with an ammeter switch to enable the current in each phase to be read or an ammeter in each phase. Generators above 50 kVA are to be provided with a wattmeter.

4.1.7.2 For alternating current generators arranged to run in parallel, each generator is to be provided with a wattmeter, and an ammeter in each phase conductor or an ammeter with a selector switch to enable measurement of current in each phase.

4.1.7.3 For paralleling of the generators, two voltmeters, two frequency meters and a synchronising aid comprising either a synchroscope and lamps, or an equivalent arrangement, are to be provided. One voltmeter and one frequency meter are to be connected permanently to the busbars, the other voltmeter and frequency meter are to be provided with arrangements to enable the voltage and frequency of any generator to be measured.

4.1.8 Instrument scales

4.1.8.1 In general main switchboard instruments are to be of accuracy class 1.5 and other switchboard instruments are to be of accuracy class 2.5.

4.1.8.2 The upper limit of the scale of every voltmeter is to be approximately 120 per cent of the normal voltage of the circuit, and the normal voltage is to be clearly indicated.

4.1.8.3 The upper limit of the scale of every ammeter is to be approximately 130 per cent of the normal rating of the circuit in which it is installed. Normal full load is to be clearly indicated.

4.1.8.4 Ammeters for use with direct current generators, and wattmeters for use with alternating current generators, which may be operated in parallel, are to be capable of indicating 15 per cent reverse-current or reverse-power respectively.

4.1.8.5 The upper limit of the scale of every wattmeter is to be approximately 130 per cent of the rated full load of the circuit in which it is installed. Rated full load is to be clearly indicated.

4.1.8.6 Frequency meters are to be capable of indicating a variation in the frequency from minus 8 per cent to plus 8 per cent of the nominal frequency of the installation.

4.1.8.7 Instruments are to have effective screening, for example, by metal enclosures, in order to diminish faulty readings caused by induction from adjacent current-carrying parts.

4.1.9 Instrument transformers

4.1.9.1 The secondary windings of instrument transformers are to be earthed.

4.1.10 Circuit-breakers

4.1.10.1 Circuit-breakers are to comply with IEC Publication 947-1 and 947-2, "Low Voltage Distribution Switchgear" or an equivalent national standard, amended where necessary for ambient temperature.

4.1.10.2 Test reports, based on the requirements of IEC Publication 947-1 and 947-2 or an equivalent national standard, are to be submitted for consideration when required.

4.1.10.3 Circuit-breakers are to be of the trip-free type i.e. the breaking action initiated by short-circuit and overcurrent relays, or by undervoltage coil, when fitted, is to be fulfilled independently of the position or operation of manual handle or of other closing devices. Further the arrangement is to be such that automatic repeated breakings/makings by short-circuits and overcurrents cannot occur.

4.1.10.4 Each circuit opening device is to be so arranged that accidental closing and opening does not occur.

4.1.10.5 Handles and operating mechanisms are to be so arranged that the hand of the operator cannot accidentally touch live metal or be injured through an arc arising from the switch or circuit-breaker, or the rupturing of a fuse. If switches are enclosed their handles are not to operate through unprotected slots.

4.1.11 Fuses

4.1.11.1 Fuses are to comply with IEC Publication 269 "Low Voltage Fuse with High Breaking Capacity" or an equivalent national standard, amended where necessary for ambient temperature.

4.1.11.2 A report, giving details of test performance, fusing characteristics, temperature and insulation tests and details of the specification to which the fuse has been tested is to be submitted for consideration when required.

4.1.11.3 Fuse-links and fuse-bases are to be marked with particulars of rated current and rated voltage. Each fuse position is to be permanently and indelibly labeled with the current-carrying capacity of the circuit protected by it and with the appropriate approved size of fuse.

4.1.12 Earthing

4.1.12.1 A good, reliable earth connection of all metallic non-current carrying parts is to be insured. Normally, a continuous earth bar will be required. If other solutions are chosen, earth-continuity test may be required.

4.1.12.2 If components such as switches, instruments, signal lamps, etc. with voltage exceeding 30V AC and 50V DC are mounted on hinged doors of switchboards or other enclosures, the doors are to be connected to the switchboards or enclosures by a separate flexible earth conductor.

4.1.12.3 Earth conductors are to be so installed that they are not likely to suffer mechanical damage or corrosion. The earth conductor is to be carried to a separate earth screw inside the enclosure of the equipment which is earthed, except when separately installed earth conductors are used.

4.1.12.4 Earth conductors inside switchboards and other enclosures are to be insulated, except when the arrangement is such that the earth conductor cannot come into contact with current-carrying parts.

