3.1.1 The minimum number of monitors, their discharge rate, their range and their height of trajectory above sea level are to comply with the requirements of Table 3.1.1.

3.1.2 The monitors are to be so arranged that the required direction, range and height of trajectory can be achieved with the required number of monitors when they are operating simultaneously.

3.1.3 The monitors are to be capable of adequate adjustment in the vertical and horizontal direction and are to be so positioned that the jets will be unimpeded within the required range of operation. The horizontal angular movement of the monitors is to be at least 90°.

3.1.4 Means are to be provided for preventing the monitor jets from impinging on the ship's structure and equipment.

3.1.5 The monitors are to be of robust construction and their seating arrangements are to be of adequate strength for all modes of operation, particular attention being paid to shock loading when all the monitors are activated simultaneously.

3.2 Monitor controls

3.2.1 The activating and the maneuvering of the monitors are to be capable of remote control. The remote control station is to be arranged in a protected control room with a good general view. The valve control is to be designed to avoid water hammer.

3.2.2 The control system is to be designed in such a manner that normal operation can be restored within 10 minutes in case of any failure in the control system.

3.2.3 In case of electrical control systems, each control unit is to be provided with overload and short-circuit protection. In case of hydraulic or pneumatic control systems, the control power units are to be duplicated.

3.2.4 In addition to the remote control, local/manual control of each monitor is to be provided.

3.3 Foam monitor system (For class notation Agni 3)

3.3.1 In addition to the water monitors, the vessel is to be equipped with 2 foam monitors, each of a capacity not less than 5000 litres/minute with a maximum foam expansion ratio of 15 : 1.

Table 3.1.1 : Water monitor system capacities

Equipment	Class Notation			
	Agni 1	Agni 2		Agni 3
Minimum number of water monitors	2	3	4	4
Minimum discharge rate per monitor [m^3/h]	1200	2400	1800	2400
No. of pumps	1-2	2-4		2-4
Minimum total pump capacity [m^3/h]	2400	7200		9600
Minimum height of throw in [m[1)]]	45	70		70
Minimum length of throw in [m[2)]]	120	150		150
Minimum fuel capacity in hours [3)]	24	96		96
Number of hose connections each side of ship	4	8		8
Number of fireman's outfits	4	8		8

Notes:

1) Measured vertically from sea level to mean impact area at a horizontal distance of at least 70 [m] from the nearest part of the vessel.

2) Measured horizontally from the mean impact area to the nearest part of the vessel when all the monitors are in operation satisfactorily.

3) Capacity for continuous operation of all monitors to be included in the total capacity of the vessel's fuel oil tanks.

3.3.2 The foam system, together with the arrangements and location of monitors, is to give a height of throw at least 50 [m] above sea level when both monitors are used simultaneously with maximum foam generation.

3.3.3 The foam concentrate tank is to have a capacity for at least 30 minutes of maximum foam generation from both foam monitors. When determining the necessary quantity of foam concentrate, the admixture is assumed to be 5 per cent.

3.3.4 The foam generating system is to be of a fixed type with separate foam concentrate tank, foam-mixing unit and pipelines to the monitors. The water supply to the system may be taken from the main pumps for the water monitors and in such cases it may be necessary to reduce the main pump pressure to ensure correct water pressure for maximum foam generation.

3.3.5 Foam monitors are to be controlled in the manner given in 3.2 and the controls are to be located in the same control room as that for water monitors.

3.4 Pumps and piping

3.4.1 The pumps and their piping system which are intended for serving the monitors are not to be available for services other than fire-extinguishing and water spraying.

3.4.2 Where the pumps are used for fixed water spray systems, the piping is to be independent of that supplying the monitors. The water spray systems are to be adequately protected against overpressure.

3.4.3 The minimum total pump capacities required are shown in Table 3.1.1.

3.4.4 The piping system from the pumps to the water monitors is to be separate from the piping system to the hose connections required for mobile fire fighting equipment.

3.4.5 The piping systems are to have arrangements to avoid overheating of the pumps at low delivery rates.

3.4.6 All piping from seawater inlets to monitors is to be protected internally and externally against corrosion to a degree at least corresponding to hot galvanizing.

3.5 Mobile fire fighting equipment

3.5.1 Hose stations

3.5.1.1 Hose stations are to be provided on each side of the ship in accordance with Table 3.1.1.

3.5.1.2 Each hose station is to be provided with a hydrant, a hose and a nozzle capable of producing a jet or a spray and simultaneously a jet and a spray. The hoses are to be 15 [m] in length and not less than 38 [mm] nor more than 65 [mm] in diameter. Where hose stations are connected to the monitor supply lines, provision is to be made to reduce the water pressure at the hydrants to an amount at which each fire hose nozzle can be safely handled by one man. The water pressure shall be sufficient to produce a water jet throw of at least 12 [m].

3.5.2 Foam generator

3.5.2.1 Vessels with class notation "Agni 2 or 3" are to have a mobile high expansion foam generator with a capacity not less than 100 [m^3/minute] for fighting of external fires.

3.5.2.2 Foam-forming liquid is to stored in containers each of about 20 litres and suitable for mobile use. The total storing capacity of foam forming liquid is to be sufficient for 30 minutes continuous foam production.

3.6 Fireman's outfits

3.6.1 The number of fireman's outfits provided in addition to those provided in accordance with Pt.6, Ch.3, Sec.4.10 is to be in accordance with Table 3.1.1. They are to be stored in a safe position which is readily accessible from the open deck.

3.6.2 The composition of a fireman's outfit is to be as follows:

- Protective clothing of material to protect the skin from heat radiating from the fire and from burns and scalding by steam. The outer surface is to be water-resistant.

- Boots and gloves of rubber or other electrically non-conducting material.

- A rigid helmet providing effective protection against impact.

- An electric safety lamp (hand lantern) of an approved type with a minimum operating period of 3 hours.

- An axe having an insulated handle.

- A self-contained breathing apparatus which is to be capable of functioning for a period of at least 30 minutes and having a capacity of at least 1200 litres of free air. Spare, fully charged air bottles are to be provided at the rate of at least one set per required apparatus.

- For each breathing apparatus a fireproof lifeline of sufficient length and strength is to be provided and is to be capable of being attached by means of a snaphook to the harness of the apparatus or to a separate belt in order to prevent the breathing apparatus becoming detached when the lifeline is operated.

3.7 Recharging of equipment

3.7.1 A suitable air compressor for recharging the bottles used in the breathing apparatus of the fireman's outfits is to be provided. It is to be capable of recharging the bottles of the breathing apparatus required to be carried in accordance with Table 3.1.1 in a time not exceeding 30 minutes.

Chapter 26

Diving Support Vessels and Diving Systems

Contents

Section	
1	*General*
2	*Requirements for Diving Support Vessels*
3	*Requirements for Diving Systems*
4	*Evacuation Systems*

Section 1

General

1.1 Application

1.1.1 The requirements of this Chapter are applicable to diving support vessels and diving systems. The Chapter covers design, construction and survey requirements of diving support vessels, diving systems and hyperbaric evacuation systems.

1.1.2 Vessels equipped with a diving system complying with the requirements of Section 3 and having diving support capability specified in Section 2 will be eligible for class notation “DSV”.

1.1.3 Diving systems covered by this Chapter may be fitted and operated from a ship, barge, mobile offshore platform or fixed offshore installation.

1.1.4 Surface and Saturation diving systems complying with the requirements would be eligible for Class notation “**DIV - SURF**” or “**DIV - SAT**” respectively. Diving systems built under the survey and in accordance with the Rules of IRS, using materials and components tested by IRS in conformity with its Rules, would receive the distinguishing mark 卐 before the Character of Class or Class Notation.

1.1.5 Classification of diving systems is carried out independent of the classification of the vessel.

1.1.6 Whilst the requirements of this Chapter are considered to meet the requirements of IMO Resolution A.831(19), as amended, the statutory requirements of the Flag Administration, where the ship, barge, mobile offshore platform or fixed offshore platform is registered, are to be complied with.

1.1.7 The certification of arrangements, systems and individual components based on recognised standards, codes, national regulations, etc., may be accepted subject to special consideration by IRS in each case.

1.1.8 The classification certificate of the diving system will indicate the name and, where applicable, the IMO number of the vessel on which it is installed. The following information will be indicated in the attachment to the classification certificate of the diving system :

- Description of the diving system including operational limitations and conditions of intended use;
- Codes and standards to which the diving system complies.

1.1.9 Diving systems classed by IRS would be entered in the Register Book. For diving systems of non-standard design, IRS may require additional checks/ tests/ surveys and may make appropriate entries in the Class Certificate and the Register Book.

1.1.10 In general, all diving systems are to undergo initial surveys for classification and periodical surveys thereafter, as defined in Pt.1, Ch.2 of the Rules. Detailed requirements for initial classification and survey of diving systems are covered in Pt. 1, Ch. 2, Sec. 18.

1.1.11 Operational records for diving systems are to be maintained in which details of operations (diving operations, maintenance, damages, repairs, etc.) are to be entered. The record is to be submitted to IRS Surveyors on request.

1.2 Assumptions

1.2.1 The classification of diving systems is based upon the assumption that:

- The diving systems would be properly maintained and operated by competent personnel;

- A pre-check procedure would be followed to ensure the proper functioning of all systems and components before start of each operation;

- The current, wave and wind conditions will be within the design limits for handling and positioning systems; and

- Any significant repairs or replacement of components of the diving system would be carried out to the satisfaction of the IRS Surveyors.

1.3 Definitions

1.3.1 For the purpose of this Chapter the terms used have the meanings defined in the following paragraphs unless expressly provided otherwise.

1.3.2 **Administration** means the Government of the State whose flag a ship or floating structure which carries a diving system is entitled to fly or in which the ship or floating structure is registered.

1.3.3 **Bottle** means a pressure container for the storage and transport of gases under pressure.

1.3.4 **Breathing gas/breathing mixture** means all gases/mixtures of gases which are used for breathing during diving operations.

1.3.5 **Surface compression chamber** means a pressure vessel for human occupancy (PVHO) installed on the diving support vessel/ platform with means of controlling the pressure inside the chamber.

1.3.6 **Diving Depth** means the water depth or equivalent pressure, to which the diver is exposed to at any time during a dive or inside a surface compression chamber or a diving bell or inside a pressure vessel for human occupancy (PVHO).

1.3.7 **Diving bell** means a submersible pressure vessel for human occupancy, including its fitted equipment, for transfer of diving personnel under pressure between the work location and the surface compression chamber.

1.3.8 **Diving system** means the whole plant and equipment necessary for the conduct of diving operations and for the evacuation of divers.

1.3.8.1 **Fixed system** means a diving system installed permanently on ships or floating structures.

1.3.8.2 **Temporary system** means a diving system installed on ships or floating structures for a period not exceeding one year.

1.3.9 **Diving Unit** means the combined diving system and diving vessel/ platform, installed and integrated to conduct diving operations.

1.3.10 **Essential Services** (in the context of this Chapter) means the services for maintaining the diving system functionality with regard to the safety, health and environment of the divers in a hyperbaric environment and at the worksite.

1.3.11 **Hyperbaric Evacuation** Hyperbaric evacuation means the emergency transport of divers under pressure from a diving unit to a place of safety where planned decompression can be completed.

1.3.12 **Hyperbaric Survival Craft (HBSC)** means a pressure vessel for human occupancy (PVHO) and associated support plant and equipment whereby divers under pressure can be safely evacuated from a ship or floating structure to a place where planned decompression can be carried out.

1.3.13 **Handling system / Launch and recovery system (LARS)** means the plant and equipment necessary for raising, lowering and transporting divers between the diving vessel/ platform and/ or the surface compression chamber into and from the sea or onto a support vessel, as the case may be These systems are used for the deployment and recovery of dive baskets, wet bells, diving bells, daughter-craft and HBSC.

1.3.14 **Hazardous areas** are those locations in which:

- an explosive gas-air mixture is continuously present, or present for long periods (zone 0);
- an explosive gas-air mixture is likely to occur in normal operation (zone 1);
- an explosive gas-air mixture it not likely to occur, and if it does it will only exist for a short time (zone 2).

1.3.15 **Life support system** means the gas supply, breathing gas system, decompression equipment, environmental control system and equipment required to provide a safe environment for the diving crew in the diving bell and the surface compression chamber under all ranges of pressure and conditions they may be exposed to during diving operations.

1.3.16 **Living compartment** means the part of the surface compression chamber which is intended to be used as the main habitation for the divers during diving operations and which is equipped for such purpose.

1.3.17 **Main components** of a diving system include the surface compression chamber, diving bell, handling system and fixed gas storage facilities.

1.3.18 **Mating device** means the equipment necessary for the connection and disconnection of a diving bell or an HBSC to a surface compression chamber.

1.3.19 **Maximum operating depth** of the diving system is the depth in [m] or feet of seawater equivalent to the maximum pressure for which the diving system is designed to operate.

1.3.20 **Pressure Vessel** means a container capable of withstanding an internal maximum working pressure greater than or equal to 1 bar.

1.3.21 **Umbilical** means the link between the diving system and the diving bell, PVHO, wet bell or diver and may contain surveillance, communication and power supply cables, breathing gas and hot water hoses. The hoisting and lowering strength member may be part of the umbilical.

1.3.22 **Closed circuit breathing system** means the system for supply of breathing gas to the diver and saving of exhaled gases for recirculation after scrubbing and replenishing.

1.3.23 **Diver heating** means the system for actively heating the divers in the water or in the inner area.

1.3.24 **Inner area** means the areas which are inside the chambers and the bell.

1.3.25 **Outer area** means the areas of the diving system that are exposed to the atmospheric conditions during the operation, i.e. outside the inner system and the room or area that surrounds or contains the diving system.

1.3.26 **Normal cubic metres** [Nm^3] is taken as volume of gas [m^3] at standard conditions of 0°C and 1.013 bar.

1.3.27 **Category A Machinery Spaces** are those spaces and trunks to such spaces as defined in the International Convention for the Safety of Life at Sea, 1974, as amended.

1.3.28 **Control Station** is a station in which one or more of the control and indicator functions are located. These may include controls and /or indicators for operation of all vital life support conditions, pressure controls, hyperbaric evacuation system, launch and recovery system, automatic sprinkler, fixed fire detection and fire alarm systems, temperature, humidity etc.

1.3.29 **LSA Code** means the International Life-Saving Appliance Code, as defined in SOLAS chapter III.

1.3.30 **Pressure vessel for human occupancy** (PVHO) means a container intended to be occupied by one or more persons that is capable of withstanding an internal or external pressure differential exceeding 0.14 bar. In general, surface compression chambers and diving bells are considered to be PVHOs.

1.3.31 **Wet bell** means a diver deployment and recovery device as a minimum fitted with a gas filled dome, a main supply umbilical from the surface (providing breathing gas and other service to a manifold inside the device), and diver excursion umbilicals terminated at the device.

1.4 Scope of Classification

1.4.1 The following parts and systems are covered by IRS certification of the diving systems (fitted onboard ship or as independent unit) and require to be inspected during manufacture and installation, as applicable:

- Chambers;
- Bell;
- Permanent gas containers;
- Other pressure vessels;
- Life support systems;
- Electrical systems;
- Fire protection, detection and extinction;
- Launch and recovery systems;
- Umbilicals;
- Pipes valves and fittings;
- Pumps and compressors;
- Helium reclamation plant;
- Gas analysers;
- Gas mixing units;
- Gas absorbers;
- Breathing systems;
- Depth gauges;
- Sanitary systems;
- Communication systems;
- Arrangement for hyperbaric rescue of divers in saturation.

1.5 Plans and particulars

1.5.1 Before commencement of construction, following plans/ particulars for diving related functions are to be submitted for approval/ information, as applicable:

a) For the total system

- Plans showing general arrangement of the diving system, location and supporting arrangement, locations of equipment, breathing gas storage, hazardous zones, interface with piping arrangement, electrical installations, etc
- Plans are to include information like maximum operating depth and maximum observation depth for the bell, maximum operation time, maximum number of divers in bell, maximum number of divers in chamber(s) and bell(s) and maximum operational sea state;
- Plans showing lay-out of control stations(s);
- Proposed programme for tests and trials of the system for normal operation and emergency use.

b) For pressure vessels

- Plans as required by Pt.4, Ch.5;
- Plans showing expansion allowances under working conditions for interconnected multi-vessels systems;
- Fabrication tolerances;
- Type of thermal insulation materials and particulars, e.g. flammability and specific heats of conductivity;
- Type of buoyancy materials and particulars, e.g. collapse water depth, specific weight, specific water absorption, etc.;
- Drawings and specifications of all windows including fabrication tolerances; and
- Media contained, filling pressures and temperatures;

- Calculations of thicknesses/ stresses and fatigue analysis.

c) Gas supply

- Piping diagrams and block diagrams for the entire gas supply system including valves and fittings;
- Details of umbilical structure;
- Proposed cleaning procedure for breathing gas system; and
- Details of gas analysis.

d) Life support system

- Piping diagrams, block diagrams and description of systems and equipment;
- Calculation of cooling and heating requirements;
- Description and plans of water supply and disposal systems;
- Description and design details of diver heating system;
- Details of valves and fittings; and
- Plans showing the arrangement and specifications of environmental control systems and equipment, diving crew facilities, sanitary and drainage systems.

e) Automation, communication and locating equipment

- General arrangement drawings/block diagrams of control equipment including list of measuring points;
- Description and details of the communication means between the diving control station and diving systems, including single line diagram;
- Equipment list covering sensors, instruments, etc.;
- Description of electronic components such as signal amplifiers, computers and peripheral units;
- General arrangement drawings and equipment lists for communication systems and signaling equipment; and
- Arrangement drawing and description of the TV system.

f) Electrical systems

- Single line distribution diagram and detailed diagram of the entire installation. The diagrams are to give information on full load, cable types and cross-sections, make, type and ratings of all fuse and switchgear;
- Failure scenarios, redundancy principles, emergency arrangement, etc.;
- Key diagrams of control and alarm circuits for all consumers;
- Plans showing arrangements of batteries with information about their make, type and rating;
- Single line diagrams of the communication systems; and
- Complete list of components and documentation on any tests carried out on all electrical equipment intended to be installed in the chamber and the bell.

g) Fire protection, detection and extinction

- List of all materials to be installed in the inner area, where possible with data on and/or evaluation of flammability in conditions under which the materials are to be used; and
- Plans and specifications of fire detection, fire alarm and fire extinction equipment for both the inner and outer areas.

h) Handling, transfer and mating systems

- A description of the system with details of operating conditions;
- Installation drawings;

- Detailed plans of transfer equipment, lifting equipment, mating equipment, substructures of handling equipment including winches;

- Detailed plans of interchangeable components and fittings;

- Piping systems and instrumentation details of hydraulic/ pneumatic systems, as applicable;

- Details of control and protective systems; and

- Details of hoist and guide ropes.

i) Umbilicals

- Plans and specifications giving details regarding particulars of conductors, minimum breaking load, minimum diameter of pulleys and drums;

- Details regarding maximum design load, elastic properties, weight per unit length.

j) Hyperbaric evacuation system

- Description of system;
- General arrangement and detailed plans of evacuation system; and
- Details of handling system and power supply.

1.5.2 Diving System Documentation

1.5.2.1 Technical and Operation Manual

.1 The diving system technical and operation manual is to include, but not limited to the following:

- the description of the system

- the list of diving equipment with reference and name of the manufacturer

- the user instructions to operate the system

- the inspection and testing programme of the diving system when installed on-board

- the emergency evacuation plan when divers are in hyperbaric chamber, when relevant.

1.5.2.2 Planned Maintenance System (PMS)

.1 Details of a planned maintenance system as defined in IMCA D-018, '*Code of Practice for the Initial and Periodic Examination and Testing of Diving Plant and Equipment*' (as amended) are to be submitted. The PMS is to include the requirements for the periodic examinations, testing and routine replacement of the components. The PMS is to ensure the traceability of the maintenance works carried out on the diving plant.

1.5.2.3 Redundancy and essential services

.1 All services supporting the divers directly, including environmental control, are to be considered as essential services as per SOLAS chapter II-1.

.2 No single failure of a component, either static or dynamic, nor a single inadvertent act should lead to life-threatening situations for any person, or to unacceptable damage to facilities or the environment. However, where a failure mode of a system or component cannot be addressed by redundancy, either:

.1 independent backup arrangements should be provided (e.g.,in the case of umbilical separation); or

.2 the system or component should be designed and built to recognized national or international standards that have appropriate safety factors for manned application in similar service conditions (e.g. PVHO rupture).

.3 Essential services for divers in the water are to have sufficient redundancy to ensure the divers can return to a safe haven within the diving bell or basket.

.4 Essential services for divers located in a diving bell or basket are to have sufficient redundancy to ensure the diver can return to a safe haven within the diving unit.

.5 Essential services for divers in the diving unit are to have sufficient redundancy to ensure that all planned decompressions can

be completed at the planned normal rate. The ability to provide hyperbaric medical care should not be adversely affected.

.6 Emergency services are not to replace the required redundancies. Emergency services are to allow divers within the diving system or in the water to safely evacuate the diving unit.

.7 Emergency power services are to be available to provide services to the surface compression chamber complex in order to complete the normal planned decompression without main power.

.8 A systematic risk assessment of the diving unit is to be carried out in order to ensure compliance with the designed redundancy level and the suitability of emergency services.

.9 The systematic risk review should consider:

a) failure of a normally static component;

b) failure of an active component or system;

c) loss of any services to the diving unit; and

d) inadvertent and intentional acts.

.10 The risk assessment of the diving unit is to take into consideration already prepared reviews for the diving platform and diving system.

.11 The risk assessment is to be confirmed by a test programme, performed when the diving system is first installed, that clearly describes the expected behaviour of the diving unit and includes all necessary procedures to allow later testing to confirm the ongoing redundancy.

.12 The systematic risk review and corresponding test programme is to be fully documented and maintained available on board the diving unit. The test programme is to establish intervals for testing acceptable to the IRS/ the Administration to ensure redundancy levels are maintained.

.13 Risk mitigation

a) Probability assessment as a means of mitigation is not acceptable without the availability of suitable industry data applicable for personnel safety levels. Such data is also to be applicable to marine conditions.

b) Any mitigations that are based on repairs are to be assessed/ tested against time assumptions. Ensuring access to spares in an acceptable timescale is to be included in documentation required in the safety management system.

c) Any failures that allow compliance with 1.5.2.3.2 and 1.5.2.3, but leave the diving unit below the designed redundancy level are to be identified to ensure such failures will result in termination of appropriate operations.

d) Mitigations or potential hidden failures that are controlled by inspection and testing are to be addressed by maintenance routines.

Section 2

Requirements for Diving Support Vessels

2.1 General

2.1.1 The requirements specific to Diving Support Vessels for assignment of Class Notation “DSV” are covered in this section.

2.2 Stability and Position Keeping

2.2.1 The diving support vessel is to comply with the stability requirements stipulated for additional class notation “STS” in Pt. 5, Ch. 8 of the Rules.

2.2.2 The diving unit is to be able to recover any diving basket, wet bell or diving bell deployed by a handling system after sustaining side damage within the extents given in the *Guidelines for the design and construction of offshore supply vessels, 2006* (resolution MSC.235(82), as amended). The final list and trim in these conditions are to be within the design limits of list and trim for the handling system; ballasting post damage may be used to achieve this.

2.2.3 Essential diving equipment, including that on or above the main deck, is to remain accessible and operable in any stage of flooding for compliance with 2.2.1 and 2.2.2 above. Equipment below the main deck for Special Purpose Ships will be considered protected if watertight bulkheads are provided fore and aft and side divisions are provided equivalent to that required under the *Guidelines for the design and construction of offshore supply vessels, 2006* (resolution MSC.235(82), as amended).

2.2.4 Diving units conducting only surface-oriented diving are to comply with the requirements for cargo ships, as a minimum.

2.2.5 The diving support vessel is to have a position keeping system for safe diving operations. For ships equipped with a dynamic positioning system, the class notation DP 2 or DP 3 is required. Anchoring systems may be accepted for position keeping provided they are generally in accordance with the requirements given in Chapter 10 of the Rules for the Construction and Classification of Mobile Offshore Drilling Units.

2.2.6 Communication systems with sufficient redundancy are to be provided between the control station of positioning system and dive control station. A manually operated alarm system is also to be provided.

2.3 Plans and Particulars

2.3.1 In addition to the plans/ documentation required for hull, machinery and systems, the plans listed in 1.5 are also to be submitted to IRS for approval.

2.3.2 Detailed plans, drawings and procedures are to be prepared for all installation activities of the diving system.

2.4 Location of Diving Equipment and Design Requirements

2.4.1 The location of diving systems is to be appropriate for carrying out safe diving operations without being affected by the operation of propellers, thrusters or anchors.

2.4.2 Siting of diving systems in hazardous areas is to be avoided. Where, due to the requirements of diving operations, systems are sited in hazardous areas, the electrical equipment is to comply with the requirements for such equipment in the particular class of hazardous areas. Diving systems are not to be located in hazardous areas designated as Zone 0, as defined in 1.3.

2.4.3 Diving systems or their parts (including hyperbaric evacuation systems) sited on decks are to be afforded reasonable protection against water, icing or any damage that may occur due to other ship operations.

2.4.4 Diving systems situated on open decks are not to be located in the vicinity of ventilation openings from machinery spaces, exhausts or ventilation outlets from galley. In general, a minimum distance of 6 [m] between ventilation outlets or exhausts and diving system ventilation inlets is considered sufficient.

2.4.5 Diving systems are not to be installed close to sources of harmful noise. In the outer areas, noise limits are to be maintained at 75 dB(A), so that personnel may be able to communicate with each other.

2.4.6 The diving system and breathing gas storage facilities are not to be located in machinery spaces unless the machinery is associated with the diving system.

2.5 Supporting Structures of Diving Equipment

2.5.1 Diving systems including equipment are to be permanently attached to the ship structure and provisions are to be made on the ship for this purpose. The fastening arrangements are to be able to meet the required survival conditions of the ship or floating structure.

2.5.2 In general, the supporting structures for diving systems are to be designed in accordance with the requirements of Part 3 of the Rules. Collision loads are to be at least one half the weight of the surface compression chamber complex in the forward direction and one quarter the weight in the aft direction.

2.5.3 Special attention is to be paid to the design of supports for pressure vessels subject to expansion/ contraction due to temperature and pressure variations. Deflections of supports are to be considered in the design of the pressure vessel.

2.5.4 The supporting structure(s) of pressure vessels are to be able to withstand the loads during periodical hydrostatic testing with

acceptable levels of deflections. Temporary supports may be considered during testing if necessary.

2.5.5 Supporting structures and foundations for handling systems and lifting appliances are to be designed according to Part 3 of the Rules and/ or other recognized standards.

2.5.6 A dynamic load factor of at least 2.2 is to be applied for supports of lifting appliances used for handling manned objects such as surface bells, baskets or Hyperbaric Evacuation Systems.

2.5.7 The side structure of the moon pool is to be strengthened for possible impact loads from diving equipment guided through the moon pool.

2.6 Sea Water Inlets

2.6.1 Design of sea inlets fitted in the hull of the diving support vessel is to be specially considered in order to protect the divers and the sea inlet systems.

2.6.2 The mesh or aperture size of any protective structure is to be such as to prevent any part of the diver or his equipment being drawn into the intake at the velocity which would occur during pump operation.

2.6.3 It is recommended that water current in the immediate vicinity of the sea inlet is not to exceed 0.5 [m/sec].

2.6.4 Recommendations available in IMCA AODC 055 '*Protection of Water Intake Points for Diver Safety*' (as amended), may be referred for more details.

2.7 Piping Systems for Oxygen and Mixed Gas

2.7.1 In general piping systems are to be designed in accordance with Pt. 4, Ch. 2 and Ch. 3 of the Rules. In addition, the following are to be ensured:

.1 Exhaust, venting and pressure relief gases from the diving system are to be released to the open air away from sources of ignition, personnel or other areas where the presence of those gases could be hazardous (such as engine room and galley exhausts). Means are to be provided to prevent any dangerous accumulation of gases.

.2 Piping systems carrying mixed gas with oxygen content greater than 22% or oxygen under high pressure are not to be located inside accommodation spaces and machinery spaces of category A or similar compartments.

.3 All high pressure piping is to be protected against mechanical damage.

.4 The system and arrangement of filters/ strainers are to be such as to maintain uninterrupted supply of gas to essential systems.

.5 Piping systems intended for use in breathing gas and oxygen systems are to be cleaned and tested for purity in accordance with an acceptable test method (for e.g. ASTM G93-03 '*Standard Practice for Cleaning Methods and Cleanliness Levels for Materials and Equipment used in Oxygen-enriched Environments*').

2.8 Gas Storage

2.8.1 Oxygen bottles are not to be stored near flammable substances. Oxygen is not to be stored or ducted in any form close to combustible substances or hydraulic equipment.

2.8.2 Oxygen bottles are to be stored in separate storage rooms with good ventilation arrangements. The rooms are to be provided with sensors for oxygen content giving an audio-visual alarm at a manned control station.

2.8.3 Two oxygen analyzers with audio-visual low-level/ high-level alarms are to be provided in enclosed spaces where gas mixtures with oxygen content less than 20% or higher than 22% are stored.

2.8.4 These analyzers are to be mounted such that one monitors the upper level and another monitors the lower level of the space.

2.9 Electrical Systems

2.9.1 In general electrical systems are to be provided in accordance with Pt. 4, Ch. 8 of the Rules. Additional/ special requirements for systems and equipment serving diving systems are given in the following :

.1 Plans/ Documentation to be submitted

.1 Design Document describing the philosophy of the overall electrical system with respect to operational modes, failure scenarios, redundancy principles, automatic changeover systems etc.

.2 General arrangement showing location of all important electrical equipment for diving system;

.3 Single line distribution system diagrams for the whole installation with information on full load, cable types and cross sections, and make, type and rating of fuse and switchgear for all distribution circuits;

.4 Calculations on load balance, including emergency consumption and battery capacities;

.5 Multi-wire diagrams of control and alarm circuits for all motors or other consumers;

.6 Plans showing arrangements of batteries, their make, type and capacity;

.7 Plans showing arrangement and single line diagrams of the communication system.

.2 Design Requirements

.1 All electrical equipment and installations, including power supply arrangements, are to be designed for the environment in which they will operate to minimize the risk of fire, explosion, electrical shock and emission of toxic gases to personnel, and galvanic action of the surface compression chamber or diving bell;

.2 Electrical cables are not to be routed close to gas piping;

.3 In the event of failure of the main source of electrical power supply to the diving system an independent source of electrical power is to be available for the safe termination of the diving operation;

.4 The ship's emergency source of electrical power may be used as an emergency source of electrical power for the diving system if it has sufficient capacity to supply the diving system and the emergency load for the vessel simultaneously;

.5 The alternative source of electrical power is to be located outside the space containing the main source of power;

.6 Main and emergency lighting are to be provided in all critical handling areas.

2.10 Fire Protection

2.10.1 The requirements for fire protection in Part 6 of the Rules are to be complied with, in general. Additional requirements for fire protection of areas containing diving equipment, auxiliaries and support systems are laid down in the following paragraphs.

2.10.2 Plans and Documentation

.1 Arrangement drawings of “outer area” spaces indicating the fire protection of the structural boundaries of these spaces. Details of insulation materials used are also to be provided;

.2 Plans and specifications of fire detection and fire extinguishing systems for ‘outer areas’.

2.10.3 Structural Fire Protection Requirements

.1 Boundaries separating enclosed “outer areas” from other enclosed spaces are to have A-60 fire integrity. Outer areas may be sub-divided into several spaces by A-0 class boundaries.

.2 Compartments in the interior of the vessel in which the diving system or its auxiliary equipment is carried are to be provided with A-60 boundaries.

.3 All doors between “outer area” and other adjacent enclosed spaces are to be of self-closing type.

4 At least one of the required escape routes from spaces not being part of “outer area” is to be independent of “outer area”.

.5 Non-metallic and insulation materials used in the diving system are to be of fire-retardant

type and non-hazardous in accordance with the FTP Code parts 2 and 5, as amended.

.6 Enclosed “outer areas” are to have separate mechanical ventilation with minimum 8 air changes per hour.

.7 Piping and cables essential for the operation of the diving system are regarded as part of the system. Where these transit from other compartments such as the main switchboard room or engine-room into an “outer area”, they are to be laid in separate structural ducts insulated to A-60 class standard.

.8 Vessels fitted with surface diving systems that do not include planned surface decompression, do not need to comply with 2.10.3.2. Further, they need not be fitted with automatic fire detection and alarm systems and fixed fire-extinguishing system.

2.10.4 Fire Detection and Alarm Systems

.1 The following requirements, as applicable, are to be complied with for outer areas in addition to the requirements in Part 6:

(a) The section or loop of fire detectors covering the “outer area” is not to cover other spaces;

(b) Fire detector panel is to be placed on the bridge with repeater panel at dive control room and in machinery control room;

(c) A visual alarm repeater is also to be situated at the diving control station.

2.10.5 Fire Extinguishing Systems

.1 Enclosed “Outer areas” situated are to be provided equipped with a fixed, manually operated fire-extinguishing system. The system is to be capable of being operated from the dive control station, bridge and/ or other locations, as necessary.

.2 The fire-extinguishing system is to be sufficient to cover the largest area bounded by A-0 class divisions.

.3 A fixed fire extinguishing system complying with the requirements of Part 6 of any of the following types is to be provided:

(a) Pressure water spraying system, approved for use in machinery spaces of Category A; or

(b) Fixed gas system.

.4 The fixed gas system is to be of a type non-hazardous to human beings,in the concentration expected in the space.

.5 When pressure vessels are situated in enclosed spaces, a manually actuated water spray system having an application rate of 10 [lit/ m^2/ min] of the horizontal projected area is to be provided to cool and protect such pressure vessels in the event of external fire.

.6 Fire hoses and nozzles provided on open decks are considered sufficient where pressure vessels are located in such areas.

.7 Where diving systems are located in open decks, the fire extinguishing arrangements in “outer areas would be specially considered.

2.10.6 Personnel Protection

.1 In addition to the fire fighters outfits required by Part 6 of the rules, an additional set is to be provided for each person required for the operation of the diving system during a fire.

.2 Control stations manned during bell recovery or launching of hyperbaric evacuation unit are to be provided with breathing apparatus.

2.10.7 Portable Fire-Extinguishers

.1 The spaces containing diving system and equipment are to be provided with sufficient number of portable fire-extinguishers so that one extinguisher is available in every 10 [m] walking distance.

2.11 Other Services

2.11.1 The diving unit is to be able to support all essential services required by the diving system, including in the event of a failure that may result in a hazardous situation. All services are to be configured to allow safe transfer to or from the diving system.

2.11.2 In order to achieve the above requirements, the following apply:

- services essential to the diving system are also to have separate independent backups;

- services are to be configured so as to prevent hazardous transfer of material or power to or from the diving system; and

all essential services required by the diving system should be in accordance with the diving system requirements.

Section 3

Requirements for Diving Systems

3.1 General

3.1.1 Requirements applicable to diving systems for assignment of class notation "**DIV-SURF**" and "**DIV-SAT**" are covered in this section.

3.1.2 In general, the notation "**DIV-SURF**" is to be assigned for diving systems, where diving operations are performed at such depths and durations that the decompression is carried out from the surface without resorting to the use of a closed diving bell.

3.1.3 In general, the notation "**DIV-SAT**" is to be assigned to saturation diving systems, where equipment is provided such that divers can live in a pressurized environment for several days or weeks. Divers are generally decompressed to surface pressure only once, at the end of their work.

3.1.4 As far as reasonable and practicable a diving system is to be designed to minimize human error and constructed so that the failure of any single component (determined, if necessary by an appropriate risk assessment) would not lead to a dangerous situation.

3.1.5 Diving systems and components thereof are to be designed for the service conditions under which they are certified to operate.

3.1.6 Materials for diving system components are to be suitable for their intended use.

3.1.7 All components in a diving system are to be designed, constructed and tested in accordance with applicable International or National standards recognised by IRS or proprietary specifications acceptable to IRS.

3.1.8 In the design of pressure vessels including accessories such as doors, hinges, closing mechanisms and penetrators, the effects of rough handling and accidents are to be considered in addition to design parameters such as pressure, temperature, vibration, operating and environmental conditions.

3.1.9 All components in a diving system are to be so designed, constructed and arranged as to permit easy cleaning, disinfection, inspection and maintenance.

3.1.10 A diving system is to include the control equipment necessary for safe performance of diving operations.

3.1.11 Diving systems generally include, but are not limited to, the items listed in Table 3.1.11

Table 3.1.11 : Indicative list of diving equipment		
Items	Saturation diving	Surface diving
Closed diving bell	*	
Wet diving bell or diver basket		*
Deck decompression chamber	*	*
Breathing supply system	*	*
Handling systems for the diving bell	*	*
Diving control stand	*	*
Clamping and under pressure transfer system	*	
Devices for controlling the atmosphere	*	*
Devices for the recovery and the purification of breathing gases	*	*
Means of production of hot water	*	
Hyperbaric Evacuation System	*	

3.2 Requirements for Diving Systems and Components

3.2.1 Environmental Conditions

3.2.1.1 Diving systems together with their accessories and fitted equipment are to be designed for the environmental conditions likely to occur at the point of installation or work location but in any case not less than that required by Table 3.2.1.1 and Table 3.2.1.2.

Table 3.2.1.1 : Minimum Design Inclinations				
Component location	**Athwartships**		**Fore-and-Aft**	
	Static	**Dynamic**	**Static**	**Dynamic**
Compression chambers and other surface installations				
On ship	± 15°	± 22.5°	± 5°	± 10°
On mobile offshore unit (on semi-submersible)	± 15°	-	± 15°	-
Diving bells and components therein	± 22.5°	± 45°	-	-

Table 3.2.1.2 : Minimum Environmental Conditions			
Location	**Temperature**	**Relative Humidity**	**Other Conditions**
In chambers	5 to 55°C	100%	Salty air
Outside chambers in air [1,2]	- 10 to + 55°C	100%	
Outside chambers in water	- 2 to 32°C	-	Salt water containing 3.5% salt
Control rooms	5 to 55°C	80%	-
1 In the case of facilities installed on the open deck, allowance is to be made for icing and temporary inundation with salt water and spray. 2 Other values will be specially considered for installation in closed spaces.			

3.2.2 Surface Compression Chambers

.1 A diving system is to, as a minimum, include either one surface compression chamber with two separate compartments, or two interconnected separate chambers so designed as to permit ingress or egress of personnel while one compartment or chamber remains pressurized. Compartments are to have a specified maximum number of occupants. This capacity will define the required outfitting of the compartment or chamber including the number of bunks, built-

in breathing systems (BIBS) and the ergonomic design.

.2 Where a surface compression chamber is to be used in circumstances in which a person is intended to remain under pressure for a continuous period of more than 12 hours, it is to be so arranged as to allow most divers to stand upright and to stretch out comfortably on their bunks. The smaller of the two compartments is to be large enough for at least two persons. One of these compartments is to be a living compartment.

.3 The living compartment and other compartments intended to be used for decompression are to have a lock through which provisions, medicine and equipment may be passed into the chamber while its occupants remain under pressure. The dimensions of the service lock are to be adequate to enable essential supplies to be transferred into the surface compression chamber. Service locks are to be designed to prevent accidental opening under pressure and, where necessary, interlocks are to be provided for this purpose.

.4 All doors are to be so designed that locking mechanisms, if provided, can be operated from both sides.

.5 Each pressure compartment is to have view ports to allow observation of all occupants from the outside.

.6 A surface compression chamber is to provide a suitable environment and facilities for the persons who use it, having regard to the type and duration of the diving operation. Where the chamber is intended to be occupied for more than 8 hours, toilet facilities are also to be provided. Toilet facilities capable of discharging the waste to the outside are to be fitted with suitable interlocks.

.7 The diving system is to be capable of allowing the safe transfer of a person under pressure from the diving bell or HBSC to the surface compression chamber (and vice versa).

.8 Facilities are to be provided for keeping the partial pressure of the CO_2 in the chamber atmosphere permanently below 0.005 bar assuming a CO_2 production rate of 0.05 [Nm^3/hour] per diver.

.9 Diving systems using mixed gas and designed for operating periods of more than 12 hours at a time are to be capable, under steady conditions, of keeping the temperature in the surface compression chamber constant to $\pm$ 1°C in the 27 - 36°C range while maintaining a relative humidity of at least 50 per cent.

.10 In the steady state, the permanent noise level (over 8 hours) in the living compartment and surface compression chamber is not to exceed 65 dB(A).

3.2.3 Diving bells

.1 A diving bell is to :

- be provided with adequate protection against mechanical damage during handling operations;

- be equipped with one extra lifting point designed to take the entire dry weight of the bell including ballast and equipment as well as the weight of the divers staying on in the bell; and

- be equipped with means whereby each diver using the bell is able to enter and leave it safely as well as with means for taking an unconscious diver up into a dry bell.

- have a service lock through which provisions, medicine and equipment may be passed into the diving bell while its occupants remain under pressure. Service locks are to be designed to prevent accidental opening under pressure and, where necessary, interlocks should be provided for this purpose. The dimensions of the service lock are to be adequate to enable essential supplies to be transferred into the diving bell.

- be fitted with a manifold (which is clearly marked and suitably protected), at a suitable point close to the main lifting attachment which is to include connections to the following main services :

  ¾ inch NPT (female) - for hot water
  - ½ inch NPT (female) – for breathing mixture

The manifold is to also incorporate connectors for the following:

- internal pressure;
- sampling of internal gas;
- communication; and
- electrical power.

.2 Diving bell doors are to be so designed as to prevent accidental opening during normal operations. All doors are to be so designed that locking mechanisms, if provided, can be operated from both sides.

.3 A diving bell is to provide a suitable environment and facilities for the persons who use it, having regard to the type and duration of the diving operation.

.4 Each diving bell is to have view ports that allow occupants to be observed and as far as practicable allow an occupant to observe divers outside the bell.

.5 Diving bells are to be so designed as to provide adequate space for the number of occupants envisaged, together with the equipment.

.6 For diving systems with only one diving bell, a suitable arrangement is to be in place to reconnect a lost bell to the diving system and allow the divers to return safely to the surface compression chamber.

.7 In diving bells, it is to be possible to keep the partial pressure of the CO_2 below 0.015 bar as a minimum requirement assuming a CO_2 production rate as specified in 3.2.2.8. Under emergency conditions, it is to be possible to hold the partial pressure of CO_2 below 0.02 bar for at least 24 hours.