4.1.13 Wiring

4.1.13.1 Insulated cables / wires connecting components are to be stranded, flame retardant and manufactured in accordance with a relevant and acceptable National Standard or equivalent International Standard.

4.2 Distribution switchboards

4.2.1 Large distribution switchboards are to be constructed in accordance with 4.1.

4.2.2 All parts which require operation in normal use are to be placed on the front or easily accessible from behind front doors.

When such parts are placed behind front doors, the interior front is to comply with enclosure type IP 20, except that fuses with accessible current-carrying parts may be permitted, provided that the door is lockable.

4.2.3 Switchboards, supplied from different supply circuits, are not to be placed in the same enclosure unless these are separated by partitions of flame retardant material.

4.2.4 Switchboards, which are provided with two or more supply circuits arranged for automatic standby connection, are to be provided with positive means to show the circuit feeding the switchboard. Such switchboards are to be provided with warning notice that all the supply circuits are to be disconnected before maintenance work is undertaken.

4.2.5 If distribution switchboards are placed in accommodation area then they are also to comply with the requirements given in Pt.6, Ch.3, Cl.3.2.2.3.2 IR.6.

4.3 Navigation lights

4.3.1 Navigation lights are to be connected separately to a distribution board reserved for this purposes only, and connected directly or through transformers to the main or emergency switchboard. The distribution board is to be accessible to the officer of the watch on the bridge. Provision is to be made on the bridge for such navigation lights to be transferred to an alternate circuit.

4.3.2 Each navigation light is to be controlled and protected in each insulated pole by a switch and fuse or circuit breaker mounted on the distribution board.

4.3.3 Where the navigation panel is situated in the midships house, the midships sub-switchboard is regarded as an extension to the main switchboard provided that it is supplied from the main switchboard by two cables each capable of carrying the full load.

4.3.4 Each navigation light is to be provided with an automatic indicator giving audio and visual indication of failure of the light. If a visual signal is used connected in series with the navigation light, means are to be provided to prevent extinction of the navigation light due to failure of the signal.

4.3.5 Transferring of power supply to an alternate circuit should not render the audio/visual alarms inoperative. Means should be provided to test the audio/visual alarms.

4.3.6 Any statutory requirements of the country of registration are to be complied with and, on application to IRS, may be accepted as an alternative to the above.

4.3.7 The voltage drop between the power supply terminals and load terminals for navigation lights is to be not more than 2.5 per cent of the rated voltage to ensure required output and colour.

4.4 Control gear

4.4.1 Control gear is to comply with IEC 60947 “Low-voltage switchgear and control gear” or an equivalent national standard, amended where necessary for ambient temperature.

4.4.2 Control gear, including isolating and reversing switches, is to be so arranged that shunt field circuits are not disconnected without adequate discharging path being provided.

4.4.3 Control gear for essential and important motors are to be separated from each other and from other current carrying parts by screens. The arrangement is to be such that maintenance work can be carried out on each unit without danger when isolated.

4.4.4 When installed in main switchboards motor control gear is to be placed in separate cubicles separated from all other parts of the switchboard by partitions of flame retardant material. The arrangements are to be such that arcs occurring by short-circuit in one cubicle cannot spread to bus-bars.

4.5 Testing

4.5.1 Switchgear and control gear assemblies with supply voltage of 60 V and above are to be tested as follows:

- High voltage test with 1000 V plus twice the rated voltage with a minimum of 2000 V. The test voltage is to be supplied for 1 minute at any frequency between 25 and 100 Hz.

- Insulation resistance measuring.

4.5.2 Switchgear and control gear assemblies with supply voltage less than 60 V are to be tested in accordance with 4.5.1 except that the test voltage is to be 500 V.

Section 5

Rotating Machines - Construction and Testing

5.1 General

5.1.1 Rotating machines are to comply with the relevant part of IEC 60092-301:1980/ AMD2:1995, or an acceptable and relevant national standard, and the requirements of this Section.

5.1.2 For all the rotating machines for essential services, manufacturer's test records are to be provided (See also Sec.1). For other machines they are to be available upon request.

5.1.3 Shaft materials for electric propulsion motors and for main engine driven generators where the shaft is part of the propulsion shafting, is to comply with applicable requirements of Pt.2, and to be certified by IRS. Shaft material for other machines is to be in accordance with either Pt.2 or recognised international or national standard.

5.1.4 The rotating parts are to be so balanced that when running at any speed in the normal working range the vibration level does not exceed the levels specified in IEC 60034.

5.1.5 The lubrication arrangement for bearings are to be effective under all operating conditions including the maximum ship inclinations specified in Ch.1 and there are to be effective means to ensure that lubricant does not reach the machine windings or other conductors and insulators.