3.2.4 Wet bells and dive baskets used for the deployment and recovery of surface oriented divers

.1 All diving platforms are to provide for safe deployment and recovery of the divers, including during a diving emergency. During any deployment, fully dressed divers should not have to climb a ladder more than 2 [m], or stairs that should be fitted with a handrail more than 4 [m], down to or up from the water surface.

.2 Wet bells and dive baskets, with the exception of those specifically for a rescue diver, are to be fitted out to carry a minimum of two divers. The structure should prevent the divers from falling out during operations and enable the recovery of a helpless diver while maintaining the safety of the rescue diver.

.3 For wet bell gas services, the onboard control point is to ensure a primary and secondary supply to both a working diver and an in-water standby diver. A diver's bail-out is an emergency supply and not considered to be a secondary supply.

.4 A minimum of 30 minutes of onboard emergency gas at the maximum planned depth is to be provided. This includes a breathing system for each diver independent of their main and bail-out diving equipment.

3.2.5 PVHO forming part of the HBSC

.1 Where a PVHO forms part of a HBSC, the following are to be complied with:

- The PVHO is to provide a suitable environment and facilities for the persons who use it, having regard to the type and duration of the evacuation.

- Where the PVHO is intended to be occupied for more than 8 hours, toilet facilities are also to be provided. Toilet facilities capable of discharging the waste to the outside are to be fitted with suitable interlocks.

- The means provided for access into the PVHO should be such as to allow safe access to or from the surface compression chambers. Interlocks are to be provided to prevent the inadvertent release of the HBSC from the surface compression chamber while the access trunking is pressurized. The mating flange is to be adequately protected from damage at all times including during the launch and recovery stages.

- All doors are to be designed to prevent accidental opening during normal operations and, if any locking mechanism is provided, it is to be operable from both sides.

- Arrangements are to be provided to enable a helpless diver to be taken into the HBSC PVHO.

- The seating or other arrangements provided are to be designed for the maximum number of occupants and provide an adequate degree of protection to the divers from impact collisions during launch and while the HBSC is deployed.

- The PVHO is to have a service lock through which provisions, medicine and equipment may be passed into the PVHO while its occupants remain under pressure. Locks are to be designed to prevent accidental opening under pressure and, where necessary, interlocks are to be provided for this purpose. The dimensions of the service lock are to be adequate to enable essential supplies to be transferred into the PVHO.

- Arrangements are to be provided to allow the occupants to be observed. Viewports are to be protected and situated so that the risk of damage is minimized.

- Where it is intended to carry out decompression of the divers after hyperbaric evacuation in another surface compression chamber, then consideration is to be given to the suitability of the mating arrangements on that surface compression chamber. Where necessary, suitable adapter and clamping arrangements are to be provided on the HBSC in accordance with Fig. 3.2.5.1 (a) and on the other surface compression chamber (for e.g. a hyperbaric reception facility) in accordance with Fig. 3.2.5.1 (b).

- The HBSC is to be fitted with a manifold (clearly marked and suitably protected) at a suitable point. The manifold is to incorporate international standard connections for the following services:

    - Internal pressure (diving depth monitoring)
    - Communications
    - Electric power supply
    - Analysis of HBSC PVHO internal environment
    - Oxygen addition
    - Built-in breathing system (BIBS) supply
    - Blow-down (Pressurization)
    - Exhaust
    - Hot water supply and return
    - Chilled water supply and return

- PVHO locks and openings that are, or may be, submerged are to be designed to be mechanically restrained to prevent loss of seal and water ingress at lower hyperbaric pressures during deployment and in any sea state. This is to include the effects of the hydrodynamic impacts of free-fall HBSC launch requirements.

- All open flange faces that may be exposed both when in air and water are to be suitably protected or provided with easily replaceable sealing faces.

- When the HBSC is waterborne, it is to be possible to access and egress the HBSC from atmospheric pressure.

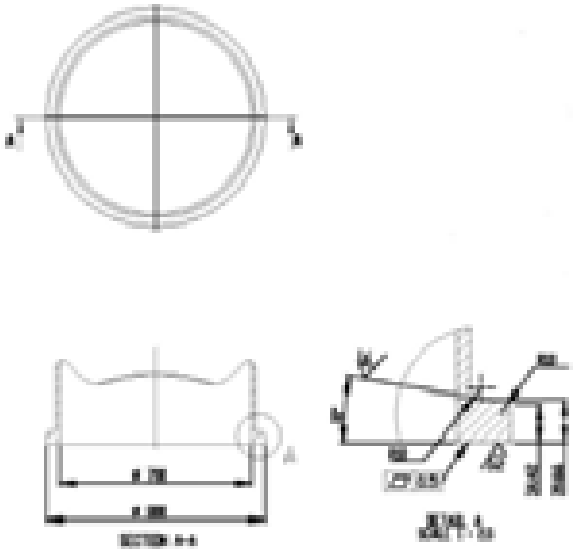

Fig. 3.2.5.1 (a): HBSC PVHO adapter and clamping arrangement

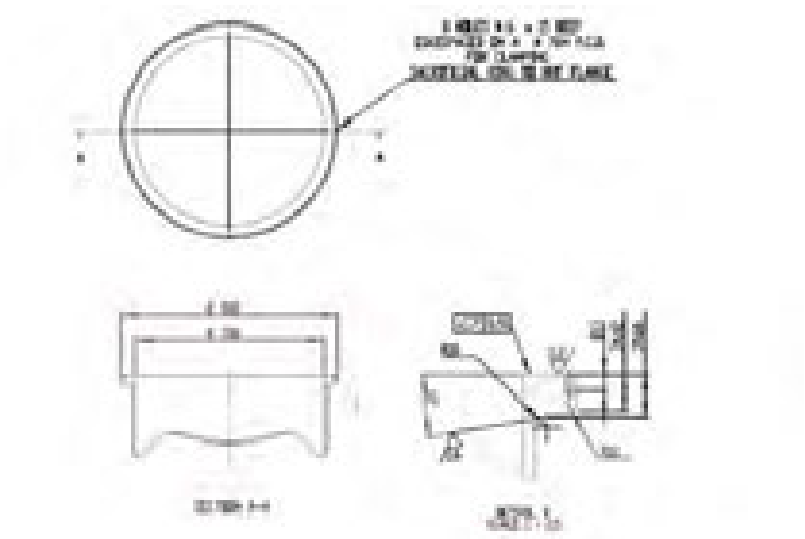

Fig. 3.2.5.1 (b): Hyperbaric reception facility PVHO adapter and clamping arrangement

3.2.6 Pipes, Valves, Fittings and Hoses

.1 Pipe systems are to be so designed as to minimize the noise inside the diving bell and surface compression chamber during normal operation.

.2 A surface compression chamber is to be equipped with such valves, gauges and other fittings as are necessary to control and indicate the internal pressure and safe environment of each compartment from outside the chamber at a centralized position.

.3 Valves, gauges and other fittings are to be provided outside the bell/ PVHO as necessary to control and indicate the pressure and safe environment within the diving bell/ PVHO. The external pressure on the diving bell/ PVHO is also to be indicated inside the bell/ PVHO.

.4 All pipe penetrations on chambers are to be fitted with two shutoff devices as close to the penetration as practicable. Where appropriate, one device is to be a non-return valve.

.5 All surface compression chambers and diving bells which may be pressurized separately are to be fitted with over pressure alarms or pressure relief valves. If pressure relief valves are fitted, a quick-operating manual shutoff valve is to be installed between

the chamber and the pressure relief valve and is to be wired opened with a frangible wire. This valve is to be readily accessible to the attendant monitoring the operation of the chamber. All other pressure vessels and bottles are to be fitted with a pressure relief device.

.6 Piping systems which may be subjected to a higher pressure than designed for are to be fitted with a pressure relief device. PVHO pressure-relief device(s) and associated pipework are to be tested for maximum gas volume flow.

.7 All materials used in oxygen system are to be compatible with oxygen at the working pressure and flow rate.

.8 The use of high-pressure oxygen piping is to be minimized by the fitting of pressure reducing devices, as close as practicable to the storage cylinders or pressure vessels.

.9 Flexible hoses, except for umbilicals, are to be reduced to a minimum.

.10 Hoses for oxygen, as far as practicable, are to be of fire-retardant construction.

.11 Piping systems carrying mixed gas or oxygen under high pressure are not to be arranged inside accommodation spaces, engine rooms or similar compartments.

.12 Exhaust lines are to be fitted with an anti-suction device on the inlet side.

.13 Gases vented from the diving system are to be vented to the open air away from sources of ignition, personnel or any area where the presence of those gases could be hazardous.

.14 All high-pressure piping is to be well protected against mechanical damage.

.15 Piping systems containing gases with more than 22 per cent oxygen are to be treated as systems containing pure oxygen.

.16 Oxygen systems with pressure greater than 1.72 bar must have slow opening shutoff valves except pressure boundary shutoff valves.

3.2.7 Breathing gas supply, storage and temperature control

.1 Each surface compression chamber and diving bell is to be fitted with adequate equipment for supplying and maintaining the appropriate breathing mixtures to its occupants at all depths down to maximum operating depth. When adding pure oxygen to the chamber, a separate piping system is to be provided. Internal oxygen inlets are be positioned so as to ensure appropriate mixing of oxygen within the PVHO.

.2 In addition to the system mentioned in 3.2.7.1 each surface compression chamber and diving bell is to contain a separately controlled built-in breathing system for oxygen, therapeutic gas or bottom mix gas with at least one mask per occupant stored inside each separately pressurized compartment and means are to be provided to prevent any dangerous accumulation of gases. A spare mask and its inlet and outlet connection points are also to be provided per compartment.

.3 The diving bell and HBSC are to be designed with a self-contained breathing gas system capable of maintaining a satisfactory concentration of breathing gas for the occupants for a period of at least 24 hours and 72 hours respectively, at their maximum operating depth. Provision is also to be made for equipment and controls for temperature control and thermal balance for occupants.

.4 Oxygen bottles are to be installed in a well-ventilated location.

.5 Oxygen bottles are not to be stored near flammable substances.

.6 The diving system and breathing gas storage facilities are not to be sited in machinery spaces if the machinery is not associated with the diving system. Where, due to the requirements of diving operations, systems are sited in hazardous areas, the electrical equipment is to comply with the requirements for such equipment in hazardous areas. Diving systems are not permitted in hazardous areas designated as Zone 0.

.7 A diving system is to include adequate plant and equipment to maintain the divers in safe thermal balance during normal operations.

.8 Means are to be provided to maintain the divers within the diving bell in thermal balance in an emergency for at least 24 hours. Such requirements may be satisfied by the use of passive means carried in the bell.

.9 For piping systems and gas storage cylinders/pressure vessels the following colour code is to be used:

Name	Symbol	Colour Code
Oxygen	O_2	White
Nitrogen	N_2	Black
Air	Air	White and black
Carbon dioxide	CO_2	Grey
Helium	He	Brown
Oxygen-helium mix gas	O_2He	White and brown
Hydrogen	H2	Red

In addition, each cylinder/ pressure vessel is to be marked with the name and symbol given above of the gases it contains. The marking and colour coding of the gas storage cylinders are to be visible from the valve end.

3.2.8 Handling system for diving bells/ surface-oriented diving

.1 A diving system is to be equipped with a main handling system to ensure safe transportation of the diving bell between the work location and the surface compression chamber. In the case of surface-oriented diving, the handling system is to ensure deployment and recovery of a dive basket or wet bell to and from maximum deployment depth. Where applicable, a diving system is to be equipped with a handling system to ensure the safe launch and recovery of a diving daughter-craft to and from the water.

.2 The handling system is to be designed with adequate safety factors, in accordance with recognised codes of construction, considering the environmental and operating conditions, including the dynamic loads which are encountered while handling the diving bell, dive basket or wet bell through the air-water interface.

.3 The handling system is to enable smooth and easily controllable handling of the diving bell.

.4 The lowering of diving bells or dive basket or wet bell or daughter craft under normal conditions is not to be controlled by brake, but by the drive system of the winches.

.5 If the energy supply to the handling system fails, brakes are to be engaged automatically.

.6 In the event of single component failure of the main handling system, an alternative means is to be provided whereby the bell/ dive basket or wet bell or daughter craft can be returned to the surface compression chamber/ embarkation point respectively. In addition, provisions are to be made for emergency retrieval of the bell if the main and alternative means fail. If this involves buoyant ascent, the bell is to have sufficient stability to maintain a substantially upright position and means are to be provided to prevent accidental release of the ballast weights. In case of surface-oriented diving, if the handling system for the working and standby divers are combined, then the failure of a single component is not to compromise the ability of the standby system to perform an emergency recovery.

.7 Handling systems and mating devices are to enable easy and firm connection or disconnection of a diving bell to a surface compression chamber, even under conditions where the support ship or floating structure is rolling, pitching or listing to predetermined angles. In the case of surface-oriented diving, the handling system is to enable smooth and easily controllable handling of the dive basket, wet bell or daughter craft, when recovered to the embarkation point, even under conditions where the diving platform is rolling, pitching or listing to predetermined angles.

.8 Where a power actuating system is used for mating operations, an auxiliary power actuating system or an appropriate means are to be provided to connect a diving bell to a surface compression chamber, in the event of failure of the normal power actuating system.

.9 The design of the handling system is to consider protection and routeing of the diving umbilical to prevent damage.

.10 In case of surface-oriented diving, handling system for primary access and egress is not required where the diver has to climb no more than 2 [m] above the water surface on a ladder, or no more than 4 [m] on stairs; the stairs are to be fitted with a handrail. However, means are to be provided:

- for diver access and egress from the water; and

- to recover a helpless diver in an emergency.

3.2.9 Other pressure vessels not intended for human occupancy

.1 Special attention is to be paid to the design and choice of material for the construction of pressure vessels containing a volume percentage higher than 22% oxygen.

.2 Oxygen and gases with an oxygen volume percentage higher than 22 per cent are to be stored in bottles or pressure vessels exclusively intended for such gases.

3.2.10 Interface between diving system and the ship or floating structure

.1 The diving system and breathing gas facilities are to be arranged in spaces or locations which are adequately ventilated and provided with suitable electric lighting.

.2 When any part of the diving system is sited on deck, particular consideration is to be given to providing reasonable protection from the sea, icing or any damage which may result from other activities on board the ship or floating structure.

.3 Provision is to be made to ensure that the diving system and auxiliary equipment are securely fastened to the ship or floating structure and that adjacent equipment is similarly secured. Consideration is to be given to the relative movement between the components of the system. In addition, the fastening arrangements are to be able to meet any required survival conditions of the ship or floating structure.

3.2.11 Fire protection, detection and extinction

.1 All materials and equipment used in connection with the diving system are to be, as far as is reasonably practicable, of fire-retardant type in order to minimize the risk of fire and sources of ignition.

.2 Spaces in the interior of ships or floating structures in which the diving or its auxiliary equipment is carried are to be provided with structural fire protection in a way similar to control stations (as defined in Pt.6, Ch.3) bounding main zones.

.3 Interior spaces containing diving equipment such as surface compression chambers, diving bells, gas storage, compressors and control stands are to be covered with an automatic fire detection and alarm system and a suitable fixed fire-extinguishing system.

.4 Portable fire extinguishers of approved types and designs are to be distributed throughout the space containing the diving system. One of the portable fire-extinguisher is to be stowed near the entrance to that space.

.5 When pressure vessels are situated in enclosed spaces, a manually actuated water spray system having an application rate of 10 [lit/m^2/per minute] of the horizontal projected area is to be provided to cool and protect such pressure vessels in the event of external fire. When pressure vessels are situated on open decks, fire hoses may be considered as providing the necessary protection.

.6 Each compartment in a surface compression chamber is to have a suitable means of extinguishing a fire in the interior which would provide rapid and efficient distribution of the extinguishing agent to any part of the chamber.

3.2.12 Electrical Systems

.1 All electrical equipment and installations, including power supply arrangements, are to be designed for the environment in which they will operate to minimize the risk of fire, explosion, electrical shock and emission of toxic gases to personnel, and galvanic action of the surface compression chamber or diving bell.

.2 Each surface compression chamber and diving bell are to have adequate means of normal and emergency lighting to allow an occupant to read gauges and operate the system within each compartment.

.3 Essential services as defined in chapter 2, as well as other services to ensure minimum comfortable conditions of habitability are to be identified and the system is to have the capacity to supply all essential services during the planned operations.

.4 In an emergency the diving bell and HBSC are to have sufficient electrical power for survivability of at least 24 hours for the diving bell and 72 hours for the HBSC respectively.

.5 The diving system switchboards (main and emergency) are to be installed in separate compartments. All emergency electric lighting systems are to be separated from the compartments housing the main and emergency switchboards.

.6 The emergency load for the diving system needs to include electrical power to systems that are essential for maintaining life support and for returning divers to a point of safety. However, the distribution system may be designed for staged reconnection/ disconnection of emergency consumers. Consumers, such as handling systems/ diver hot water, may be disconnected after divers in the water are recovered to the surface compression chamber complex. Similarly emergency consumers such as environmental control of the surface compression chamber complex (that are not time-critical) may be connected manually after switchover to emergency electrical power. Where manual intervention is required to manage the emergency electrical power system, these switchboards are to be easily accessible within the diving system area.

.7 An emergency source of electrical power is to be provided for the diving system complying with the minimum requirements of SOLAS regulation II-1/43, as well as the following:

- where using the diving platform's emergency electrical power, there is to be enough electrical power capacity to supply the emergency load for the diving system and for the diving platform simultaneously;
- have a minimum fuel capacity of 18 hours and be able to be refuelled;
- be able to safely terminate the diving operation, including decompression of the divers;
- be suitably protected within a deck house structure; and
- be suitably ventilated, to ensure continuous operations in the design environment.

.8 Emergency lighting as defined in SOLAS regulations II-1/43.2.1 and 43.2.2 is to be additionally provided for

- each PVHO location
- each handling system location
- associated diving equipment not housed within the control room or machinery spaces of the diving system.

.9 Battery charging arrangements are to be designed to prevent overcharging under normal or fault conditions. Battery storage compartments are to be provided with means to prevent over pressurization and vent to a safe place. When battery charger /battery combinations are used as DC power supply systems, adequate measures are to be taken to keep the voltage within specified limits.

.10 Electrical equipment fitted within the PVHO are to be suitable for the intended purpose, including hyperbaric use and the specified gas, and high humidity levels and marine applications. Additionally,:

- electrical enclosures subject to pressure are to include suitable gas relief devices, where applicable;

- cabling and electrical components are not to emit gas toxic volatiles that create a hazardous environment;

- equipment supply voltage is to be kept at a minimum; and

- electrical power services, including battery arrangements, are to be suitable for hyperbaric use.

.11 Electrical and electronic diving equipment are to comply with the requirements for electromagnetic compatibility in the *'General requirements for electromagnetic compatibility (EMC) for all electrical and electronic ship's equipment'* (Resolution A.813(19)).

.12 In-water and hyperbaric electrical equipment are to comply with the safe voltage requirements in Table 3.2.12.12 on safe voltage, body resistance and current. Additionally:

- For electrically heated suits, the diver's body resistance is to be 100 ohms and the safe body current is to be divided by 2.5 for all applications.

- Electrical equipment used subsea and in hyperbaric conditions are to be supplied from a transformer with the

secondary winding isolated, such that there is not an obvious path if a fault develops. Isolation requirements are to include high-integrity isolation components and a safe insulator barrier.

- Residual current devices fitted are to have a reaction time of less than 20 [ms].

.13 For diving equipment and plant that have automated functions, a systematic engineering assessment of the diving system and its subsystems is to be carried out (e.g. FMEA). The assessment is to identify all components and control systems that contain automated functions during normal operation, maintenance and testing phases within the diving system.

Table 3.2.12.12 Safe voltage requirements for in-water and hyperbaric electrical equipment

Supply	Safe Body Current (mA)	Body Route Resistance Ω (Ohms)	Safe Voltage	
			Maximum V	Nominal V
DC without a suitable trip device	40	750	30	24
AC without a suitable trip device	10	750	7.5	6
DC with a suitable trip device	570	500	285	250
AC with a suitable trip device	500	500	250	220
Note: A suitable trip device is one with a reaction time of 20ms or less.				

3.2.13 Control Systems

.1 The diving system is to be so arranged as to ensure that centralized control of the safe operation of the system can be maintained under all weather conditions.

.2 As a minimum, facilities are to be provided at the central dive control position to monitor the values of the parameters as indicated in the following tables (as relevant and applicable):

Table 3.2.13 (a): PVHO Compartment Monitoring

Parameters	**Compartments**		
	Surface compression chamber (Each Lock)	**Diving bell**	**HBSC**
Pressure or diving depth [1,2]	X	X[2]	X
Temperature [1,3]	X		X
Humidity	X		X
Oxygen partial pressure [1,3]	X	X	X
CO_2 partial pressure[1,3]	X	X	X
Video Surveillance	X	X	X
Special Environments			
Contaminants[4]	-	X	-

1 These parameters are to be indicated continuously.

2 Pressure or depth both inside and outside bell is to be indicated.

3 High and low alarms are to be provided (audible and visible).

4 As identified in project working areas requiring this monitoring, such as H_2S and hydrocarbon contaminated worksites.

Table 3.2.13 (b): Diver Monitoring					
Parameters					
	Diver 1	**Diver 2**	**Standby Diver**	**Reclaim Gas**	**Machinery**
Pressure or diving depth [1]	X	X	X	-	-
Oxygen partial pressure [1,2]	X	X	X	X	-
CO_2 partial pressure[1,2]	-	-	-	X	-
CO[1,2]	-	-	-	X	-
Diver's suit heating medium [1,2]	X	X	X	-	
1. These parameters are to be indicated continuously. 2. A high and low alarms is to be fitted (audible and visible).					

Table 3.2.13 (c): Central Dive Control Monitored Pressurization and Breathing Gas Sources		
	Primary Source of Gas	**Independent Secondary Source of Gas**
Surface Oriented Diving		
One Working Diver	One	One
Two Working Divers – Alternative 1	One per diver	One per two divers
Two Working Divers – Alternative 2	One for two divers	One per diver
Surface Standby Diver	One (separate from working divers)	One (Common with working divers' secondary source)
Wet Bell Services	One	One (Can be from onboard gas)
Saturation Diving		
Diving Bell	One (from surface)	One (can be from surface or onboard gas)
Working Divers	One (from surface)	
Bell Man	One onboard gas or surface	One common with working divers
Oxygen	One onboard gas	-

Table 3.2.13 (d): Central Saturation Control Monitored Pressurization and Breathing Gas Sources		
	Primary Source of Gas	**Independent Secondary Source of Gas**
Each Chamber Compartment	One	One (this can be a separate source and common pipe to the compartment)

Notes:

1. The term "source" is used to describe a means of providing the breathing or pressurization gas going into the control panel. The term "supply" is used to refer to the breathing or pressurization gas going to the diver/ dive basket/ wet-bell/ PVHO from the control panel.

2. The fundamental principle for the provision of breathing gas to divers is that any diver is to have ready access to two sources of breathing gas (a primary and a secondary source), where, at least one of which is to be supplied solely for the individual's own use, i.e. provide an independent supply of breathing gas.

3. The diver's bail-out is not considered as a primary or secondary source. The air supply to each diver is to be arranged such that if one line fails then this does not interfere with the supply to another diver.

.3 Provision is to be made within the bell and HBSC for an independent means of monitoring oxygen and carbon dioxide levels.

.4 The pressure gauges of compression chambers are to give a reading accurate to ± 0.3 per cent of the full instrument scale subject to a maximum deviation of 30 [cm] of water column. All other pressure gauges are to be accurate to 1 per cent of the full instrument scale.

.5 Oxygen injection systems are to be designed to prevent an uncontrolled flow of oxygen.

.6 Confined areas with gas control systems using gases with an oxygen content less than 20% or greater than 22% are to have continuous oxygen monitoring with high-level and low-level audio-visual alarms.

.7 Facilities are to be provided at the central control position to monitor and provide appropriate alarms for when any life-support parameter is outside acceptable limits.

3.2.14 Communications and Relocation Systems

.1 The communication system is to be arranged for direct two-way communication between the control stand and the :

- Diver(s) in water
- Standby diver
- each compartment of the surface compression chambers including the HBSC
- service lock positions when not located in immediate vicinity of the control stand
- back-up control panels
- diving system handling positions
- dynamic positioning control station, only when required by Section 2.2 (position keeping)
- diving platform bridge, ship's command center or any other operational control area.

and where applicable, the:

- diving bell, wet bell, dive basket and HBSC
- HBSC launch position
- HBSC operator’s position

- deck operations (wireless communication acceptable)

- crane operator (wireless communication acceptable)

- remotely operated vehicle (ROV) operator

- control stand on the daughter craft and the diving platform bridge (wireless communication acceptable)

- Systems are to be hardwired unless stated otherwise.

.2 Alternative means of communication with divers in the surface compression chamber, HBSC and diving bell are to be available in emergency. All secondary communication systems are to operate for a minimum of 30 minutes without main electrical power.

.3 Each PVHO is to be connected to a speech unscrambler when used with gas systems, including helium.

.4 A self-contained through-water communication system with a minimum operating duration of 24 hours is to be provided for emergency communication with diving bells when operating under water.

.5 Communications between dive control, the diving bell or wet bell, the standby diver and the divers in the water are to be recorded (audio and video) and retained for a minimum of 24 hours after the dive is completed.

.6 Where diving is carried out from a diving platform operating with dynamic positioning (DP), then an audio and visual alarm activated by the DP operator is to be fitted at the dive control stand/ station to inform the supervisor of the DP status. It is to be able to be tested before each dive when operating on DP.

.7 Primary and secondary means of communication between dive control and the bridge are to be provided and available at all times. One of the means of communication is to operate without the need for external electrical power supply. If the vessel is operating in DP, the primary means of communication is to be a direct hardwired two-way link.

.8 The diving unit general alarm is to be audible in the dive and saturation control stands. This alarm is to be mutable to ensure communication is not interrupted with the diver(s). Muting of the alarm is to be time-limited and there is to be visual indication of the alarm status.

.9 A diving bell is to have an emergency locating device with a frequency of 37.5 [kHz] designed to assist personnel on the surface in establishing and maintaining contact with the submerged diving bell if the umbilical to the surface is severed. The emergency locating device is to include the following components:

.1 Transponder

.1 The transponder is to be provided with a pressure housing capable of being operated to atleast the maximum operating depth of the diving bell containing batteries and equipped with saltwater activation contacts. The batteries are to be of the readily available “alkaline” type and, if possible, be interchangeable with those of the diver and surface interrogator/ receiver.

.2 The transponder is to be designed to operate with characteristics as indicated in Table 3.2.14.5.1.2

.2 Diver-held interrogator/ receiver

.1 The interrogator/ receiver is to be provided with a pressure housing capable of operating to atleast the maximum operating depth with pistol grip and compass. The front end is to contain the directional hydrophone array and the rear end, the three-digit LED display readout calibrated in metres. Controls are to be provided for "on/ off receiver gain" and "channel selection". The battery pack is to be of the readily available "alkaline" type and, if possible, be interchangeable with that of the interrogator and transponder.

.2 The interrogator/ receiver is to be designed to operate with characteristics as indicated in Table 3.2.14.5.2.2

.10 In addition to the communication systems referred to above, a standard bell emergency communication tapping code is to be adopted, as given in Table 3.2.14.6, for use between persons in the bell and rescue divers.

A copy of this tapping code is to be displayed inside and outside the bell and also in the dive control room.

Table 3.2.14.5.1.2 Transponder Characteristics
Common emergency reply frequency : 37.5 [kHz]
Individual interrogation frequencies - Channel A : 38.5 ± 0.05 [kHz] - Channel B : 39.5 ± 0.05 [kHz
Receiver Sensitivity : 15 dB referred to 1 [µbar]
Minimum Interrogation pulse width : 4 [ms]
Turnaround delay : 125.7 ± 0.2 [ms]
Reply frequency : 37.5 ± 0.05 [kHz]
Maximum interrogation rates - More than 20% of battery life remaining : Once per second - Less than 20% of battery life remaining : Once per 2 seconds
Minimum transponder output power : 85dB referred to 1 µbar at 1 m
Minimum transducer polar diagram : -6dB at ± 135° solid angle, centered on the transponder vertical axis and transmitting towards the surface
Minimum listening life in water : 10 weeks
Minimum battery life replying at 85 dB : 5 days

Table 3.2.14.5.2.2 Interrogator/ Receiver Characteristics
Common emergency reply frequency : 37.5 [kHz]
Individual interrogation frequencies - Channel A : 38.5 [kHz] - Channel B : 39.5 [kHz]
Minimum transmitter output power : 85dB referred to 1µbar at 1 m
Transmit pulse : 4 [ms]
Directivity : ± 15°
Capability to zero range on transponder
Maximum detectable ranges : more than 500 [m]

Table 3.2.14.6 Standard Bell Emergency Tapping Code

Tapping Code	Situation
3.3.3	Communication opening procedure (inside and outside)
1	Yes or affirmative or agreed
3	No or negative or disagreed
2.2	Repeat please
2	Stop
5	Have you a got a seal?
6	Stand by to be pulled up
1.2.1.2	Get ready for through water transfer (open your hatch)
2.3.2.3	You will NOT release your ballasts
4.4	Do release your ballast in 30 minutes from now
1.2.3	Do increase your pressure
3.3.3	Communication closing procedure (inside and outside)

3.3 Classification and Surveys of Diving Systems

3.3.1 Classification of diving systems built under survey of IRS:

a) All equipments/ components specified in 1.4 are required to be manufactured under survey of IRS Surveyors.

b) All systems are to be installed and tested under the supervision and to the satisfaction of IRS Surveyors.

3.3.2 Classification of diving systems not built under survey of IRS:

3.3.2.1 Details of the diving system, as required by 1.5, together with copies of manufacturer certificates for all components are to be submitted for review;

3.3.2.2 Upon satisfactory review of the documents stated in (a) above, a survey of the installation would be carried out by IRS Surveyors, based upon which the classification of the installation would be considered by IRS;

3.3.2.3 The documentation related to functional tests is to be submitted and where necessary, individual tests are to be repeated;

3.3.2.4 Existing Class and period of Class, as well as any requirements which have been made conditional upon the existing Class are to be intimated to IRS;

3.3.2.5 If the diving system holds the Class of another recognized Classification Society, the survey of individual parts may be deferred pending the next due date. A survey of these parts within the scope of an Annual Survey may be sufficient.

3.3.2.6 Special attention is to be paid to the following:

a) All decompression chambers, bells and other pressure vessels;

b) Safety valve arrangement on pressure vessels;

c) Gas storage, especially oxygen storage with regards to hazards during a potential fire;

d) Fire detection and fire protection arrangements;

e) Electrical installations, especially installations in hazardous areas;

f) Strength of structure supporting the diving equipment.

3.3.3 Suspension/ retention/ withdrawal of Class

.1 In general, the suspension/ retention/ withdrawal of Class of diving systems is to be in accordance with the provision of Pt.1, Ch. 1 of the Rules. The following aspects are to be additionally noted for diving systems:

.2 The period of Class of permanently installed diving systems would be identical to that of the machinery plant of the diving support ship or floating structure. The Class will be maintained as long as the diving system is subjected to all prescribed surveys, and any modifications and repairs found to be necessary are carried out to the satisfaction of IRS.

.3 If the diving system is not subjected to the prescribed surveys at their due dates, the Class would be suspended.

.4 If the diving system has suffered damage affecting its Class or if such damage may be assumed, a survey is to be performed before diving operations commence. IRS is to be notified of such damage as a matter of course.

.5 Where it is found that the diving system no longer complies with the requirements of the Rules on the basis of which the Class was assigned, or if the operator fails to carry out repairs or alterations considered necessary by IRS within a specified period, as agreed upon, the Class of the diving system will expire.

.6 If the repairs or modifications required by IRS have been carried out and the system is subjected to a Re-classification Survey, the original Character of Classification may be reinstated. This survey is to be carried out in accordance with the requirements for a Class Renewal Survey.

.7 For diving systems which are out of operation for some time or their diving support vessel, floating structure or offshore plant is laid up; the period of Class will remain unchanged. On request, surveys which fall due may be deferred until the diving system is replaced into service. The total scope of the

surveys required thereafter would be determined by IRS for each case individually.

3.3.4 Surveys during Construction

3.3.4.1 Survey during construction and installation of the diving system will include the verification of the following items:

a) Compliance of the design of the diving system, scantlings and arrangements with the approved plans, IRS rule requirements, applicable national regulations and specified standards;

b) Certification of materials and components as per the Rule requirements;

c) Compliance with the fabrication tolerances and to the requisite quality standards;

d) Cleaning of piping systems conducting gas in life support systems in accordance with an approved cleaning procedure;

e) Cleaning and sealing of Gas cylinders;

f) All tests are carried out as per requirements.

3.3.4.2 The extent and method of survey is to be agreed prior to the work being carried out.

3.3.4.3 Tests/trials

.1 A comprehensive test plan is to be submitted for approval for carrying out tests after completion of installation of the diving system. This plan is to include testing details for, at least the following :

- Pressure tests
- Gas leakage tests
- Handling systems
- Life support systems
- Safety systems
- Electrical systems
- Instrumentation
- Environmental control systems
- Sea trials.

3.3.4.4 Leak Test

.1 Leak testing is to be carried out as per approved procedures. Details of leak tests are given in Pt.1, Ch. 2, 18.3.1.1.1.

3.3.4.5 Pressure Test

.1 Pressure tests are also to be carried out as per approved procedures. Details of pressure tests are provided in Pt.1, Ch. 2, 18.4.2.

.2 The following equipment/ systems are to be tested for hydrostatic pressure in accordance with recognized standards or design codes:

- New chambers and bells
- New gas cylinders
- New air and gas storage tanks
- New hot water tanks
- New piping

3.3.4.6 Pressure Vessels for Human Occupancy

.1 The manufacturers of pressure vessels for human occupancy are to be approved by IRS, when the pressure vessels are certified by IRS.

.2 The pressure vessels are to be designed and manufactured to internationally recognized codes/ standards.

.3 ASME PVHO-1 “Safety Standard for Pressure Vessels for Human Occupancy” is to be used for design of acrylic plastic windows.

3.3.4.7 In addition to the above, the scope of initial survey of other items/ components of the diving systems is as indicated in Table 3.3.4.7

Table 3.3.4.7 Initial Survey Requirements for Diving Systems[1]	
Pressure Equipment	
Pressure Vessels for Human Occupancy	
Examine/ verify (as applicable)	- certified materials are used; - sufficient strength in foundations and support for chambers and gas cylinders; - vessel is constructed in accordance with approved drawings; - flanges, sealing surfaces, openings for windows and hatches are satisfactory with regard to tolerances and for sealing systems; - out of roundness for vessels intended for external pressure are within tolerances; - welds are tested; - pressure tests upon completion are satisfactory.
Gas Storage	
Examine (as applicable)	As per the requirements for renewal survey
Pressure Vessels in Supply and Return Lines	
Examine (as applicable)	As per the requirements for renewal survey
Pumps and Compressors	
Examine and test (as applicable)	As per the requirements for renewal survey
System components including piping, umbilicals, hoses, valves, filters	
Examine and test (as applicable)	- Piping systems to be tested to 1.5 x the design pressure; - Cleaning of the hoses, piping and mountings to be undertaken carefully to ensure that the oxygen system is free from impurities like oil, grease etc, that may cause a fire hazard; - Leakage test of total deep diving system to be carried out with heliox mixture, after installation of piping.
Controls	
Gas Supply Control	
Examine/ Verify (as applicable)	As per the requirements for renewal survey
Gas Distribution System	
Examine/ Verify (as applicable)	As per the requirements for renewal survey
Depth/ Pressure Control	
Examine/ Verify (as applicable)	As per the requirements for renewal survey
Temperature and Humidity Control	
Examine/ Verify (as applicable)	As per the requirements for renewal survey
Gas Contamination Analysis	
Examine/ Verify (as applicable)	As per the requirements for renewal survey
Sanitary/ Domestic Systems	
Examine/ Verify (as applicable)	As per the requirements for renewal survey
Auxiliary Services to Life Support Equipment	
Examine/ Verify (as applicable)	- Electrical components installed inside chambers/ bells are to be of a construction suitable to withstand high humidity and oxygen atmosphere content; - Components installed outside bell are to be of watertight type and pressure tested to at least 1.3 x maximum design pressure.
Communication	
Examine/ Verify (as applicable)	Primary, secondary, emergency means of communication and alarms to be examined as per the requirements for renewal surveys.

Table 3.3.4.7 (Contd.)

Launch and Recovery Systems	
General	
Examine/ Verify (as applicable)	For submergence launch and recovery system: (i) Examine all strength members as per approved drawings, certificates for hoisting ropes/ wires, books, sheaves, shackles etc (ii) Load test (including static and running loads[2]) of all lifting equipment. Bell launch and recovery systems to be tested as integral units. (iii) Test of emergency bell retrieval procedures; For surface launch and recovery : (i) As per the requirements for renewal survey
Controls	
Examine/ Verify (as applicable)	As per the requirements for renewal survey
Auxiliary services to launch and recovery system	
Examine/ Verify (as applicable)	Pipes and hoses to be tested to 1.5 x the maximum allowable working pressure (MAWP)
Safety Equipment	
Examine/ Verify (as applicable)	As per scope of annual, third annual survey and renewal surveys

Notes

1 : Requirements for renewal surveys of diving systems are given in Section 18 of Pt. 1, Ch. 2
2 : Running load test to be carried out at 1.25 x the safe working load.

3.3.5 Surveys after Construction

3.3.5.1 The periodical surveys for diving support vessels are to be carried out in accordance with the applicable requirements of Pt. 1, Ch. 2.

3.3.5.2 Periodical surveys of diving systems fitted permanently onboard the ships are to be harmonised with those for the ships.

3.3.5.3 Periodical surveys of permanently fitted diving systems, independent diving systems or diving systems fitted temporarily onboard the ships are to be carried out in accordance with the requirements stipulated in Pt. 1, Ch. 2, Sec. 18 of the Rules.

Section 4

Evacuation Systems

4.1 General

4.1.1 An evacuation system is to be provided with sufficient capacity to evacuate all divers under pressure, in the event of the ship having to be abandoned, and is to be in accordance with the provisions of the Guidelines and Specifications for Hyperbaric Evacuation Systems (HES), IMO Res A.692(17), as amended.

4.1.2 In general, the HBSC is to be designed, constructed and tested in accordance with the applicable aspects of the LSA Code, chapter IV (Survival craft). Specific deviations for HBSC from the LSA Code, as indicated in the *International Code of Diving Safety, 2023*, as amended are to be complied with, as relevant and applicable, for the following aspects:

- Carrying capacity
- Access arrangements
- Buoyancy, Freeboard and Stability
- Propulsion
- Equipment and Fittings
- Semi-submerged HBSCs
- Markings
- Type of HBSC (whether totally enclosed type or free-fall type)

4.1.3 Statutory requirements of the Flag Administration, where the ship, barge, mobile offshore platform or fixed offshore platform is registered, are also to be complied with.

4.2 Design Requirements

4.2.1 The design and construction of the HBSC is to be such that it is suitable for the environmental conditions envisaged, account being taken of the horizontal or vertical dynamic snatch loads that may be imposed on the system and its lifting points particularly during evacuation and recovery.

4.2.2 The HBSC is to be capable of being recovered by a single point lifting arrangement. Means are to be provided on the unit to permit a swimmer to hook on or connect the lifting arrangement.

4.2.3 A single lift point and associated lift load path is to be designed for a load 3 times the weight of the fully loaded HBSC. A minimum factor of safety of 2 to yield is to be applied for structures and 4 for loose gear including suspension chains, links and blocks. A static proof load test of not less than 3 times the weight of the fully loaded HBSC is to be applied.

4.2.4 Where HBSCs are semi-submerged PVHOs, the pressure boundary of the PVHO may be the HBSC hull.

4.2.5 In the design of pressure vessels including accessories such as doors, hinges, door landings, closing mechanisms, penetrators and viewports, the effects of rough handling are to be considered in addition to design parameters such as pressure, temperature, vibration, operating and environmental conditions.

4.2.6 In general, piping penetrations through the chamber are to have isolating valves on both sides.

4.2.7 Materials used in the construction of HBSCs are to be suitable for their intended use.

4.2.8 Components in the HBSC are to be so designed, constructed and arranged as to permit easy inspection, maintenance, cleaning and, where appropriate, disinfection.

4.2.9 Component parts of a HBSC are to be designed, constructed and tested in accordance with recognized national/ international standards acceptable to the Administration/ IRS.

4.2.10 The HBSC is to be provided with the necessary control equipment to ensure its safe operation and the well-being of the divers.

4.2.11 Special arrangements and instructions are to be provided externally to enable the HBSC to be recovered safely. The instructions are to be located where they will be legible when the HBSC is floating.

4.2.12 HBSCs are not to be located in hazardous areas of Zone 0 or Zone 1. Other

hazardous areas and high fire risk areas are to be avoided as far as is reasonably practicable.

4.2.13 The HBSC is to be designed for the rescue of all divers in the diving system at the maximum operating depth.

4.2.14 The compression chamber is to provide a suitable environment and adequate facilities, including, where appropriate, seat belts, for the maximum number of persons for which the unit is designed.

4.2.15 The seating or other arrangements provided are to be designed to provide an adequate degree of protection to the divers from impact collisions during launch and while the unit is afloat.

4.2.16 Where the chamber is intended to be occupied for more than 12 hours, arrangements for the collection or discharge of human waste are to be provided. The discharge arrangements are to be fitted with suitable interlocks.

4.2.17 The means provided for access into the compression chamber is to allow safe access to or from the surface compression chambers. Interlocks are to be provided to prevent the inadvertent release of the HBSC from the surface compression chamber while the access trunk is pressurized.

4.2.18 The mating flange is to be adequately protected from damage at all times including during the launch and recovery stages.

4.2.19 Arrangements are to be provided to enable an unconscious diver to be taken into the unit.

4.2.20 Compression chamber doors are to be so designed as to prevent accidental opening while pressurized.

4.2.21 All doors are to be so designed that, where fitted, the locking mechanisms can be operated from both sides.

4.2.22 Arrangements are to be provided to allow the occupants to be observed. If viewports are provided they are to be situated so that risk of damage is minimized.

4.2.23 Where it is intended to carry out decompression of the divers after hyperbaric evacuation in another surface compression chamber, then suitability of the mating arrangements on that surface compression chamber are to be specially considered. A suitable adapter and clamping arrangements are to be provided, where necessary,

4.2.24 A medical lock is to be provided and be so designed as to prevent accidental opening while the compression chamber is pressurized. Interlock arrangements are to be provided for this where necessary. The dimensions of the medical lock are to be adequate to enable essential supplies, including scrubber canisters, to be transferred into the compression chamber, and be of such dimensions as to minimize the loss of gas when the lock is being used.