5.1.6 Steps are to be taken to prevent the ill effects of flow of currents circulating between the shaft and bearings.

5.1.7 Where welding is proposed to be applied to shafts of machines for securing armature arms or spiders, stress relieving is to be carried out after welding. The proposal is to be submitted for scrutiny and approval.

5.1.8 The construction of alternating machines, are to be capable of withstanding a sudden short circuit at their terminals under any operating condition.

5.1.9 Effective means are to be provided to prevent the accumulation of moisture and condensation within the machines when they are stopped with a provision that such means are switched on at stand-still and switched off at starting.

5.1.10 Coolers : Water-air heat exchangers of rotating machines are to be of the double tube type. In a normally attended position a visual and audible alarm is to be given to monitor water cooler leakage.

5.2 Rating

5.2.1 Ship's service generators including their exciters, and continuously rated motors are to be suitable for continuous duty at their full rated output at maximum cooling air or water temperature for an unlimited period, without the limits of temperature rise in 5.3 being exceeded. Other generators and motors are to be rated in accordance with the duty which they are to perform, and when tested under rated load conditions the temperature rise is not to exceed the values in 5.3.

5.3 Temperature rise

5.3.1 The limits of temperature rise specified in Table 5.3.1 are based on a cooling air temperature of 45°C and a cooling water temperature of 30°C.

5.3.2 If the temperature of the cooling medium is known to exceed the value given in 5.3.1, the permissible temperature rise is to be reduced by an amount equal to the excess temperature of the cooling medium. These temperature rises

are, if necessary to be reduced to satisfy the requirements of flame-proof equipment.

5.3.3 If the temperature of the cooling medium is known to be permanently less than the value given in 5.3.1, the permissible temperature rise may be increased by an amount equal to the difference between the declared temperature and that given in 5.3.1 upto a maximum of 15°C.

Table 5.3.1 : Limits of temperature rise in °C

Item		Part of machines	Method of measurement of temp.	Temperature rise °C					
				Air cooled machines insulation class			Water cooled machines insulation class		
				A	E	B	A	E	B
1	(a)	a.c. windings of turbine type machines having output of 5000 KVA or more	ETD or R	50	60	70	70	80	90
	(b)	a.c. windings of salient-pole and of induction machines having output of 5000 KVA or more, or having a core length of one metre or more	ETD or R	50	60	70	70	80	90
2	(a)	a.c. windings of machines smaller than in item 1	R	50	65	70	70	85	90
			T	40	55	60	60	75	80
	(b)	Field windings of a.c. and d.c. machines having d.c. excitation other than those in items 3 and 4	R	50	65	70	70	85	90
			T	40	55	60	60	75	80
	(c)	Windings of armatures having commutators	R	50	65	70	70	85	90
			T	40	55	60	60	75	80
3		Field windings of turbine-type machines having d.c. excitation	R	-	-	80	-	-	100
4	(a)	Low-resistance field windings of more than one layer and compensating windings	T,R	50	65	70	70	85	90
	(b)	Single-layer windings with exposed bare surfaces	T,R	55	70	80	75	90	100
5		Permanently short-circuited insulated windings	T	50	65	70	70	85	90
6		Permanently short-circuited windings, uninsulated	T	The temperature rise of these parts shall in no case reach such a value that there is a risk of injury to any insulating or other material on adjacent parts					
7		Iron core and other parts not in contact with windings	-	The temperature rise of these parts shall in no case reach such a value that there is a risk of injury to any insulating or other material on adjacent parts					
8		Iron core and other parts in contact with windings	T	50	65	70	70	85	90
9		Commutators and slip-rings, open or enclosed	T	50	60	70	70	80	90

Notes:-

1 T = Thermometer method
R = Resistance method
ETD = Embedded Temperature Detector

2 When the commutators, sliprings or bearings of machines provided with water coolers are not in the enclosed air circuits-cooled by the water cooler, but are cooled by the ambient cooling air, the permissible temperature rise above the ambient cooling air should be the same as for ventilated machines.

3 When Class F or Class H insulation is employed, the permitted temperature rises are respectively 20°C and 40°C higher than the values given for Class B insulation.

4 Classes of insulation are to be in accordance with IEC Publication 85 (1957) - "Recommendations for the classification of material for the insulation of electrical machinery and apparatus in relation to their thermal stability in service".

5.3.4 The limits of temperature rise of electric slip couplings are to be in accordance with Table 5.3.1, except that when a squirrel cage element is used the temperature of this element is not to reach an injurious value. The temperature of the field windings is not to exceed these limits at all speeds of operation. Arrangements for reducing the excitation of self ventilated couplings at low operational speeds are permissible.