4.2.25 Stability and Buoyancy

.1 HBSCs designed to float are be provided with adequate stability for all envisaged operating and environmental conditions and be self-righting. In determining the degree of stability to be provided, consideration is to be given to the adverse effects of large righting moments on the divers.

.2 The effect which equipment and rescue personnel, required to be placed on the top of the system to carry out a recovery from the sea, may have on the stability of the HBSC, are also to be taken into account.

.3 The HBSC is to be fitted with a tow arrangement suitable in function and strength for towing the HBSC in the following conditions:

- 3 knots to the top of sea state 3; and

- holding the HBSC in position up to sea state 7.

The tow arrangement is to be designed to minimize human operation when connecting the tow.

.4 Towing attachment points are to be so situated that there is no likelihood of the HBSC being capsized as a result of the direction of the tow line. Where towing harnesses are provided they are to be lightly clipped or secured to the unit and, so far as is possible, be free from snagging when pulled free.

.5 HBSCs designed to float are to have sufficient reserves of buoyancy to enable the necessary rescue crew and equipment to be carried.

.6 Where HBSCs are designed to be placed on board a rescue vessel, attachment points are to be provided on the unit to enable it to be secured to the deck.

4.2.26 Life Support Systems

.1 Means are to be provided to maintain all the occupants in thermal balance and in a safe and breathable atmosphere for all environmental conditions envisaged - air temperature, sea temperature and humidity - and with the maximum and minimum number of divers likely to be carried.

.2 In determining the duration and amount of life support necessary, consideration is to be given to the geographical and environmental conditions, the oxygen and gas consumption and carbon dioxide generation under such conditions, the heat input or removal and the emergency services that may be available for the decompression of the divers.

.3 Gas losses as a result of using toilet facilities which discharge to outside the HBSC and medical lock operation are to be taken into account in determining the amount of gases required. The effects of hypothermia are to be considered and the effectiveness of the arrangements provided are to be established as far as is reasonable and practicable under all conditions envisaged. However, in no such case should the duration of the unit's autonomous life-support endurance be less than 72 hours.

.4 In addition to any controls and equipment fitted externally, compression chambers are to be provided with adequate controls within for supplying and maintaining the appropriate breathing mixtures to the occupants, at any depth down to the maximum operating depth.

.5 The persons operating the chamber, whether they are within or outside it, are to be provided with adequate controls to provide life support. As far as practicable, the controls are to be capable of operation without the person who operates them having to remove his/ her seat belt.

.6 Two separate distribution systems are to be provided for supplying oxygen to the compression chamber.

.7 Components in the system are to be suitable for oxygen service.

.8 Adequate equipment is to be provided and be suitably situated to maintain O_2 and CO_2 levels and thermal balance within acceptable limits while the life-support equipment is operating.

.9 In addition to any instrumentation necessary outside the compression chamber, suitable instrumentation is to be provided within the chamber for monitoring the partial pressures of O_2 and CO_2. The same are to be capable of operation for the duration of the available life support period.

.10 Where it is intended that divers may be decompressed within the HBSC, provision is to be made for the necessary equipment and gases, including therapeutic mixtures, to enable the decompression process to be carried out safely.

.11 An adequate supply of food and water is to be provided within the HBSC. In determining, in particular, the amount of water to be provided, consideration is to be given to the area of operation and the environmental conditions envisaged.

.12 A breathing system is to be provided with a sufficient number of masks for all the occupants under pressure.

.13 Provision is to be made external to the HBSC, and in a readily accessible place, for the connection of emergency hot or cold water and breathing therapeutic mixture. The dimensions of the connections provided are to be as follows:

- 3/4 in. NPT (female) - hot or cold water
- 1/2 in. NPT (female) - breathing mixture

The connections are to be clearly and permanently marked and be suitably protected.

.14 In HBSCs designed to pass through fires; the breathing gas bottles and piping systems and other essential equipment are to be adequately protected.

.15 In addition, thermal insulation is to be nontoxic and suitable for this purpose.

.16 First-aid equipment, sickness bags, paper towels, waste disposal bags and all necessary operational instructions for equipment within the compression chamber are to be available within the chamber, on board the parent vessel and ashore.

4.2.27 Fire Protection and Extinction

.1 Materials used in the construction and installation are to be non- combustible and nontoxic, as far as practicable.

.2 A fire-extinguishing system is to be provided in the HBSC which is to be suitable for exposure to all depths down to the maximum operating depth.

.3 HBSCs on ships required to be provided with fire-protected lifeboats are to be provided with a similar degree of fire protection.

.4 In HBSCs that are semi-submerged PVHO and may be used to transport divers through fires, consideration is to be given, where practicable, to providing an external water spray system for cooling purposes (see 2.11.6).

4.2.28 Electrical Arrangements

.1 Electrical equipment within the compression chamber is to be designed for hyperbaric use, high humidity levels and marine application. They are to be designed to minimize the risk of electrical capacity depletion as a result of a fault, fire or explosion, electric shock, the emission of toxic gases and galvanic action.

.2 Power supplies required for the operation of life-support systems and other essential services are to be sufficient for the life-support duration.

.3 The battery charging arrangements are to be designed to prevent overcharging under normal or fault conditions. The battery storage compartment is to be provided with means to prevent over-pressurization and any gas released is to be vented to a safe place.

.4 Each compression chamber is to be provided with a source of lighting sufficient for the life-support time and of sufficient luminosity to allow the occupants to read gauges and operate essential systems within the chamber.

4.2.29 Launch and Recovery of HBSCs

.1 Means are to be provided for the safe and timely evacuation and recovery of the unit and due consideration is to be given to the environmental and operating conditions and the dynamic snatch and impact loadings that may be encountered.

.2 Where appropriate, the increased loadings due to water entrainment are to be considered.

.3 Where the primary means of launching depends on the ship's main power supply, then a secondary and independent launching arrangement is to be provided.

.4 The lowering of the HBSC under normal conditions is not to be controlled by brakes, but by the drive system of the winches. If the power to the handling system fails, brakes are to be engaged automatically. The brake is to be provided with manual means of release. In the event of an electrical power failure of the launching appliance, in addition to the requirement for gravity or stored mechanical power in the LSA Code, an emergency power supply is to be provided. The launching appliance need not be provided with hand gear as required by chapter 6.1.2.6 of the LSA code.

.5 The launching arrangements provided are to be designed to ensure easy connection or disconnection of the HBSC from the surface compression chamber and for the transportation and removal of the unit from the ship under the same conditions of trim and list as those for the ship's other survival craft.

.6 Where a power-actuated system is used for the connection or disconnection of the HBSC and the surface compression chamber; a manual or stored power means of connection or disconnection is also to be provided.

.7 The means provided for release of the falls or lift wire after the unit is afloat is to provide for easy disconnection, particular attention being given to units not provided with an attendant crew.

.8 Where the HBSC is designed to be recovered from the sea, or from a ship in a seaway, consideration is to be given to the mode of recovery.

.9 Adequate equipment is to be provided on the unit to enable safe recovery. Permanently marked, clear instructions are to be provided adjacent to the lifting equipment as to the correct method for recovery, including the total weight of the HBSC.

.10 The effect of entrained water and any bilge water which may affect the total weight to be lifted by the recovery vessel is to be considered. Absorption of the dynamic snatch loads imposed during the recovery of the HBSC from the sea is also to be considered.

4.2.30 Communication and Locating Devices

.1 If breathing mixtures containing helium or hydrogen are used, a self-contained primary communication system fitted with an unscrambler device is to be arranged for direct two-way communication between the divers and those outside the compression chamber. A secondary communication system is also to be provided.

.2 In addition to the communication system referred to in 4.2.30.1, a standard bell emergency communication tapping code is to be provided, as indicated in Table 3.2.14.6. Copies of the tapping code are to be permanently displayed inside and outside the HBSC.

.3 HBSCs designed to be waterborne are to be provided with a strobe light and radar reflector.

.4 HBSCs designed to be placed on the sea-bed to await independent recovery are to be provided with an acoustic transponder. The transponder is to be suitable for operation with a diver-held interrogator-receiver which will be retained on board the parent ship. The equipment provided is to meet the requirements indicated in 3.2.14.9.

4.3 Marking and Information to be provided on HBSCs

4.3.1 Dedicated HBSCs are to be coloured orange and be provided with retro-reflective material to assist in their location during hours of darkness.

4.3.2 Each HBSC designed to be waterborne is to be marked with at least three identical signs as shown in Fig 4.3.2. One of these markings is to be on top of the unit and be clearly visible from the air. The other two are to be mounted vertically on both sides and as high as possible and should be capable of being seen while the unit is afloat.

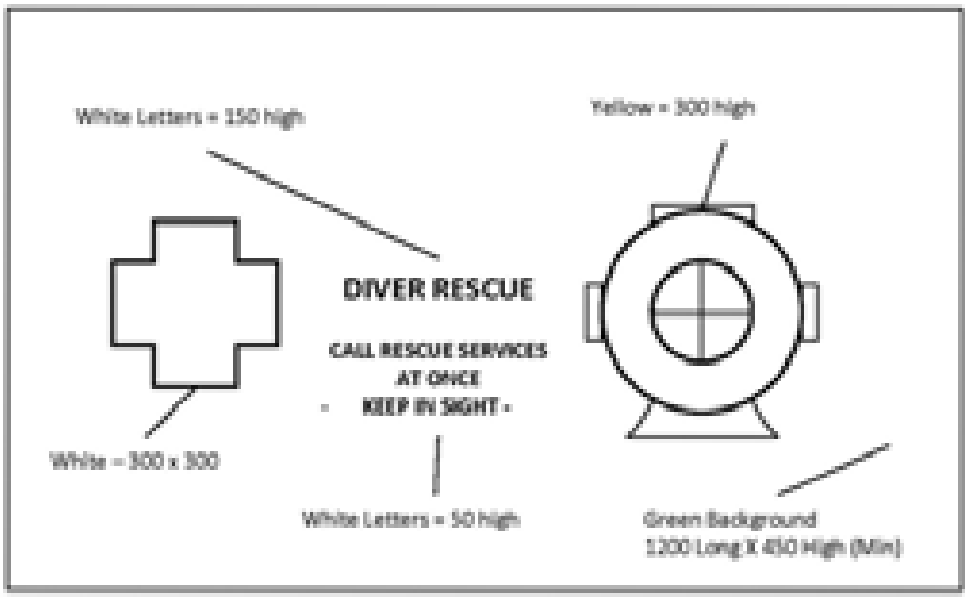

Fig 4.3.2 : Marking on Hyperbaric Evacuation Units

4.3.3 Whilst the unit is afloat, the following instructions and equipment, as applicable, are to be clearly visible and kept readily available:

- Towing arrangements and buoyant towline;
- All external connections, particularly for the provision of emergency gas, hot/ cold water and communications;
- Maximum gross weight of unit in air;
- Lifting points;
- Name of parent ship and port of registration;
- Emergency contact telephone and fax numbers.

4.3.4 Warning Instructions

.1 Where appropriate, the following instructions are to be permanently displayed on every HBSC in two separate locations so as to be clearly visible while the unit is afloat:

.1 Unless specialized diving assistance is available

- Do not touch any valves or other controls;
- Do not try to get occupants out;
- Do not connect any gas, air, water or other supplies;
- Do not attempt to give food, drinks or medical supplies to the occupants; and
- Do not open any hatches.

4.4 Surveys of Hyperbaric Evacuation Systems

4.4.1 General/ Initial Survey Requirements

.1 Statutory requirements of state/ national authorities/ flag administrations are to be kept in mind, whilst approving and surveying HES.

.2 The interface between the HES and the installed diving system is to be examined carefully so that the HES does not become a hazard to the diving system operations.

.3 HES are connected to the diving system and are to be surveyed in the same manner as the main diving system. Corrosion on the chamber exterior is to be examined carefully due to high humidity levels.

.4 Apart from the drawings/ documents being examined (as listed in 1.5), the following need to be specifically examined:

- Sufficient Built in Breathing Systems (BIBS) fitted and functional;
- BIBS overboard dump fitted and functional;
- locking mechanism fitted and functional;
- doors can be opened from both sides;
- doors can be secured "open";
- equalization can be done if appropriate;
- seatbelts for the maximum complement of divers provided;
- lighting fitted and functional;
- toilet provided;
- protective headgear provided
- recovery system available
- falls of sufficient length, where applicable.

.5 Examine if the HES is marked as per requirements, stipulated in 4.3 and a copy of the tapping code is placed inside and outside the chamber, as stipulated in 3.2.14.6.

.6 Examine, if arrangements to lift an injured diver are provided

.7 Examine, if the HBSC has undergone a stability test to ensure that it floats at correct orientation. Launch the HBSC and examine if the free-floating unit is positively buoyant, when fully equipped and manned.

.8 In installations where the saturation diving system is mounted on an offshore production and/ or drilling platform, examine if the HES has some form of propulsion or other suitable method of rapid clearance from the installation.

.9 Confirm, that the HES is able to accommodate the maximum number of divers (as per design) that may be under pressure

.10 Confirm, that the HES is included in the Planned Maintenance System, as per the Operation Manual and contingency plans are also available

.11 Confirm that written procedures for launching of the HES including responsibilities of operators, manning of stations, etc. are available.

.12 Examine, if first aid kit, (as per scale and applicable requirements) is provided.

4.4.2 Periodical Surveys

.1 Periodical surveys of HES are to be carried out as per the requirements in Pt. 1, Ch.2, Sec. 18, 18.5.2.

End of Chapter

Chapter 27

Helicopter Decks

Contents

Section

1 *General*

2 *Design Loads*

3 *Structural Requirements*

Section 1

General

1.1 Application

1.1.1 The requirements of this Chapter apply to vessels with erected landing platform for helicopters or a landing area arranged directly on weather deck or top of deckhouse.

1.1.2 Where the landing area forms part of a weather or erection deck, the scantlings are also to comply with the requirements given in Pt.3, Ch.9 for decks in the same position.

1.1.3 Vessels built in compliance with the above requirements will be eligible to be assigned class notation "HELDK".

1.2 Arrangements

1.2.1 The landing area is to be sufficiently large to allow for the landing and manoeuvring of the helicopter, and is to be approached by a clear landing and take-off sector, the extent of which is to comply with the applicable regulations of National or other authorities.

1.2.2 The landing area is to be free of any projections above the level of the deck. Projections in the zone surrounding the landing area are to be kept below the heights permitted by the regulations.

1.2.3 Suitable arrangements are to be made to minimize the risk of personnel or machinery sliding off the landing area. A non-slip surface and anchoring devices are to be provided.

1.2.4 Arrangements are to be made for drainage of the platform, including drainage of spilt fuel.

1.3 Documentation

1.3.1 Plans showing scantlings and arrangement of the structure and particulars of the materials of construction are to be submitted for approval. The type, size, maximum total weight of the helicopter and its fore-and-aft distribution is to be indicated on the plans.

1.4 Materials

1.4.1 The grades of steel and aluminium materials are to be in compliance with the requirements to hull materials given in Pt.3, Ch.2.

1.4.2 Where aluminium alloy platforms are connected to steel structures, detail of the arrangements in way of the connections including those to prevent galvanic corrosion are to be submitted for approval.

Section 2

Design Loads

2.1 General

2.1.1 The scantlings of each structural element is to be based on the most unfavourable of the following loading conditions:

- Extreme functional loads (landing) together with hull still water loads.

- Extreme environmental loads acting on hull, helicopter deck and helicopter in stowed transit position, if applicable, together with hull still water loads. The effect of icing is to be included for erected structures.

2.2 Landing forces

2.2.1 The total vertical force from the helicopter during landing is to be taken not less than:

$$P = 2\ g_o\ M_H\ .\ 10^3\ [N]$$

where,

M_H = the maximum take-off mass in tonnes of helicopter.

Landing force (P_w) acting on a wheel or a group of wheels, is to be obtained by considering that the total force P is distributed on the helicopter's landing gear in the same manner as when the helicopter is resting on a horizontal surface and the helicopter's centre of gravity is in its normal position in relation to the landing gear.

2.2.2 A horizontal sliding force of $0.5\ g_o\ M_H\ 10^3$ [N] may have to be taken into account for hatch covers and bolted platforms.

2.3 Gravity and inertia forces (due to ship motions and accelerations)

2.3.1 The static and dynamic design forces caused by the platform structure itself and, if applicable, by the helicopter in stowed position are to be considered. The effect of icing is to be additionally considered, if applicable.

2.4 Sea and weather loads

2.4.1 The sea pressure for superstructure deck and top of houses is to be taken in accordance with Pt.3, Ch.4. For elevated platforms with free water passage below, the sea pressure may be taken as:

$p = 0.0075$ [N/mm^2] forward of 0.15 L from FP.

$= 0.0025$ [N/mm^2] aft of 0.15 L from FP.

2.4.2 For structures where wind suction forces may be of importance, (e.g. bolted platforms), wind lift forces are to be taken into account by:

$$P_L = 1.2\ A\ .\ 10^3\ [N]$$

where,

A = deck area [m^2] of the platform.

Section 3

Structural Requirements

3.1 Deck plating and stiffening

3.1.1 Decks for helicopters supported on wheels with pneumatic tyres are to have scantlings in accordance with the following:

Thickness of deck plating is not to be less than:

$$t = f\,(s+1000)\,\sqrt{P_w}\,\sqrt{k}\,10^{-5} + t_c \text{ [mm]}$$

where,

f = 1.90 for separate platforms of steel or aluminium

= 2.05 for weatherdecks, in general

= 2.20 for longitudinally framed strength deck and for weather deck hatch covers of steel or aluminium

= 2.85 for transversely framed strength deck

s = stiffener spacing [mm]

P_w = Landing force [N], acting on the wheel or group of wheels considered as per 2.2.1

k = the material factor as per Pt.3, Ch.2, Sec.1.2 for steel

$= \frac{235}{\sigma_a}$ for aluminium alloys

σ_a = 0.2% proof stress or 70% of the ultimate strength of the aluminium alloy material, whichever is lesser [N/mm^2]

t_c = 2.0 [mm] for steel

= 1.0 [mm] for aluminium.

3.1.2 Section modulus of deck stiffeners is not to be less than:

$$Z = \frac{BM}{\sigma} \text{ [cm}^3\text{]}$$

BM = bending moment [N-m] for the most unfavourable location of landing forces (point loads), assuming 50% fixity at ends.

σ = 180/k [N/mm^2] in general; to be reduced by still water longitudinal hull girder stress for strength deck longitudinals.

= 160/k [N/mm^2] for weather deck hatch covers.

3.1.3 Each stiffener to girder connection is to have a shear area not less than:

$$A = 1.25\,P_w\,k\,10^{-4} \text{ [cm}^2\text{]}.$$

3.1.4 Decks for helicopters supported on tubular skids are to have scantlings in accordance with the following:

- Thickness of deck plating is to be not less than that obtained using the formula in 3.1.1 taking P_w as 0.9P, where P is the total landing force as per 2.2.1.

- Section modulus of stiffeners is to be as per 3.1.2.

3.2 Girders and supporting structures of separate platforms

3.2.1 The scantlings are normally to be based on the following allowable stresses:

Normal stress, $\sigma \leq 160/k$ [N/mm^2]

Shear stress, $\tau \leq 90/k$ [N/mm^2].

3.2.2 The helideck supporting members are to satisfy the buckling criteria as per Pt.3, Ch.3, Sec.6.

3.2.3 The critical buckling stress of plating acting as girder flange is to satisfy the buckling criteria as per Pt.3, Ch.3, Sec.6 taking η as 0.67.

Tripping brackets and local stiffening of plating are to be provided where necessary.

3.2.4 In the case of landing on a hatch cover section which is underlying in the packing joint, the strength and spacing of cleats must be sufficient to keep the connection intact and weathertight.

End of Chapter

Chapter 28

Single Point Mooring

Contents

Section

1 *General*

2 *General Arrangement*

3 *Mooring Components*

4 *Supporting Hull Structures*

5 *Strength Criteria*

Section 1

General

1.1 Application

1.1.1 The requirement of this chapter applies to ships fitted with standardized equipment complying with the recommendations of the Oil Companies International Marine Forum (OCIMF) for mooring at single point mooring or single buoy mooring terminals. Vessels complying with these requirements will be assigned class notation 'SPM' as per Pt.1, Ch.1 of Rules.

1.1.2 Where some components of mooring equipment are used for both single point mooring and for the bow emergency towing arrangements, the requirements for emergency towing arrangements (specified in Pt.5, Ch.2) are also to be complied with.

1.1.3 Where the mooring components are to be type approved, the requirements given in 'Certification Scheme for Type Approval of Products' are also to be complied with.

1.2 Documentation for approval

1.2.1 The following plans are to be submitted to IRS for approval:

- General layout of the associated equipment at the forecastle/fore deck.
- Construction drawing of the bow chain stoppers, bow fairleads and pedestal roller fairleads, together with material specifications and relevant calculations.
- Plans of the supporting structure in way of chain stoppers, fairleads, roller pedestals, winches and capstans.
- Arrangements for pull back from tugs, wherever applicable.

1.3 Documentation for information

1.3.1 The following documentation is to be submitted for information.

- Specifications of winches or capstans giving the continuous duty pull and brake holding capacity.
- DWT, in tonnes, of the ship at summer load line.

Section 2

General Arrangement

2.1 General

2.1.1 Suitable equipment and arrangements are to be provided near the bow of the vessel for heaving onboard a standard chafing chain of 76 [mm] diameter using a pick-up rope and for securing the chain to the strong point.

2.1.2 The strongpoint is to be a chain cable stopper.

2.1.3 Typical schematic layouts of the forecastle deck are shown in Fig.2.1.3(a), (b), (c) for reference.

2.1.4 Where tugs are used for pull back, suitable arrangements for connecting the lines from tugs are to be provided.

2.2 Equipment components

2.2.1 The equipment for mooring is to generally consist of the following components :

- bow chain stopper;
- bow fairlead;
- pedestal roller fairlead;
- winch or capstan.

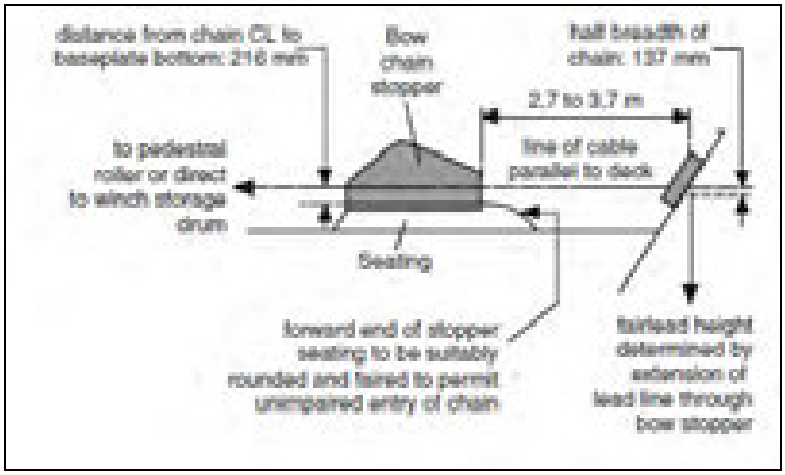

Fig. 2.1.3 (a) Typical forecastle deck layout

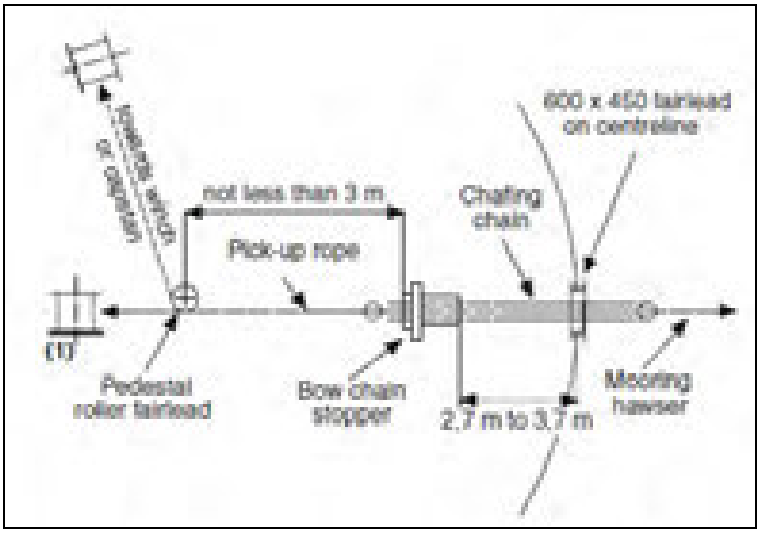

Fig. 2.1.3 (b) Typical forecastle deck layout (DWT ≤ 150000 t)

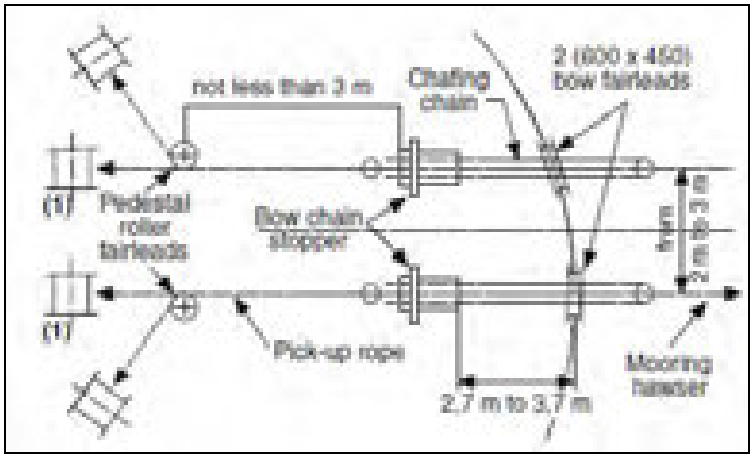

Fig. 2.1.3 (c) Typical forecastle deck layout (DWT > 150000 t)

Section 3

Mooring Components

3.1 General

3.1.1 The ship is to be equipped with bow chain stoppers complying with the requirements in Table 3.1.1 and suitable for a standard chafing chain of 76 [mm] in diameter.

The requirements for materials, manufacture, testing and certification of the 76 [mm] chafing chain are given in Part 2, Chapter 10, Section 5.15 of the Rules. Grade R3 and R4, indicated in Part 2, Chapter 10 are to be used corresponding to Safe working load of 200 [t] , 250 [t] and 350 [t] respectively, as applicable. (See Table 3.1.1).

Note : Chafing chains are not required to be part of ship's equipment when supplied by the SPM terminal operator.

3.1.2 Where the safe working loads are increased to take into account the local environmental conditions, the same is to be clearly stated on plans submitted for approval.

Table 3.1.1 : Required Number and SWL of Chain stoppers

Deadweight [t]	Number	Safe working load (SWL) [t] (kN)
DWT ≤ 100000	1	200 (1962)
100000 < DWT ≤ 150000 Note : Ships in this size range may elect to fit two stoppers to ensure full range terminal acceptance	1	250 (2452)
DWT > 150000	2	350 (3433)

3.1.3 The scantlings of all parts of bow chain stopper and bow fairleads are to be in accordance with the strength criteria given in Sec.5.

3.1.4 The bow chain stoppers and bow fairleads are to be made of fabricated steel, steel castings or forgings complying with relevant requirements given in Pt.2, Chapters 3, 4 and 5 respectively. They are to be permanently marked with the SWL.

Use of spheroidal graphite (SG) iron casting may be accepted for the main framing of the chain stopper provided that:

- The part concerned is not intended to be a component part of a welded assembly.
- The SG iron casting is of ferritic structure with an elongation not less than 12%.
- The yield stress at 0.2% strain is to be measured and certified.
- The internal structure of the component is to be inspected by means of non-destructive examination.

The material used for the stopping device (pawl or hinged bar in chain stoppers is to have mechanical properties similar to that of a Grade CC3 chain cable or better.

3.2 Bow chain stopper

3.2.1 The stoppers are to be capable of securing the common stud links of the chafing chain cable when the stopping device (chain engaging pawl or bar) is in the closed position and of freely passing the chain cable and its associated fittings when the stopping device is in the open position.

3.2.2 Chain stoppers may be of the hinged bar type or of pawl (tongue) type or of other equivalent design.

Typical arrangements of chain stoppers are shown in Fig.3.2.2.

3.2.3 The stopping device (chain engaging pawl or bar) of the chain stopper is to be so arranged as to prevent it from gradually working to the open position from the closed position which would release the chafing chain and allow it to pay out.

Stopping devices are to be easy and safe to operate and are to be properly secured in the open position.

3.2.4 Chain stoppers are to be located between 2.7 [m] and 3.7 [m] inboard from the bow fairleads (See Fig.2.1.3).

When positioning, due consideration is to be given to the correct alignment of the stopper relative to the direct lead between bow fairlead and pedestal roller fairlead.

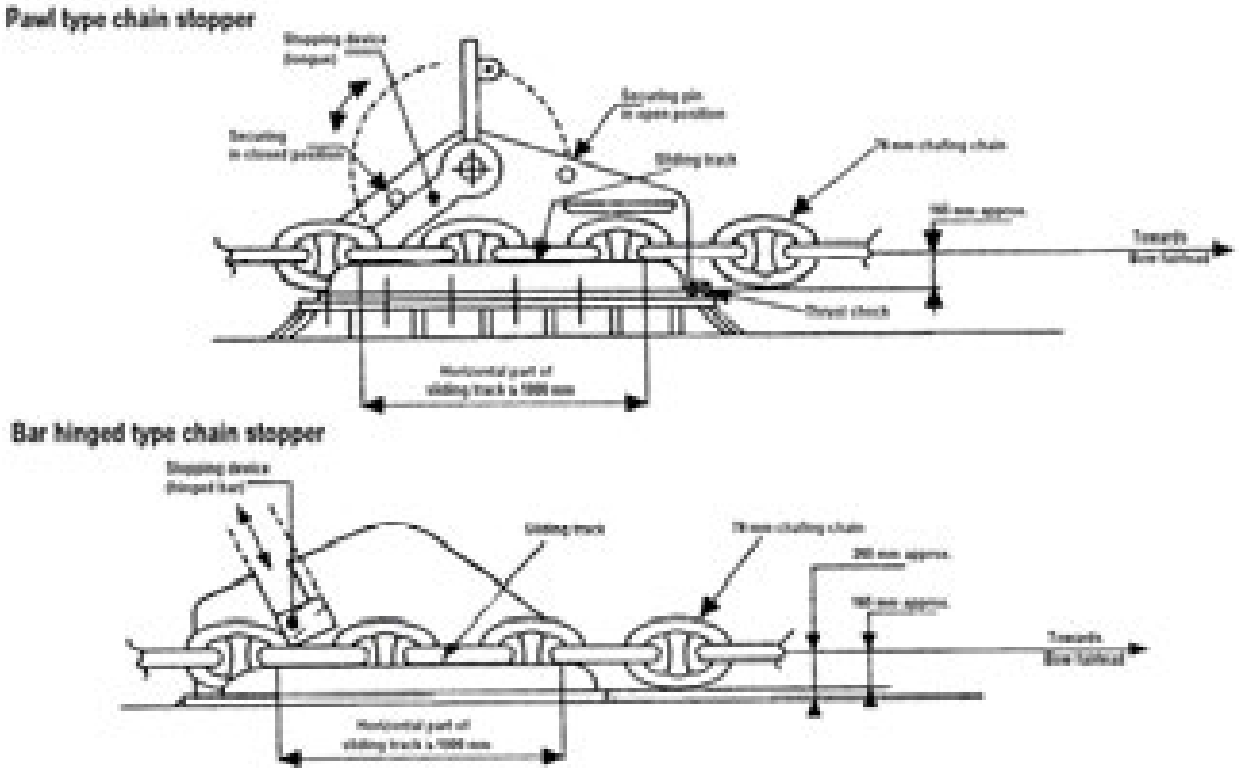

Fig.3.2.2 : Typical bow chain stoppers

3.2.5 Stopper support structures are to be trimmed to compensate for any camber and/or sheer of the deck. The leading edge of the stopper base plate is to be faired to allow for the unimpeded entry of the chafing chain into the stopper.

3.2.6 Where the chain stopper is bolted to a seating welded to the deck, the bolts are to be relieved from shear force by efficient thrust chocks capable of withstanding horizontal force equal 1.5 times the required working load satisfying the strength criteria specified in Sec.5.

Mechanical properties of bolt material are to be not less than Grade 8.8 of ISO standard No.898/1. (Grade 10.9 is recommended). The bolts are to be pre-stressed in accordance with relevant standards and their tightening is to be suitably checked.

3.2.7 Some SPM operators may require a second bow chain stopper for all sizes of conventional tankers.

3.2.8 DP bow loading tankers specifically designed for offshore terminals are to be fitted with specialized bow chain stoppers, integrated with cargo loading system emergency shutdown systems. Requirements for these specialized systems may be referred in the OCIMF '*Guidelines for Offshore Tanker Operations*'.

3.3 Bow fairleads

3.3.1 One bow fairlead is to be fitted for each bow chain stopper (See Fig.2.1.3).

3.3.2 For ships of more than 150000 t DWT, where two bow fairleads are required, the fairleads are to be spaced 2.0 [m] centre to centre apart, if practicable and in no case be more than 3.0 [m] apart.

For ships of 150000 t DWT or less for which only one bow fairlead is required (See Table 3.1.1), it is in general to be fitted on the centreline.

3.3.3. Bow fairleads are to be capable of withstanding a load equivalent to the safe working load (SWL) of the bow chain stopper that they serve, and, in such condition, meeting the strength criteria specified in Sec.5. The load position is to be based on hawser angles as follows:

- in the horizontal plane, up to 90° from the ship's centreline, both starboard and portside

- in the vertical plane, up to 30° above and below horizontal.

3.3.4 Fairleads are normally of a closed type (as Panama chocks) and are to have an opening large enough to pass the largest portion of the chafing gear, pick-up rope and associated fittings.

For this purpose, the inner dimensions of the bow fairlead openings are to be at least 600 [mm] in width and 450 [mm] in height.

3.3.5 Fairleads are to be oval or round in shape.

The lips of the fairleads are to be suitably faired in order to prevent the chafing chain from fouling on the lower lip when heaving inboard.

The ratio of the diameter of the bearing surface of the fairlead to the diameter of the chafing chain, is to be not less than 7 to 1.

3.3.6 The fairleads are to be located as close as possible to the deck and, in any case, in such a position that the chafing chain is approximately parallel to the deck when it is under strain between the chain stopper and the fairlead.

3.4 Pedestal roller fairleads

3.4.1 Pedestal roller fairleads are to be used only when the mooring arrangement design is not permitting direct straight leads to a winch storage drum. The number of pedestal roller fairleads for each bow chain stopper is not to exceed two, and the angle of change of direction of the pick-up rope is to be kept as low as possible

3.4.2 Pedestal roller fairleads are to be so positioned as to provide a direct lead to bow chain stopper and bow fairlead. (See Fig.2.1.3).

They are to be fitted not less than 3 [m] behind the bow chain stopper.

3.4.3 The pedestal roller fairleads are to be capable to withstand a horizontal force equal to:

- the resultant force due to an assumed pull of 225 [kN] in the pick-up rope; or
- 225 [kN], whichever is greater.

Stresses generated by this horizontal force are not to exceed those given in 5.2.

3.4.4 It is recommended that the fairlead roller is to have a diameter not less than 7 times the diameter of the pick-up rope. Where the diameter of the pick-up rope is unknown it is recommended that the roller diameter should be at least 400 [mm].

3.5 Winches or capstans

3.5.1 Winches or capstans used to handle the mooring gear are to be capable of exerting a continuous duty pull of not less than 150 [kN] and withstanding a braking pull of not less than 225 [kN]. Winches or capstans used to handle the mooring gear are to be capable of heaving inboard a load of at least 15 [t]. W

3.5.2 Winch storage drums used to stow the pick-up rope, are to be of sufficient size to accommodate 150 [m] of rope of 80 [mm] diameter.

Section 4

Supporting Hull Structures

4.1 General

4.1.1 The bulwark plating and stays are to be suitably reinforced in the region of the fairleads.

4.1.2 Deck structures in way of bow chain stoppers, including deck seatings and deck connections, are to be suitably reinforced to comply with the strength criteria specified in Sec.5.

4.1.3 The deck structures in way of the pedestal roller fairleads and in way of winches or capstans as well as the deck connections are to be reinforced to withstand, respectively, the horizontal force defined in 3.4.3 or the braking pull defined in 3.5.1 and to meet the strength criteria specified in Sec.5.

4.1.4 The deck plating in way of the mooring capacity mentioned in 4.1.2 and 4.1.3 is to be increased by means of suitable insert plates.

4.1.5 Main welds of the bow chain stoppers with the hull structure are to be inspected by means of non-destructive examination for their complete length.

Section 5

Strength Criteria

5.1 Design loads

5.1.1 The bow chain stopper and the bow fairlead are to be designed considering a horizontal chafing chain tension equal to 2 times the SWL given in Table 3.1.1.

5.2 Allowable stresses

5.2.1 The equivalent stress, σ_e, induced by the load given in 5.1.1 is not to exceed 1.0 σ_y or 0.6 σ_u whichever is lesser.

where,

$$\sigma_e = \sqrt{\sigma^2 + 3\tau^2}$$

σ = tensile stress
τ = shear stress
σ_y = Minimum yield stress [N/mm^2], of the component material
σ_u = Tensile strength [N/mm^2], of the component material.

Vapour Control Systems

Contents

Section

1	*General Requirements*
2	*Vapour Piping Systems*
3	*Instrumentation*
4	*Vapour Balancing*
5	*Operational Instructions*
6	*Operational Limitations and Conditions to be Reflected in the Instruction Manual*
7	*List of Cargoes – Vapour Control*

Section 1

General Requirements

1.1 Application

1.1.1 The requirements given in this chapter apply to systems for control of vapour emissions from cargo tanks on ships which are assigned class Notation 'OIL TANKER' or 'CHEMICAL TANKER' or 'ORE OR OIL CARRIER' or 'OIL OR BULK CARRIER'.

1.2 Class notations

1.2.1 Vessels complying with the requirements given in this chapter except those given in 3.2.2 and Section 4, will be eligible to be assigned class notation 'VCS1'.

Compliance with these requirements is considered to meet the requirements of IMO MSC/Circ.585.

Such vessels, when additionally complying with requirements of Section 4 (vapour balancing), will be assigned class notation 'VCS1-B'.

1.2.2 Vessels complying with the requirements in this chapter, except Section 4, and the requirements of United States Coast Guard given in the regulation CFR46 Part 39 - "Vapour Control Systems", will be eligible to be assigned class notation 'VCS2'.

Such vessels, when additionally complying with requirements of Section 4(vapour balancing), will be assigned class notation 'VCS2-B'.

1.3 Definitions

1.3.1 '*Diluted'* means the condition in which the concentration of a flammable gas in a flammable gas/air mixture is less than 50% of the lower explosive limit of the gas.

1.3.2 '*Enriched*' means the condition in which the concentration of a flammable gas in a flammable gas/air mixture is not less than 150% of the upper explosive limit of the gas. When flammable gases are mixed to achieve an enriched condition, the upper explosive limit of the flammable gas mixture shall be used.

1.3.3 '*Flammable cargoes*' means cargoes of crude oil, petroleum products and chemicals having a flashpoint not exceeding 60°C (closed cup test), as determined by an approved flashpoint apparatus and a Reid vapour pressure which is below atmospheric

pressure and other liquid products having a similar fire hazard.

1.3.4 '*Inerted*' means the condition in which the oxygen content in a flammable gas/air mixture is 8% or less by volume.

1.3.5 '*Independent*' as applied to two systems means that one system will operate with a failure of any part of the other system except power sources and electrical feeder panels.

1.3.6 '*Maximum allowable transfer rate'* means the maximum volumetric rate at which a tanker may receive cargo or ballast.

1.3.7 '*Tanker vapour connection'* means the point in a tanker's fixed vapour collection system where it connects to a vapour collection hose or arm.

1.3.8 '*Terminal vapour connection'* means the point in a terminal's vapour collection system where it connects to a vapour collection hose or a vapour collection arm.

1.3.9 '*Vapour balancing'* means the transfer of vapour displaced from the tank of a tanker receiving cargo into a tank of a facility delivering cargo via a vapour collection system.

1.3.10 '*Vapour collection system'* means an arrangement of piping and hoses used to collect vapour emitted from a tanker's cargo tanks and transport the vapour to a vapour processing unit.

1.3.11 '*Vapour destruction unit'* means a vapour processing unit that destroys cargo vapour by a means such as incineration.

1.3.12 '*Vapour dispersion system'* means a vapour processing unit which releases cargo vapour to the atmosphere through a venting system not located on the tanker being loaded or ballasted.

1.3.13 '*Vapour emission control system'* means an arrangement of piping and hoses used to control vapour emissions collected from a tanker and includes the vapour collection system and the vapour processing unit.

1.3.14 '*Vapour processing unit'* means the components of a vapour control system that recovers, destroys or disperses vapour collected from a tanker.

1.3.15 '*Vapour recovery unit'* means a vapour processing unit that recovers cargo vapour by a non-destructive means such as lean oil absorption, carbon bed adsorption or refrigeration.

1.3.16 '*Service ship'* means a ship which receives and transports liquid cargoes between a facility and another ship and vice versa.

1.3.17 '*Topping-off operation'* means operation of transfer of liquid cargo from a service ship to another ship in order to load the receiving ship at a deeper draft.

1.4 Documentation

1.4.1 The following plans and particulars are to be submitted:

a) A schematic drawing of the vapour piping systems giving information about material, dimensions, pressure rating etc. Details about penetrations, joining etc. are also to be submitted.

b) A schematic drawing of the gauging and overfill protection equipment showing:

- Working principle
- Independent control
- Location of electrical equipment in gas dangerous area
- Single line diagram of intrinsically safe equipment
- Use of explosion protected equipment with reference drawing together with certificates.

c) A schematic drawing of the venting system (Inert Gas System if relevant) including necessary data for verifying venting capacities of the P/V valves. Pressure monitoring and alarm system to be documented including wiring diagrams, cable penetrations and connections etc.

d) Pressure drop calculations comparing cargo transfer rate to pressure drop from the farthest tank to the vapour connection, including any hoses used. Calculation to be made for each cargo handled at the maximum and minimum transfer rate.

e) Overfill alarm calculations showing time available between alarm setting and overfill at max. loading rate for each tank.

f) Determination of maximum loading rate.

g) Fitting and test certificate for detonation flame arrester, if relevant.

h) Fitting and documentation regarding oxygen analyzer and alarm etc., if relevant.

i) Details of insulating flange, if relevant.

j) Instruction manual.