5.3.5 Alternating current machines of 5000 kVA output and above and propulsion motors having a total axial core length of 1m or more (including the ventilating duct), are to have at least three embedded temperature detectors. With multicore machines the total length is to be taken as the sum of the individual core lengths.

5.4 Generator control

5.4.1 Each alternating current generator, unless of the self-regulating type, is to be provided with automatic means of voltage regulation; voltage build-up is not to require an external source of power.

5.4.2 The voltage regulation of any alternating current generator with its regulating equipment is to be such that at all loads, from zero to full load at rated power factor, the rated voltage is maintained within $\pm$2.5 per cent under steady conditions. There is to be provision at the voltage regulator to adjust the generator no load voltage.

5.4.3 Generators, and their excitation systems, when operating at rated speed and voltage on no-load are to be capable of absorbing the suddenly switched, balanced, current demand of the largest motor or load at a power factor not greater than 0.4 with a transient voltage dip which does not exceed 15 per cent of rated voltage. The voltage is to recover to rated voltage within a time not exceeding 1.5 seconds.

5.4.4 The transient voltage rise at the terminals of a generator is not to exceed 20 per cent of rated voltage when rated KVA at a power factor not greater than 0.8 is thrown off.

5.4.5 Generators are to be capable of maintaining under steady state short circuit conditions a current of at least three times the full load rated current for a duration of at least two seconds or where precise data is available for the duration of any longer time delay which may be provided by a tripping device for discrimination purposes.

5.4.6 Generators required to run in parallel are to be stable from no load [kW] up to the total combined full load [kW] of the group, and load sharing is to be such that the load on any generator does not normally differ from its proportionate share of the total load by more than 15 per cent of the rated output [kW] of the largest machine or 25 per cent of the rated output [kW] of the individual machine, whichever is less.

5.4.7 When generators are operated in parallel, the kVA loads of the individual generating sets are not to differ from the proportionate share of the total kVA load by more than 5 per cent of the rated kVA output of the largest machines.

5.4.8 Generators running in parallel may have a common neutral connection to earth provided they are suitably designed to avoid excessive circulating currents.
This is particularly important if the generators are of different size and make.
Generators in which the third harmonic content of the waveform does not exceed 5 per cent may be considered adequate.

Note : This would mostly occur with a neutral bus with a single grounding resistor with the associated neutral switching. Where individual resistors are used, circulation of the third harmonic currents between paralleled generators is minimized.

5.5 Overloads

5.5.1 Machines are generally to be capable of withstanding, on test, without injury, the following overload conditions :

a) D.C. generators - an excess current of 50 per cent for 15 seconds after attaining the temperature rise corresponding to rated load, the terminal voltage being maintained as near the rated value as possible. This requirement does not apply to the overload torque capacity of the prime mover.

b) A.C. generators - an excess current of 50 per cent for 2 minutes, at 0.6 power factor, after attaining the temperature rise corresponding to rated load, the terminal voltage and frequency being maintained as near the rated values as possible. This requirement does not apply to the overload torque capacity of the prime mover.

c) Motors - At rated speed or in the case of a range of speeds, at the highest and lowest speeds, under gradual increase of torque, the voltage and frequency being maintained as near to their rated value as possible, the appropriate excess torque given below. Synchronous motors and synchronous induction motors are required to withstand the excess torque without falling out of synchronism and without adjustment of the excitation current preset at the value corresponding to rated load.

d.c. motors	50 per cent for 15 seconds
polyphase a.c. synchronous motors	50 per cent for 15 seconds
polyphase a.c. synchronous induction motors	35 per cent for 15 seconds
polyphase a.c. induction motors	60 per cent for 15 seconds

d) Propulsion machines - Overload tests for propulsion machines will be given special consideration for each installation.

5.6 Brushgear

5.6.1 The final running position of brushgear is to be clearly and permanently marked.

5.6.2 Direct current motors and generators are to operate with fixed brush setting from no load to the momentary overload specified without injurious sparking, or damage to the commutator or brushes. The commutation is to be checked with an excess current of 20 per cent and for a period of time sufficient to judge its quality.

5.6.3 Alternating current commutator motors are to operate over the specified range of load and speed without injurious sparking.

5.7 Inspection and testing

5.7.1 On all machines intended for essential services, tests specified in Table 5.7.1 are to be carried out. See also Section 1 'Surveys', subsection 1.3. Any other relevant tests required by the national standards are also to be carried out.

Type tests are to be carried out on a prototype machine or on the first of a batch of machines and routine tests carried out on subsequent machines.