Section 2

Vapour Piping Systems

2.1 Material

2.1.1 Permanent piping

Piping material is to be as required for cargo tank venting system.

2.1.2 Flexible hoses

Material of hoses is to be resistant to vapours handled and hoses are to comply with the following:

- Maximum allowable working pressure is to be at least 0.34 bar.
- The hoses are to be capable of withstanding at least 0.14 bar vacuum without collapsing.
- Burst pressure is not to be less than five times the maximum allowable working pressure.
- The hoses are to be electrically continuous with a maximum resistance of 10,000 ohms.
- Hoses are to be abrasion resistant and non-kinking.
- Be provided with suitable hose handling equipment.

2.2 Vapour collection piping

2.2.1 General

Each vessel is to have vapour collection piping which is permanently installed, with a tanker vapour connection located as close as practical to the loading manifold. In lieu of permanent piping, chemical tankers are permitted to have a permanent vapour connection at each cargo tank for connection to a vapour hose which should be kept as short as practicable and in no case longer than 3 [m].

If a tanker simultaneously collects vapours from cargoes, which react in a hazardous manner with other cargoes these incompatible vapours are to be kept separate throughout the entire vapour collection system.

Means are to be provided to eliminate liquid condensate which may collect in the system, such as draining and collecting liquid from each low point in the line.

Vapour collection piping is to be electrically bonded to the hull and to be electrically continuous.

When inert gas distribution piping is used for vapour collection piping means to isolate the inert gas supply from the vapour collection system is to be provided. The inert gas main isolation valve required in Pt.6, Ch.8, Cl.15.2.2.3.1.3 may be used to satisfy this requirement.

The vapour collection system is not to disable the proper operation of the cargo tank venting system. However, a vapour collection piping may be common or partly common with the vent piping and/or the Inert Gas System and Inert Gas Piping System piping (Pt.5, Ch.2, Sec.8).

2.2.2 Vapour manifold

OCIMF's Recommendations for Oil Tanker Manifolds and Associated Equipment (latest revision) is also to be referred.

An isolation valve capable of manual operation is to be provided at each tanker vapour connection. The operating position of this

valve is to be readily determined visually (open/closed indication).

The end of each vapour collection pipe or vapour collection hose is to be readily identifiable to prevent mis-connection.

In order to prevent the possible mis-connection of the vapour manifold to a shoreside terminal liquid loading line, each vapour connection flange is to conform to the applicable industry standard (OCIMF). This provision is applicable regardless of the size of the ship.

Number and position

Four vapour connections are to be provided, two on each side of the ship, with presentation flanges at the same height above the deck as the cargo manifold. One vapour connection is to be located forward of the manifold and one located aft of the manifold on each side of the ship.

Labelling

The first 1.0 [m] inboard of each manifold is to be painted on its exterior surfaces, excluding flange faces. The painted area is to be divided into three bands with the outboard and inboard bands being red and 100 [mm] wide and the centre band being yellow and 800 [mm] wide.

2.3 Capacity

2.3.1 Pressure drop calculations

The capacity of the vapour collection system is to be documented through pressure drop / flowrate curves. When calculating pressure drop the following is to be used:

a) Vapour growth rate, (VGR) i.e. increase of flowrate due to vapourization of the cargo:

$$VGR = 1 + 0.25\frac{P_v, 45}{86.2}$$

P_v, 45 = saturated vapour pressure at 45°C in kPa abs.

b) Density of the cargo vapour and air/inert gas mixture (δ_{va},45):

δ_{va},45 = [SG_v V_v,45 + V_a,45] 0.0324 $P_{p/v}$

SG_v = specific gravity of cargo vapour.

V_v,45 = partial volume of vapour at

$$45°C = \frac{P_v,45}{P_t,45}$$

Where,

P_t,45 = total vapour air pressure at 45°C in kPa abs.

V_a,45 = partial volume of air at 45°C = 1 – V_v,45

$P_{p/v}$ = cargo tank P/V valve pressure setting in kPa abs.

c) Maximum cargo tank pressure is not to exceed 80% of opening pressure of the P/V valves.

Note:

- For oil tankers calculations using mixture density of 3.0 [kg/m^3] and vapour growth rate of 1.25 will cover all cargoes the ship may carry.

- For chemical tankers mixture density of 3.6 [kg/m^3] and vapour growth rate of 1.2 will cover all chemicals except those with a Reid's vapour pressure above atmospheric (IBC Code 15.14). For these cargoes additional calculations are needed using values applicable for the actual cargoes. (See Section 7).

Section 7 lists density and vapour growth values for a range of actual cargoes.

Section 3

Instrumentation

3.1 Cargo gauging

3.1.1 Cargo tank gauging equipment

Each cargo tank of a tanker that is connected to a vapour collection system is to be equipped with a cargo gauging device which:

- provides a closed gauging arrangement that does not require opening the tank to the atmosphere during cargo transfer;

- allows the operator to determine the liquid level in the tank for the full range of liquid levels in the tank;
- indicates the liquid level in the tank, at the location where cargo transfer is controlled.

- if portable, is installed on tank during the entire transfer operation.

3.2 Cargo tank level alarms

3.2.1 High level alarm

Each cargo tank of a tanker is to be equipped with a high level alarm system, which is to:

- be independent of the cargo gauging system. However, for vessels where the notation VCS2 is envisaged, a high level alarm system integral with the cargo gauging system will be accepted.

- come into operation when the normal tank loading procedures fail to stop the tank liquid level exceeding the normal full condition;

- give a visual and audible tank high level alarm to the ship's operator;

- have alarms fitted in the cargo control room, where provided, but in each case in such a position that they are immediately received by responsible members of the crew;

- give alarm in the event of loss of power to the alarm system or failure of the electrical circuitry to the tank level sensor;

- be able to be function tested from the outside of the tank for proper operation prior to each transfer or contain an electronic self-testing feature which monitors the condition of the alarm circuitry and sensor.

3.2.2 Overfill alarm

For vessels where the notation VCS2 is envisaged, each cargo tank of a tanker is to be equipped with an overfill alarm system (High-high level) which is to:

- be independent of the cargo gauging system and the high level alarm system specified in 3.2.1 above.

- come into operation after the high level alarm, but early enough to allow for action to prevent tank overflow.

- give a visual and audible tank overfill alarm to the ship's operator.

- have alarms fitted in the cargo control room, where provided and in the cargo deck area.

- give alarm in the event of loss of power to the alarm system or failure of the electrical circuitry to the tank level sensor;

- be able to be checked from the outside of tank for proper operation prior to each transfer or contain and electronic self-testing feature which monitors the condition of the alarm circuitry and sensor.

3.3 Vapour pressure alarms

3.3.1 General

Each vapour collection system is to be fitted with a pressure sensing device that senses the pressure in the main vapour collection line, which:

- has a pressure indicator located on the vessel where the cargo transfer is controlled e.g. cargo control room (CCR);

- has a high pressure and a low pressure alarm that:
    - is audible and visible on the vessel where cargo transfer is controlled e.g. CCR;
    - give alarms at a high pressure of not more than 90 percent of the lowest pressure relief valve setting in the cargo tank venting system;
    - give alarms at a low pressure of not less than 100 [mm] WG for an inerted tankship, or the lowest vacuum relief valve setting in the cargo tank venting system for a non-inerted tank.

Pressure sensors fitted in each cargo tank are acceptable as equivalent to pressure sensors fitted in each main vapour collection line.

Section 4

Vapour Balancing

4.1 General

4.1.1 Application

Requirements in this section apply to ship's engaged in the transportation of bulk liquid cargoes between a facility and another ship and vice versa. Compliance with these requirements is necessary for assignment of additional qualifier "B" to the class notations VCS1 or VCS2. (i.e. VCS1-B or VCS2-B, as applicable).

4.2 Design and equipment

4.2.1 Where the cargo tanks on a ship discharging cargo and a ship receiving cargo are inerted, the discharging ship must:

- have a means to inert the vapour transfer hose prior to transferring cargo vapour;
- have an oxygen analyzer with a sensor or sampling connection fitted within 3 [m] of the ship vapour connection which:
    - activates an audible and visible alarm at a location on the discharging ship where cargo transfer is controlled when the oxygen content in the vapour collection system exceeds 8 percent by volume;
    - has an oxygen concentration indicator located on the discharging ship from where the cargo transfer is controlled;
    - has a connection for injecting a span gas of known concentration for calibration and testing of the oxygen analyzer. (The installation of the oxygen analyzer is to be specially considered).

4.2.2 Where the cargo tanks on a ship discharging cargo are not inerted the vapour collection line on the receiving ship is to be fitted with an approved detonation arrester located within 3 [m] of the ship vapour connection.

4.2.3 An electrical insulating flange or one length of non-conductive hose is to be provided between the ship vapour connection on the service ship and the vapour connection on the ship being lightered or topped-up.

Section 5

Operational Instructions

5.1 Instruction manual

5.1.1 Operational instructions

Each tanker utilizing a vapour emission control system is to be provided with written operational instructions covering the particular system installed on the tanker. The instructions are to encompass the purpose and principles of operation of the vapour emission control system and provide an understanding of the equipment involved and associated hazards. In addition the instructions are to provide an understanding of operating procedures, piping connection sequence, start-up procedures, normal operations and emergency procedures. Instructions are also to include an understanding of the shoreside terminal equipment and operating procedures. The instructions are to be in working language of the ship and additionally a copy in English language is to be available on board ship.

Instructions are to contain information on the tanker's vapour collection system including:

- a line diagram of the tanker's vapour collection piping indicating the locations and purpose of all control and safety devices;
- the maximum allowable transfer rate as limited by the venting capacity of the pressure or vacuum relief valves, or any other factor which would limit the transfer rate;
- the maximum pressure drop in the ship's vapour collection system for various transfer rates;
- the pressure relief settings of each pressure and vacuum relief valve;
- pre-transfer procedures;
- procedures are to be followed in the event of a fault during vapour collection operations.

The operational limitations and conditions given in Section 6 are to be reflected in the Operational Instructions.

Section 6

Operational Limitations and Conditions to be Reflected in the Instruction Manual

6.1 Procedures

6.1.1 Established industry guidelines are to be observed, as applicable, with regard to preparation for transfer and transfer of cargo and ballast into cargo tanks.

6.1.2 The rate of cargo transfer is not to exceed the maximum allowable transfer rate as determined by the lesser of the following:

- the venting capacity of the pressure relief valves in the cargo tank venting system divided by a factor of at least 1.25

- the vacuum relieving capacity of the vacuum relief valves in the cargo tank venting system

- the rate based on pressure drop calculations for a given pressure at the vapour connection facility, such that the pressure in any cargo tank connected to the vapour collection system does not exceed 80% of the opening set pressure of any pressure relief valve in the cargo tank venting system.

6.1.3 When the venting capacity is dimensioned for thermal breathing only, the capacity of the P/V breaker as required by SOLAS for IG systems is to be regarded as the basis for venting in the determination of the total permissible loading rate.

6.1.4 A cargo tank is not to be filled higher than the level at which the overfill alarm is set.

6.1.5 A cargo tank is not to be opened to the atmosphere for gauging or sampling while the tanker is connected to a vapour emission control system unless loading to the tank is stopped, the tank is isolated from any other tank which is in the process of being loaded and precautions are taken to reduce any pressure in the cargo tank vapour space and prevent an electrostatic spark from occurring.

6.1.6 If the tanker is equipped with an inert gas system the isolation valve required by Pt.6, Ch.8, Cl.15.2.2.3.1.3 is to remain closed during vapour transfer.

6.1.7 Unless equipped with an automatic self-test and circuit monitoring feature, each tank level alarm system required by 3.2 on a cargo tank being loaded, is to be tested at the tank for proper operation prior to the start of cargo transfer.

Section 7

List of Cargoes – Vapour Control

7.1 List of cargoes

7.1.1 This list covers a range of cargoes normally carried and gives vapour pressure and specific gravity, as well as density of vapour/air mixture and vapour growth rate at 45°C.

Chemical name	Vapour pressure 45°C kPa, abs.	Vapour specific gravity	Vap/air density 45°C [kg/m^3]	Vapour growth rate
Acetic acid	6,34	2,07	1,413	1,02
Acetic anhydride	2,76	3,50	1,414	1,01
Acetone	68,95	2,00	2,098	1,20
Acetone cyanohydrin	2,76	2,90	1,396	1,01
Acetonitrile	0,21	1,41	1,339	1,00
Acrylic acid	2,76	2,48	1,383	1,01
Acrylonitrile	34,47	1,80	1,642	1,10

Chapter 30

Environmental Protection

Contents

Section

1 *General Requirements*
2 *CLEAN-SEA Notation*
3 *CLEAN- AIR Notation*
4 *Environmental Protection – EP Notation*

Section 1

General Requirements

1.1 Application

1.1.1 A ship or a marine structure meeting the requirements for Environmental protection of this chapter will be assigned notations indicated in 1.1.2 to 1.1.4 below and a suitable entry will be made in the Register Book. Compliance with this chapter and the assignment of notations is optional.

1.1.2 In order to be eligible for the class notation “EP”, a ship is to meet the requirements covered in Section 2, Section 3 and Section 4.

1.1.3 Section 2 gives the requirements to be complied with for control and prevention of polluting substances into the sea. A ship meeting the requirements of this section will be eligible for notation “CLEAN-SEA”.

1.1.4 Section 3 gives the requirements to be complied with for control and prevention of emission of polluting substances in the air. A ship meeting the requirements of this section will be eligible for notation “CLEAN- AIR”.

1.1.5 It is a prerequisite for assignment of the class notation EP that the applicable requirements of the following Annexes to the International Convention for the Prevention of Pollution from ships, MARPOL 73/78, as amended are fully complied with.

i) Annex I – Regulations for the Prevention of Pollution by Oil
ii) Annex II – Regulations for the Control of Pollution by Noxious Liquid Substances in Bulk
iii) Annex III – Regulations for the Prevention of Pollution by Harmful Substances Carried by Sea in Packaged Form
iv) Annex IV – Regulations for the Prevention of Pollution by Sewage from Ships
v) Annex V – Regulations for the Prevention of Pollution by Garbage from Ships
vi) Annex VI – Regulations for the Prevention of Air Pollution from ships.

In addition to above, the following International Standards, guidelines and recommendations are also to be complied with, as applicable:

i) Diesel Engine Exhaust NOx Content – NOx Technical Code, (2008), as amended.
ii) Refrigerants and fire-fighting gases – Montreal Protocol on Substances that Deplete the Ozone Layer
iii) Shipboard Incinerators – IMO Resolution MEPC 244(66) 2014 Standard Specification for

Shipboard Incinerators, as amended by MEPC.368(79).

iv) Cargo Vapour Emission Control – IMO standard for Vapour Emission Control Systems, MSC/Circ.585 or USCG Title 46 CFR Part 39 Vapour Control System (See part 5, Ch. 29 of the Rules for Construction and Classification of Steel ships)

v) Ballast Water – International Convention for the Control and Management of Ships' Ballast Water and Sediments (BWM Convention)

vi) International Convention on the Control of Harmful Anti-fouling Systems on Ships, 2001.

Where the flag administration has additional requirements to the above related environmental protection, those requirements are to be complied with and applicable certificates of compliance are to be obtained by the owners, for assignment of the EP notation.

1.1.6 Compliance with the rules are to be verified through inspection, measurements and sampling of defined environmental parameters in accordance with the requirements of the rules in this chapter and with identified standards or guidelines.

1.1.7 Environmental management systems, e.g. ISO 14000, are not part of the rules. Fulfillment of the requirements in the rules may, however, facilitate goals and improvement tasks defined through ISO 14000 implementation.

1.1.8 Special ship types and ships with unconventional propulsion machinery systems see Table 1; will be subject to special consideration covering specific items not covered by the standard rules. Tankers for oil smaller than 150 tons gross tonnage and other ships smaller than 400 tons gross tonnage will also be subject to special consideration.

1.1.9 Any matter detrimental to the environmental performance of the ship in turn affecting the assignment of the EP class notation should be notified to IRS.

Table 1 : Ship types and propulsion machinery systems that will be specially considered

Ship types: Liquefied gas carriers Floating storage, production and offloading systems
Propulsion machinery systems: Gas turbines

1.2 Definitions : main parameters

1.2.1 Emissions to air or emissions

All emissions to air which are caused by or needed for the operation of the ship, energy consumers, cargo, passengers and crew on board a vessel and any toxic emissions caused by operation, protection and conservation of vessel or cargo.

1.2.2 Discharges to sea or discharges

All discharges to sea which are caused by or needed for operation of the ship, energy consumers, cargo, passengers and crew on board a vessel and any toxic discharges caused by protection and conservation of vessel or cargo.

1.2.3 Deliveries to shore

Delivery of potential pollutants to shore for controlled disposal, recycling etc.

1.2.4 Accidental emissions or discharges

All emissions to air or discharges to sea, caused by unforeseen or unplanned events, of substances needed for energy consumers, cargo, passengers and crew on board a vessel and any toxic emissions caused by protection and conservation of vessel or cargo.

1.3 Definitions and characteristics, systems and components

1.3.1 "Ballast Water" means water with its suspended matter taken on board a ship to control trim, list, draught, stability or stresses of the ship.

1.3.2 Ballast water system

Ballast water systems comprise:

- Tanks for ballast water
- Associated piping and pumping systems.

1.3.3 Ballast water Management: means mechanical, physical, chemical and biological processes, either singularly or in combination, to remove, render harmless or avoid the uptake or discharge of Harmful Aquatic Organisms and Pathogens within Ballast Water and Sediments.

1.3.4 Bilge water

Bilge water is oily water removed from the machinery space bilges. Bilge water removed from cargo holds of bulk carriers and general cargo vessels is not affected by the rules in this chapter.

1.3.5 Cargo handling systems

Cargo handling systems covered by the rules in this chapter comprise:

- Cargo tank vents for tankers with cargoes where evaporation may occur during loading, transport and discharge. (e.g. Tanker for Oil, Tanker for Chemicals, Tanker for Liquefied Gas)

- Pumping and piping systems for tankers carrying cargoes that may cause global or local pollution.

1.3.6 Cargo residues

Cargo residues cover remains of cargo (oil or chemical contaminated water from cargo tank area, slop tanks and cargo pump room). Cargo residues may be present in discharged water used for cleaning cargo tanks and discharged ballast water from tankers without 100% segregated ballast tanks.

1.3.7 Casualty

Casualties covered by the rules in this chapter are defined as serious unplanned incident(s), e.g. grounding, collision or other incident damaging the hull's structural integrity, fire, sinking etc. The consequence of a situation of total loss will be:

- Cargo, or cargo containment system, is damaged and cargo spilt into the sea
- The integrity of the ship is damaged causing oil spills, etc.

1.3.8 Combustion machinery

Combustion machinery comprises:

- Internal combustion engines, both marine diesel engines and gas turbines
- Boilers.

The rules in this chapter cover the emission of oxides of nitrogen (NO_x) and sulphur (SO_x) from combustion machinery exhaust gases to the atmosphere

1.3.9 Fire-fighting system

The rules in this chapter cover the active fire-fighting media used in fixed fire-righting systems.

1.3.10 Garbage

Garbage includes all kinds of food wastes, domestic wastes and operational wastes, all plastics, cargo residues, cooking oil, fishing gear and animal carcasses excluding fresh fish and parts thereof, generated during normal operation of the ship and liable to be disposed of continuously or periodically except those substances excluded specifically. Garbage generated by passengers on passenger vessels is included in the rules in this chapter.

Systems for garbage treatment include the following:

- Garbage sorting systems, typically: glass, paper, metals etc.
- Compacting systems
- Storage systems
- Incinerators.

Sewage and waste oils are defined separately and not as garbage.

1.3.11 Painting and antifouling systems

Antifouling paint of the underwater area gives a continuous discharge of active ingredients to the sea. This effect is covered by the rules in this chapter.

In addition, painting and antifouling systems emit volatile organic compounds (VOC) during application. This effect is not considered by the rules in this chapter.

1.3.12 Port

The ship is considered in port from ordering "stand by" prior to entering port to ordering "full ahead" when leaving the port. The time will be confirmed by entries in the ship's logbook.

1.3.13 Refrigeration systems

The rules in this chapter cover refrigerant media used in refrigeration plants on conventional reefer ships, fishing vessels, liquefied gas carriers with re-liquefaction plants and other ships with centralized cargo refrigeration systems. They are also applicable for centralized air conditioning and refrigeration systems onboard. Domestic type stand-alone air conditioning units and refrigerators are not covered.

Refrigerants may escape to the atmosphere through refrigeration system leakage, service work and dismantling at the end of the system's working life.

1.3.14 Sewage

Sewage is defined to include:

- Drainage and other wastes from all toilets, urinals and WC scuppers. For passenger ships this applies both for crew and passenger areas
- Drainage from medical premises (dispensary, sick bay etc.) via wash basins, wash tubs and scuppers located in such rooms
- Drainage from spaces containing living animals, or
- Other waste waters when mixed with any of the drainage systems defined above.

Systems for sewage handling have varying complexity including:

- Holding tanks
- Sewage treatment plants, e.g.:
  - Disinfecting
  - System for separating solids from liquids
  - Comminuters/grinders
  - Discharge systems, ashore, or to sea.

1.3.15 Waste oil

Shipboard waste oils comprise the following:

- Used lubrication and hydraulic oils
- Oil leaked from lubrication and hydraulic oil systems
- Leakage from fuel oil systems
- Sludge from fuel and lubrication oil treatment systems (separators, filters, etc.).

Waste oils may be dealt with onboard, or pumped ashore. Cargo residues in slop tanks, etc. are considered separate from operational waste oils.

1.4 Abbreviations

BCH Code	Code for the Construction and Equipment of Ships Carrying Dangerous Chemicals in Bulk (Bulk Chemical Code)
CFC	Common name for refrigerants, e.g. : CFC-11 (Trichlorofluoromethane), CFC-12 (Dichlorofluoromethane) etc.
CFR	Code of Federal Regulations
GWP	Global Warming Potential (CO_2 = 1, time horizon 100 years)
HCFC	Hydrochlorofluorocarbons
HFC	Hydrofluorocarbons
IACS	International Association of Classification Societies
IAPP Certificate	International Air Pollution Prevention Certificate
IBC Code	The International Code for the Construction and Equipment of ships Carrying Dangerous Chemicals in Bulk
IOPP Certificate	International Oil Pollution Prevention Certificate
ISM Code	"International Safety Management (ISM) Code"' means the International Management Code for the Safe Operation of Ships and for Pollution Prevention as adopted by the Organization (IMO) by resolution A.741(18), as may be amended by the Organization. (ISM Code 1.1)
ISO	International Organization for Standardisation
IMO	International Maritime Organization
MARPOL or MARPOL 73/78	The International Convention for the Prevention of Pollution from Ships, 1973 as modified by the Protocol of 1978 thereto
MSC	Maritime Safety Committee (IMO)
MEPC	Maritime Environmental Protection Committee (IMO)
NO_x	Oxides of nitrogen
ODP	Ozone depleting potential (Compared to CFC 11)
SCR	Selective Catalytic Reduction
SO_x	Oxides of sulphur
TBT	Tributyltin (active ingredient in antifouling paint)
USCG	US Coast Guard
VOC	Volatile organic compound
SEEMP	Ship Energy Efficiency Management Plan
EEDI	Energy Efficiency Design Index
IEE Certificate	International Energy Efficiency Certificate

1.5 International recommendations, standards and references

1.5.1 International recommendations, standards and references have been used as foundation for the rules, although even if the rule requirements may be more stringent. When setting the emission and discharge limits and determining the measuring procedure, due consideration has been given to technical and practical limitations inherent in the design and construction of different types of ships.

1.5.2 International recommendations, standards and references with provisions used by IRS when developing the rules are reflected in the references specified in 1.1.5. Unless a particular edition is explicitly referred to, the latest edition of each standard applies.

1.6 Information and Documentation

1.6.1 All plans, certificates, operational procedures and other documentation of compliance as detailed in section 2, 3 and 4 are to be available to IRS prior to assigning the class notation “CLEAN-SEA” OR “CLEAN-AIR” OR “ EP”.

1.6.2 Discharge limiting and monitoring equipment are to be certified as type approved.

1.7 Environmental management Plan

1.7.1 An Environmental Management Plan, specific to the ship is to be developed and submitted to IRS for information describing at least the procedures given in sections 2, 3 and 4 respectively.

Section 2

Clean Sea Notation

2.1 Application

2.1.1 This section gives the requirements applicable for assignment of the Notation "CLEAN-SEA"

2.2 Information and Documentation

2.2.1 Table 2.1 lists the documents, to be submitted for approval and/or information in connection with prevention of polluting substances into sea:

i) by oil
ii) by noxious liquid substances
iii) by harmful substances carried by sea in packaged form
iv) by sewage
v) by garbage
vi) by other sources

The documents listed in Table 2.1 do not take account of drawings necessary for the issuance of the "International Pollution Prevention certificate for the Carriage of Noxious Liquid Substances in Bulk" or of the "International Certificate of Fitness for the Carriage of dangerous Chemicals in Bulk" or of the "International Certificate of Fitness for the Carriage of Liquefied Gases in Bulk", as applicable.

Guidance note:

It should be noted that some of the required documentation is additional to and different from documentation normally considered "Class documentation" as delivered from the new building yard. This is in particular the case for operational procedures specified in section 2, 3 or 4 as applicable that may require input from the Owner.

2.3 Design and procedural requirements

2.3.1 Prevention of sea pollution by oils

2.3.1.1 General

Provided the ship has been granted a valid IOPP certificate issued by an Administration or by a recognized organization on behalf of an Administration, in accordance with MARPOL 73/78 Annex I, as applicable, the additional specific requirements as per 2.3.1.2, 2.3.1.3 & 2.3.1.4 apply.

Table 2.1 : Documents to be submitted in connection with prevention of polluting substances into sea		
No.	**A/I**	**Document**
1	I	Copy of the IOPP Certificate
2	A	Drawings with indication of tanks' volume and distance from the base line and shell plates as per 2.3.1.2 **(1)**
3	A	Schemes of the fuel oil, lubricating oil and relevant residue systems details containing the necessary information to verify the requirements as per 2.3.2 **(1)**
4	I	Oil Systems Record Book
(1) if these details are shown in the drawings which are used for the classification of the ship, such drawings and schemes may also be used to verify the requirements of these rules. Note : A = to be submitted for approval; I = to be submitted for information.		
5	I	Copy of the "International Pollution Prevention Certificate for the Carriage of Noxious Liquid Substances in Bulk" or copy of the "International Certificate of Fitness for the Carriage of Dangerous Chemicals in Bulk" or copy of the "International Certificate of Fitness for the Carriage of Liquefied Gases in Bulk, as applicable.
(1) I = to be submitted for information.		
6	I	General arrangement plan with indication of the zone intended for the stowage of the harmful packaged substances in relation to the other zones of the ship
7	I	Plans of systems and equipment to discharge the harmful substances in case of emergency and to dispose of and water wash possible leaks
(1) I = to be submitted for information.		
8	I	General arrangement plan with indication of the sewage treatment plant enclosing details on treatment procedures (2)
9	I	Copy of the ISPP Certificate and type approval certificate for the sewage treatment plant according to MEPC 227(64).
10	A	Calculation of volume of holding tank(s) for sewage
11	I	General information on control and monitoring systems (2)
12	I	Sewage record book
Note A = to be submitted for approval; I = to be submitted for information. (2) Not required if the sewage treatment plant is an approved type.		
13	I	General information on garbage treatment equipment (2) (3)
14	A	Garbage management plan including garbage record book as specified by MARPOL 73/78 Appendix to Annex V
15	I	General description of control and monitoring systems of garbage treatment equipment (2)
Note: A = to be submitted for approval; I = to be submitted for information. **(2)** Not required if the garbage treatment equipment is of an approved type. **(3)** For incinerators see Sec.3.		

16	A	Ballast water management plan, including a ballast water record book, developed in accordance with G4 Guidelines (MEPC.127(53)) (Earlier approved plans in accordance with IMO Res.A.868(20) may be accepted unless the plan requires revision due to the installation of a ballast water management system.)
17	I	Copy of the AFS Certificate and details of TBT free antifouling paint
18	A	Calculation of volume of grey water holding tank(s) (passenger ships only)
19	I	Grey water record book (passenger ships only)
Note: A = to be submitted for approval; I = to be submitted for information.		
20	I	Ship Environmental Management Plan giving details as per 2.3.1.4, 2.3.3.6, 2.3.4.4, 2.3.5.4, 2.3.6.4 and 2.4.
Note I = to be submitted.		

2.3.1.2 Tank arrangement

a) For the purpose of these rules, tanks for fuel oil, sludge tanks and tanks for lubricating oil, whether or not for waste, of capacity exceeding 30 [m^3] are to be considered. Tanks with capacity not exceeding 30 [m^3] may be excluded provided the aggregate capacity of such excluded tanks is not greater than 600 [m^3]. Overflow tanks are to be included unless they are provided with an alarm for detection of liquid and operational procedures are foreseen for keeping such tanks empty. Double bottoms for lubricating oil located under the main engine are not considered in these Rules.

b) Such tanks are to be located above the moulded line of the bottom shell plating nowhere less than the distance 'h' specified below:

h = B/20 [m] or 2.0 [m] whichever is lesser.
The minimum value of h = 0.76 [m].
In the turn of the bilge area and at locations without a clearly defined turn of bilge, the tank boundary lines are to run parallel to the line of the midship flat bottom as shown in Fig.2.3.1.1.

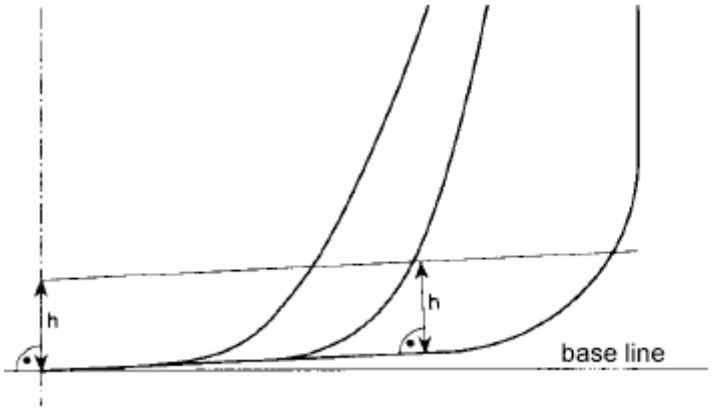

Fig.2.3.1.1 : Minimum distance of tank boundaries above bottom shell

c) For ships having an aggregate oil tank capacity of less than 5000 [m^3], such tanks are to be located inboard of the moulded line of the side shell plating, nowhere less than the distance "w" measured at right angles to the side shell as specified below: (See Fig.2.3.1.2).

w = 0.4 + 2.4 C/20000 [m];

The minimum value of w = 1.0 [m], however for individual tanks with oil capacity of less than 500 [m^3] the minimum value is 0.76 [m].

"C" is the total volume of the oil tanks [m^3] at 98% tank filling.

d) For ships having an aggregate oil tank capacity of 5000 [m^3] and over, such tanks are

to be located inboard of the moulded line of the side shell plating, nowhere less than the distance “w” measured at right angles to the side shell as specified below: (See Fig.2.3.1.2)

w = 0.5 + C/20000 [m] or 2.0 [m], whichever is the lesser.
The minimum value of w = 1.0 [m].

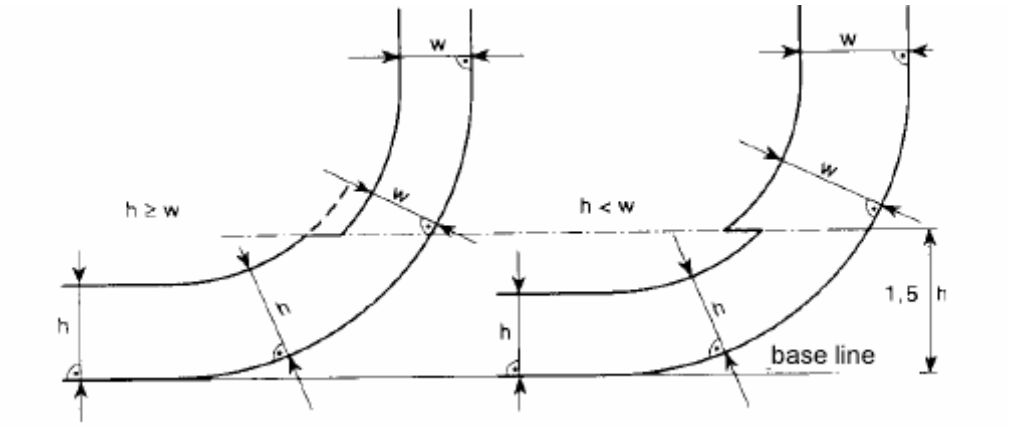

Fig. 2.3.1.2 : Minimum distance of tank boundaries from side shell

e) Lines of oil piping located at a distance from the ship’s bottom of less than “h” as defined in b) or from the ship’s side less than “w” as defined in c) and d) above, are to be fitted with valves or similar closing devices within or immediately adjacent to the oil tank.

These valves are to be capable of being brought into operation from a readily accessible enclosed space the location of which is accessible from the navigation bridge or propulsion machinery control position without traversing exposed decks. The valves are to close in case of remote control system failure (fail in a closed position) and are to be kept closed at sea at any time when the tank contains oil except that they may be opened during oil transfer operations.

f) Small suction wells in oil tanks may extend below the boundary line defined by the distance “h” provided that the distance between the well bottom and the bottom shell plating is not less than 0.5h.

g) Tanks of any volume intended to contain fuel or lubricating oil are not to be used also for ballast water.

h) All tanks and cofferdams, if any, around the tanks are to be so arranged as to be adequately inspected; such cofferdams are to be effectively protected against corrosion by means of proper protective coatings of a light colour in order to be easily examined.

2.3.1.3 Systems

i) Fuel oil and lubricating oil system

a) All fuel oil and lubricating oil tanks of capacity greater than 10 [m^3] are to be fitted with an overflow system and a high level alarm.

Acceptable alternatives are:

- An overflow system and a flow alarm in the overflow main
- No overflow system and two high level alarms (for instance at 90% and 95% of filling).

b) The alarms signals are to be given in a suitable station from which bunkering or transfer operations are controlled.

ii) Oily bilge water system for machinery spaces

a) The oil filtering equipment, complying with MARPOL Annex I, is to be provided with an oil content meter and with a 15 ppm alarm combined with automatic stopping device.

b) The effluent from the 15 ppm filtering equipment is to be capable of being

recirculated to a bilge holding tank. Bilge Holding tank is to be so arranged as to allow periodical removal of sediments and is to be fitted for the pre-separation of bilge water before transferring it to the separating or filtering equipment. Bilge holding tank is to be separate and independent from the sludge tanks.

c) The volume V of such a tank, in [m^3] is to be at least:

$V = 1 + 5.5P \cdot 10^{-4}$

Where P is the power of the propulsion engine plant in kW. In any case volume V need not be greater than 15 [m^3] .

In specific cases for instance with regard to the service, range and installed power, will be specially considered.

d) For ships operating with fuel oil having a mass density at 15°C greater than 0.94 [kg/cm^3] and viscosity at 50°C greater than 110 centistokes, the possibility of heating such a tank is to be provided.

iii) Sludge tank

a) Ships operating with heavy fuel oil are to be provided with tanks for sludge from the fuel oil purifiers without internal structures and with a suitable heating system.

b) The sludge tank is to be so arranged as to allow periodical removal of sediments. Sludge is either to be disposed of onboard through the incinerator or discharged ashore and is to be recorded in the oil record book.

c) Use of boilers for sludge disposal onboard is not allowed unless a treatment system or special device is installed to improve emissions generated by sludge incineration, subject to IRS's approval.

d) The total capacity of sludge tanks is to meet the criteria specified in MARPOL Annex I, Unified Interpretations 16.1 and 16.2, as applicable, based on the maximum period of voyage between ports where sludge can be discharged ashore, daily fuel oil consumption, homogenizers or sludge incinerators installed, and fuel purification.

2.3.1.4 Procedures

a) The lub.oil consumption of all systems having an oil to sea interface, such as main and auxiliary engines cooled by sea water, controlled pitch propellers, sterntubes, bow and stern thrusters, stabilizers, PODs etc., is to be recorded at least once a week in an "Oil Systems, record book" aimed at detecting, through unusually high consumption, oil leakage through sealing.

The log-book is to contain the list of all systems concerned, the consumption of each system recorded at least every week and corrective actions when carried out.

b) The Ship Environmental Management Plan referred to in 2.4 is to include procedures covering the following:

- Oily waste management including discharge criteria;
- Preparation, filling in and maintenance of the oil record book and of the "Systems oil consumption log-book";
- Periodical calibration, at least every twelve months, of the oil content meter referred to in 2.3.1.3; documentation is to be kept on board for examination during periodical surveys;
- Periodical cleaning of the bilge holding tank and of the sludge tank;
- Spillage during bunkering;
- Periodical checks of the overflow systems/alarms.

2.3.2 Prevention of sea pollution by noxious liquid substances carried in bulk as cargo

2.3.2.1 Provided the ship has been granted a valid "NLS" or a valid "ICOF CHE" certificate, as applicable, issued by an Administration or by a recognized organisation on behalf of an Administration, in accordance with MARPOL

73/78 Annex II, as applicable, there are no additional specific requirements to be complied with on this matter for the purpose of the issuance of the CLEAN-SEA notation.

2.3.3 Prevention of sea pollution by harmful substances carried by sea as cargo in packaged form

2.3.3.1 General

Harmful substances carried as cargo in packaged form are to be properly stowed and secured so as to minimize the hazards to the marine environment, according to MARPOL 73/78 Annex III, as amended.

2.3.3.2 Stowage

a) Harmful substances are to be properly stowed and secured so as to minimize the hazards to the marine environment without impairing the safety of the ship and persons on board.

b) Certain harmful substances may, for sound scientific and technical reasons, need to be prohibited for carriage or be limited as to the quantity which may be carried aboard any one ship. In limiting the quantity, due consideration is to be given to the size, construction and equipment of the ship, as well as the packaging and the inherent nature of the substances.

c) Each ship carrying harmful substances is to have a special list or manifest setting forth the harmful substances on board and the location thereof. A detailed stowage plan which sets out the location of the harmful substances on board may be used in place of such special list or manifest.

2.3.3.3 Empty packages

Empty packages which have been used previously for the carriage of harmful substances are themselves to be treated as harmful substances, unless adequate precautions have been taken to ensure that they contain no residue that is harmful to the marine environment.

2.3.3.4 Marking

a) Packages containing harmful substances are to be marked suitably with the correct technical name (trade names alone are not to be used) and, additionally, are to be durably marked or labeled to indicate that the substance is a marine pollutant. Such identification is to be supplemented where possible by other means, for example, by use of the relevant United Nations number.

b) The method of marking the correct technical name and of affixing labels on packages containing a harmful substance is to be such that this information will still be identifiable on packages surviving at least three months' immersion in the sea. In considering suitable marking and labeling, account is to be taken of the durability of the materials used and of the surface of the package.

c) Packages containing small quantities of harmful substances may be exempted from the marking requirements.

2.3.3.5 Leaks

a) Jettisoning of harmful substances carried in packaged form is not permitted, except where necessary for the purpose of ensuring the safety of the ship or saving life at sea.

b) Appropriate measures based on the physical, chemical and biological properties of harmful substances are to be taken to regulate the washing of leakages overboard, provided that compliance with such measures would not impair the safety of the ship and persons on board.

2.3.3.6 Procedures

The Ship Environmental Management Plan referred in 2.4 is to include procedures addressing the requirements of this item.

2.3.4 Prevention of sea pollution by sewage

2.3.4.1 General

Provided the ship has been given a valid ISPP Certificate issued by an Administration or by a recognized organization on behalf of an Administration, in accordance with MARPOL 73/78 Annex IV, as applicable, the additional specific requirements as per 2.3.4.2 to 2.3.4.4 are to be complied with.

2.3.4.2 Discharge of sewage at sea

All sewage discharges whether to sea or shore based facilities are to be recorded in the sewage record book with indication of the date, location and quantity of sewage discharged and are to comply with MARPOL Annex IV discharge requirements.

2.3.4.3 Sewage treatment plant

a) A sewage treatment plant, meeting operational requirements based on the standards and test methods as detailed in Resolution MEPC.227(64), as amended, is to be installed on board.

b) The ship is to be equipped with holding tank(s) for sewage with sufficient capacity to allow storage of sewage when in port or in no discharge areas. The minimum total capacity of such tank(s) is to be 2 days based on the maximum number of persons on board and 96 litres/person/day if a conventional system is used and 11 litres/person/day if a vacuum system is used.

   A smaller volume, in any case not lower than 50% of the above capacity, may be accepted provided that:

   - The ship is equipped with a post-treatment system for sewage, able to reduce the volume of the effluent (ex. By recycling part of the treated sewage water for on board use);
   - 2 days retention is ensured;
   - Technical documentation, including results of onboard tests, of the system's efficiency and of effluent volume reduction is documented to the satisfaction of IRS.

c) The sewage holding tank is to have a visual means of indication of the amount of its contents e.g.: float gauge.

d) The ship is to be equipped with a pipe leading to the exterior convenient for the discharge of sewage to a reception facility; such pipe is to be fitted with a standard shore connection in compliance with MARPOL Annex IV, and the materials, piping, fittings and equipment are to comply with the applicable requirements of the various Sections of these Rules.

e) Sewage holding tanks are to be equipped with high level alarms.

2.3.4.4 Procedures

The Ship Environmental Management Plan referred to in 2.4 is to include procedures covering the following:

- Sewage management including discharge criteria and use of holding tanks in port and no discharge areas;
- Preparation, filling in and maintenance of the sewage record book;
- Procedures for the cleaning and safe entry of sewage treatment systems and holding tanks, including the use of suitable personal protective equipment, are to be provided and implemented
- Only for passenger and ro-ro passenger ships, periodical analysis, at least every 6 months, of samples of the effluent to verify compliance with IMO Resolution MEPC 227(64) the results of such analysis are to be included in the sewage record book and made available during periodical surveys. The analysis is to be performed by an approved test laboratory;
- Disposal of sewage treatment plant residues.
  If the ship is not in a condition to dispose at sea of sewage treatment plant residues in accordance with international or national regulations, such residues are to be disposed of ashore or by incineration.

2.3.5 Prevention of sea pollution by garbage

2.3.5.1 General

The applicable requirements of MARPOL 73/78 Annex V, as amended, are to be complied with, in addition to the following additional specific requirements.

2.3.5.2 Placards, garbage management plans and garbage record-keeping

a) Placards which notify the crew and passengers of the disposal requirements of MARPOL Annex V are to be fitted on board as applicable.

b) The placards are to be written in the official language of the State whose flag the ship is entitled to fly and, for ships engaged in voyages to ports or offshore terminals under the jurisdiction of other States, in English or French or Spanish

c) A garbage management plan and record book is to be available on board. This plan is to provide written procedures for collecting, storing, processing and disposing of garbage, including the use of the equipment on board. It is also to designate the person in charge of carrying out the plan. Such plan is to be in accordance with the guidelines in Appendix 1 and written in the working langue of the crew.

d) For passenger ships, special consideration in the garbage management plan is to be given to the following potentially hazardous wastes:

- Photographic and x-ray development fluids
- Dry-cleaning solvents and waste fluids
- Print shop fluids
- Photocopying and laser printer cartridges
- Unused pharmaceuticals and those which are past their use-by-date
- Batteries
- Fluorescent and Mercury vapor lamp bulbs.

2.3.5.3 Waste recycling

For passenger ships other than ro-ro passenger ships:

a) a strategy of waste recycling is to be foreseen, adopted and documented;

b) the minimum total quantity of wastes landed for recycling (Wr) is to be 50% of recyclable wastes produced on board (Wb), where Wb = 40 Kg/person/year based on the number of persons the ship is certified to carry.

The amount of waste landed for recycling is to be recorded in the garbage record book and different wastes are to be collected and landed separately.

Fore the purpose of this Rule, recyclable wastes are:

- Plastic
- Aluminum
- Glass
- Paper-cardboard.

2.3.5.4 Procedures

The Ship Environmental Management Plan referred to in 2.4 is to include procedures covering the Garbage management and waste recycling, according to 2.3.5.

2.3.6 Prevention of sea pollution by other sources

2.3.6.1 Transfer of harmful aquatic organisms and pathogens through ballast water.

A ballast water management plan, including a ballast water record book, is to be developed in accordance with IMO G-4 Guidelines (Earlier approved plans in accordance with IMO Res.A.868(20) may be accepted unless the plan requires revision due to the installation of a ballast water management system).

Unless stricter requirements are enforced by the Port State, it is recommended that ballast water exchange is carried out during international voyages at not less than 200 miles from the nearest land or, if not possible, at not less than 50 miles from nearest land in a zone with water depth not less than 200 [m] taking into account IMO Guidelines G-6 and G-11. The ship is not to be required to deviate from its intended voyage, or delay the voyage in order to comply with these requirements.

Ballast Water Management Systems are to be type approved in accordance with BWMS Code or Res. MEPC 279(70) or Res. MEPC. 174(58), as applicable, based on the date of installation.

2.3.6.2 Antifouling system

a) Antifouling systems for the hull are to be of TBT-free type.

b) The AFS Certificate and documentation of the TBT-free antifouling system are to be kept on

board for checking during periodical surveys.

2.3.6.3 Release of grey water

The requirements of this item apply only to passenger and ro-ro passenger ships

a) Ships are to be equipped with holding tank(s) for grey water with sufficient capacity to allow storage of grey water when in port for at least 2 days. The total capacity of grey water holding tanks is to be based on the maximum number of persons on board and 200 litre/person/day.

b) Grey water holding tanks are to be equipped with high level alarms.

c) If the same tanks are used to hold treated sewage and grey water, their capacity is to be at least the sum of the capacities for the treated sewage holding tanks in 2.3.4.3 and the tanks for grey water.

   A smaller volume, in any case not lower than 50% of the above capacity, may be accepted provided that:

   - The ship is equipped with a system for treating grey-water, able to reduce the volume of the effluent (e.g. by recycling part of the treated grey water for on board use);
   - 2 days retention is ensured;
   - Technical documentation, including results of onboard tests, of the system's efficiency and of effluent volume reduction is documented to the satisfaction of IRS.

d) The discharging criteria do not apply when the discharge of grey water is necessary for securing the safety of the ship and those on board, or saving life at sea, or when the discharge results from damage to the ship or its equipment.

e) All grey water discharges whether to sea or shore base facilities are to be recorded in the grey water record book with indication of the date, location and quantity of grey water discharged. If the grey water is discharged to sea, the records are to include information on distance to the nearest land.

2.3.6.4 Procedures

The Ship Environmental Management Plan referred to in 2.4 is to include procedures required in 2.3.6 including the grey water discharge criteria and use of holding tanks in ports and in no discharge areas.

2.4 Ship Environmental Management Plan

An Environmental Management Plan, specific to the ship, is to be developed and made available on board.

The Manual is to contain at least the procedures required as per 2.3.1.4, 2.3.3.6, 2.3.4.4, 2.3.5.4 and 2.3.6.4 and is to include:

- The officer/s in charge for carrying out each procedure.
- Documents and manuals required
- Log-books/records to be filled in
- Time schedule when applicable (e.g. checking, sampling, etc.).

The Ship Environmental Management Plan is to be submitted to IRS for information.

2.5 Inspections and Tests

2.5.1 Inspections and testing during construction

2.5.1.1. Materials

Materials for piping and equipment which are used for the construction of equipment and systems to be installed on board in connection with the requirements of this section are to be tested in accordance with the sections of the Rules applicable to similar types of piping or equipment and their class and/or design conditions.

2.5.2 Tests and inspection during fabrication

Piping and equipment relative to the means for preventing sea pollution, as stated in this

section, are to be inspected and tested during fabrication in accordance with the sections of the rules applicable to the type of piping or equipment and the relevant class and/or design conditions.

2.5.3 Inspection and testing after installation onboard

2.5.3.1 After installation on board, the equipment and systems installed in connection with the requirements of this section are to be tested in the presence of the Surveyor under operating conditions. The control, monitoring and alarm system are also to be tested in the presence of the Surveyor or their functioning is to be simulated by a procedure agreed with IRS.

Section 3

Clean Air Notation

3.1 Application

3.1.1 This section gives the requirements applicable for the assignment of the notation CLEAN-AIR.

3.2 Scope

3.2.1

a) The notation CLEAN-AIR is assigned to ships fitted with efficient means to control and prevent the emission of polluting substances in the air, in accordance with Pt. 1, Ch.1.

b) The requirements of this section are intended to prevent air pollution from any of the following hazards in addition to those stipulated by MARPOL 73/78 Annex VI:

- Emissions of ozone depleting substances
- Emissions contributing to global warming
- Emissions of nitrogen oxides (NO_x)
- Incinerators

In order for the notation CLEAN-AIR to be assigned, all the above polluting hazards are to be considered and the ship is to be fitted with means and/or operational measures to simultaneously prevent all those which are applicable, in relation to its characteristics and the likelihood of producing any or all of such emissions.

3.3 Additional requirements for oil tankers, chemical tankers and gas carriers

3.3.1 A ship which is classed with one or more of the following class notations:

- Oil tanker
- Chemical tanker
- Liquefied gas carrier
- Ore or Oil Carrier
- Oil or Bulk Carrier

is also to comply with the requirements of Part 5, Ch 29, in respect of prevention of vapour emissions.

The assignment of VCS1 or VCS2 notation is prerequisite for assigning the notation CLEAN-AIR.

3.4 Definitions

3.4.1 Ozone Depleting Substances.

Ozone depleting substances are those substances, which are defined in paragraph 4 of Article 1 of the Montreal Protocol on Substances that Deplete the Ozone Layer, 1987, listed in Annexes A, B, C, or E to the Protocol in force at the time of the application of these Rules.

In general, the following ozone depleting substances are used on ships; however, this list is not to be considered comprehensive of all ozone depleting substances that for any reason may be found in a ship.

- Halon 1211– Bromochloridefluoromethane
- Halon 1301 – Bromotriflurometha ne
- Halon 2402
- Halon 114B2 – 1,2-Dibromo-1,1,2,1-tetrafluoroethane
- CFC-11 – trichlorofluoromethane
- CFC-12 – Dichlorodicluoromethane
- CFC-113 – Trichloro-1,2,2-trifluoroethane
- CFC-114 – 1,2-Dichloro-1,1,2,2,-tetrafluoroethane
- CFC-115 – Chloropentafluoroethane.

3.4.2 Shipboard incineration

Shipboard incineration is the incineration of wastes or other matter on board a ship, if such wastes or other matter are generated during the normal operation of that ship.

3.4.3 Ozone depleting potential

Ozone depleting potential (ODP) is the potential of ozone depletion compared to CFC-11. Values of ODP for ozone depleting gasses are provided in the "Montreal Protocol on Substances that Deplete the Ozone Layer".

Table 3.1 : Documents to be submitted for prevention of emission of ozone depleting substances, incinerators, environment management plan SOx emissions

No.	A/I	Document
1	I	General arrangements of refrigeration plants
2	A	Scheme of refrigerating plant(s) showing the retention facilities as per 3.5.4
3	A	Data sheets with list of intended refrigerants to be used in the different refrigeration systems and their GWP and ODP
4	I	Refrigerant record book
(1) A = to be submitted for approval; I = to be submitted for information.		
Document for incinerator		
5	I	Copy of type approval certificate of statement of compliance with IMO Res. MEPC 244(66), as amended by MEPC.368(79).
6	I	Design data, including at least design pressure and design temperature, as applicable (2)
7	A	Piping diagram (2)
8	I	System for waste supply and in incinerator feeding (2)
9	A	Instrumentation, monitoring, alarm and control systems (2)
10	I	Operating manual
Note: A = to be submitted for approval; I = to be submitted for information. (2) Not required if the incinerator is of an approved type.		
11	I	Ship Environmental Management Plan as per 3.5.6, 3.6.9, 3.8.2, 3.9.1.
Note: I = to be submitted for information.		
Documents for Sox emissions		
12	A	Detailed plans of systems and equipment to limit SOx emission in the SOx emission control areas (2)
13	A	Ship SOx Emission Control Plan (SECP) (if EGCS is fitted onboard)
14	A	EGC System Technical Manual (Scheme A or B, as relevant and applicable)
15	A	Onboard Monitoring Manual (OMM)
16	I	Fuel changeover procedure
17	I	Ship Implementation Plan (prepared in accordance with MSC.1/Circ.878)
Note: A = to be submitted for approval I = to be submitted for information; (2) Only if such systems and equipment are installed.		
Documents for NOx emissions		
18	A	NOx Technical File

No.	A/I	Document
Documents for CO_2 emissions		
19	I	Ship Energy Efficiency Management Plan (SEEMP)
20	A	Preliminary EEDI Technical File [2]
21	A	Model Test Program for EEDI calculation [2]
22	I	Model Test Report for EEDI Calculation [2]
23	A	Sea Trial Program for EEDI calculation [2]
24	I	Sea Trial Report for EEDI calculation [2]
25	A	Final EEDI Technical File [2]
Note : (1) A = to be submitted for approval; I = to be submitted for information. (2) Only for ship types for which EEDI is applicable as required by MARPOL Annex VI Chapter 4		

3.4.4 Global warming potential

Global warming potential (GWP) is the potential global warming of a gas compared with CO2 on a time horizon of 100 years. Values of GWP for various refrigerants and gases are published by the US Environmental Protection Agency (EPA).

3.4.5 Documents to be submitted

3.4.6 Table 3.1 lists the documents to be submitted for the assessment of the measures taken to prevent the emission of ozone depleting substances and sulphur oxides

- Requirement of Incinerators
- Preparation of environment management plan

The documents in Table 3.1 are additional to those relative to refrigerating installations and fire-fighting systems listed in the applicable sections of the Rules.

3.5 Emission of ozone depleting substances

3.5.1 Application

a) The following requirements apply to ships with refrigerating facilities, such as refrigerated cargo ships, liquefied gas carriers with reliquefaction plants and other ships with centralized cargo refrigeration systems.

b) They also apply to:

- Centralized refrigeration systems for provision stores
- Centralized air conditioning plants
- Fixed fire-fighting systems.

c) They do not apply to domestic type stand-alone refrigerators and air conditioning units.

3.5.2 Halogenated substances

a) The use of halogenated substances (e.g. Halon and CFC) as refrigerant or fire-fighting means is prohibited, with the exception of hydro-chlorofluorocarbons (HCFCn), which are permitted until 1 January, 2020.

b) Refrigerants of centralized refrigeration systems are to have a global warming potential, GWP < 2000.

3.5.3 Prevention of leakage

a) Means are to be provided to limit leaks to the atmosphere of refrigerants or their vapours in the event of failure of the plant, as well as in the case of discharge of refrigerant to an onshore reception facility.

b) Annual refrigerant leakage is to be less than 10% of the total refrigerant charge of each system. The leakage is to be documented by consumption figures recorded in a refrigerant log-book to be kept on board and made available during periodical surveys.

c) Procedures need to be established such that, in the event that annual leakage exceeds 10%, corrective actions are undertaken.

3.5.4 Evacuation facilities

The system is be fitted with evacuation (e.g. compressors) and retention facilities having the capability to retain all the refrigerants, should the need to evacuate the whole plant arise in an emergency.

3.5.5 Maintenance and servicing

The plant is to be designed in such a way as to minimize the risks of medium release in the case of maintenance, repair or servicing, i.e. it is to be designed considering the possibility of isolating those sections which are to be serviced by a system of valves and bypasses, in such a way as not to stop the operation of the plant while in service, preventing the risk of release of the medium outside of the plant.

3.5.6 Procedures

The Ship Environmental Management Plan, as per 3.9.1 is to contain the following:

- Procedures to be followed to minimize the risk of depleting the refrigerant or the refrigerant vapours in all operative and emergency conditions

- Procedures for preparing, filing and updating the refrigerant log-book.

3.6 Emission of oxides of nitrogen (NOx) from Marine diesel engines

3.6.1 Requirements for emissions from diesel engines apply to all diesel engines with power output in excess of 130 kW, except emergency diesel engines, engines installed in lifeboats and any other device or equipment intended to be used solely in case of emergency.

3.6.2 The maximum allowed total emission levels for marine diesel engines installed onboard shall be as defined in 3.6.3 for NO_x and 3.7.1 and 3.7.2 for SO_x.

3.6.3 NO_x emissions shall comply with the limits defined in MARPOL 73/78, Annex VI, Reg.13: Nitrogen Oxide (NO_x).

3.6.4 The reduction of oxides of nitrogen can be achieved by the introduction of equipment and arrangements such as, but not limited, to, those listed below:

- Engine adjustments or modifications
- Water addition to the combustion process by water injection, emulsification or humidification
- Using gas (as per IGF Code) as fuel
- Exhaust Gas Recirculation
- Selective Catalytic Reduction (SCR).

3.6.5 All arrangements, fuel oil additives etc. introduced to reduce the NO_x emission levels are subject to IRS approval and shall:

- be operated according to manufacturer's instructions
- allow normal engine performance and safe operation in case of failure
- have features so that its operations and performance can be documented by a log book record
- have sufficient mechanical fastening to ensure safe ad steady support and avoid damaging vibrations
- where applicable, have adequate hatches for inspection and maintenance of installations or systems.

3.6.6 The following arrangements will be subject to special considerations:

- arrangements where NO_x reduction is carried out on more than one engine

- arrangements using SCR cleaning where the reactor unit is positioned between the engine and the turbo blower.

3.6.7 For ships where NO_x emissions are controlled by devices added to the fuel or exhaust systems, such devices shall be operated and controlled in accordance with procedures incorporating the manufacturer instructions and IRS's approval.

3.6.8 For ships fitted with Exhaust Gas Recirculation (EGR), the discharge of EGR Bleed-Off water is to comply with Res. MEPC 307(73).

Guidance note :

Engine modification and adjustments

NO_x reductions by modification of engine parameters, water injection, fuel emulsification and/or by adjusting engine settings in order to influence the combustion characteristics, should be specified by the engine manufacturer and carried out under his supervision. The chosen combination of modifications and adjustments should aim to avoid an increase in the engine's fuel consumption.

Selective Catalytic Reduction (SCR)

Requirements for storage and use of SCR reductants are indicated in Part 4, Chapter 4, Section 4, Clause 4.14.

The reducing agent should be specified by the manufacturer. If other agent than Urea-solution is used, this will be subjected to special considerations.

In the case where the NO_x emission level is used to verify or control the reduction agent injection rate, the level should be detected by an analyser based upon one of the following methods:

- Electrochemical cell
- Infrared chemiluminescene.

NO_x level measurements
NO_x level measurements on engines with NO_x reduction arrangements should comply with methods as decided by IRS.

3.6.9 The Ship Environmental Management Plan is to include as a minimum the following:

a) procedures for periodical checks of the emission related engine parameters and components referred to in the technical file. The periodical checks are to be carried out at least every 6 months and after maintenance or replacement of any such component;

b) procedures of preparing, filing in and updating the engine record book.

c) Methods to control NOx emissions.

d) Means are to be provided to check proper operation of the equipment.

3.7 Emission of oxides of sulphur (SOx)

3.7.1 Sulphur content of any fuel oil used on board ships is not to exceed the limits as required by MARPOL 73/78 Annex VI, Regulation 14. SO_x emission limits are generally achieved by use of low sulphur content fuel oil. Other Approved Alternative arrangements providing an equivalent level of environmental protection will be considered.

3.7.1.1 If an Exhaust Gas Cleaning System (EGCS) is fitted in order to obtain the required reductions of SO_x, it is to be certified to IMO Resolution MEPC.340(77) – 2021 Guidelines for Exhaust Gas Cleaning Systems. Also for ships fitted with EGCS a SOx Emission Compliance Plan (SECP) complying MEPC.340(77) is to be submitted for approval. Further, EGC System Technical Manual (as per Scheme A or B, as relevant and applicable) and the Onboard Monitoring Manual (OMM) are to be submitted for approval.

3.7.1.2 The discharge washwater is to satisfy the criteria given in the Resolution MEPC.340(77).

3.7.2 Changes of fuel type when entering and leaving port, or SO_x - controlled areas are to be documented by entries in the ship's logbook.

3.8 Incinerators

3.8.1 Applicability

a) The following requirements apply to ships with a permanently installed shipboard incinerator, generally complying with the requirements of IMO Resolution MEPC 244(66), as amended by MEPC.368(79)

"Standard specifications for shipboard incinerators". Shipboard incinerators described in MARPOL Annex VI, regulation 16(2) are to have IMO type approval certificate for assigning CLEAN-AIR notation.

b) Ships without a permanently installed incinerator, which use the main or auxiliary boilers for incinerating oil sludge generated during normal operations, cannot be assigned CELAN-AIR notation.

3.8.2 Miscellaneous requirements

a) Shipboard incinerators cannot be used to incinerate the following substances:

- Cargo residues of substances indicated in Annexes I, II and III of the IMO International Convention for the Prevention of Pollution from Ships 1973/78, "MARPOL 73/78" as amended and related contaminated packing materials.

- Polychlorinated biphenyl (PCBs)

    - Garbage, as defined in Annex V of "MARPOL 73/78", containing more than traces of heavy metals.
    - refined petroleum products containing halogen compounds;
    - sewage sludge and sludge oil either of which is not generated on board the ship; and
    - exhaust gas cleaning system residues.

b) A Manufacturer's operating manual for the incinerator is to be provided on board.

c) Safety measures

1) The flue gas outlet temperature is to be continuously monitored.

2) For incinerators fed continuously by an automatic feeding systems, the waste supply is to be shut off if the temperature indicated above falls below 850°C.

3) For batch loaded incinerators, the unit is to be designed in such a way that the temperature in the combustion chamber reaches 600°C in not less than 5 minutes.

d) The Ship Environmental Management Plan as per 3.9.1 is to address the procedures required as per para a).

3.9 Ship Environmental Management Plan

3.9.1 An Environmental Management Plan, specific to the ship, is to be developed and made available on board.

- The indication of person(s) in charge for each procedure to be carried out
- Documents and manuals required
- Log-books/records to be filled in
- Time schedule when applicable (e.g. periodical checks).

The Ship Environmental Management Plan is to be submitted to IRS for information.

3.10 Inspections and tests

3.10.1 Installations to limit the emission of refrigerants

a) Materials

Materials for piping and equipment specifically designed to limit the emission of refrigerants are to be tested in accordance with the applicable requirements for testing materials intended to be used for the construction of similar types of piping and equipment and their classes and/or design conditions.

b) Tests and inspection during fabrication

Piping and equipment specifically designed to limit the emission of refrigerants are to be inspected and tested during fabrication in accordance with the requirements applicable to similar types of piping or equipment and their classes and/or design conditions.

c) Tests after installation

After installation on board, the plant acceptance trials are to include the operation of the evacuation of all of the refrigerant from the plant to the reception facilities without any release of refrigerant and/or refrigerant vapours. The control,

monitoring and alarm systems are also to be tested in the presence of the Surveyor, or their functioning is to be simulated by a procedure agreed with IRS.

3.10.2 Incinerators

The incinerator is to be IMO type approved and after installation function tests as described in operation manual are to be carried out.

3.11 Energy Efficiency

3.11.1 Attained Energy Efficiency Design Index (EEDI) is to be calculated for ship types as required by MARPOL Annex VI Chapter 4.

3.11.2 Preliminary EEDI Technical file is to be submitted for approval, calculating the Attained EEDI in accordance with IMO Guidelines on "The Method of Calculation of The Attained Energy Efficiency Design Index (EEDI) For New Ships".

3.11.3 The verification, survey and certification of EEDI is to be carried out in accordance with IMO Guidelines on Survey and Certification of The Energy Efficiency Design Index (EEDI).

3.11.4 The Final EEDI Technical File is to be submitted incorporating necessary corrections after sea trials.

3.11.5 The attained EEDI is to be less than the Required EEDI for the particular ship type and size and applicable phase as per MARPOL Annex VI Chapter 4.

3.11.6 Ship Energy Efficiency Management Plan (SEEMP) is to be prepared in accordance with IMO Guidelines and kept onboard ship at all times.

Section 4

Environment Protection (EP) Notation

4.1 General

4.1.1 The notation "EP" (Environmental Protection) will be assigned to vessels complying with the requirements of this section.

4.1.2 The requirements given in section 2 and 3 of Rules are also to be complied with as required for CLEAN-SEA and CLEAN-AIR notations.

4.2 Ship recycling

4.2.1 General

Some of the problems associated with ship recycling might be addressed at the design and construction stage, not only in relation to the ships themselves but also in respect of ships equipment.

The first step is to identify any potentially hazardous materials which might be incorporate, as a matter of routine, in the structure of ships and their equipment and, where practicable, consider using less hazardous alternatives.

4.2.2 Initial stage

The initial stages might include an evaluation of:

a) the type, amount and potential hazard of materials utilized and their location on board a ship;

b) the activities expected during the operation of the ship and any potentially hazardous wastes which might be generated; and

c) the feasibility of addressing the potential for hazardous waste generation by considering:

   1) product reformulation – installing components utilising less potentially hazardous materials;

   2) cleaner production technologies – which generate less waste;

3) process medication – to generate less waste;

4) input substitution – utilizing less potentially hazardous consumables or those which generate less waste; and

d) on-site, closed-loop recycling – systems that recycle wastes on board the ship.

4.2.3 Design stage

When designing and constructing a vessel, due account is to be taken of the ship's ultimate disposal, by:

a) using materials which can be recycled safely and in an environmentally sound manner; and

b) minimizing the use of materials known to be potentially hazardous to health and the environment.

4.2.4 Inventory of hazardous materials

In order to contribute towards minimizing potential problems related to protection of the environment in the recycling of vessels, guidelines on ship recycling have been adopted by IMO with resolution A.962(23) to given guidance to all stakeholders in the ship recycling process.

An inventory of hazardous materials is to be developed according to the above mentioned Resolution A.962 (23) – IMO Guidelines on Ship recycling, paragraph 5.

The inventory is a document facilitating the application of these Guidelines providing information with regard to materials known to be potentially hazardous utilized in the construction of the ship its equipment and systems. This is to accompany the ship throughout its operating life. Successive Owners of the ship are to maintain the accuracy of the inventory and incorporate into it all relevant design and equipment changes, with the final Owner delivering the document, with the ship, to the recycling facility.

4.3 Documents to be submitted

a) Table 4.1 lists the plans and documents to be submitted.

b) Table 4.2 lists the procedures and record books to be submitted.

Table 4.1 : Documents to be submitted		
No.	**A/ I**	**Document**
1	I	Copy of the NLS certificate or “International Certificate of Fitness for the Carriage of Dangerous Chemicals in Bulk” or “International Certificate of Fitness for the Carriage of Liquefied Gases in Bulk”, as applicable
2	I	Copy of IOPP Certificate
3	A	Drawings of the bilge system including volume of the bilge holding tank (4)
4	I	Copy of the type approval certificate of the oil filtering equipment and alarm
5	A	Schematic arrangement of the fuel oil, lubricating oil and relevant overflow system containing the information necessary to verify the requirements of 2.3.1.3 (4)
6	I	Copy of the approved SOPEP plan including the list of emergency equipment
7	I	Details of enrolment in an Emergency Response Service
8	I	Copy of the ISPP Certificate and copy of the sewage treatment plant type approval certificate
9	A	Drawings of the sewage system including piping, holding tank for sewage and alarms (4)
10	A	Calculation of volume of holding tank for sewage (4)
11	I	Copy of the AFS Certificate or statement of compliance
12	A	Drawings of the grey-water system including piping, holding tank and alarms (1) (4)
13	A	Calculation of volume of grey water holding tank (1) (4)
14	A	Data sheets with the list of refrigerants and fixed fire-fighting means used, their quantity and GWP values (4)
15	A	Details of plans of systems and equipment to limit SOx emissions in SOx emission control areas (2) (4)
16	A	Drawings of fuel oil system, arrangements and procedures for use of separate fuel oil according to requirements given in 3.11 (4)
17	I	Incinerator type approval certificate (2)
18	I	Documentation of compliance with technical requirements for the class notation VCS (3)
19	I	Copy of the EIAPP Certificate or statement of compliance for each engine detailed in 3.6 issued by a recognized organization, as applicable
20	A	Engine Technical File and record book for each engine detailed in 3.6.
21	A	Details and operating manual(s) of NOx control equipment referred to in 3.6 (2)
22	I	General arrangement plan with indication of the zone intended for the stowage of the harmful packaged substances in relation to the other zones of the ship
23	I	Plans of systems and equipment to discharge the harmful substances in case of emergency and to dispose of and wash possible leaks
24	A	SOx Emission Control Plan (SECP) [For ships fitted with EGCS)
25	A	EGC System Technical Manual (Scheme A or B, as relevant and applicable)
26	A	Onboard Monitoring Manual (OMM)
27	I	Ship Implementation Plan (prepared in accordance with MSC.1/Circ.878)
28	A	Preliminary EEDI Technical File [5]
29	A	Model Test Program for EEDI calculation [5]
30	I	Model Test Report for EEDI Calculation [5]
31	A	Sea Trial Program for EEDI calculation [5]
32	I	Sea Trial Report for EEDI calculation [5]

Table 4.1 : (Contd.)		
No.	**A/ I**	**Document**
33	A	Final EEDI Technical File [5]
34	I	Copy of International Energy Efficiency Certificate (IEE Certificate)

(1) Passenger ships only
(2) Only if such a system is installed on board
(3) Only ships having service notation according to 3.3
(4) For ships in service, alternative documentation may be accepted provided it is sufficient for the execution of the initial survey
(5) Only for ship types for which EEDI is applicable as required by MARPOL Annex VI Chapter 4.

Note : A = to be submitted for approval
I = to be submitted for information.

Table 4.2 : Operational Procedures and Record Books		
No.	**A/ I**	**Document**
1	I	Oil systems record book
2	I	Sewage record book
3	A	Garbage management plan including garbage record book
4	A	Ballast water management plan including ballast water record book
5	I	Grey water record book (2)
6	I	Refrigerant log book and procedures as per 3.5
7	I	Oily wastes management procedures according to 2.3.1.4b)
8	I	Accidental oil discharge management procedures according to 2.3.1.4b)
9	I	Sewage management procedures according to 2.3.4.4
10	I	Garbage management and waste recycling procedures according to 2.3.5(1)
11	I	Grey water management procedures according to 2.3.5(2)
12	I	Ship Environmental Management Plan
13	I	Fuel management procedures for controlling SOx
14	I	Incinerator management procedures according to 3.8
15	A	Inventory of Hazardous materials according to 4.2.4
16	I	Ship Energy Efficiency Management Plan (SEEMP)
17	A	EGCS Record Book (If fitted)

(1) Only for passenger ships other than ro-ro passenger ships
(2) Only for passenger ships and ro-ro passenger ships

Note : A – to be submitted for approval
I – to be submitted for information.

4.4 Inspections, tests and surveys

4.4.1 Inspections and testing during construction

Materials, systems or equipment which are installed on board or modified in order to comply with the requirements of this Section 3 are to be surveyed and tested according to the applicable Rules of IRS.

4.4.2 Initial survey

Following the satisfactory review and approval of the plans and other documentation detailed in 4.2, an initial survey is to be carried out on board in order to:

- Verify that hull and machinery arrangements are in accordance with the approved documentation;
- Test, in the presence of the Surveyor and under working conditions, the equipment and systems covered by these Rules including their control, monitoring and alarms;
- Verify and presence on board of the Ship Environmental Manager;
- Verify the presence on board of the certificates, record and log-books, and Environmental Management Plan requested by these Rules;
- Carry out the engine parameter check according to the engine technical file, of the engines;
- For existing ships, assess and document the satisfactory maintenance of equipment and systems.

Section 1

General

1.1 Application

1.1.1 The requirements in this Chapter are intended to achieve a successful ergonomic design of the bridge and bridge equipment, which will improve the reliability and efficiency of navigation. These contain ergonomic requirements as well as a functionally oriented bridge layout to support watch-keeping personnel in their tasks by a user-centred design of the bridge equipment and layout.

1.1.2 Ships complying with the requirements of this Chapter may be assigned additional Class notations **BD**, **BDS** or **IBS** as indicated in 1.1.3 to 1.1.5.

1.1.3 Additional class notation '**BD**' (Bridge Design) will be assigned to ships complying with requirements of Section 1 through Section 3 of this Chapter, as applicable. Requirements for bridge design and layout are indicated in these Sections.

1.1.4 Additional class notation '**BDS**' (Bridge Design and Systems) will be assigned to ships complying with requirements of Section 1 through Section 4 of this Chapter, as applicable. Requirements for vital equipment and systems are indicated in Section 4.

1.1.5 Additional class notation '**IBS**' (Integrated Bridge System) will be assigned to Ships fitted with integrated bridge system which allows simplified and centralized bridge operation of the main functions of Navigation, Communication and manoeuvring of the vessel including monitoring of such critical systems, complying with the requirements of Section 1 through Section 7 of this Chapter, as applicable.

1.2 Reference testing and performance standards

1.2.1 IEC 60945:2002, Maritime navigation and radio-communication equipment and systems – General requirements – Methods of testing and required test results.

IEC:61162 (all parts) Maritime navigation and radio-communication equipment and systems – Digital interfaces.

IEC 61174:2015 - Electronic Chart Display and Information System (ECDIS) - Operational and performance requirements, methods of testing and required test results

ISO 8468:2007 – Ship's bridge layout and associated equipment – requirements and guidelines.

IMO A.823(19) – Performance standards for automatic radar plotting aids (ARPAs).

IMO A.1021(26) – Code on alerts and indicators 2009.

IMO A.694(17) – General requirements for shipborne radio equipment forming part of the global maritime distress and safety system (GMDSS) and for electronic navigational aids.

SN.1/Circ.288 – Guidelines for Bridge Equipment and Systems, Their Arrangement and Integration (BES)

IMO MSC.302(87) – Adoption of Performance standards for Bridge Alert Management

IMO MSC/Circular 566:1991 – Provisional guideline on the conduct of trials in which the officer of the navigational watch acts as the sole lookout in periods of darkness.

IMO MSC.Res.252(83) (as amended by MSC.Res.452(99) – Performance standards for integrated navigation systems.

1.3 Definitions

1.3.1 Configuration of complete system : all operational functions of the IBS Bridge as installed.

1.3.2 Configuration available : operation(s) allocated to and available at each workstation.

1.3.3 Configuration in use : operation(s) and task(s) currently in use at each workstation.

1.3.4 Connectivity : a complete data link and the presence of valid data.

1.3.5 Essential functions : functions related to determination, execution and maintenance of safe course, speed and position of the ship in relation to the waters, traffic and weather conditions.

Such functions include but are not limited to:

- Route planning
- Navigation
- Collision avoidance
- Manoeuvring
- Docking
- Monitoring of internal safety systems
- External and internal communication related to safety in bridge operation and distress situations.

1.3.6 Essential information : that information which is necessary for the monitoring of essential functions.

1.3.7 Functionality: ability to perform an intended function. The performance of a function normally involves a system of displays and instrumentation.

1.3.8 Statutory requirements : IMO Conventions, Regulations, Resolutions, Codes, Recommendations, Guidelines, Circulars and related ISO and IEC standards.

1.3.9 Integrated bridge system (IBS) : any combination of systems which are interconnected in order to allow centralized access to sensor information from workstations to perform two or more of the following operations:

- Passage execution
- Communications
- Machinery monitoring
- Loading, discharging and cargo monitoring
- HVAC monitoring for passenger ships.

1.3.10 Integrity : ability of a system to provide users with accurate, timely, complete and unambiguous information and warnings within a specified time when the system is not in use.

1.3.11 Latency : time interval between an event and the resulting information, including time for processing, transmission and reception.

1.3.12 Multi-function display: a single visual display unit which can present, either simultaneously or through a series of selectable pages, information from more than one operation of a IBS.

1.3.13 Novel systems or equipment: systems or equipment which embody new features not fully covered by provisions of SOLAS V but which provide at least equivalent standard of safety (SOLAS Regulation 19.6).

1.3.14 Part : individual subsystem, equipment or module.

1.3.15 Performance check : a representative selection of short qualitative tests, to confirm correct operation or essential functions of the IBS.

1.3.16 Sensor : a device which provides information to or is controlled or monitored by the IBS.

1.3.17 Workstation : A position at which one or several tasks, constituting a particular activity, is carried out.

1.3.18 Navigation workstation : A workstation at which the navigator may carry out all tasks relevant for deciding, executing and maintaining course and speed in relation to waters and traffic. The instrumentation and controls at the navigation workstation should allow the navigator to:

- Analyse the traffic situation;
- Monitor position, course, track, speed, time, propeller revolutions and pitch, rudder angle, depth of water, rate of turn and wind speed and direction;
- Alter course and speed;
- Effect internal and external communications;
- Give and receive sound signals;
- Control navigational lights;
- Monitor and acknowledge navigational alarms;
- Confirm his well-being and watch-keeping awareness; and
- Record navigational data.

1.3.19 Main steering position : That part of the navigation workstation where those controls and instrumentation relevant to controlling the ship's course are located.

1.3.20 Conning position : A place on the bridge which is used by navigators when commanding, manoeuvring and controlling a ship.

1.3.21 Voyage planning workstation : A workstation at which the navigator may carry out the following tasks without affecting the actual navigation of the vessel:

- Examine and update charts and other relevant documentation;
- Plan a voyage as a series of waypoints, courses, speeds and turns;
- Calculate an estimated time of arrival at various points on the voyage; and
- Determine and plot the ship's position.

1.4 Abbreviations used in this chapter

1.4.1 Abbreviations used in this Rules and annexes :

AIS	:	Automatic identification system
ARPA	:	Automatic radar plotting aid
BNWAS	:	Bridge navigational watch and alarm system
DSC	:	Digital selective calling
EGC	:	Enhanced group call
EPIRB	:	Emergency position indicating radio beacon
GMT	:	Greenwich Mean Time
HF	:	High Frequency
INMARSAT	:	International Mobile Satellite Organization
ISO	:	International Standards Organization
ITU-R	:	International Telecommunication Union – radio sector
IBS	:	Integrated Bridge System
ITU-T	:	International Telecommunication Union – telecommunication sector
MARPOL	:	IMO Convention for the prevention of pollution by ships
MEPC	:	Marine Environmental Protection Committee of IMO
MF	:	Medium Frequency
MSC	:	Maritime Safety Committee of IMO
NAV	:	IMO Subcommittee on Safety of Navigation
NAVTEX	:	System for broadcast and reception of maritime safety information
OOW	:	Officer of the watch
r.p.m.	:	Revolutions per minute
UTC	:	Universal coordinated time
VDU	:	Visual display unit
VHF	:	Very high frequency
ECDIS	:	Electronic Chart Display Information System

Section 2

Documentation

2.1 Documents to be submitted

2.1.1 Relevant plans and data are to be submitted for approval and/or information as follows:

2.1.2 The documents / details given below are required to be submitted for **BD**, **BDS** and **IBS** notations. A complete layout and dimensional details of the bridge area and workstations installed therein. This is to include:

a) Arrangements of windows, including dimensions and angles of inclination, dimensions of frames, height above deck surface of upper and lower edges, type of glass and details of clear view arrangements (wipers, fresh water wash, de-icing / de-misting, sunscreens, etc.)

b) Fields of vision from the bridge workstations, including any blind sectors caused by obstructions outside of the wheelhouse.

c) Location and arrangement of workstations, including dimensions of consoles, layout of instrumentation and controls, handrails, seating, etc.

d) Clearances between floor and ceiling or between floor and the underside of ceiling mounted instruments, throughout the wheelhouse.

e) Arrangements for the general illumination of the bridge and the individual illumination of workstation instruments and controls.

f) Details of wheelhouse ventilation and heating systems.

g) Details of internal communication systems operable from the bridge.

h) Arrangements / details of exterior catwalk in front of bridge windows.

i) Details of non-skid flooring

j) Details of wheelhouse doors, including hold-back arrangements.

k) Location of toilet.

l) Arrangements for drainage of bridge decks.

m) Arrangements / details as to the measures to be taken to minimize hazards to personnel.

2.1.3 All electrical and electronic appliances installed on the bridge and vicinity of the bridge (also refer Section 4, Cl. 4.6) other than mandatory navigation and communication equipment; having been type tested according to IEC 60945:2002 (EMC tested for conducted and radiated emission), as well as loose equipment placed on board by the builder or owner are to be listed, and be provided with at least the following information. The list and the evidence of equipment are to be kept onboard.

- Equipment description
- Manufacturer
- Type / model
- Evidence of EMC compatibility which may be:
  - type approval certificate covering EMC requirements for bridge installations;
  - test certificate or report / conformity statement; or exemption statement.

Section 3

Bridge Design

3.1 Bridge Design

3.1.1 General

a) The bridge is to be designed and arranged with the aim of:

- Facilitating tasks to be performed by the bridge team and the pilot in making full appraisal of the situation and in navigating the ship safely under all operational conditions.

- Promoting effective and safe bridge resource management.

- Allowing for expeditious, continuous and effective information processing and decision-making by the bridge team and the pilot.

- Preventing or minimizing excessive or unnecessary work and any condition or distraction on the bridge which may cause fatigue or interfere with the vigilance of the bridge team and the pilot.

b) The design of bridge is to be governed by:

- The functions and related tasks to be carried out on the bridge, systems used and methods of task performance.

- The fields of vision required for visual observations from each of the workstations.

- Composition of the bridge team and the procedures required for safe operations under all identified conditions.

- The type and range of equipment to be provided for performance of the tasks at the individual workstations and elsewhere on the bridge.

- Performance standards for equipment mentioned in 1.2

3.1.2 Arrangement

a) Consoles, including the chart table, are to be positioned, so that the instrumentation they contain is mounted in such a manner as to face a person looking forward. As far as practicable, operating surfaces are to be normal to the operator's line of sight.

b) From other workstations within the wheelhouse it is to be possible to monitor the navigation workstation and to maintain an effective lookout.

c) The main access to the bridge is to be by means of an internal stairway. Secondary external access is also to be provided.

d) Clear passage of at least 7000 [mm] width is to be available to allow movement around the bridge with a minimum of inconvenience. Particular attention is to be paid to the following routes which are to be as direct as possible:

- From bridge wing to bridge wing, a clear passage of at least 1200 [mm] in width;

- Between the internal entrance to the bridge and the route as above a clear passage of at least 700 [mm] in width is to be provided;

- Between adjacent workstations, a clear passage of at least 700 [mm] is to be provided.

e) The distance from the bridge front bulkhead or from any console and installation placed against the front bulkhead, to any console or installation placed away from the bridge front is to be preferably 1000 [mm] and not less than 800 [mm].

f) Space necessary for operating at a workstation is to be considered as part of the workstation and is not to be part of the passageway.

g) The clear height between the wheelhouse deck surface covering and the underside of the deckhead is to be at least 2250 [mm]. The lower edge of deckhead mounted equipment is to be at least 2100 [mm] in open areas, passageways and at standing workstations.

h) The height of entrances and doors to the wheelhouse from adjacent passageways is to be at-least 2000 [mm].

i) All wheelhouse doors are to be operable with one hand. Bridge wing doors are not to be self-closing and means are to be provided to hold the doors open.

j) Toilet facilities are to be provided on or adjacent to the bridge.

3.1.3 Lighting

3.1.3.1 The level of lighting is to enable bridge personnel to perform all bridge tasks, including maintenance and chart and office work, by day and night. Controls, indicators, instruments, keyboards, etc. on the bridge are to be capable of being seen in the dark, either by means of internal lighting within the equipment or the wheelhouse lighting system. A satisfactory level of flexibility within the lighting system is to be available to enable the bridge personnel to adjust the lighting in brightness and direction as required in different areas of the bridge and by the needs of individual instruments and controls.

3.1.3.2 All illumination and lighting of instruments, keyboards and controls are to be adjustable down to zero, except the lighting of alarm indicators and the controls of dimmers which are to remain readable.

3.1.4 Field of vision

3.1.4.1 The requirements of Pt.3, Ch.11, Sec.4, Cl.4.2 are to be complied with.

3.1.4.2 It is to be possible to observe all objects necessary for navigation, including other traffic and navigation marks, in any direction from inside the wheelhouse. In this respect, there is to be a field of view around the ship of 360° obtained by an observer moving within the confines of the wheelhouse.

3.1.4.3 The view of the sea surface from the conning position and the navigation workstation is not to be obscured by more than two ship lengths, or 500 [m], whichever is less, forward of the bow to 10° on either side, irrespective of the ship's draught, trim and deck cargo.

3.1.4.4 Blind sectors caused by cargo, cargo gear and other obstructions outside of the wheelhouse forward of the beam obstructing the view of the sea surface as seen from the conning position and the navigation workstation are not to exceed 10° each. The total arc of blind sectors is not to exceed 20° and the clear sector between blind sectors shall be at least 5°. However, in the view described in 3.1.4.3 each individual blind sector is not to exceed 5°.