5.7.2 The high voltage test is to be carried out at 1000 plus twice the rated voltage with a minimum of 2000 V on new machines, preferably at the conclusion of the temperature rise test. The test is to be applied between the windings and the frame with the core connected to the frame and to any windings or sections of windings not under test. Where both ends of each phase are brought out to accessible separate terminals, each phase is to be tested separately. The test is to be made with alternating voltage at any convenient frequency between 25 and 100 Hz of approximately sine wave form. The test is to be commenced at a voltage of not more than one half of the full-test voltage and is to be increased progressively to full value, the time allowed for the increase of the voltage from half to full value being not less than 10 seconds. The full test voltage is then to be maintained for one minute and then reduced to one half full value before switching off.

5.7.3 When additional high voltage tests are required on a machine which has already passed its tests or on machines after repair, the voltage of such further tests is to be 75 per cent of the value given in 5.7.2.

5.7.4 Immediately after the high voltage tests the insulation resistances are to be measured using a direct current insulation tester between:

a) all current carrying parts connected together and earth,

b) all current carrying parts of different polarity or phase, where both ends of each polarity or phase are individually accessible.

The minimum values of test voltages and corresponding insulation resistances are given in Table 5.7.4. The insulation resistance is to be measured close to the operating temperature, or an appropriate method of calculation is to be used.

Table 5.7.1 : Tests to be carried out on electrical rotating machines

Sr. No.	Tests	a.c. Generators		Motors	
		Type test (1)	Routine test (2)	Type test (1)	Routine test (2)
1.	Examination of the technical documentation, as appropriate and visual inspection	X	X	X	X
2.	Insulation resistance measurement	X	X	X	X
3.	Winding resistance measurement	X	X	X	X
4.	Verification of the voltage regulation system	X	X(6)		
5.	Rated load test and temperature rise measurement	X		X	
6.	Overload test	X	X(4)	X	X(4)
7.	Verification of steady short-circuit conditions (3)	X			
8.	Overspeed test	X	X	X(5)	X(5)
9.	Dielectric strength test	X	X	X	X
10.	No load test	X	X	X	X
11.	Verification of degree of protection	X		X	
12.	Verification of bearings	X	X	X	X

(1) For machines of less than 100 kW, type tests on prototype machine is acceptable. For 100 kW or more, tests on at least the first of each batch of machines are to be carried out.
(2) The report of machines routine tested is to contain the manufacturer's serial number of the machine which has been type tested and the test results.
(3) Verification of steady short-circuit condition applies to synchronous machines only.
(4) Only applicable for machines of essential services rated above 100 kW. For routine tests, overcurrent test may be carried out in lieu of overload test.
(5) Not applicable for squirrel cage motors.
(6) Only functional test of voltage regulator system.

Table 5.7.4 : Minimum values of test voltages and corresponding insulation resistances

Related Voltage V_R (V)	Minimum Test Voltage (V)	Minimum Test Insulation Resistance (MΩ)
$V_R \leq 250$	$2 \times V_R$	1
$250 < V_R \leq 1000$	500	1
$1000 < V_R \leq 7200$	1000	$(V_R / 1000) + 1$
$7200 < V_R \leq 15000$	5000	$(V_R / 1000) + 1$

Section 6

Converting Equipment

6.1 Transformers

6.1.1 The following requirements apply to transformers of 5 kVA and above.

6.1.2 Transformers are to comply with the requirements of IEC Publication 76 or an acceptable and relevant national standard amended where necessary for ambient temperature.

6.1.3 Transformers may be of the dry type, encapsulated or liquid filled type.

6.1.4 Transformers are to be placed in easily accessible well ventilated spaces free from any gaseous or acid fumes. They are to be clear of non-protected ignitable materials, and so arranged as to be protected against shocks and any damage resulting from water, oil, liquid fuel, steam etc.

6.1.5 The live parts of transformers are to be provided with means of protection against accidental contact.

6.1.6 Transformers are to be double wound except those for motor starting.

6.1.7 Windings of air cooled transformers are to be treated to efficiently resist moisture, sea air and oil vapours.

Effective means are to be provided to prevent the accumulation of moisture and condensation within the transformers, when de-energized.

6.1.8 Each transformer is to be provided with a nameplate of corrosion- resistant metal giving information on make, type, serial number, insulation class and any other technical data necessary for the application of the transformer.

6.1.9 Liquid fillings for transformers are to be non-toxic and of a type which does not readily support combustion. Liquid filled transformers are to have a pressure relief-device with an alarm and there is to be a suitable means provided to contain any liquid which may escape from the transformer.

6.1.10 When forced cooling is employed, whether air or liquid, there is to be monitoring of the cooling medium and transformer winding temperature with an alarm should these exceed preset limits. There are to be arrangements so that the load may be reduced to a level commensurate with the cooling available.