3.1.4.5 The horizontal field of vision from the conning position and the navigation workstation is to extend over an arc from more than 22.5° abaft the beam on one side, through forward, to more than 22.5° abaft the beam on the other side.

3.1.4.6 From the main steering position, the field of vision is to extend over an arc from dead ahead to at least 60° on each side.

3.1.4.7 From each bridge wing, the field of vision is to extend over an arc from at least 45° on the opposite bow through dead ahead and then aft to 180° from dead ahead.

3.1.4.8 There is to be a line of sight from the port wing to the starboard wing through the wheelhouse.

3.1.4.9 The ship's side is to be visible from the bridge wing.

3.1.4.10 From work stations for functions other than navigation, the field of vision is to enable an effective lookout to be maintained and, in this respect, is to extend at least over an arc from 90° on the port bow, through forward, to 22.5° abaft the beam on the starboard side.

3.2 Temperature control

3.2.1 An adequate air conditioning or mechanical ventilation system, together with sufficient heating according to climatic conditions, is to be provided in order to maintain temperature within 22°C to 30°C and the humidity within the range 20 percent to 60 percent. The discharge of hot or cold air is not to be directed towards bridge personnel. Control of this system is to be provided in the wheelhouse.

Section 4

Bridge Design and Systems

4.1 Documents

4.1.1 In addition to the documents indicated in Section 2, the following documents are to be submitted for **BDS** notation :

(a) A list of navigational equipment. This is to include for each item the manufacturer's name and code number, together with copies of relevant type approval certificates. The workstations with navigational equipment are to be fitted in line with requirements of Table 6.1 (for navigation and traffic surveillance, monitoring, manual steering and docking);

(b) A complete operational description of the relevant monitoring systems including a list of alarms and displays. This may be accomplished by means of simplified block diagrams of navigation equipment, internal communication systems and watch monitoring and alarm transfer systems and central alarm panel (where provided) including a list of alarms;

(c) A simplified one-line diagram of power supplies to the bridge equipment, circuit protection ratings and settings, cable sizes, rating of connected loads, detailed description and interactions, etc.;

(d) Operating / technical manuals for installed navigation equipment / systems;

(e) Sea trial test schedule.

4.2 Arrangement

a) The bridge configuration, arrangement of consoles and equipment location are to be such as to enable the officer of the watch to perform navigational tasks and other functions allocated to the bridge, as well as maintain an effective lookout. The following tasks are to be supported:

- Navigation and manoeuvring;
- Monitoring;
- Manual steering;
- Docking;
- Planning;
- Safety;
- Communications; and
- Conning.

b) Equipment and associated displays and indicators are to be sited at clearly defined workstations.

c) Consoles, including the chart table, are to be positioned, so that the instrumentation they contain is mounted in such a manner as to face a person looking forward. As far as practicable, operating surfaces are to be normal to the operator's line of sight.

d) Space necessary for operating at a workstation is to be considered as part of the workstation and is not to be part of the passageway.

4.3 Communication systems

4.3.1 A telephone system is to be provided to enable two-way speech communication between the wheelhouse and at least in the following locations:

- machinery control station space;

- emergency steering position in the steering gear compartment;
- master's and navigating officers' cabins, offices, mess and public rooms.

4.3.2 The bridge is to have priority over the system.

4.3.3 A list of extension numbers is to be clearly displayed adjacent to each telephone.

4.4 Power interruptions and shutdown

4.4.1 The distribution boards supplying power to the navigation equipment / system are to be fed by two exclusive circuits, one from main source of power and one from an emergency source of power. The power supplies to the distribution boards are to be arranged with automatic changeover facilities between the two sources.

4.5 Power supply

4.5.1 Power to the navigation equipment / system is to be supplied:

a) from the main and emergency sources of electrical power with automated changeover through a local distribution board with provision to preclude inadvertent shutdown;

b) from a transitional source of electrical power for a duration of not less than 1 min; and

c) Uninterrupted power supplies. Each vital equipment listed below is to be connected to an UPS. The UPS is to supply the vital bridge equipment with continuous power during a loss of ship's power for a minimum period of 15 minutes. The UPS is to prevent power transients as ship service power is lost and restored such that no loss of control or mal-operation of the bridge units results from these transitions.

4.5.2 Battery charge circuits within each unit are to be capable of re-charging the battery from 40% capacity to 80% capacity within 8 hours. Batteries are to be protected from undercharge and overcharge. Battery charging is to be automatic and is not to affect normal operation. The equipment regarded as vital is at least one each of the following:

i) one radar with ARPA (including antenna) installed at work station for navigation and manoeuvring;
ii) ECDIS;
iii) GNSS;
iv) Gyro compass; and
v) Internal Communication System.

4.6 EMI/EMC

4.6.1 All electrical and electronic equipment on the bridge and vicinity of the bridge are to be installed such that electromagnetic interference does not affect the proper functioning of the navigational systems and equipment. Installation of the equipment in accordance with the guidelines and recommendations included in IEC 60533:2015 or an acceptable equivalent standard would generally be considered to meet the requirement.

Note: Bridge and vicinity of the bridge covers deck and bridge zone, i.e.

- The wheelhouse including bridge wings
- Control rooms, characterized by equipment for inter-communication, signal processing, radio communication and navigation, auxiliary equipment

- Area in close proximity to receiving and/or transmitting antennas and large openings in the metallic structure (equipment beyond 5 meters need not be considered for this purposes).

4.6.2 Passive-EM equipment, defined in 4.6.3, which is excluded from the scope of EMC since it is considered not liable to cause or be susceptible to disturbances need not be tested, but are to be provided with an exemption statement.

4.6.3 *Passive EM equipment*: Equipment is considered a passive EM equipment if, when used as intended (without internal protection measures such as filtering or shielding) and without any user intervention, it does not create or produce any switching or oscillation of current or voltage and is not affected by electromagnetic disturbances. Examples of such equipment are as follows:

- cables and cabling systems, cables accessories

- equipment containing only resistive loads without any automatic switching device; e.g. simple domestic heaters with no controls, thermostat, or fan

- batteries and accumulators.

4.7 Earthing

4.7.1 Earthing of the navigational equipment and systems is to be as per manufacturer's instructions.

4.8 Tests and trials

4.8.1 Navigational equipment and systems are to be tested to the satisfaction of the attending surveyor meeting the relevant IMO performance standards.

Section 5

Integrated Bridge Systems

5.1 Documentation

5.1.1 In addition to the documents indicated in Section 4, the following documents are to be submitted for **IBS** notation:

(a) Details and arrangements of the workstations and systems. The functions available are to be as given in Table 6.1.

(b) The sea trial program is to include test details of the electronic chart display and information systems (EDCIS) and integrated bridge system (IBS).

5.2 System requirements

5.2.1 In addition to the requirements indicated in Section 3 and Section 4, the following requirements are to be complied with:

5.2.2 The IBS is to comply with all applicable IMO requirements as contained in the reference regulations listed in Section1, 1.2 or other relevant IEC Standards. Parts executing multiple operations are to meet the requirements specified for each individual function they can control, monitor or perform.

5.2.3 Each part of an IBS is to meet the relevant requirements of IMO Resolution A.694(17) as detailed in IEC 60945:2002.

5.2.4 The integrated bridge system is to be of an approved type.

5.2.5 Integration

5.2.5.1 The system is to provide functional integration meeting the following requirements:

a) The functionality of the IBS is to ensure that its operation is at least as effective as for stand-alone equipment.

b) Continuously displayed information is to be reduced to the minimum necessary for safe operation of the ship. Supplementary information is to be readily accessible.

c) Where multifunction displays and controls are used to perform functions necessary for safe operation of the ship they are to be duplicated and interchangeable.

d) It is to be possible to display the complete system configuration, the available configuration and the configuration in use.

e) Each part to be integrated is to provide details of its operational status and the latency and validity of essential information. Means are to be provided within the IBS to make use of this information.

f) An alternative means of operation is to be provided for essential functions.

g) An alternative source of essential information is to be provided. The IBS is to identify loss of either source.

h) The source of information (sensor, result of calculation or manual input) is to be displayed continuously or upon request.

5.2.6 Data Exchange

5.2.6.1 Interfacing within the IBS is to comply with IEC 61162, as applicable.

5.2.6.2 Data exchange is to be consistent with safe operation of ship.

5.2.6.3 The integrity of the data flowing on the network is to be ensured.

5.2.6.4 A failure in the connectivity is not to affect independent functionality.

5.2.6.5 The network is to be such that in the event of a single failure between the nodes, a clear indication of the failure is available, the sensors and displays on the network continue to operate and the data transmission between them is maintained.

5.2.7 Failure analysis

5.2.7.1 A failure analysis is to be performed and documented.

5.2.7.2 Parts, functions and connectivity are to be identified.

5.2.7.3 Possible failures of parts and connectivity associated with essential functions and information are to be identified.

5.2.7.4 Consequences of failures with respect to operation, function or status of the IBS are to be identified.

5.2.7.5 Each failure is to be classified with respect to its impact on the IBS taking into account relevant characteristics, such as detectability, ease of diagnosis, testability, replaceability and compensating and operating provisions.

5.2.7.6 The results of the failure analysis are to confirm the possibility of continued safe operation of the ship.

5.2.8 Quality Assurance

5.2.8.1 The IBS is to be designed, developed, produced, installed and serviced by companies certified to ISO 9001:2000.

5.2.9 Alarm management

5.2.9.1 The IBS alarm management, as a minimum, is to comply with the requirements of the Code of Alerts and Indicators (IMO resolution A.1021(26)) and the alarms required for each navigational equipment by IMO standards.

5.2.9.2 Appropriate alarm management on priority and functional groups is to be provided within the IBS.

5.2.9.3 The number of alarm types and their release are to be kept as low as possible by providing indications for information of lower importance.

5.2.9.4 Alarms are to be displayed so that the alarm reason and resulting functional restrictions can be easily understood. Indications are to be self-explanatory.

5.2.9.5 Alarms are to be prioritized as follows:

a) Emergency Alarms: Alarms which indicate that immediate danger to human life or to the ship and its machinery exists and that immediate action is to be taken.

b) Alarms: conditions requiring immediate attention and action by the bridge team to avoid any kind of hazardous situation and to maintain the safe operation of the ship and escalation required as alarm from not acknowledged warning.

c) Warning: conditions or situations which require immediate attention for precautionary reasons, to make the bridge team aware of conditions which are not immediately hazardous, but may become so.

d) Caution: awareness of a condition which still requires attention out of the ordinary consideration of the situation or of given information.

5.2.9.6 The following alarms are to be provided and included in the centralized alarm system:

- Off-course
- Off-track (where automatic track following is provided)
- Way point approaching, (where automatic track following is provided)
- Position fix inaccurate/lost
- Loss of heading input
- Loss of speed log input
- Equipment or sub-system failure
- Gyro mis-match
- Echo-sounder
- Radar CPA
- Navigational light failure
- Steering gear alarms
- Bridge navigational watch alarm system failure.

The audible alarms at the central panel and the relevant workstation are to be silenced when acknowledged from either location. However, it is to be possible to acknowledge the flickering light and bring to steady state only from the relevant work station.

5.2.9.7 Manual adjustment of any of the facilities of the integrated bridge system is to reset automatically the watch safety interval timer.

5.2.10 Power interruptions and shutdown

5.2.10.1 If subjected to an orderly shut-down, the IBS should, upon turn-on, come to an initial default state.

5.2.10.2 After a power interruption full functionality of the IBS is to be available after recovery of all subsystems. The IBS is not to increase the recovery time of individual subsystem functions after power restoration.

5.2.10.3 If subjected to a power interruption the IBS is to, upon restoration of power, maintain the configuration in use and continue automated operation, as far as practicable. Safety related automatic functions are to be restored only upon confirmation by the operator.

5.2.11 Power supply

5.2.11.1 Power supply requirements indicated in 4.5 are applicable.

5.2.11.2 Power supply requirements applying to parts of the IBS as a result of other IMO requirements are also to remain applicable.

5.3 Operational requirement

In addition to the operational requirements indicated in Section 4, following requirements are to be complied with.

5.3.1 Human factors

5.3.1.1 The IBS is to be capable of being operated by personnel holding appropriate certificates.

5.3.1.2 The man-machine interface (MMI) is to be designed so as to be easily understood and in a consistent style for all integrated functions.

5.3.1.3 Operational information is to be presented in a readily understandable format without the need to transpose, compute or translate.

5.3.1.4 Indications, which may be accompanied by a short low intensity acoustic signal are to occur when:

- An attempt is made to execute an invalid function
- An attempt is made to use invalid information.

5.3.1.5 If an input error is detected by the system it is to require the operator to correct the error immediately. Messages actuated by an input error are to guide the correct responses, e.g. not simply “Invalid entry”, but “Invalid entry, re-enter set point between 0 to 100”.

5.3.1.6 Layered menus are to be presented in a way which minimizes the added workload to find and return from the desired functions.

5.3.1.7 An overview is to be easily available to assist the operator in the use of a multiple page system. Each page is to have a unique identifier.

5.3.1.8 Where multi-function displays are used, they are to be in colour. Continuously displayed information and functional areas, e.g. menus, are to be presented in a consistent manner.

5.3.1.9 For actions which may cause unintended results, the IBS is to request confirmation from the operator.

Note 1 : Examples of such actions are:

- Attempting to change position and next waypoint while in track mode steering.

- Attempting to switch on bow thruster when insufficient electrical power is available.

5.3.1.10 Functions requested by the operator are to be acknowledged or clearly indicated by the IBS on completion.

5.3.1.11 Default values, where applicable, are to be indicated by the IBS when requesting operator input.

5.3.1.12 The size, colour and density of text and graphic information presented on a display are to be such that it may be easily read from the normal operator position under all operational lighting conditions. (ref ISO 8468-6.2.3).

5.3.1.13 Symbols used in mimic diagram are to be standardized throughout the system’s displays.

5.3.1.14 All information is to be presented on a background providing high contrast and emitting as little light as possible at night.

5.3.1 The design of bridges is to be governed by:

a) The range, layout and location of workstations required for performance of bridge functions

b) The fields of vision required for visual observations from each of the workstations.

c) The type and range of equipment to be provided for performance of the tasks at the individual workstations

5.3.2 Arrangement

5.3.2.1 Equipment and associated displays and indicators are to be sited at clearly defined workstations.

5.3.2.2 It is to be possible to monitor the navigation workstation and to maintain an effective lookout from other workstations within the wheelhouse.

5.3.2.3 Space necessary for operating at a workstation is to be considered as part of the workstation and is not to be part of the passageway.

5.3.3 Training

5.3.3.1 Manufacturers of integrated bridge systems are to provide training facilities for the ship's crew. This training may take place ashore or on board and is to be carried out using suitable material and methods to cover the following topics:

a) General understanding and operation of the system:

- Knowledge and understanding of the system's configuration and application.
- Usage and understanding of the operating manual.
- Usage and understanding of electronic "HELP" functions, if provided in the system.
- Familiarization with the system using safe trial modes.

b) Mastering of uncommon conditions in the system:

- Detecting and locating of failures.
- Resetting the system to safe default values and modes.
- Operating safely without certain sensor data or parts.
- Possibilities for repair on board.
- Identifying the potential for unintended results

5.4 Work stations

5.4.1 The bridge and workstation arrangement is to be based on relevant functional requirements and designed in accordance with established principles of ergonomics for safe and efficient operations, enabling the navigator to perceive all relevant information and execute pertinent actions with a minimum workload.

5.4.2 Workstations for additional functions may be located on the bridge provided the performance of such functions does not interfere with the tasks of maintaining safe control of the ship. Workstations for additional functions may include workstations for:

- Extended communication functions
- Monitoring and control of ballasting and cargo operations
- Extended monitoring of machinery
- Miscellaneous.

5.5 Navigation workstation

5.5.1 A workstation for navigation is to be arranged to enable efficient operation by one person under normal operating conditions. The workstation area is to be sufficient to allow at least two operators to use the equipment simultaneously. The arrangement of instruments and controls is to allow the use of all instruments and controls necessary for navigating and manoeuvring in any normal working position.

5.5.2 An adequate conning position is to be provided close to the forward center window. If the view in the centerline is obstructed by large masts, cranes, etc. two additional conning positions giving a clear view ahead are to be provided, one on the port side and one on the starboard side of the centerline, no more than 5 [m] apart. In addition to the conning position, a second position with a view of the area immediately in front of the bridge superstructure is to be provided close to a forward window or, alternatively, the conning position is to be wide enough to accommodate two persons.

5.5.3 The main steering position is to be located on the ship's centerline, unless the view ahead is obstructed by large masts, cranes, etc. In this case, the steering position is to be located a distance to starboard of the centerline sufficient to obtain a clear view ahead and special steering references for use by day and night are to be provided, e.g. sighting marks forward.

5.5.4 The following facilities are to be provided at the navigation workstation:

- Radar and radar plotting facilities
- Position-fixing system displays
- Echo sounder display
- Speed and distance indications
- Gyrocompass displays
- Magnetic compass display
- Wind speed and direction indication
- Steering controls and indication see Pt.4, Ch.6 and Ch.7
- Rate of turn indication
- Course/track controls and indications
- Main propulsion and thruster controls and indication
- Watch safety system acknowledge
- Watch safety system manual initiation
- Internal communications system
- VHF radiotelephone
- Time indication
- Window clear view controls
- Navigation lights controls
- Whistle control
- Morse light keys
- Wheelhouse/equipment lighting controls
- Automatic ship identification system (AIS) information
- Sound reception system where fitted.

Section 6

Carriage Requirements

6.1.1 The navigation equipment to be carried on board for the performance of various functions are listed in Table 6.1.

6.1.2 Navigational systems and equipment are to be of a type approved by the national administration and in conformity with appropriate performance standards not inferior to those adopted by IMO from time to time. Documentary evidence to this effect is to be submitted. See SOLAS 1974 as amended, Ch.V, Reg.18.

6.1.3 Where alternative means of fulfilling the navigational requirements are permitted, the means are to be approved by the national administration and in conformity with appropriate performance standards.

6.1.4 Two functionally independent radars or alternative means are to be provided to determine and display the range and bearing of radar transponders and other surface craft, obstructions, buoys, shorelines and navigational marks. One of the radars is to operate in the X-band (9 GHz) and the other is to operate in the S-band (3 GHz). Both radars are to include automatic tracking aids to determine collision risks, and at least one radar is to be equipped with an automatic radar plotting aid (ARPA), capable of tracking at least 20 targets, while the other is to be either ARPA or an automatic tracking aid (ATA).

6.1.5 A gyrocompass or alternative means for determining, displaying and transmitting the ship's heading is to be provided. The heading information is to be used directly by the radars, radar plotting aids and automatic identification system. The gyrocompass is to be provided with a gyrocompass heading repeater located at the emergency steering position in the steering gear compartment and gyrocompass bearing repeater(s) allowing bearings to be taken over 360°.

6.1.6 Where automatic track following is provided, sufficient warning is to be given of the approach of a waypoint, so that, in the event of no acknowledgement from the officer of the watch, there is adequate time for the backup navigator to reach the bridge and accept the change of course.

6.1.7 A speed log or alternative means of indicating the ship's speed and distance through water is to be provided. The speed through water measurement is to be used directly by the ARPA as an aid to collision avoidance.

6.1.8 A speed log or alternative means of indicating the ship's speed and distance over ground is to be provided. Speed over ground is to be indicated in both the fore-aft and athwartships directions.

Table 6.1 : Navigational Equipment

Workstation for	Main functions to be performed	Equipment	Remarks
Navigation and traffic surveillance manoeuvering (See Note 1)	• Observation of all vessels and objects • Recognizing dangerous situations • Deciding on collision avoidance actions • Checking vessel's own signal • Checking own course and speed • Keeping and/or changing own course and speed (track keeping) • Checking own position • Handling own internal communication on board	Gyro compass heading indicator	For IBS notation, two independent gyro compasses are to be provided on the bridge
		Magnetic compass heading indicator	
		Course reminder (set course) indicator	
		Auto pilot / track control system / alternative means	Automatically maintaining ship's heading or a straight track. Immediate restoration of manual control to be possible when required
		Steering gear pump selector switch	
		Steering mode selector switch	
		Steering position indicator	
		Rudder angle indicator	
		Rate-of-turn indicator and controller	For vessels of 50000 GT or greater
		Speed and distance indicator	For IBS notation, the speed measuring system is to be independent of the position-fixing systems
		Echosounders with adjustment controls	
		9 GHz radar and 3 GHz radar	
		Automatic traffic surveillance system including ARPA	

Table 6.1 (Contd.)			
Workstation for	**Main functions to be performed**	**Equipment**	**Remarks**
	• Handling communication vessel/vessel and vessel/shore (VHF)	Position fixing equipment/system including automatic visual position indicator	Two types of receivers are to be provided. One of the systems is to be GPS or equivalent and the other GLONASS, or other means such as radar
	• Releasing alarms	Officer of the watch check-alertness acknowledgement device	
	• Perception of group alarms with aids for decision-making	Back-up navigator call alarm device	Two-way communication wireless portable device to be provided
	• Observation of weather and seaway	Facilities for use of navigation charts	This may be separated from the navigation and traffic surveillance/ maneuvering workstation
	• Acknowledging watch check-alertness alarm	Vessel's automatic identification system	
		Voyage data recorder (VDR/S-VDR)	
		Propulsion engines/thrusters controls including emergency stops	Compliance with Part 4, Chapter 4, Section 9 & Part 4, Chapter 7 of the Rules is to be met
	• Keeping deck log (a Dictaphone may be used)	Propulsion engine revolution	If reduction geared engine
		Pitch indicator	For controllable-pitch propeller
		Propeller revolutions indicator	
		Wind direction and velocity indicator	
	• Sounding signals	Air and water temperature and humidity indicator	
		Automatic telephone system	
		Radio-communication/GMDSS equipment	
		NAVTEX automatic receiver and recorder	For navigational and meteorological warning purpose. To comply with IMO Res. A.617(15) – Implementation of the NAVTEX system as a component of the worldwide navigational warning service

Table 6.1 (Contd.)			
Workstation for	**Main functions to be performed**	**Equipment**	**Remarks**
		Signal transmitter for: - whistle - automatic device for fog signal - general alarm - morse signaling light	
		Search light controls	
		Controls for windscreen wiper, washer, heater	
		Night vision equipment	
		Sound reception system	If required
		Workstation lighting control device	
		HVAC controls	
		Clock	
		Group alarms and reset controls	
Monitoring (See Note 1)	• Observation of all vessels and objects • Recognizing dangerous situations • Handling own internal communication on board • Handling communication vessel/ vessel and vessel/shore • Perception of group alarms with aids for decision-making • Releasing alarms • Observation of weather and seaway • Acknowledging watch check alertness alarm • Checking own course and speed • Keeping deck log	Gyro compass heading indicator	For IBS notation, the speed measuring system is to be independent of the position-fixing systems
		Rudder angle indicator	
		Rate-of-turn indicator	For vessels of 50000 GT or greater
		Speed and distance indicator	For IBS notation, the speed measuring system is to be independent of the position-fixing systems
		Echosounders	
		9GHz radar and 3 GHz radar	
		Officer of the watch check-alertness acknowledgment device	
		Propulsion engines/ thrusters emergency stops	
		Pitch indicator	For controllable-pitch propeller
		Propeller revolutions indicator	

Table 6.1 (Contd.)			
Workstation for	**Main functions to be performed**	**Equipment**	**Remarks**
	• When workstation is occupied by an additional navigator, provides assistance to navigator at the navigation and traffic surveillance/ maneuvering workstation	Automatic telephone system	
	• When workstation is occupied by a pilot advisers to vessel's command	Radio-communication/ GMDSS equipment	
		Signal transmitter for whistle/foghorn	
		Controls for windscreen wiper, washer, heater	
		Workstation lighting control device	
		Clock	

Table 6.1 (Contd.)			
Workstation for	**Main functions to be performed**	**Equipment**	**Remarks**
		Required alarms and reset controls	In addition to the alarms/indicators which may be required by the various IMO Resolutions referenced in this chapter and pertinent flag Administration, the following conditions are to be alarmed at the monitoring workstation a) Off-course b) Off-track c) Planned route deviation d) Pre-warning of approach-way point and closest point of approach e) Off-preset water depth f) Gyro compass failure g) Failure of alarms prescribed in 3.6 and section 5 of this Chapter. h) Failure of power supply to distribution panel serving relevant equipment (Alarming of the above conditions at the monitoring workstation is not a substitute for alarming at the required relevant workstations)
Manual steering (Helmsman's) [See Note 1]	• Steering vessel according to rudder angle orders • Steering vessel according to course instruction • Steering vessel following landmark / sea marks • Acknowledging watch check alertness alarm	Gyro compass heading indicator (repeater)	
		Magnetic compass heading indicator	
		Course reminder (set course) indicator	
		Manual steering with override and selector control switches including steering wheel/steering lever	
		Rudder angle indicator	
		Rate-of-turn indicator	For vessels of 50000 GT or greater
		Watch check-alertness acknowledgement device	
		Automatic telephone system	

Table 6.1 (Contd.)			
Workstation for	**Main functions to be performed**	**Equipment**	**Remarks**
		Controls for windscreen wiper, washer, heater	
Docking (Bridge wings)	• Giving instructions, performing and controlling change of course • Giving instructions, performing and controlling change of speed • Giving instructions, performing and controlling change of thruster • Handling communication with maneuvering stations • Handling communication with tugs, pilot boat • Watching water surface along vessel's side • Releasing signals • Acknowledging watch check alertness alarm	Gyro compass heading indicator	
		Steering position selector switch	
		Rudder controls	
		Rudder angle indicator	
		Rate-of-turn indicator	For vessels of 50000 GT or greater
		Propulsion engines/ thrusters controls	
		Propulsion engine revolution	If reduction geared engine
		Pitch indicator	For controllable pitch propeller
		Propeller revolutions indicator	
		Lateral thrust and lateral movement of vessel, indicator	If thrusters are fitted
		Longitudinal movement of vessel, indicator	
		Wind direction and velocity indicator	
		Echosounder	
		Officer of the watch check-alertness acknowledgement device	
		Whistle controls	
		Search light and Morse lamp controls	
		Automatic telephone system	
		Radio-communication/ GMDSS equipment	
		Workstation lighting control device	
Centralized Bridge	As listed in 1.3.9	Equipment required for the navigation and traffic surveillance / maneuvering and monitoring workstations	
		Central alarm panel	
		ECDIS	

Table 6.1 (Contd.)			
Workstation for	**Main functions to be performed**	**Equipment**	**Remarks**
Route Planning	Determination of favourable course and optimum speed, taking into account weather conditions, current, etc. and route planning	ECDIS including navigation planning station	
	Giving instructions as to the course and speed	Route planning devices	
	Calculation of tidal data	Chart table	
	Handling nautical records, documents, publications	Position-fixing receiver	
	Handling weather reports	Retaining device for drawing triangles, dividers, magnifying lens, pencils, etc.	
	Determination of documentation of position in case of conventional operation	Weather chart plotter	
	Control of rate and error of chronometer, deviation, radio deviation, documentation of same	Main clock	
	Keeping deck log	Chronometer with receiving facility for time signals	
	External communication for planning operation using the chart	Log, including distance indicator, course plotter	
		Officer of the watch check-alertness acknowledgement device	
		Barograph	
		Command printer	
		Automatic telephone system	
	Acknowledging watch check alertness alarm	Echosounder	
		Officer of the watch check-alertness acknowledgement device	
		Whistle controls	
		Search light and Morse lamp controls	
		Automatic telephone system	

Table 6.1 (Contd.)

Note:

1) As the navigation and traffic surveillance / maneuvering, monitoring and manual steering workstations are functionally interrelated and usually installed in close proximity from each other, considerations will be given to the omission of duplicate equipment required at each of the aforementioned workstations.

Section 7

Tests and Trials

7.1 General

7.1.1 The tests to be carried out as indicated in this section are intended to supplement and not to replace the testing of parts that is required to meet the relevant IMO performance standards. The tests are intended to ensure that when the parts are integrated there is no degradation of their individual functionality.

7.1.2 In all instances the performance standards for parts will form the minimum test requirement for an integrated system.

7.1.3 During trails, navigational equipment and systems are to be tested to the satisfaction of the attending surveyor in accordance with the test program. The test program is to include following systems as minimum:

a) Course information system
b) Automatic steering system
c) Speed measuring system
d) Depth measuring system
e) Radar system
f) Automatic traffic surveillance system
g) Position fixing system
h) Watch monitoring and alarm transfer system
i) Route planning system
j) Vessel's automatic identification system
k) Sound reception in bridge, if fitted
l) Radio communication system
m) Centralised bridge workstation provided to enable the navigator to perform necessary navigational, monitoring/alarm and communication functions as required for IBS.

7.1.4 The trial program is to include test details of electronic chart display and information system (ECDIS) and integrated bridge system. The system is to be tested to verify that failure of one sub system does not affect any other sub system. In case of failure of integrated navigational system, it is to be possible to operate the primary navigational equipment / systems functions independently.

2	*Structural Requirements*
3	*Machinery Requirements for Polar Class Ships*

Section 1

Polar Class Descriptions and Application

1.1 Application

1.1.1 This chapter gives the additional requirements for ships constructed of steel and intended for independent navigation in ice-infested polar waters.

Class notations and related requirements for general ice class and those for operation in Northern Baltic are given in Pt.5, Ch.21.

1.1.2 Ships that comply with requirements of this chapter can be considered for a Polar Class notation as listed in Table 1.2.1. If the hull and machinery are constructed such as to comply with the requirements of different Polar Classes, then both the hull and machinery will be assigned the lower of these classes in the Certificate of Classification. Compliance of the hull or machinery with the requirements of a higher Polar Class will also to be indicated in the Certificate of Classification or equivalent.

1.1.3 Ships which are assigned a Polar Class notation and complying with the relevant specific requirements of this chapter may be given the additional notation "**Icebreaker**". "**Icebreaker**" refers to any ship having an operational profile that includes escort or ice management functions, having powering and dimensions that allow it to undertake aggressive operations in ice-covered waters.

1.1.4 For ships which are assigned a Polar Class notation, the hull form and propulsion power are to be such that the ship can operate independently and at continuous speed in a representative ice condition, as defined in Table 1.2.1 for the corresponding Polar Class. For ships and ship-shaped units which are intentionally not designed to operate independently in ice, such operational intent or limitations are to be explicitly stated in the Certificate of Classification or equivalent.

1.1.5 For ships which are assigned a Polar Class notation **PC 1** through **PC 5**, bows with vertical sides, and bulbous bows are generally to be avoided. Bow angles are to be in general, within the range specified in 2.3.1 v).

1.1.6 For ships which are assigned a Polar Class notation **PC 6** and **PC 7**, and are designed with a bow with vertical sides or bulbous bows, operational limitations (restricted from intentional ramming) in design conditions are to be stated in the Certificate of Classification or equivalent.

1.2 Polar classes

1.2.1 The Polar Class (PC) notations and descriptions are given in Table 1.2.1. It is the responsibility of the Owner to select an appropriate Polar Class. The descriptions in Table 1.2.1 are intended to guide owners, designers and administrations in selecting an appropriate Polar Class to match the requirements for the ship with its intended voyage or service.

1.2.2 The Polar Class notation is used to convey the differences between classes with respect to operational capability and strength.

1.2.3 Definitions for nomenclature used in Table 1.2.1:

1.2.3.1 First year ice : Sea ice of not more than one winter's growth, thickness 30 [cm] to 2 [m] in general. This is subdivided into thin / medium / thick first year ice as noted below:

Thin first year ice :	First year ice of less than 70 [cm] thickness
Medium first year ice:	First year ice of 70 to 120 [cm] thickness
Thick first year ice:	First year ice of over 120 [cm] thickness

1.2.3.2 Second year ice : Old ice which has survived only one summer's melt, typically thickness upto 2.5 [m].

1.2.3.3 Multi year ice : Old ice upto 3 [m] thick in general, which has survived at least two summer's melt.

Table 1.2.1 : Polar Class Descriptions

Polar Class	Ice descriptions (based on WMO Sea ice nomenclature; see 1.2.3 for definitions)
PC 1	Year-round operation in all polar waters
PC 2	Year-round operation in moderate multi-year ice conditions
PC 3	Year-round operation in second-year ice which may include multi-year ice inclusions
PC 4	Year-round operation in thick first-year ice which may include old ice inclusions
PC 5	Year-round operation in medium first-year ice which may include old ice inclusions
PC 6	Summer / autumn operation in medium first-year ice which may include old ice inclusions
PC 7	Summer / autumn operation in thin first-year ice which may include old ice inclusions

1.3 Upper and lower ice waterlines

1.3.1 The upper and lower ice waterlines upon which the design of the ship has been based will be indicated in the Certificate of Classification. The upper ice waterline (UIWL) is defined by the maximum draughts fore, amidships and aft. The lower ice waterline (LIWL) is defined by the minimum draughts fore, amidships and aft.

1.3.2 The lower ice waterline is to be determined with due regard to the ship's ice-going capability in the ballast loading conditions. The propeller is to be fully submerged at the lower ice waterline.

Section 2

Structural Requirements

2.1 Application and Definitions

2.1.1 This section gives the structural requirements to be complied with for assignment of polar class notations defined in Section 1.

2.1.2 Definitions

2.1.2.1 The length L_{UI} is the distance, in [m], measured horizontally from the fore side of the stem at the intersection with the upper ice waterline (UIWL) to the after side of the rudder post, or the centre of the rudder stock if there is no rudder post. L_{UI} is not to be less than 96%, and need not be greater than 97%, of the extreme length of the upper ice waterline (UIWL) measured horizontally from the fore side of the stem. In ships with unusual stern and bow arrangement the length L_{UI} will be specially considered.

2.1.2.2 The ship displacement Δ_{UI} is the displacement, in [k-tonnes] of the ship corresponding to the upper ice waterline (UIWL). Where multiple waterlines are used for determining the UIWL, the displacement is to be determined from the waterline corresponding to the greatest displacement.

2.2 Hull areas

2.2.1 The hull of all Polar Class ships is divided into areas reflecting the magnitude of the loads that are expected to act upon them. In the longitudinal direction, there are four regions: bow, bow intermediate, midbody and stern. The bow intermediate, midbody and stern regions are further divided in the vertical direction into the bottom, lower and icebelt regions. The extent of each hull area is illustrated in Fig.2.2.1.

2.2.2 Notwithstanding Fig.2.2.1, the boundary between the bow and bow intermediate regions is not to be forward of the intersection point of the line of the stem and the ship baseline.

2.2.3 Notwithstanding Fig.2.2.1, the aft boundary of the bow region need not be more than $0.45L_{UI}$ aft of the fore side of the stem at the intersection with the upper ice waterline (UIWL).

2.2.4 The boundary between the bottom and lower regions is to be taken at the point where the shell is inclined 7 deg. to the horizontal.

2.2.5 If a ship is intended to operate astern in ice regions, the aft section of the ship is to be designed using the bow and bow intermediate hull area requirements. This will be indicated in the appendix to the classification certificate.

2.2.6 Notwithstanding Fig.2.2.1, if the ship is assigned the additional notation “**Icebreaker**”, the forward boundary of the stern region is to be at least $0.04L_{UI}$ forward of the section where the parallel ship side at the upper ice waterline (UIWL) ends.

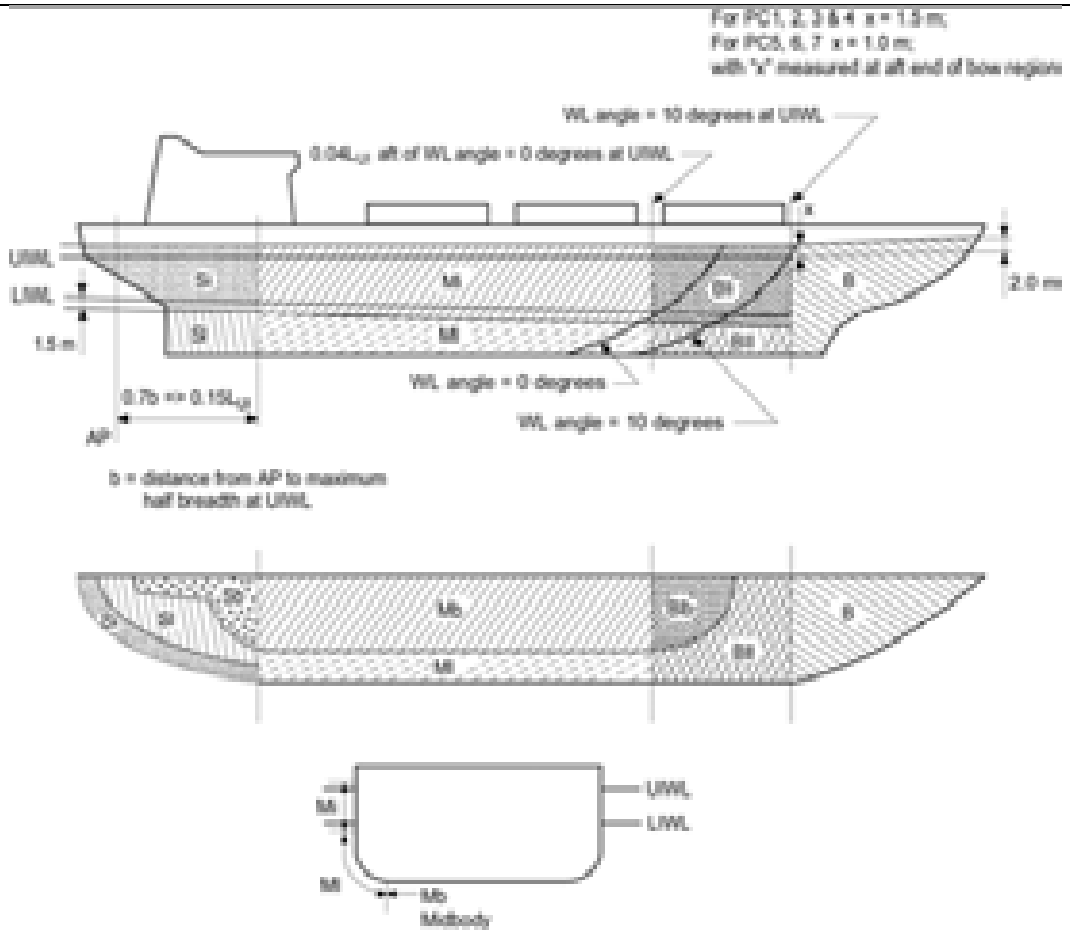

Fig.2.2.1 : Hull area extents

2.3 Design ice loads

2.3.1 General

i) A glancing impact on the bow is the design scenario for determining the scantlings required to resist ice loads.

ii) The design ice load is characterized by an average pressure (P_{avg}) uniformly distributed over a rectangular load patch of height (b) and width (w).

iii) Within the bow area of all Polar Class Ships and within the bow intermediate icebelt area of Polar Class PC6 and PC7, the ice load parameters are functions of the actual bow shape. To determine the ice load parameters (P_{avg}, b and w), it is required to calculate the following ice load characteristics for sub-regions of the bow area; shape coefficient (f_{ai}), total glancing impact force (F_i), line load (Q_i) and pressure (P_i).

iv) In other ice-strengthened areas, the ice load parameters (P_{avg}, b_{NONBOW} and w_{NONBOW}) are determined independently of the hull shape and based on a fixed load patch aspect ratio, AR = 3.6.

v) Design ice forces calculated according to 2.3.2.1 iii) are applicable for bow forms where the buttock angle γ at the stem is positive and less than 80 deg, and the normal frame angle β' at the centre of the foremost sub-region, as defined in 2.3.2.1 i), is greater than 10 deg. See Fig. 2.3.2.1.

vi) Design ice forces calculated according to 2.3.2.1 iv) are applicable for ships which are assigned the Polar Class PC6 or PC7 and have a bow form with vertical sides. This includes bows where the normal frame angles β' at the considered sub-regions, as defined in 2.3.2.1 i), are between 0 and 10 deg.

vii) For ships which are assigned the Polar Class PC6 or PC7, and equipped with bulbous bows, the design ice forces on the bow are to be determined according to 2.3.2.1 iv). In addition, the design forces are not to be taken less than those given in 2.3.2.1 iii), assuming fa = 0.6 and AR = 1.3.

viii) For ships with bow forms other than those defined in v) to vii), design forces will be specially considered.

ix) Ship structures that are not directly subjected to ice loads may still experience inertial loads of stowed cargo and equipment resulting from ship ice interaction. These inertial loads, based on accelerations are to be considered in the design of these structures.

2.3.2 Glancing impact load characteristics

The parameters defining the glancing impact load characteristics are reflected in the class factors listed in Table 2.3.2 and Table 2.3.3.