6.1.11 The inherent regulation of transformers at their rated output is to be such that voltage drop to any point in the installation does not exceed that allowed by 2.3.

6.1.12 All transformers are to be constructed to withstand, without damage, the thermal and mechanical effects of a short-circuit at the terminals of any winding for 2 seconds with rated primary voltage and frequency without damage. This may be required to be verified by type test or random test.

6.1.13 The temperature rise of windings of transformers above the ambient temperatures given in Ch.1, when measured by resistance, during continuous operation at the maximum rating, is not to exceed :

a) For dry type transformers, air cooled

- 50°C for Class A;
- 60°C for Class E;
- 70°C for Class B;
- 90°C for Class F; and
- 110°C for Class H.

b) For liquid filled transformers

- 50°C - where air provides cooling of the fluid;
- 65°C - where water provides cooling of the fluid.

6.1.14 The tests given hereunder are to be carried out on all transformers at the manufacturer's works and a certificate of tests issued by the manufacturer.

a) High voltage test : The test voltage is to be applied, preferably after the temperature rise test, to each winding in turn, between the winding under test and the remaining

windings, core, frame and tank or casing connected together and to earth. The test is to be made with 1 kV a.c. plus twice the highest voltage between lines with a minimum of 2.5 KV at any frequency between 25 and 100 Hz and maintained for 1 minute without failure.

b) When additional high voltage tests are carried out and for transformers that have been rewound or subject to extensive repair, the test voltage may be limited to a value which is 75 per cent of that stated in (a).

c) Induced high voltage test : To test between turns, coils and terminals, an a.c. voltage is to be applied between the above parts corresponding to twice the voltage appearing between these parts when rated voltage is applied to the terminals. The duration of the test is to be 1 minute for any test frequency up to and including twice the rated frequency.

d) Insulation resistance : The insulation resistance of each winding in turn to all the other windings, core, frame and tank or casing connected together and to earth is to be measured after the high voltage test and recorded together with the temperature of the transformer at the time of the test.

e) Temperature rise : One transformer of each size and type is to be given a temperature rise test. For transformers of rating 100 KVA and above, it will be accepted that the temperature rise test is made on one of several identical transformers manufactured and tested at the same time.

6.2 Semiconductor equipment

6.2.1 The requirements of 6.2.2 to 6.2.16 apply to semiconductor equipment rated for 5 [kW] upwards.

6.2.2 Semiconductor equipment is to comply with the requirements of IEC 146: Semiconductor convertors, or an acceptable and relevant national standard amended where necessary for ambient temperature.

6.2.3 Semiconductor static power converter equipment is to be rated for the required duty having regard to peak loads, system transients and overvoltage.

6.2.4 Converter equipment may be air or liquid cooled and is to be so arranged that it cannot remain loaded unless effective cooling is maintained. Alternatively the load may be automatically reduced to a level commensurate with the cooling available.

6.2.5 Liquid cooled converter equipment is to be provided with leakage alarms and there is to be a suitable means provided to contain any liquid which may leak from the system. Where the semiconductors and other current carrying parts are in direct contact with the cooling liquid, provision is to be made for monitoring the liquid to ensure it has a satisfactory resistivity.

6.2.6 Where forced cooling is used there is to be temperature monitoring of the heated cooling medium with an alarm and shutdown when the temperature exceeds a preset value.

6.2.7 Cooling fluids are to be non-toxic and of low flammability.

6.2.8 Converter equipment is to be so arranged that the semiconductor devices, fuses, control and firing circuit boards may be readily removed from the equipment for repair or replacement.

6.2.9 Test and monitoring facilities are to be provided to permit identification of control circuit faults and faulty components.

6.2.10 Protection devices fitted for converter equipment protection are to ensure that, under fault conditions, the protective action of circuit breakers, fuses or control systems is such that there is no further damage to the convertor or the installation.

6.2.11 Converter equipment, including any associated transformers, reactors, capacitors and filters, if provided, is to be so arranged that the harmonic distortion, and voltage spikes, introduced in to the ships electrical system are restricted to a level necessary to ensure that it causes no malfunction of equipment connected to the electrical installation.

6.2.12 Overvoltage spikes or oscillations caused by commutation or other phenomena, are not to result in the supply voltage waveform deviating from the superimposed equivalent sine wave by more than 10 percent of the maximum value of the equivalent sine wave.

6.2.13 When converter equipment is operated in parallel, load sharing is to be such that under normal operating conditions overloading of any unit does not occur and the combination of

parallel equipment is stable throughout the operating range.

6.2.14 When converter equipment has parallel circuits there is to be provision to ensure that the load is disturbed uniformly between the parallel paths.

6.2.15 Transformers, reactors, and other circuit devices associated with convertor equipment are to be suitable for the distorted voltage and current waveforms to which they may be subjected.

6.2.16 Tests at the manufacturer's works are to include

- high voltage test for one minute applied between terminals and earthed parts at a frequency between 25 - 100 Hz. For system voltage up to 60 V the test voltage is to be 600 V; for system voltage between 60 - 90 V the test voltage is to be 900 V; for system voltage over 90 V the test voltage is to be twice the system voltage plus 1000 V;
- functional tests;
- temperature rise test; and
- such other agreed tests as are necessary to demonstrate the suitability of the equipment for its intended duty. Details of tests are to be submitted for consideration when required.

Section 7

Miscellaneous Equipment

7.1 Accumulator batteries

7.1.1 General

7.1.1.1 The requirements of this Section apply to permanently installed secondary batteries of the vented type.

7.1.1.2 A vented type battery is one in which the electrolyte can be replaced and which may release gas whilst operating on charge and overcharge.

7.1.1.3 Proposals for the use of other types of secondary batteries may be submitted for consideration.

7.1.2 Construction

7.1.2.1 The cells of all vented type batteries are to be so constructed and secured as to prevent spilling of the electrolyte due to inclinations of 40 degrees from normal. The filling plugs are to be so constructed as to prevent spilling of electrolyte due to ship's movements, e.g. rolling and pitching.

7.1.2.2 All batteries are to be provided with durable labels of flame retardant material, giving information on the application for which the battery is intended, voltage and capacity. Instructions are to be fitted either at the battery or at the charging device giving information on maintenance and charging.

7.1.3 Location

7.1.3.1 Alkaline batteries and lead acid batteries of the vented type are not to be installed in the same compartment.

7.1.3.2 Batteries are to be located in such a manner that they are not exposed to excessive heat, extreme cold, spray, steam or other conditions which would impair performance or accelerate deterioration.

7.1.3.3 Batteries are not to be located in an accommodation space.

7.1.3.4 Large batteries are to be installed in a compartment assigned to them only. A box on deck would meet this requirement if adequately ventilated and provided with means to prevent ingress of water, and provided the intended service is assured in cold conditions.

7.1.3.5 Engine starting batteries are to be located as close as practicable to the engine(s) served. If such batteries cannot be accommodated in the battery compartment, they are to be installed so that adequate ventilation is ensured.

7.1.4 Installation

7.1.4.1 Batteries should be so arranged that each cell or crate of cells is accessible from the top and at least one side.

7.1.4.2 Cells or crates are to be carried on non-absorbent insulating supports. Similar insulators are to be fitted to prevent any movement of cells arising from the motion of the vessel. Adequate space for circulation of air is to be ensured.

7.1.4.3 Where acid is used as the electrolyte for a vented type battery, a tray of acid resisting material is to be provided below the cells unless the deck below is similarly protected.

7.1.4.4 The interiors of all compartments for vented type batteries, including the shelves, are to be painted with corrosion resistant paint with consideration given to the type of electrolyte actually used.

7.1.4.5 A permanent notice is to be fitted to all compartments for vented type batteries prohibiting naked lights and smoking in the compartment.

7.1.5 Ventilation

7.1.5.1 Battery compartments, lockers and boxes are to be adequately ventilated by an independent ventilating system to avoid accumulation of inflammable gases. Particular attention should be given to the fact that these gases are lighter than air and tend to accumulate at the top of the spaces.

7.1.5.2 The battery compartment is to be provided with an effective air inlet near the floor level.

7.1.5.3 Natural ventilation may be employed if ducts of adequate size can be run directly from the top of the compartment to the open air with no part of the duct more than 45 degrees from the vertical. If natural ventilation is impracticable, mechanical ventilation providing at least 30 changes of air per hour is to be installed. Interior surfaces of ducts and fans are to be painted with corrosion-resistant paint. Fan motors are not to be located in the air stream.

7.1.5.4 Necessary precautions are to be taken to prevent sparking due to possible contact by the ventilation fan blades with fixed parts.

7.1.5.5 All openings through the battery compartment bulkheads or decks, other than ventilation openings, are to be effectively sealed. (Also refer Pt.6, Ch.2, Cl.2.2.1).

7.1.6 Electrical equipment

7.1.6.1 Switches, fuses and other electrical equipment liable to cause an arc should not normally be installed in battery compartments. Where such equipment is necessary for operational reasons, the equipment should be certified for Group II C gases and temperature Class T1 in accordance with IEC 79, "Electrical Apparatus for Explosive Gas Atmospheres" or an equivalent national standard.