Table 2.3.2 : Class factors to be used in 2.3.2.1 iii)

Polar Class	Crushing failure class factor (CF_C)	Flexural failure class factor (CF_F)	Load patch dimensions class factor (CF_D)	Displacement class factor (CF_{DIS})	Longitudinal strength class factor (CF_L)
PC1	17.69	68.60	2.01	250	7.46
PC2	9.89	46.80	1.75	210	5.46
PC3	6.06	21.17	1.53	180	4.17
PC4	4.50	13.48	1.42	130	3.15
PC5	3.10	9.00	1.31	70	2.50
PC6	2.40	5.49	1.17	40	2.37
PC7	1.80	4.06	1.11	22	1.81

Table 2.3.3: Class factors to be used in 2.3.2.1 iv)

Polar Class	Crushing failure Class Factor (CF_{CV})	Line load Class Factor (CF_{QV})	Pressure Class Factor (CF_{PV})
PC6	3.43	2.82	0.65
PC7	2.60	2.33	0.65

2.3.2.1 Bow area

i) In the bow area, the force (F), line load (Q), pressure (P) and load patch aspect ratio (AR) associated with the glancing impact load scenario are functions of the hull angles measured at the upper ice waterline (UIWL). The influence of the hull angles is captured through calculation of a bow shape coefficient (f_a). The hull angles are defined in Fig.2.3.2.1.

ii) The waterline length of the bow region is generally to be divided into 4 sub-regions of equal length. The force (F), line load (Q), pressure (P) and load patch aspect ratio (AR) are to be calculated with respect to the mid-length position of each sub-region (each maximum of F, Q and P is to be used in the calculation of the ice load parameters P_{avg}, b and w).

iii) The Bow area load characteristics for bow forms defined in 2.3.1 v) are determined as follows:

a) Shape coefficient, fa_i, is to be taken as

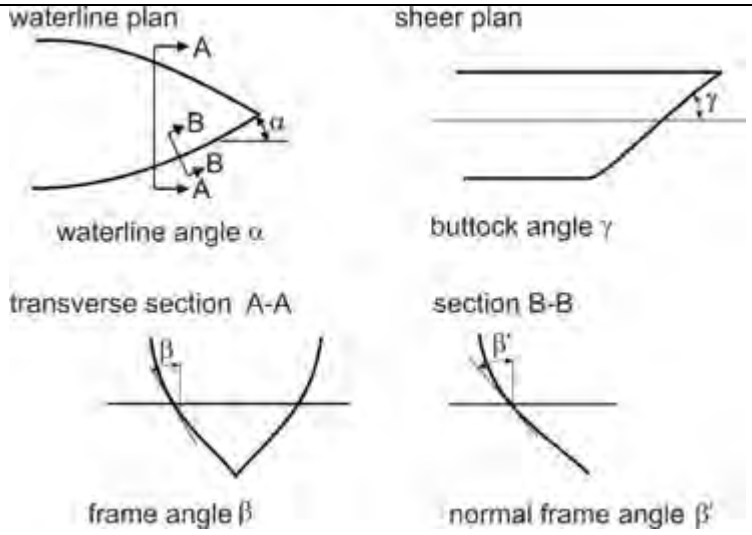
fa_i = minimum ($fa_{i,1}$; $fa_{i,2}$; $fa_{i,3}$)

where,

$fa_{i,1} = (0.097 - 0.68\ (x/L_{UI} - 0.15)^2\ ) \cdot \alpha_i / (\beta'_i)^{0.5}$

$fa_{i,2} = 1.2 \cdot CF_F / (\sin(\beta'_i) \cdot CF_C \cdot \Delta_{UI}^{0.64})$

$fa_{i,3} = 0.60$



Note :

β' = normal frame angle at upper ice waterline [deg]
α = upper ice waterline angle [deg]
γ = buttock angle at upper ice waterline (angle of buttock line measured from horizontal) [deg]
tan(β) = tan(α) / tan(γ)
tan(β') = tan(β) cos(α)

Fig.2.3.2.1 : Definition of hull angles

b) Force, F:

$F_i = fa_i \cdot CF_C \cdot \Delta_{UI}^{0.64}$ [MN]

c) Load patch aspect ratio, AR:

$AR_i = 7.46 \cdot \sin(\beta'_i) \geq 1.3$

d) Line load, Q:

$Q_i = F_i^{0.61} \cdot CF_D / AR_i^{0.35}$ [MN/m]

e) Pressure, P:

$P_i = F_i^{0.22} \cdot CF_D^2 \cdot AR_i^{0.3}$ [MPa]

where,

i = sub-region considered

L_{UI} = rule length [m] as defined in 2.1.2.1

x = distance [m] from the fore side of the stem at the intersection with the upper ice waterline (UIWL) to station under consideration

α = waterline angle [deg], see Fig.2.3.2.1

β' = normal frame angle [deg], see Fig.2.3.2.1

Δ_{UI} = displacement as defined in 2.1.2.2 , not to be taken less than 5 [k-tonnes]

CF_C = Crushing Failure Class Factor from Table 2.3.2

CF_F = Flexural Failure Class Factor from Table 2.3.2

CF_D = Load patch dimensions Class Factor from Table 2.3.2

iv) The Bow area load characteristics for bow forms defined in 2.3.1 vi) are determined as follows:

a) Shape coefficients, fa_i, is to be taken as

$fa_i = \alpha_i / 30$

b) Force, F_i

$F_i = fa_i \ CF_{CV} \ \Delta_{UI}^{0.47}$ [MN]

c) Line load, Q_i :

$Q_i = F_i^{0.22}$ CF_{QV} [MN/m]

d) Pressure, P_i
$P_i = F^{0.56}$ CF_{PV} [MPa]

Where

i = sub-region considered

α = waterline angle [deg], see Fig.2.3.2.1

Δ_{UI} = displacement as defined in 2.1.2.2, not to be taken less than 5 [k-tonnes]

CF_{CV} = Crushing failure Class Factor from Table 2.3.3

CF_{QV} = Line load Class Factor from Table 2.3.3

CF_{PV} = Pressure Class Factor from Table 2.3.3

2.3.2.2 Hull areas other than the bow

In the hull areas other than the bow, the force (F_{NONBOW}) and line load (Q_{NONBOW}) used in the determination of the load patch dimensions (b_{NONBOW}, w_{NONBOW}) and design pressure (P_{avg}) are determined as follows:

a) Force, F_{NONBOW}:

$F_{NONBOW} = 0.36 . CF_C . DF$ [MN]

b) Line load, Q_{NONBOW}:

$Q_{NONBOW} = 0.639 . F_{NONBOW}^{0.61} . CF_D$ [MN/m]

where,

CF_C = Crushing Failure Class Factor from Table 2.3.2

DF = ship displacement factor

$= \Delta_{UI}^{0.64}$ if $\Delta_{UI} \leq CF_{DIS}$

$= CF_{DIS}^{0.64} + 0.10 (\Delta_{UI} - CF_{DIS})$ if $\Delta_{UI} > CF_{DIS}$

Δ_{UI} = displacement as defined in 2.1.2.2 , not to be taken less than 10 [k-tonnes]

CF_{DIS} = Displacement class factor from Table 2.3.2.

CF_D = load patch dimensions Class Factor from Table 2.3.2.

2.3.3 Design load patch

i) In the bow area of all ships and the bow intermediate icebelt area for ships with class notation PC6 and PC7, the design load patch has dimensions of width, w_{BOW} and height b_{BOW} defined as follows:

$w_{BOW} = F_{BOW} / Q_{BOW}$ [m]

$b_{BOW} = Q_{BOW} / P_{BOW}$ [m]

where,

F_{BOW} = maximum force F_i in the bow area [MN]

Q_{BOW} = maximum line load Q_i in the bow area [MN/m]

P_{BOW} = maximum pressure P_i in the bow area [MPa]

ii) In hull areas other than those covered by i) above, the design load patch has dimensions of width, w_{NONBOW} and height, b_{NONBOW}, defined as follows:

$w_{NONBOW} = F_{NONBOW} / Q_{NONBOW}$ [m]

$b_{NONBOW} = w_{NONBOW} / 3.6$ [m]

where,

F_{NONBOW} = force as defined in 2.3.2.2 a) [MN]

Q_{NONBOW} = line load as defined in 2.3.2.2 b) [MN/m]

2.3.4 Pressure within the design load patch

i) The average pressure, P_{avg}, within a design load patch is determined as follows:

$P_{avg} = F / (b . w)$ [MPa]

where,
F = F_{BOW} or F_{NONBOW} as appropriate for the hull area under consideration [MN]

b = b_{BOW} or b_{NONBOW} as appropriate for the hull area under consideration [m]

w = w_{BOW} or w_{NONBOW} as appropriate for the hull area under consideration [m]

ii) Areas of higher, concentrated pressure exist within the load patch. In general, smaller areas have higher local pressures. Accordingly, the peak pressure factors listed in Table 2.3.4 are used to account for the pressure concentration on localized structural members.

Table 2.3.4 : Peak pressure factors		
Structural Member		**Peak Pressure Factor (PPF_i)**
Plating	Transversely-framed	$PPF_p = (1.8 – s) \geq 1.2$
	Longitudinally-framed	$PPF_p = (2.2 – 1.2 \, . \, s) \geq 1.5$
Frames in transverse framing systems	With load distributing stringers	$PPF_t = (1.6 – s) \geq 1.0$
	With no load distributing stringers	$PPF_t = (1.8 – s) \geq 1.2$
Frames in bottom structures		$PPF_s = 1.0$
Load carrying stringers, Side longitudinals, Web frames		$PPF_s = 1$, if $S_w \geq 0.5 \, . \, w$ $PPF_s = 2.0 – 2.0 \, . \, S_w / w$, if $S_w < (0.5 \, . \, w)$
where, s = frame or longitudinal spacing [m] S_w = web frame spacing [m] w = ice load patch width [m]		

2.3.5 Hull area factors

i) Associated with each hull area is an area factor that reflects the relative magnitude of the load expected in that area. The Area Factor (AF) for each hull area is listed in Table 2.3.5.

ii) In the event that a structural member spans across the boundary of a hull area, the largest hull area factor is to be used in the scantling determination of the member.

iii) Due to their increased manoeuvrability, ships having propulsion arrangements with azimuthing thruster(s) or "podded" propellers are to have specially considered stern icebelt (S_i) and stern lower (S_l) hull area factors.

iv) For ships assigned the additional notation "**Icebreaker**", the Area Factor (AF) for each hull area is listed in Table 2.3.6.

Table 2.3.5 : Hull area factors (AF)									
Hull Area		**Area**	**Polar Class**						
			PC1	**PC2**	**PC3**	**PC4**	**PC5**	**PC6**	**PC7**
Bow (B)	All	B	1.00	1.00	1.00	1.00	1.00	1.00	1.00
Bow intermediate (BI)	Icebelt	BI_i	0.90	0.85	0.85	0.80	0.80	1.00*	1.00*
	Lower	BI_l	0.70	0.65	0.65	0.60	0.55	0.55	0.50
	Bottom	BI_b	0.55	0.50	0.45	0.40	0.35	0.30	0.25
Midbody (M)	Icebelt	M_i	0.70	0.65	0.55	0.55	0.50	0.45	0.45
	Lower	M_l	0.50	0.45	0.40	0.35	0.30	0.25	0.25
	Bottom	M_b	0.30	0.30	0.25	**	**	**	**
Stern (S)	Icebelt	S_i	0.75	0.70	0.65	0.60	0.50	0.40	0.35
	Lower	S_l	0.45	0.40	0.35	0.30	0.25	0.25	0.25
	Bottom	S_b	0.35	0.35	0.30	0.25	0.15	**	**
Note : * See 2.3.1 (iii). ** Indicates that strengthening for ice loads is not necessary.									

Table 2.3.6 : Hull area factors (AF) for ship with additional notation "Icebreaker"									
Hull Area		**Area**	**Polar Class**						
			PC1	**PC2**	**PC3**	**PC4**	**PC5**	**PC6**	**PC7**
Bow (B)	All	B	1.00	1.00	1.00	1.00	1.00	1.00	1.00
Bow Intermediate (BI)	Icebelt	BI_i	0.90	0.85	0.85	0.85	0.85	1.00	1.00
	Lower	BI_l	0.70	0.65	0.65	0.65	0.65	0.65	0.65
	Bottom	BI_b	0.55	0.50	0.45	0.45	0.45	0.45	0.45

	Lower	S_l	0.55	0.50	0.45	0.45	0.45	0.45	0.45
	Bottom	S_b	0.35	0.30	0.30	0.30	0.30	0.30	0.30

2.4 Shell plate requirements

2.4.1 The required minimum shell plate thickness, t, is given by:

$t = t_{net} + t_s$ [mm]

where,

t_{net} = plate thickness required to resist ice loads according to 2.4.2 [mm]

t_s = corrosion and abrasion allowance according to 2.11 [mm].

2.4.2 The thickness of shell plating required to resist the design ice load, t_{net}, depends on the orientation of the framing.

In the case of transversely-framed plating ($\Omega \geq 70$ deg), including all bottom plating, i.e. plating in hull areas BI_b, M_b and S_b, the net thickness is given by:

$t_{net} = 500 \cdot s \cdot ((AF \cdot PPF_p \cdot P_{avg}) / \sigma_y)^{0.5} / (1 + s / (2 \cdot b))$ [mm]

In case of longitudinally-framed plating ($\Omega \leq 20$ deg), when $b \geq s$, the net thickness is given by:

$t_{net} = 500 \cdot s \cdot ((AF \cdot PPF_p \cdot P_{avg}) / \sigma_y)^{0.5} / (1 + s / (2 \cdot l))$ [mm]

In case of longitudinally-framed plating ($\Omega \leq 20$ deg), when $b < s$, the net thickness is given by:

$t_{net} = 500 \cdot s \cdot ((AF \cdot PPF_p \cdot P_{avg}) / \sigma_y)^{0.5} \cdot (2 \cdot b / s - (b / s)^2)^{0.5} / (1 + s / (2 \cdot l))$ [mm]

In case of obliquely-framed plating ($70 \text{ deg} > \Omega > 20$ deg), linear interpolation is to be used:

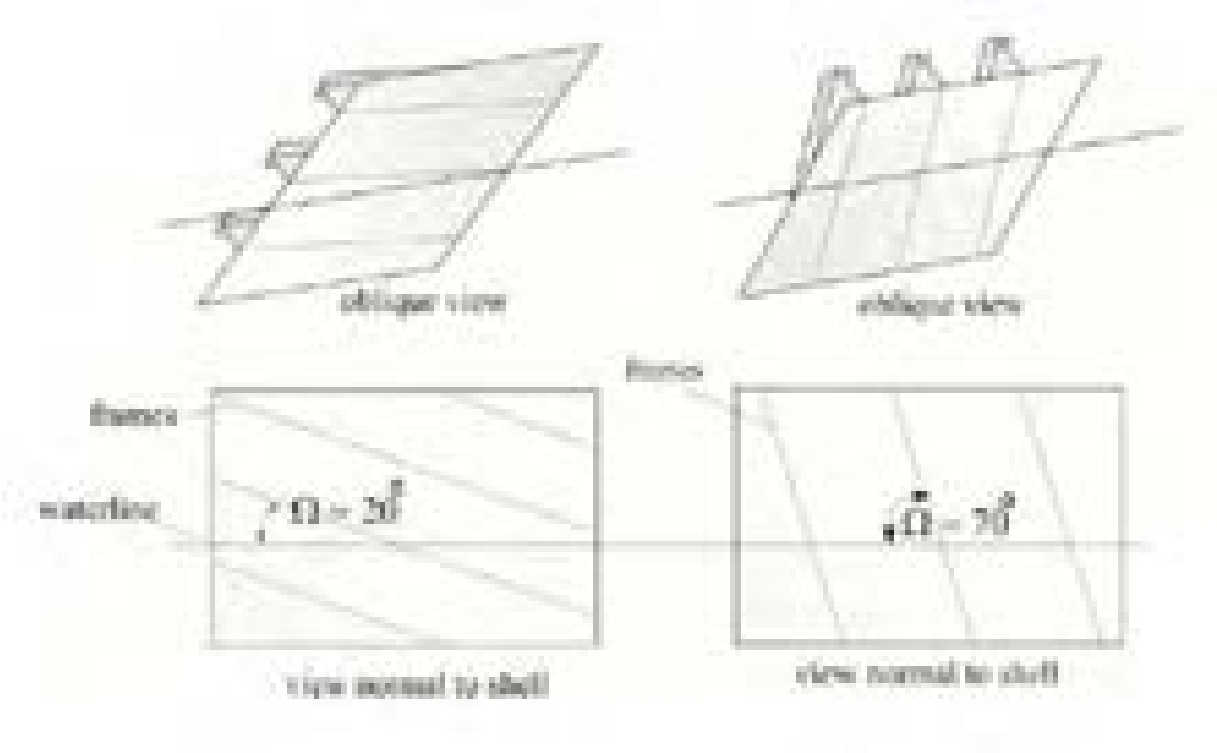

Fig.2.4.2 : Shell framing angle Ω

where,

Ω = smallest angle between the chord of the waterline and the line of the first level framing as illustrated in Fig.2.4.2 [deg.]

s = transverse frame spacing in transversely-framed ships or longitudinal frame spacing in longitudinally-framed ships [m]

AF = Hull area factor from Table 2.3.5 or Table 2.3.6.

PPF_p = Peak pressure factor from Table 2.3.4

P_{avg} = average patch pressure according to 2.3.4

σ_y = minimum upper yield stress of the material [N/mm^2]

b = height of design load patch [m], where b is to be taken not greater than (l - s/4) in the case of determination of the net thickness for transversely framed plating .

l = distance between frame supports, i.e. equal to the frame span as given in 2.5.5, but not reduced for any fitted end brackets [m]. When a load-distributing stringer is fitted, the length l need not be taken larger than the distance from the stringer to the most distant frame support.

2.5 Framing – General

2.5.1 Framing members of Polar Class ships are to be designed to withstand the ice loads defined in 2.3.

2.5.2 The term “framing member” refers to transverse and longitudinal local frames, load-carrying stringers and web frames in the areas of the hull exposed to ice pressure, see Fig.2.2.1.

2.5.3 The strength of a framing member is dependent upon the fixity that is provided at its supports. Fixity can be assumed where framing members are either continuous through the support or attached to a supporting section with a connection bracket. In other cases, simple support is to be assumed unless the connection can be demonstrated to provide significant rotational restraint. Fixity is to be ensured at the support of any framing which terminates within an ice-strengthened area.

2.5.4 The details of framing member intersection with other framing members, including plated structures, as well as the details for securing the ends of framing members at supporting sections are to be in accordance with Pt.3, Ch.3.

2.5.5 The effective span of a framing member is to be determined on the basis of its moulded length. If brackets are fitted, the effective span may be reduced in accordance with Pt.3, Ch.3. Brackets are to be configured to ensure stability in the elastic and post-yield response regions.

2.5.6 When calculating the section modulus and shear area of a framing member, net thicknesses of the web, flange (if fitted) and attached shell plating are to be used. The shear area of a framing member may include that material contained over the full depth of the member, i.e. web area including portion of flange, if fitted, but excluding attached shell plating.

2.5.7 The actual net effective shear area. A_w, of a transverse or longitudinal local frame is given by:

$A_w = h\, t_{wn} \sin \varphi_w / 100$ [cm^2]

h = height of stiffener [mm], see Fig.2.5.7

t_{wn} = net web thickness [mm]

$= t_w - t_c$

t_w = as built web thickness [mm], see Fig.2.5.7

t_c = corrosion deduction [mm] to be subtracted from the web and flange thickness (specified as t_s in 2.11.3, however not less than that given in Pt.3, Ch.3, Sec.2).

φ_w = smallest angle between shell plate and stiffener web, measured at the midspan of the stiffener, see Fig.2.5.7. The angle φ_w may be taken as 90 degrees provided the smallest angle is not less than 75 degrees.

2.5.8 When the cross-sectional area of the attached plate flange exceeds the cross-sectional area of the local frame, the actual net effective plastic section modulus, Z_p, of a transverse or longitudinal frame is given by:

$$Z_p = 0.05 A_{pn}.t_{pn} + 0.0005 h_w^2\, t_{wn} \sin\varphi_w + 0.1 A_{fn} \left(h_{fc} \sin\varphi_w - b_w \cos\varphi_w\right) \quad [cm^3]$$

h, t_{wn}, t_c and φ_w as given in 2.5.7 and s as given in 2.4.2

A_{pn} = net cross-sectional area of the local frame [cm^2]

t_{pn} = fitted net shell plate thickness [mm] (complying with t_{net} as required by 2.4.2)

h_w = height of local frame web [mm], see Fig.2.5.7

A_{fn} = net cross-sectional area of local frame flange [cm^2]

h_{fc} = height of local frame measured to center of the flange area [mm], see Fig.2.5.7

b_w = distance from mid thickness plane of local frame web to the centre of the flange area [mm], see Fig.2.5.7

When the cross-sectional area of the local frame exceeds the cross-sectional area of the attached plate flange, the plastic neutral axis is located a distance z_{na} above the attached shell plate, given by:

$z_{na} = (100\, A_{fn} + h_w\, t_{wn} - 1000\, t_{pn}\, s) / (2\, t_{wn})$ [mm]

and the net effective plastic section modulus, Z_p,of a transverse or longitudinal frame is given by:

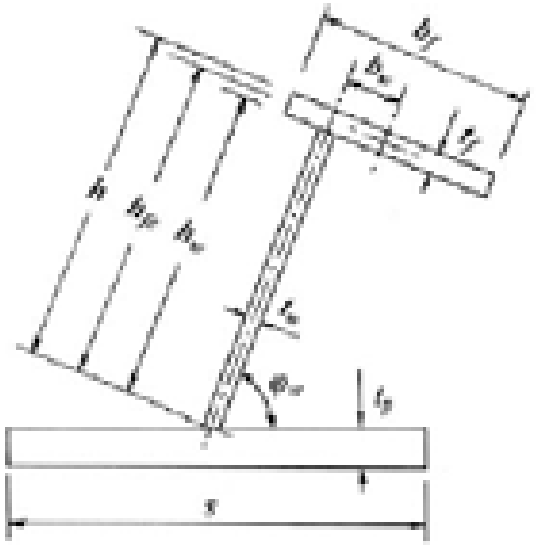

Fig.2.5.7 : Stiffener geometry

$$Z_p = t_{pn}\, s\left[Z_{na} + t_{pn}/2\right]\sin\varphi_w + 0.0005\left(\left(h_w - z_{na}\right)^2 + z_{na}^2\right) t_{wn}\sin\varphi_w + 0.10A_{fn}\left(\left(h_{fc} - z_{na}\right)\sin\varphi_w - b_w\cos\varphi_w\right)\,[cm^3]$$

2.5.9 In the case of oblique framing arrangement (70 deg > Ω > 20 deg, where Ω is defined as given in 2.4.2), linear interpolation is to be used.

2.6 Framing – Local frames in bottom structures and transverse local frames in side structures

2.6.1 The local frames in bottom structures (i.e. hull areas B_{lb}, M_b and S_b) and transverse local frames in side structures are to be dimensioned such that the combined effects of shear and bending do not exceed the plastic strength of the member. The plastic strength is defined by the magnitude of midspan load that causes the development of a plastic collapse mechanism. For bottom structure the patch load is to be applied with the dimension (b) parallel with the frame direction.

2.6.2 The actual net effective shear area of the frame, A_w, as defined in 2.5.7, is to comply with the following condition: $A_w \geq A_t$, where:

$A_t = 100^2 \cdot 0.5 \cdot LL \cdot s \cdot (AF \cdot PPF_t \cdot P_{avg}) / (0.577 \cdot \sigma_y)$ [cm^2]

where,

LL = length of loaded portion of span

= lesser of a and b [m]

a = local frame span as defined in 2.5.5 [m]

b = height [m] of design ice load patch as defined in 2.3.3 i) or 2.3.3 ii)

s = spacing of local frame [m]

AF = Hull Area Factor from Table 2.3.5 or 2.3.6

PPF = Peak Pressure Factor, PPF_t or PPF_s as appropriate from Table 2.3.4

P_{avg} = average pressure [MPa] within load patch as defined in 2.3.4

σ_y = minimum upper yield stress of the material [N/mm^2]

2.6.3 The actual net effective plastic section modulus of the plate / stiffener combination, Z_p, as defined in 2.5.8, is to comply with the following condition : $Z_p \geq Z_{pt}$, where Z_{pt} is to be the greater calculated on the basis of two load conditions : a) ice load acting at the midspan of the local frame, and b) the ice load acting near a support. The A1 parameter defined below reflects these two conditions:

$Z_{pt} = 100^3 \cdot LL \cdot Y \cdot s \cdot (AF \cdot PPF_t \cdot P_{avg}) \cdot a \cdot A_1 / (4 \cdot \sigma_y)$ [cm^3]

where,

AF, PPF_t, P_{avg}, LL, b, s, a and σ_y are as given in 2.6.2

$Y = 1 – 0.5 . (LL / a)$

A_1 = maximum of

$A_{1A} = 1 / (1 + j / 2 + k_w . j / 2 . [(1 – a_1^2)^{0.5} – 1])$

$A_{1B} = (1 - 1 / (2 . a_1 . Y)) / (0.275 + 1.44 . k_z^{0.7})$

j = 1 for a local frame with one simple support outside the ice-strengthened areas

= 2 for framing local frame without any simple supports

$a_1 = A_t / A_w$

A_t = minimum shear area [cm^2] of the local frame as given in 2.6.2

A_w = effective net shear area [cm^2] of the local frame (calculated according to 2.5.7)

$k_w = 1 / (1 + 2 . A_{fn} / A_w)$ with A_{fn} as given in 2.5.8

$k_z = z_p / Z_p$ in general

= 0.0 when the frame is arranged with end bracket

z_p = sum of individual plastic section modulii of flange and shell plate as fitted [cm^3]

$= (b_f . t_{fn}^2 / 4 + b_{eff} . t_{pn}^2 / 4) / 1000$

b_f = flange breadth [mm], see Fig.2.5.7

t_{fn} = net flange thickness [mm]

$= t_f – t_c$ (t_c as given in 2.5.7)

t_f = as-built flange thickness [mm], see Fig.2.5.7

t_{pn} = the fitted net shell plate thickness [mm] (not to be less than t_{net} as given in 2.4)

b_{eff} = effective width of shell plate flange [mm]

= 500 s

Z_p = net effective plastic section modulus [cm^3] of the local frame (calculated according to 2.5.8).

2.6.4 The scantlings of the local frame are to meet the structural stability requirements of 2.9.

2.7 Framing – Longitudinal local frames in side structures

2.7.1 Longitudinal local frames in side structures are to be dimensioned such that the combined effects of shear and bending do not exceed the plastic strength of the member. The plastic strength is defined by the magnitude of midspan load that causes the development of a plastic collapse mechanism.

2.7.2 The actual net effective shear area of the frame, A_w, as defined in 2.5.7, is to comply with the following condition: $A_w \geq A_L$, where:

$A_L = 100^2 . (AF . PPF_s . P_{avg}) . 0.5 . b_1 . a / (0.577 . \sigma_y)$ [cm^2]

where,

AF = Hull area factor from Table 2.3.5 or Table 2.3.6

PPF_s = Peak pressure factor from Table 2.3.4

P_{avg} = average pressure within load patch as defined in 2.3.4 [MPa]

$b_1 = k_o . b_2$ [m]

$k_o = 1 – 0.3 / b'$

$b' = b / s$

b = height of design ice load patch from 2.3.3 i) or ii) [m]

s = spacing of longitudinal frames [m]

$b_2 = b (1 – 0.25 . b')$ [m], if $b' < 2$

= s [m], if $b' \geq 2$

a = effective span [m] of longitudinal local frame as given in 2.5.5

σ_y = minimum upper yield stress of the material [N/mm^2]

2.7.3 The actual net effective plastic section modulus of the plate / stiffener combination, Z_p, as defined in 2.5.8, is to comply with the following condition: $Z_p \geq Z_{pL}$, where:

$Z_{pL} = 100^3 . (AF . PPF_s . P_{avg}) . b_1 . a^2 . A_4 / (8 . \sigma_y)$ [cm^3]

where,

AF, PPF_s, P_{avg}, b_1, a and σ_y are as given in 2.7.2

$A_4 = 1 / (2 + k_{wl} . [(1 – a_4^2)^{0.5} – 1])$

$a_4 = A_L / A_w$

A_L = minimum shear area for longitudinal as given in 2.7.2 [cm^2]

A_w = net effective shear area of longitudinal (calculated according to 2.5.7) [cm^2]

$K_{wl} = 1 / (1 + 2 . A_{fn} / A_w)$ with A_{fn} as given in 2.5.8.

2.7.4 The scantlings of the longitudinals are to meet the structural stability requirements of 2.9.

2.8 Framing – Web frames and load-carrying stringers

2.8.1 Web frames and load-carrying stringers are to be designed to withstand the ice load patch as defined in 2.3. The load patch is to be applied at locations where the capacity of these members under the combined effects of bending and shear is minimized.

2.8.2 Web frames and load-carrying stringers are to be dimensioned such that the combined effects of shear and bending do not exceed the permissible stresses given below:

Shear stress $\tau = \sigma_y / \sqrt{3}$

Bending stress $\sigma_b = \sigma_y$

Equivalent stress $\sigma_e = \sqrt{\sigma_b^2 + 3\tau^2} = 1.15\,\sigma_y$

Where the structural configuration is such that members do not form part of a grillage system, the appropriate peak pressure factor (PPF) from Table 2.3.4 is to be used. Special attention is to be paid to the shear capacity in way of lightening holes and cut-outs in way of intersecting members.

2.8.3 For determination of scantlings of load carrying stringers, web frames supporting local frames, or web frames supporting load carrying stringers forming part of a structural grillage system, appropriate methods as outlined in 2.17 are normally to be used.

2.8.4 The scantlings of web frames and load-carrying stringers are to meet the structural stability requirements of 2.9.

2.9 Framing – structural stability

2.9.1 To prevent local buckling in the web, the ratio of web height (h_w) to net web thickness (t_{wn}) of any framing member is not to exceed:

For flat bar sections:

$$h_w / t_{wn} \leq 282 / (\sigma_y)^{0.5}$$

For bulb, tee and angle sections:

$$h_w / t_{wn} \leq 805 / (\sigma_y)^{0.5}$$

where,

h_w = web height
t_{wn} = net web thickness
σ_y = minimum upper yield stress of the material [N/mm^2]

2.9.2 Framing members for which it is not practicable to meet the requirements of 2.9.1 (e.g. load carrying stringers or deep web frames) are required to have their webs effectively stiffened. The scantlings of the web stiffeners are to ensure the structural stability of the framing member. The minimum net web thickness for these framing members is given by:

$t_{wn} = 2.63 \times 10^{-3} . c_1 . (\sigma_y / (5.34 + 4 . (c_1 / c_2)^2))^{0.5}$ [mm]

where,

$c_1 = h_w – 0.8 . h$ [mm]

h_w = web height of stringer / web frame [mm] (see Fig.2.9.2)

h = height of framing member penetrating the member under consideration (0 if no such framing member) [mm] (see Fig.2.9.2)

c_2 = spacing between supporting structure oriented perpendicular to the member under consideration [mm] (see Fig.2.9.2)

σ_y = minimum upper yield stress of the material [N/mm^2]

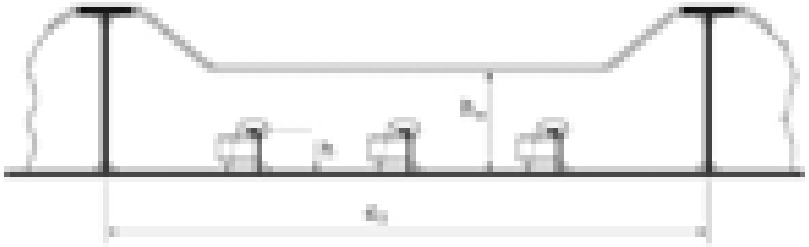

Fig.2.9.2 : Parameter definition for web stiffening

2.9.3 In addition, the following is to be satisfied:

$t_{wn} \geq 0.35 \, . \, t_{pn} \, . \, (\sigma_y / 235)^{0.5}$

where,

σ_y = minimum upper yield stress of the shell plate in way of the framing member [N/mm^2]

t_{wn} = net thickness of the web [mm]

t_{pn} = net thickness of the shell plate in way of the framing member [mm]

2.9.4 To prevent local flange buckling of welded profiles, the following are to be satisfied:

i) The flange width, b_f [mm], is not to be less than five times the net thickness of the web, t_{wn}.

ii) The flange outstand, b_{out} [mm], is to meet the following requirement:

$b_{out} / t_{fn} \leq 155 / (\sigma_y)^{0.5}$

where,

t_{fn} = net thickness of flange [mm]

σ_y = minimum upper yield stress of the material [N/mm^2].

2.10 Plated structures

2.10.1 Plated structures are those stiffened plate elements in contact with the hull and subject to ice loads e.g. bulkheads, decks etc. These requirements are applicable to an inboard extent which is the lesser of:

i) web height of adjacent parallel web frame or stringer; or

ii) 2.5 times the depth of framing that intersects the plated structure

2.10.2 The thickness of the plating and the scantlings of attached stiffeners are to be such that the degree of end fixity necessary for the shell framing is ensured.

2.10.3 The stability of the plated structure is to adequately withstand the ice loads defined in 2.3.

2.11 Corrosion / abrasion additions and steel renewal

2.11.1 Effective protection against corrosion and ice-induced abrasion is recommended for all external surfaces of the shell plating for Polar Class ships.

2.11.2 The values of corrosion / abrasion additions, t_s, to be used in determining the shell plate thickness are listed in Table 2.11.2.

2.11.3 Polar Class ships are to have a minimum corrosion addition of t_s = 1.0 [mm] applied to all internal structures within the ice-strengthened hull areas, including plated members adjacent to the shell, as well as stiffener webs and flanges.

2.11.4 Steel renewal for ice strengthened structures is required when the gauged thickness is less than t_{net} + 0.5 [mm]

Table 2.11.2 : Corrosion / abrasion additions for shell plating						
Hull Area	**t_s [mm]**					
	With effective protection			**Without effective protection**

Bow intermediate lower; midbody and stern icebelt	2.5	2.0	2.0	5.0	4.0	3.0
Midbody and stern lower; bottom	2.0	2.0	2.0	4.0	3.0	2.5

2.12 Materials

2.12.1 Steel grades of plating for hull structures are to be not less than those given in Table 2.12.1 based on the as-built thickness, the Polar Class and the material class of structural members given in accordance to 2.12.2.

2.12.2 Material classes specified in Pt.3, Ch.2, Table 2.2.1a) are applicable to Polar Class ships regardless of the ship's length. In addition, material classes for weather and sea exposed structural members and for members attached to the weather and sea exposed shell plating of polar ships are given in Table 2.12.2. Where the material classes in Table 2.12.2 and those in Pt.3, Ch.2, Table 2.2.1a) differ, the higher material class is to be applied.

2.12.3 Steel grades for all plating and attached framing of hull structures and appendages situated below the level of 0.3 [m] below the lower ice waterline, as shown in Fig.2.12.3 are to be obtained from Table 2.2.1f) and Table 2.2.2 of Pt.3, Ch.2 based on the material class for structural members in Table 2.12.2 above, regardless of Polar Class.

2.12.4 Steel grades for all weather exposed plating of hull structures and appendages situated above the level of 0.3 [m] below the lower ice waterline, as shown in Fig.2.12.3 are to be not less than given in Table 2.12.1.

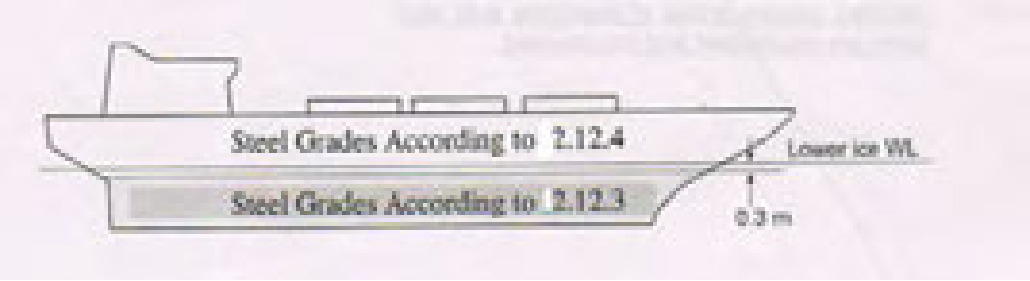

Fig.2.12.3 : Steel grade requirements for submerged and weather exposed shell plating

Table 2.12.2 : Material classes for structural members of polar ships	
Structural Members	**Material Class**
Shell plating within the bow and bow intermediate icebelt hull areas (B, BI_i)	II
All weather and sea exposed SECONDARY and PRIMARY, as defined in Table 2.2.1a) of Pt.3, Ch.2, structural members outside $0.4L_{UI}$ amidships	I
Plating materials for stem and stern frames, rudder horn, rudder, propeller nozzle, shaft brackets, ice skeg, ice knife and other appendages subject to ice impact loads	II
All inboard framing members attached to the weather and sea-exposed plating including any contiguous inboard member within 600 [mm] of the plating	I
Weather-exposed plating and attached framing in cargo holds of ships which by nature of their trade have their cargo hold hatches open during cold weather operations	I
All weather and sea exposed SPECIAL, as defined in Table 2.2.1a) of Pt.3, Ch.2, structural members within $0.2L_{UI}$ from FP	II

Φ – Not Applicable

Notes:

1) Includes weather-exposed plating of hull structures and appendages, as well as their outboard framing members, situated above a level of 0.3 [m] below the lowest ice waterline.

2) Grades D, DH are allowed for a single strake of side shell plating not more than 1.8 [m] wide from 0.3 [m] below the lowest ice waterline.

2.12.5 Castings are to have specified properties consistent with the expected service temperature for the cast component.

2.13 Longitudinal strength

2.13.1 Application

2.13.1.1 A ramming impact on the bow is the design scenario for the evaluation of the longitudinal strength of the hull

2.13.1.2 Intentional ramming is not considered as a design scenario for ships which are designed with vertical or bulbous bows, see 1.1.6. Hence the longitudinal strength requirements given in 2.13 is not to be considered for ships with stem angle γ_{stem} equal to or larger than 80 [deg].

2.13.1.3 Ice loads are only to be combined with still water loads. The combined stresses are to be compared against permissible bending and shear stresses at different locations along the ship's length. In addition, sufficient local buckling strength is also to be verified.

2.13.2 Design vertical ice force at the bow

2.13.2.1 The design vertical ice force at the bow, F_{IB}, is to be taken as

F_{IB} = minimum ($F_{IB.1}$; $F_{IB.2}$) [MN]

where,

$F_{IB.1} = 0.534 \cdot K_I^{\ 0.15} \cdot \sin^{0.2}(\gamma_{stem}) \cdot (\Delta_{UI} \cdot K_h)^{0.5} \cdot CF_L$ [MN]

$F_{IB.2} = 1.20 \cdot CF_F$ [MN]

K_I = indentation parameter = K_f / K_h

a) for the case of a blunt bow form

$K_f = (2 \cdot C \cdot B_{UI}^{1-e_b} / (1 + e_b))^{0.9} \cdot \tan(\gamma_{stem})^{-0.9.(1+e_b)}$

b) for the case of wedge bow form (α_{stem} < 80 deg), e_b = 1 and the above simplifies to
$K_f = (\tan(\alpha_{stem}) / \tan^2(\gamma_{stem}))^{0.9}$

$K_h = 0.01 \cdot A_{wp}$ [MN/m]

CF_L = longitudinal strength class factor from Table 2.3.2

e_b = bow shape exponent which best describes the waterplane (see Fig.2.13.2.1a) and (Fig.2.13.2.1b)
= 1.0 for a simple wedge bow form
= 0.4 to 0.6 for a spoon bow form
= 0 for a landing craft bow form

An approximate e_b determined by a simple fit is acceptable

γ_{stem} = stem angle to be measured between the horizontal axis and the stem tangent at the upper ice waterline [deg] (buttock angle as per Fig.2.3.2.1 measured on the centerline)

α_{stem} = waterline angle measured in way of the stem at the upper ice waterline (UIWL) [deg] (see Fig. 2.13.2.1a)

$C = 1 / (2 \cdot (L_B / B_{UI})^{e_b})$

B_{UI} = moulded breadth corresponding to the upper ice waterline (UIWL) [m]

L_B = bow length used in the equation $y = B_{UI} / 2 \cdot (x/L_B)^{e_b}$ [m] (see Fig.2.13.2.1a) and Fig.2.13.2.1b)

Δ_{UI} = displacement as defined in 2.1.2.2, not to be taken less than 10 [k-tonnes]

A_{wp} = waterplane area corresponding to the upper ice waterline (UIWL) [m^2]

CF_F = flexural failure class factor from Table 2.3.2

2.13.3 Design vertical ice shear force

2.13.3.1 The design vertical ice shear force, F_I, along the hull girder is to be taken as:

$F_I = C_f \cdot F_{IB}$ [MN]

where,

C_f = longitudinal distribution factor to be taken as follows:

a) Positive shear force

C_f = 0.0 between the aft end of L_{UI} and 0.6L_{UI} from aft
C_f = 1.0 between 0.9L_{UI} from aft and the forward end of L_{UI}

b) Negative shear force

C_f = 0.0 at the aft end of L_{UI}
C_f = -0.5 between 0.2 L_{UI} and 0.6L_{UI} from aft
C_f = 0.0 between 0.8L_{UI} from aft and the forward end of L_{UI}

Intermediate values are to be determined by linear interpolation

2.13.3.2 Shear strength is to be checked as per Pt.3, Ch.5, Sec.4 by substituting the design vertical ice shear force for the design vertical wave shear force. The permissible shear stress τ is to be determined from Table 2.13.5.

2.13.4 Design vertical ice bending moment

2.13.4.1 The design vertical ice bending moment, M_I, along the hull girder is to be taken as:

$$M_I = 0.1 \cdot C_m \cdot L_{UI} \cdot \sin^{-0.2}(\gamma_{stem}) \cdot F_{IB} \quad [MNm]$$

where,

L_{UI} = length as defined in 2.1.2.1 [m]

γ_{stem} is as given in 2.13.2.1

F_{IB} = design vertical ice force at the bow [MN]

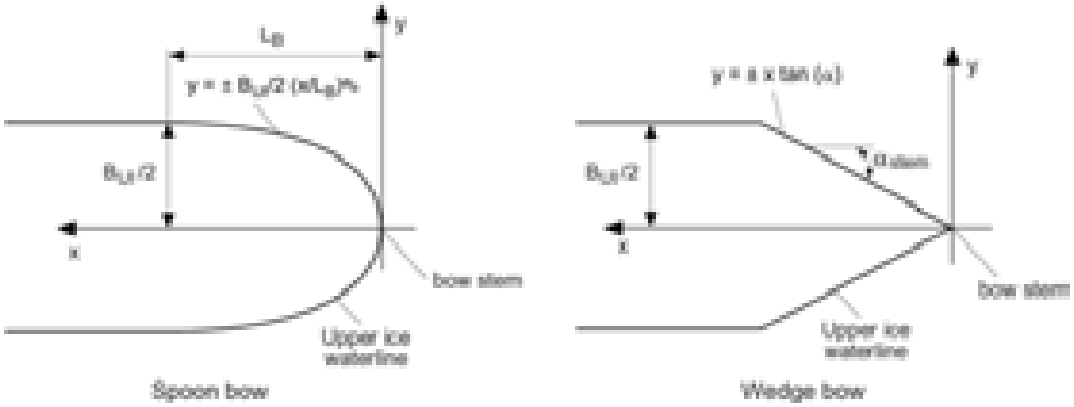

Fig.2.13.2.1a) : Bow shape definition

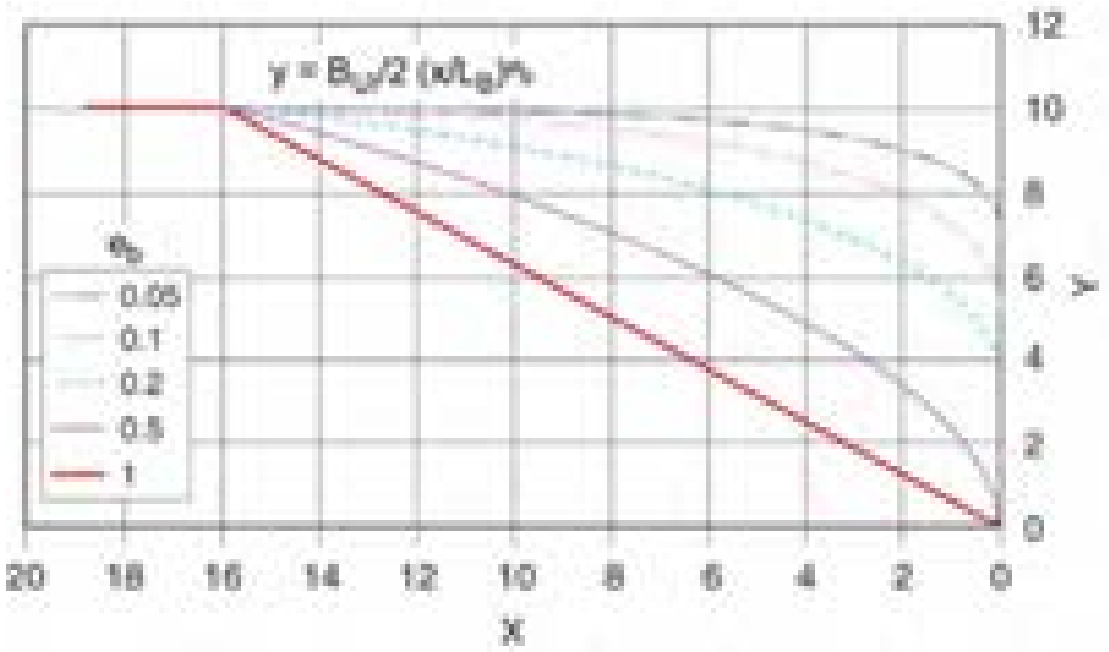

Fig.2.13.2.1b) : Illustration of e_b effect on the bow shape for B_{UI} = 20 and L_B = 16

C_m = longitudinal distribution factor for design vertical ice bending moment to be taken as follows:

C_m = 0.0 at the aft end of L_{UI}
C_m = 1.0 between $0.5L_{UI}$ and $0.7L_{UI}$ from aft
C_m = 0.3 at $0.95L_{UI}$ from aft
C_m = 0.0 at the forward end of L_{UI}

Intermediate values are to be determined by linear interpolation

2.13.4.2 The required section modulus of the hull girder is to be determined as per Pt.3, Ch.5, 3.3.1 by substituting the design vertical ice bending moment for the design vertical wave bending moment. The ship still water bending moment is to be taken as the permissible still water bending moment in sagging condition. The permissible bending stresses is to be determined from Table 2.13.5.