7.1.6.2 Cables, with the exception of those pertaining to the battery or the local lighting, are not to be installed in battery compartments except where installation in other locations is impracticable.

7.1.7 Number and rating of batteries

7.1.7.1 Where batteries are used for starting main engines, at least two batteries are to be fitted of such combined size that requirements of Ch.4 are complied with.

7.1.8 Charging facilities

7.1.8.1 All batteries are to be provided with charging devices, suitable for the actual service. Generally, automatically regulated charging devices are to be used, operating as floating service with the battery and giving trickle-charging when the battery is fully charged, or with change-over arrangement for full(quick)-charging and automatic trickle-charging. Other forms for charging arrangements, e.g. charging through resistors from a DC net with higher voltage, will be specially considered.

7.1.8.2 In direct current systems means are to be provided to isolate the batteries from the low voltage systems when being charged from a higher voltage system.

7.1.8.3 Charging devices are to be provided with suitable switch and fuse gear for protection against faults such as short circuit, overload and connection failures.

7.1.9 Maintenance of records for batteries

a) Where batteries are fitted for use for essential and emergency services a schedule of such batteries is to be compiled and maintained. The schedule, which is to be submitted for review during new building

survey and subsequently verified during annual surveys, is to include at least the following information regarding the battery(ies):

- Type and manufacturer's type designation
- Voltage and ampere-hour rating
- Location
- Equipment and/or system(s) served
- Maintenance / replacement cycle dates
- Date(s) of last maintenance and/or replacement
- For replacement batteries in storage, the date of manufacture and shelf life.[1)]

b) Procedures are to be put in place to ensure that when batteries are replaced, they are of an equivalent type.

c) Where vented[2)] type batteries replace valve-regulated sealed[3)] types, it is to be ensured that there is adequate ventilation[4)] and that IRS requirements relevant to the location and installation of vented types batteries are complied with.

d) Details of the schedule and of the procedures are to be included in the ship's safety management system and be integrated into the ship's operational maintenance routine.

Notes:

1) Shelf life is the duration of storage under specified conditions at the end of which a battery retains the ability to give a specified performance.

2) A vented battery is one in which the cells have a cover provided with an opening through which products of electrolysis and evaporation are allowed to escape freely from the cells to atmosphere.

3) A valve-regulated battery is one in which cells are closed but have an arrangement (valve) which allows the escape of gas if the internal pressure exceeds a predetermined value.

4) The ventilation arrangements for installation of vented type batteries which have charging power higher than 2kW are to be such that the quantity of air expelled is at least equal to:

$Q = 110\ I\ n$

where,

n = number of cells in series

I = maximum current delivered by the charging equipment during gas formation, but not less than 25 percent of the maximum obtainable charging current in amperes.

Q = quantity of air expelled in litres/hr.

The ventilation rate for compartments containing valve-regulated batteries may be reduced to 25 per cent of that given above.

7.2 Luminaries - construction and testing

7.2.1 General

7.2.1.1 Lighting which is essential for safety and working is to comply with the following provisions.

7.2.1.2 Lighting fittings installed in engine rooms or similar spaces where they are exposed to the risk of mechanical damage are to be provided with suitable grilled mechanical guards to protect their lamps and glass globes against such damage.

7.2.1.3 Precautions are to be taken so that a lamp for one voltage cannot be inserted in a lampholder for another voltage.

7.2.2 Incandescent lighting

7.2.2.1 The voltage of tungsten filament lampholders is not to exceed:

a) Bayonet fitting

Normal	B22 250 V
Small (single contact)	B15 s 130 V
Small (double contact)	B15 d 130 V

b) Screw fitting

Goliath	E40 250 V
Medium	E27 250 V
Small	E14 250 V
Miniature	E10 24 V

7.2.2.2 Lamps are to be in accordance with the following :

B22	upto 200 W
E27	upto 200 W
E40	upto 3000 W

7.2.2.3 Lampholders are to be constructed of flame-retarding and non- hygroscopic material. All metal parts are to be of robust construction. Goliath lampholders are to be provided with means for locking the lamp in the holder. The temperature of cable connections is not to exceed the maximum conductor temperature permitted for the cable as given in Table 3.3.1.

7.2.3 Fluorescent lighting

7.2.3.1 The ratings of tubular fluorescent lamps are not to exceed 250 V and 80 W.

7.2.3.2 Fittings, reactors, capacitors and other auxiliaries are not to be mounted on surfaces which are subject to high temperatures.

7.2.3.3 Capacitors of 0.5mF and above are to be provided with a means of prompt discharge on disconnection of the supply.

7.2.4 Discharge lighting