2.13.5 Longitudinal strength criteria

2.13.5.1 The strength criteria provided in Table 2.13.5 are to be satisfied. The design stress is not to exceed the permissible stress.

Table 2.13.5 : Longitudinal strength criteria

Failure Mode	Applied Stress	Permissible stress when $\sigma_y / \sigma_u \leq 0.7$	Permissible stress when $\sigma_y / \sigma_u > 0.7$
Tension	σ_a	$\eta \cdot \sigma_y$	$\eta \cdot 0.41 (\sigma_u + \sigma_y)$
Shear	τ_a	$\eta \cdot \sigma_y / \sqrt{3}$	$\eta \cdot 0.41 (\sigma_u + \sigma_y) / \sqrt{3}$
Buckling	σ_a	σ_{cr} for plating and for web plating of stiffeners $\sigma_{cr}/1.1$ for stiffeners	
	τ_a	τ_{cr}	

where,

σ_a = applied vertical bending stress [N/mm^2]

τ_a = applied vertical shear stress [N/mm^2]

σ_y = minimum upper yield stress of the material [N/mm^2]

σ_u = ultimate tensile strength of material [N/mm^2]

σ_{cr} = critical buckling stress in compression, according to Pt.3, Ch.3, Sec.6 [N/mm^2]

τ_{cr} = critical buckling stress in shear, according to Pt.3, Ch.3, Sec.6 [N/mm^2]

η = 0.8.

η = 0.6 for ships which are assigned the additional notation "**Icebreaker**".

2.14 Stem and stern frames

2.14.1 When the vessel has a sharp edged stem (see Fig.2.8.1of Pt.5, Ch.21) the thickness of the stem side plate is not to be less than 1.2 times the required plate thickness of the adjacent shell plating.

2.14.2 The plate thickness of a shaped plate stem and in the case of a blunt tow, any part of the shell which forms an angle of 30° or more to the centerline in a longitudinal plane is to be not less than 1.2 times the required thickness of the adjacent shell plating.

2.15 Appendages

2.15.1 All appendages are to be designed to withstand forces appropriate for the location of their attachment to the hull structure or their position within a hull area.

2.15.2 Load definition and response criteria are to be specially considered.

2.16 Local details

2.16.1 The end connections of longitudinal and transverse secondary members, web frames and stringers subjected to ice-induced loads are to be supported to transfer the loads to the supporting members. The area of end connections are to be such that shear stress does not exceed $\sigma_y / \sqrt{3}$ [N/mm^2], where σ_y is the yield stress of the material.

2.16.2 The loads carried by a member in way of cut-outs are not to cause instability. Where necessary, the structure is to be stiffened.

2.17 Direct calculation

2.17.1 Direct calculation are not to be utilized as an alternative to the analytical procedures prescribed for the shell plating and local frame requirements given in 2.4, 2.6 and 2.7.

2.17.2 Direct calculations are to be used for load carrying stringers and web frames forming part of a grillage system.

2.17.3 Where direct calculation is used to check the strength of structural systems, the load patch specified in 2.3 is to be applied, without being combined with any other loads. The load patch is to be applied at locations where the capability of these members under the combined effects of bending and shear is minimized. Special attention is to be paid to the shear capacity in way of lightening holes and cut-outs in way of intersecting members.

2.17.4 The strength evaluation of web frames and stringers may be performed based on linear or non-linear analysis. Recognized structural idealization and calculation methods are to be applied, but the detailed requirements are to be specially considered. In the strength evaluation, the guidance given in 2.17.5 and 2.17.6 may generally be considered.

2.17.5 If the structure is evaluated based on linear calculation methods, the following are to be considered:

1) Web plates and flange elements in compression and shear to fulfil relevant buckling criteria
2) Nominal shear stresses in member web plates to be less than $\sigma_y/\sqrt{3}$
3) Nominal von Mises stresses in member flanges to be less than 1.15 σ_y

2.17.6 If the structure is evaluated based on non-linear calculation methods, the following are to be considered:

1) The analysis is to reliably capture buckling and plastic deformation of the structure
2) The acceptance criteria are to ensure a suitable margin against fracture and major buckling and yielding causing significant loss of stiffness
3) Permanent lateral and out-of plane deformation of considered member are to be minor relative to the relevant structural dimensions.
4) Detailed acceptance criteria to be decided specially

2.18 Welding

2.18.1 All welding within ice-strengthened areas is to be of the double continuous type.

2.18.2 Continuity of strength is to be ensured at all structural connections.

Section 3

Machinery Requirements for Polar Class Ships

3.1 Application

3.1.1 The contents of this section apply to main propulsion, steering gear, emergency and auxiliary systems essential for the safety of the ship and the crew.

3.1.2 The vessel operating conditions are defined in Section 1.

3.1.3 The requirements herein are additional to those applicable for the basic open water operation of the vessel.

3.2 Documentation and design

3.2.1 Following drawings and particulars are to be submitted.

3.2.1.1 Details of the intended environmental operational conditions and the required polar strengthening for the machinery, if different from ship’s polar class.

3.2.1.2 Detailed drawings and descriptions of the main propulsion machinery, steering, emergency and auxiliary machinery and information on the essential main propulsion load control functions. The descriptions are to include operational limitations.

3.2.1.3 Description detailing where main, emergency and auxiliary systems are located and how they are protected to prevent problems from freezing, ice and snow accumulation and evidence of their capability to operate in the intended environmental conditions.

3.2.1.4 Calculations and documentation indicating compliance with the requirements of this section.

3.2.2 System design

3.2.2.1 Systems subject to damage by freezing are to be drainable.

3.2.2.2 Vessels classed PC1 to PC5 inclusive are to have means to ensure sufficient vessel operation in the case of propeller damage including the Controllable Pitch (CP)mechanism. Sufficient vessel operation means that the vessel is to be able to reach safe haven (safe location) where repairs can be undertaken. This may be achieved either by a temporary repair at sea, or by towing, assuming assistance is available. This would lead however to a condition of approval.

3.2.2.3 Means are to be provided to free a stuck propeller by turning it in reverse direction. This is to be possible for a propulsion plant intended for unidirectional rotation.

3.2.2.4 The propeller is to be fully submerged at the ships LIWL.

3.3 Materials

Materials are to be of an approved ductile material. Ferritic nodular cast iron may be used for parts other than bolts. For nodular cast iron an averaged impact energy value of 10 J at testing temperature is regarded as equivalent to the Charpy V test requirements defined below.

3.3.1 Materials exposed to sea water

3.3.1.1 Materials exposed to sea water, such as propeller blades, propeller hubs and cast thruster bodies are to have an elongation not less than15% on a test specimen according to *Pt.2, Ch.2, Mechanical Testing Procedures.*

3.3.1.2 Charpy V-notch impact testing is to be carried out for materials other than bronze and austenitic steel. The tests are to be carried out on three specimens at minus 10 ºC, and the average energy value is to be not less than 20 J. However, Charpy V impact test requirements of *Pt.2, Ch.4, Sec.2 or Pt.2, Ch.4, Sec.4* as applicable for ships with ice class notation, are also to be applied to ships covered by this section..

3.3.2 Materials exposed to sea water temperature

3.3.2.1 Charpy V-notch impact testing is to be carried out for materials other than bronze and austenitic steel. The tests are to be carried out on three specimens at minus 10 ºC, and the average energy value is to be not less than 20 J. However, the Charpy V impact test requirements of *Pt.2, Ch.4, Sec.2* as applicable for ships with ice class notation, are also to be applied to ships covered by this Section.

3.3.2.2 This requirement applies to components such as but not limited to blade bolts, CP-mechanisms, shaft bolts, propeller shaft, strut-pod connecting bolts, etc. This requirement does not apply to surface hardened components, such as bearings and gear teeth or sea water cooling lines (heat exchangers, pipes, valves, fittings etc.). For a definition of structural boundaries exposed to sea water temperature see *Sec.2, Fig 2.12.3*.

3.3.3 Material exposed to low air temperature

3.3.3.1 Materials of exposed machinery and foundations are to be manufactured from steel or other approved ductile material. An average impact energy value of 20 J taken from three Charpy V tests is to be obtained at 10 ºC below the lowest design temperature. Charpy V impact tests are not required for bronze and austenitic steel.

3.3.3.2 This requirement does not apply to surface hardened components, such as bearings and gear teeth. For a definition of structural boundaries exposed to air temperature see *Sec.2, Fig 2.12.3*.

3.4 Definitions

3.4.1 Definition of Symbols

Table 3.4.1 : Definition of symbols		
Symbol	**Unit**	**Definition**
c	m	chord length of blade section
$c_{0.7}$	m	chord length of blade section at 0.7R propeller radius
CP	-	controllable pitch
D	m	propeller diameter
d	m	external diameter of propeller hub (at propeller plane)
d_{pin}	mm	diameter of shear pin
D_{limit}	m	limit value for propeller diameter
EAR		expanded blade area ratio
F_b	kN	maximum backward blade force for the ship's service life (negative sign)
F_{ex}	kN	ultimate blade load resulting from blade failure through plastic bending
F_f	kN	maximum forward blade force for the ship's service life (positive sign)
F_{ice}	kN	ice load
$(F_{ice})_{max}$	kN	maximum ice load for the ship's service life
FP	-	fixed pitch
h_0	m	depth of the propeller centreline from lower ice waterline (LIWL)
H_{ice}	m	Ice block dimension for propeller load definition
I	kgm^2	equivalent mass moment of inertia of all parts on engine side of component under consideration
I_t	kgm^2	equivalent mass moment of inertia of the whole propulsion system
k	-	shape parameter for Weibull distribution
LIWL	m	lower ice waterline
m	-	slope for S-N curve in log/log scale
M_{BL}	kNm	blade bending moment
MCR	-	maximum continuous rating
N	-	number of ice load cycles
n	rev/s	propeller rotational speed
n_n	rev/s	nominal propeller rotational speed at MCR in free running condition
N_{class}	-	reference number of ice impacts per propeller revolution per ice class
N_{ice}	-	total number of ice load cycles on propeller blade for the ship's service life
N_R	-	reference number of ice load cycles for equivalent fatigue stress (10^8 cycles)
N_Q	-	number of propeller revolutions during a milling sequence
$P_{0.7}$	m	propeller pitch at 0.7R radius
$P_{0.7n}$	m	propeller pitch at 0.7R radius at MCR in free running condition
$P_{0.7b}$	m	propeller pitch at 0.7R radius at MCR in bollard condition
PCD	m	pitch circle diameter

$Q(\varphi)$	kNm	Torque
Q_{Amax}	kNm	maximum response torque amplitude as a simulation result
Q_{emax}	kNm	maximum engine torque
$Q_F(\varphi)$	kNm	Ice torque excitation for frequency domain calculations
Q_{fr}	kNm	friction torque in pitching mechanism; reduction of spindle torque
Q_{max}	kNm	maximum torque on the propeller resulting from propeller/ice interaction
Q_{motor}	kNm	electric motor peak torque
Q_n	kNm	nominal torque at MCR in free running condition
$Q_r(t)$ Q_{peak}	kNm kNm	response torque along the propeller shaft line maximum of the response torque $Q_r(t)$
Q_{smax}	kNm	maximum spindle torque of the blade for the ship's service life
Q_{sex}	kNm	extreme spindle torque corresponding to the blade failure load F_{ex}
Q_{vib}	kNm	Vibratory torque at considered component, taken from frequency domain open water TVC
R	m	propeller radius
S	-	Safety factor
S_{fat}	-	Safety factor for fatigue
S_{ice}	-	Ice strength index for blade ice force
r	m	blade section radius
T	kN	Hydrodynamic propeller thrust in bollard condition
T_b	kN	maximum backward propeller ice thrust for the ship's service life
T_f	kN	maximum forward propeller ice thrust for the ship's service life
T_n	kN	propeller thrust at MCR in free running condition
T_r	kN	maximum response thrust along the shaft line
T_{kmax}	kNm	maximum torque capacity of flexible coupling
T_{kmax2}	kNm	T_{kmax} at N=1 load cycle
T_{kmax1}	kNm	T_{kmax} at $N=5\cdot10^4$ load cycles
T_{kv}	kNm	vibratory torque amplitude at $N=10^6$ load cycles
ΔT_{kmax}	kNm	maximum range of T_{kmax} at $N=5\cdot10^4$ load cycles
T	m	maximum blade section thickness
z	-	number of propeller blades
z_{pin}	-	number of shear pins
α_i	deg	duration of propeller blade/ice interaction expressed in rotation angle
γ_ε	-	the reduction factor for fatigue; scatter and test specimen size effect
γ_v	-	the reduction factor for fatigue; variable amplitude loading effect
γ_m	-	the reduction factor for fatigue; mean stress effect
ρ	-	a reduction factor for fatigue correlating the maximum stress amplitude to the equivalent fatigue stress for 10^8 stress cycles
$\sigma_{0.2}$	MPa	proof yield strength (at 0.2% plastic strain) of material

σ_{exp}	MPa	mean fatigue strength of blade material at 10^8 cycles to failure in sea water
σ_{fat}	MPa	equivalent fatigue ice load stress amplitude for 10^8 stress cycles
σ_{fl}	MPa	characteristic fatigue strength for blade material
σ_{ref1}	MPa	reference stress $\sigma_{ref1} = 0.6 \cdot \sigma_{0.2} + 0.4 \cdot \sigma_u$
$\sigma_{ref\,2}$	MPa	reference stress $\sigma_{ref2} = 0.7 \cdot \sigma_u$ or $\sigma_{ref2} = 0.6 \cdot \sigma_{0.2} + 0.4 \cdot \sigma_u$ whichever is less
σ_{st}	MPa	maximum stress resulting from F_b or F_f
σ_u	MPa	ultimate tensile strength of blade material
$(\sigma_{ice})_{bmax}$	MPa	principal stress caused by the maximum backward propeller ice load
$(\sigma_{ice})_{fmax}$	MPa	principal stress caused by the maximum forward propeller ice load
$(\sigma_{ice})_{Amax}$	MPa	maximum ice load stress amplitude at the considered location on the blade
σ_{mean}	MPa	mean stress
$(\sigma_{ice})_A(N)$	MPa	blade stress amplitude distribution

3.4.2 Definition of Loads

Table 3.4.2 : Definition of loads

	Definition	Use of the load in design process
F_b	The maximum lifetime backward force on a propeller blade resulting from propeller/ice interaction, including hydrodynamic loads on that blade. The direction of the force is perpendicular to 0.7R chord line. See Figure 1.	Design force for strength calculation of the propeller blade.
F_f	The maximum lifetime forward force on a propeller blade resulting from propeller/ice interaction, including hydrodynamic loads on that blade. The direction of the force is perpendicular to 0.7R chord line.	Design force for calculation of strength of the propeller blade.
Q_{smax}	The maximum lifetime spindle torque on a propeller blade resulting from propeller/ice interaction, including hydrodynamic loads on that blade.	In designing the propeller strength, the spindle torque is automatically taken into account because the propeller load is acting on the blade as distributed pressure on the leading edge or tip area.
T_b	The maximum lifetime thrust on propeller (all blades) resulting from propeller/ice interaction. The direction of the thrust is the propeller shaft direction and the force is opposite to the hydrodynamic thrust.	Is used for estimation of the response thrust T_r. T_b can be used as an estimate of excitation for axial vibration calculations. However, axial vibration calculations are not required in the rules.

T_f	The maximum lifetime thrust on propeller (all blades) resulting from propeller/ice interaction. The direction of the thrust is the propeller shaft direction acting in the direction of hydrodynamic thrust.	Is used for estimation of the response thrust T_r. T_f can be used as an estimate of excitation for axial vibration calculations. However, axial vibration calculations are not required in the rules.
Q_{max}	The maximum ice-induced torque resulting from propeller/ice interaction on one propeller blade, including hydrodynamic loads on that blade.	Is used for estimation of the response torque (Q_r) along the propulsion shaft line and as excitation for torsional vibration calculations.
F_{ex}	Ultimate blade load resulting from blade loss through plastic bending. The force that is needed to cause total failure of the blade so that plastic hinge is caused to the root area. The force is acting on 0.8R.	Blade failure load is used to dimension the blade bolts, pitch control mechanism, propeller shaft, propeller shaft bearing and trust bearing. The objective is to guarantee that total propeller blade failure should not cause damage to other components.
Q_{sex}	Maximum spindle torque resulting from blade failure load	Is used to ensure pyramid strength principle for the pitching mechanism
Q_r	Maximum response torque along the propeller shaft line, taking into account the dynamic behavior of the shaft line for ice excitation (torsional vibration) and hydrodynamic mean torque on propeller.	Design torque for propeller shaft line components.
T_r	Maximum response thrust along shaft line, taking into account the dynamic behavior of the shaft line for ice excitation (axial vibration) and hydrodynamic mean thrust on propeller.	Design thrust for propeller shaft line components.

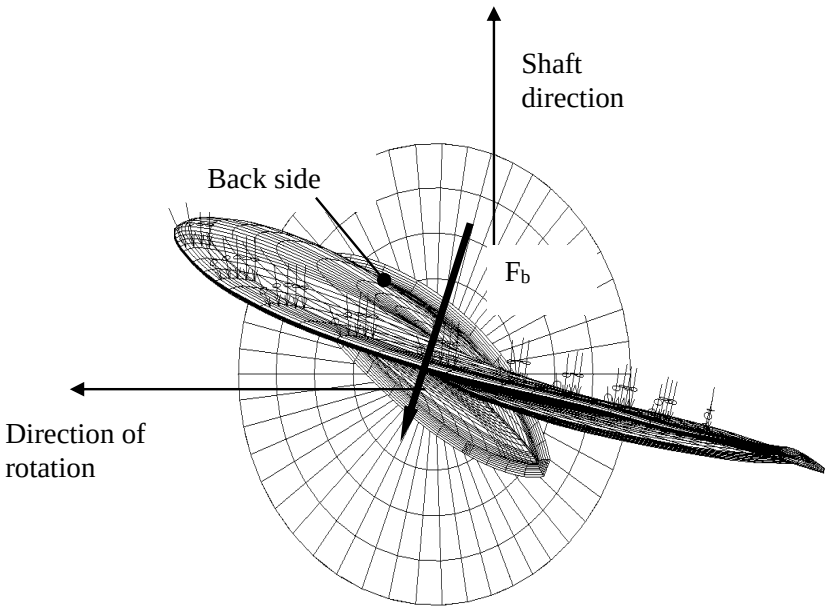

Fig. 3.4.2 : Direction of the backward blade force resultant taken perpendicular to the chord line at radius 0.7R. Ice contact pressure at leading edge is shown with small arrows.

3.5 Design Ice Loads

3.5.1 General

3.5.1.1 These Rules cover open and ducted type propellers situated at the stern of a vessel having controllable pitch or fixed pitch blades. Ice loads on bow-mounted propellers will receive special consideration. The given loads are expected, single occurrence, maximum values for the whole ship's service life for normal operational conditions, including loads resulting from directional change of rotation where applicable. These loads do not cover off-design operational conditions, for example when a stopped propeller is dragged through ice. These Rules also cover loads due to propeller ice interaction for azimuthing and fixed thrusters with geared transmission or an integrated electric motor (geared and podded propulsors). However, the load models of the regulations do not include propeller/ice interaction loads when ice enters the propeller of a turned azimuthing thruster from the side (radially) or loads when ice blocks hit on the propeller hub of a pulling propeller. Ice loads resulting from ice impacts on the body of thrusters are to be estimated on a case by case basis, however are not included within the following section.

3.5.1.2 The loads given in clause 3.5.3 are total loads including ice-induced loads and hydrodynamic loads (unless otherwise stated) during ice interaction and are to be applied separately (unless otherwise stated) and are intended for component strength calculations only.

3.5.1.3 F_b is the maximum force experienced during the lifetime of the ship that bends a propeller blade backwards when the propeller mills an ice block while rotating ahead. F_f is the maximum force experienced during the lifetime of the ship that bends a propeller blade forwards when a propeller mills an ice block while rotating ahead. F_b and F_f originate from different propeller/ice interaction phenomena, which do not act simultaneously. Hence, they are to be applied separately.

3.5.2 Ice class factors

3.5.2.1 The dimensions of the considered design ice block are H_{ice} x $2H_{ice}$ x $3H_{ice}$. The design ice block and ice strength index (S_{ice}) are used for the estimation of propeller ice loads. Both H_{ice} and S_{ice} are defined for each Ice class in Table 3.5.2.1.

Table 3.5.2.1 : Design Ice Class Factors

Ice Class	H_{ice} [m]	S_{ice} [-]
PC1	4.0	1.2
PC2	3.5	1.1
PC3	3.0	1.1
PC4	2.5	1.1
PC5	2.0	1.1
PC6	1.75	1
PC7	1.5	1

3.5.3 Propeller Ice Interaction Loads

3.5.3.1 Maximum backward blade force F_b for open propellers

when $D < D_{limit}$,

$$F_b = 27 \cdot S_{ice} \cdot [n \cdot D]^{0.7} \cdot \left[\frac{EAR}{Z}\right]^{0.3} \cdot D^2 \quad \text{[kN]}$$

when $D \geq D_{limit}$,

$$F_b = 23 \cdot S_{ice} \cdot [n \cdot D]^{0.7} \cdot \left[\frac{EAR}{Z}\right]^{0.3} \cdot [H_{ice}]^{1.4} \cdot D$$

[kN]

where $D_{limit} = 0.85 \,.\, (H_{ice})^{1.4}$

Here n is the nominal rotational speed at MCR in the free running condition for CP-propellers and 85% of the nominal rotational speed (at MCR free running condition) for FP-propeller (regardless of driving engine type) [rps].

For vessels with the additional notation Icebreaker, the above stated backward blade force F_b is to be multiplied by a factor of 1.1.

3.5.3.2 Maximum forward blade force F_f for open propellers

when $D < D_{limit}$

$$F_f = 250 \cdot \left[\frac{EAR}{Z}\right] \cdot D^2 \text{ [kN]}$$

when $D \geq D_{limit}$

$$F_f = 500 \cdot \left[\frac{1}{1 - \frac{d}{D}} \right] \cdot H_{ice} \cdot \left[\frac{EAR}{Z} \right] \cdot D \text{ [kN]}$$

where,

$$D_{limit} = \left(\frac{2}{1 - \frac{d}{D}} \right) H_{ice}$$

3.5.3.3 Loaded area on the blade for open propellers

Load cases 1-4 are to be covered, as given in Table 3.5.3.3, for CP and FP propellers. In order to obtain blade ice loads for a reversing propeller, load case 5 is to be covered for propellers where reversing is possible.

Table 3.5.3.3 : Loaded areas and load case definition for open propellers

	Force	Loaded area	Right-handed propeller blade seen from behind
Load case 1	F_b	Uniform pressure applied on the back of the blade (suction side) to an area from 0.6*R* to the tip and from the leading edge to 0.2 times the chord length.	Load case 2	50% of F_b	Uniform pressure applied on the back of the blade (suction side) on the propeller tip area outside 0.9*R* radius.	
Load case 3	F_f	Uniform pressure applied on the blade face (pressure side) to an area from 0.6*R* to the tip and from the leading edge to 0.2 times the chord length.	Load case 4	50% of F_f	Uniform pressure applied on propeller face (pressure side) on the propeller tip area outside 0.9*R* radius.	Load case 5	60% of F_f or 60% of F_b, whichever is greater	Uniform pressure applied on propeller face (pressure side) to an area from 0.6*R* to the tip and from the trailing edge to 0.2 times the chord length	
3.5.3.4 Maximum backward blade ice force F_b for ducted propellers

when D < Dlimit :

$$F_b = 9.5 \cdot S_{ice} \cdot [n \cdot D]^{0.7} \cdot \left[\frac{EAR}{Z} \right]^{0.3} \cdot D^2 \text{ [kN]}$$

when D ≥ D_{limit} :

$$F_b = 66 \cdot S_{ice} \cdot [n \cdot D]^{0.7} \cdot \left[\frac{EAR}{Z} \right]^{0.3} \cdot [H_{ice}]^{1.4} \cdot D^{0.6}$$

[kN]

where:

$D_{limit} = 4 \cdot H_{ice}$ [m]

n is to be taken as in 3.5.3.1

For vessels with the additional notation Icebreaker, the above stated backward blade force F_b is to be multiplied by a factor 1.1.

3.5.3.5 Maximum forward blade force, F_f for ducted propellers

when $D \leq D_{limit}$

$$F_f = 250 \cdot \left[\frac{EAR}{Z}\right] \cdot D^2 \quad [kN]$$

when $D > D_{limit}$

$$F_f = 500 \cdot \left[\frac{EAR}{Z}\right] \cdot D \cdot \frac{1}{\left(1 - \frac{d}{D}\right)} \cdot H_{ice} \quad [kN]$$

$$\text{where} D_{limit} = \frac{2}{\left(1 - \frac{d}{D}\right)} \cdot H_{ice} \quad [m]$$

3.5.3.6 Loaded area on the blade for ducted propellers

Load cases 1 and 3 are to be covered as given in Table 3.5.3.6 for all propellers. In order to obtain blade ice loads for a reversing propeller, load case 5 is to be covered for propellers, where reversing is possible.

Table 3.5.3.6 : Loaded areas and load case definition for ducted propellers

	Force	Loaded area	Right handed propeller blade seen from behind
Load case 1	F_b	Uniform pressure applied on the back of the blade (suction side) to an area from 0.6*R* to the tip and from the leading edge to 0.2 times the chord length.	Load case 3	F_f	Uniform pressure applied on the blade face (pressure side) to an area from 0.6*R* to the tip and from the leading edge to 0.5 times the chord length.	Load case 5	60% of F_f or 60% of F_b, whichever is greater	Uniform pressure applied on propeller face (pressure side) to an area from 0.6*R* to the tip and from the trailing edge to 0.2 times the chord length.	
3.5.3.7 Maximum blade spindle torque, Q_{smax} for open and ducted propellers

The spindle torques Q_{smax} around the axis of the blade fitting are to be determined both for the maximum backward blade force F_b and forward blade force F_t,which are applied as per Table 3.5.3.3 and Table 3.5.3.6. If the above method gives a value which is less than the default value given by the formula below, the default value is to be used.

Default value : $Q_{smax} = 0.25 \cdot F \cdot C_{0.7}$ [kNm]

where,

F is taken as either F_b or F_f, whichever has the greater absolute value.

The blade failure spindle torque Q_{sex} is defined under 3.5.4.

3.5.3.8 Load distributions (spectra) for blade loads

The Weibull-type distribution (probability that F_{ice} exceeds $(F_{ice})_{max}$), as given in Fig 3.5.3.8 is used for the fatigue design of the blade

$$P\left(\frac{F_{ice}}{(F_{ice})_{\max}} \geq \frac{F}{(F_{ice})_{\max}}\right) = e^{\left(-\left(\frac{F}{(F_{ice})_{\max}}\right)^{k} \cdot \ln(N_{ice})\right)}$$

where:

k = shape parameter of the spectrum

N_{ice}= number of load cycles in the spectrum, see 3.5.3.9

F_{ice} = random variable for ice loads on the blade, $0 \leq F_{ice} \leq (F_{ice})_{max}$.

This results in a blade stress amplitude distribution

$$(\sigma_{ice})_A(N) = (\sigma_{ice})_{A\max} \cdot \left\{1 - \frac{\log(N)}{\log(N_{ice})}\right\}^{\frac{1}{k}}$$

where:

$$(\sigma_{ice})_{A\max} = \frac{(\sigma_{ice})_{f\max} - (\sigma_{ice})_{b\max}}{2}$$

The shape parameter k=0.75 is to be used for the ice force distribution of an open propeller and the shape parameter k=1.0 for that of a ducted propeller blade.

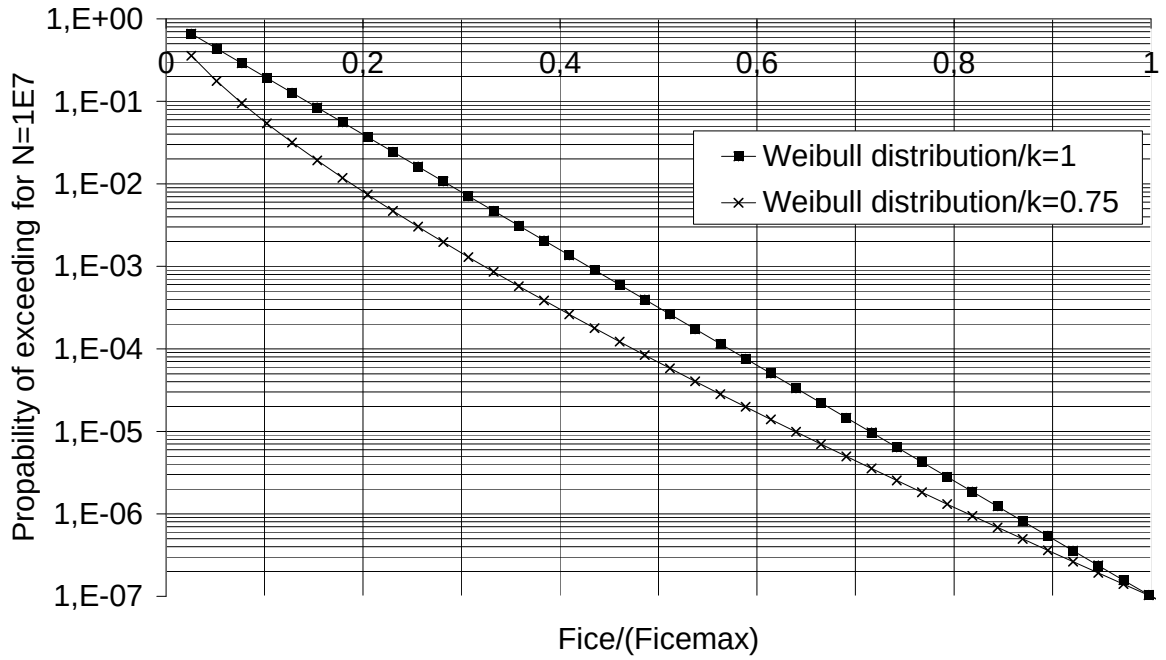

Fig 3.5.3.8 : The Weibull-type distribution (probability that F_{ice} exceeds $(F_{ice})_{max}$) that is used for fatigue design.

3.5.3.9 Number of ice loads

Number of load cycles N_{ice} in the load spectrum per blade is to be determined according to the formula:

$$N_{ice} = k_1 \cdot k_2 \cdot N_{class} \cdot n$$

where:

N_{class} = reference number of impacts per propeller revolution for each ice class (Table 3.5.3.9)

Table 3.5.3.9 : Reference number of impacts							
Ice Class	PC1	PC2	PC3	PC4	PC5	PC6	PC7
N_{class}	21 x 10^6	17 x 10^6	15 x 10^6	13 x 10^6	11 x 10^6	9 x 10^6	6 x 10^6

k1 = 1 for centre propeller
= 2 for wing propeller
= 3 for pulling propeller (wing and centre)

k2 = 0.8 - f when f < 0
= 0.8 - 0.4·f when 0 ≤ f ≤ 1
= 0.6 - 0.2·f when 1 < f ≤ 2.5
= 0.1 when f > 2.5

where the immersion function f is:

$$f = \frac{h_o - H_{ice}}{D/2} - 1$$

If h_0 is not known, h_0= D/2.

For vessels with the additional notation Icebreaker, the above stated number of load cycles N_{ice} is to be multiplied by a factor of 3.

For components that are subject to loads resulting from propeller/ice interaction with all the propeller blades, the number of load cycles (N_{ice}) is to be multiplied by the number of propeller blades (Z).

3.5.4 Blade Failure Load for both Open and Ducted Propellers

3.5.4.1 Bending Force, F_{ex}

The minimum load required resulting in blade failure through plastic bending. This is to be calculated iteratively along the radius of the blade from blade root to 0.5R using below equation with the ultimate load assumed to be acting at 0.8R in the weakest direction.

The blade failure load is:

$$F_{ex} = \frac{0.3 \cdot c \cdot t^{2\cdot} \cdot \sigma_{ref1}}{0.8 \cdot D - 2 \cdot r} \cdot 10^3 \quad \text{[kN]}$$

where:

$$\sigma_{ref1} = 0.6 \cdot \sigma_{0.2} + 0.4 \cdot \sigma_u \quad \text{[MPa]}$$

σ_u (minimum ultimate tensile strength to be specified on the drawing) and $\sigma_{0.2}$ (minimum yield or 0.2% proof strength to be specified on the drawing) are representative values for the blade material

c, t and r are respectively the actual chord length, maximum thickness and radius of the cylindrical root section of the blade, which is the weakest section outside the root fillet located typically at the termination of the fillet into the blade profile.

IRS may approve alternative means of failure load calculation by means of an appropriate stress analysis reflecting the non-linear plastic material behaviour of the actual blade. A blade is regarded as having failed, if the tip is bent by more than 10% of the propeller diameter.

3.5.4.2 Spindle Torque, Q_{sex}

The maximum spindle torque due to a blade failure load acting at 0.8R is to be determined. The force that causes blade failure typically reduces when moving from the propeller centre towards the leading and trailing edges. At a certain distance from the blade centre of rotation the maximum spindle torque will occur. This maximum spindle torque is to be defined by an appropriate stress analysis or using equation below.

$Q_{sex} = \max(c_{LE0.8};\ 0.8 \cdot c_{TE0.8}) \cdot C_{spex} \cdot F_{ex}$ [kNm]

Where:

$$C_{spex} = C_{sp} \cdot C_{fex} = 0.7 \cdot \left(1 - \left(4 \cdot \frac{EAR}{Z}\right)^3\right)$$

C_{sp} is non-dimensional parameter taking into account the spindle arm

C_{fex} is non-dimensional parameter taking into account the reduction of blade failure force at the location of maximum spindle torque.

If C_{spex} is below 0.3, a value of 0.3 is to be used for C_{spex}.

$c_{LE0.8}$ is the leading edge portion of the chord length at 0.8R

$c_{TE0.8}$ is the trailing edge portion of the chord length at 0.8R

The Fig 3.5.4.2 illustrates the spindle torque values due to blade failure loads across the whole chord length.

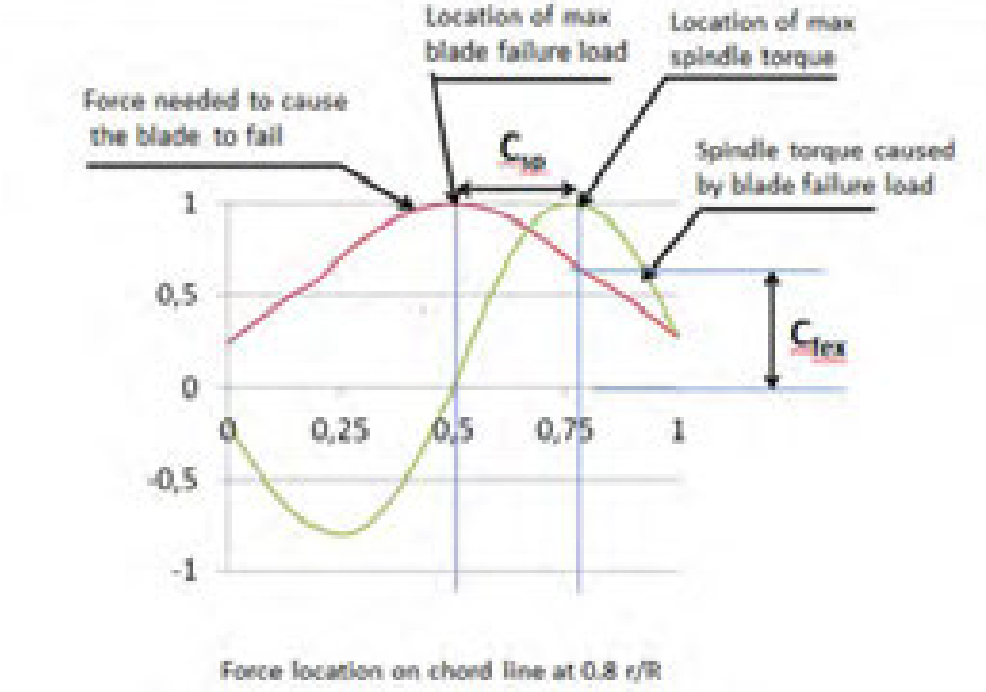

Fig 3.5.4.2 : Schematic figure showing blade failure load and related spindle torque when the force acts at different location on the chord line at radius 0.8R.

3.5.5 Axial design loads acting on open and ducted propellers

3.5.5.1 Maximum ice thrust on propeller T_f and T_b acting on open and ducted propellers

The maximum forward and backward ice thrusts are given by the following formula:

$$T_f = 1.1 \cdot F_f \ [\text{kN}]$$

$$T_b = 1.1 \cdot F_b \ [\text{kN}]$$

However, the load models within this section do not include propeller/ice interaction loads where an ice block hits the propeller hub of a pulling propeller.

3.5.5.2 Design thrust along the propulsion shaft line for open and ducted propellers

The design thrust along the propeller shaft line is to be calculated with the formulae below. The greater value of the forward and backward directional load is to be taken as the design load for both directions. The factors 2.2 and 1.5 take into account the dynamic magnification resulting from axial vibration.

In a forward direction

$$T_r = T + 2.2 \cdot T_f \ [\text{kN}]$$

In a backward direction

$$T_r = 1.5 \cdot T_b \ [\text{kN}]$$

If the hydrodynamic bollard thrust, T, is not known, T is to be taken as follows:

Table 3.5.5.2 : Guidance for bollard thrust values

Propeller type	T
CP propellers (open)	1.25 T_n
CP propellers (ducted)	1.1 T_n
FP propellers driven by turbine or electric motor	T_n
FP propellers driven by diesel engine (open)	0.85 T_n
FP propellers driven by diesel engine (ducted)	0.75 T_n

Here, T_n is the nominal propeller thrust at MCR in the free running open water condition.

For pulling type propellers ice interaction loads on propeller hub is to be considered in addition to the above.

3.5.6 Torsional design loads acting on open and ducted propellers

3.5.6.1 Design ice torque on propeller Q_{max} for open propellers

Q_{max} is the maximum torque on a propeller resulting from ice/propeller interaction.

when $D < D_{limit}$:

$$Q_{\max} = k_{open} \cdot \left[1 - \frac{d}{D}\right] \cdot \left[\frac{P_{0.7}}{D}\right]^{0.16} \cdot [n \cdot D]^{0.17} \cdot D^3$$

[kNm]

where:

k_{open} = 14.7 for PC1 – PC5;

and

k_{open} = 10.9 for PC6 – PC7

when $D \geq D_{limit}$:

$$Q_{\max} = 1.9 \cdot k_{open} \cdot \left[1 - \frac{d}{D}\right] \cdot [H_{ice}]^{1.1} \cdot \left[\frac{P_{0.7}}{D}\right]^{0.16} \cdot [n \cdot D]^{0.17} \cdot D^{1.9}$$

[kNm]

where:

$D_{limit} = 1.8 \cdot H_{ice}$ [m]

n is the rotational propeller speed in rev/s in bollard condition. If not known, n is to be taken as follows:

Table 3.5.6.1 : Guidance for rotational speeds to calculate torsional loads

Propeller type	Rotational speed n
CP propellers	n_n
FP propellers driven by turbine or electric motor	n_n
FP propellers driven by diesel engine	0.85 n_n

For CP propellers, the propeller pitch $P_{0.7}$ is correspond to MCR in bollard condition. If not known, $P_{0.7}$ is to be taken as $0.7 \cdot P_{0.7n}$, where $P_{0.7n}$ is the propeller pitch at MCR in free running condition.

3.5.6.2 Design ice torque on propeller Q_{max} for ducted propellers

when $D \leq D_{limit}$:

$$Q_{\max} = k_{ducted} \cdot \left[1 - \frac{d}{D}\right] \cdot \left[\frac{P_{0.7}}{D}\right]^{0.16} \cdot [n \cdot D]^{0.17} \cdot D^3$$

[kNm]

where:

k_{ducted} = 10.4 for PC1 – PC5

and

k_{ducted} = 7.7 for PC6 – PC7

when $D > D_{limit}$:

$$Q_{\max} = 1.9 \cdot k_{ducted} \cdot \left[1 - \frac{d}{D}\right] \cdot [H_{ice}]^{1.1} \cdot \left[\frac{P_{0.7}}{D}\right]^{0.16} \cdot [nD]^{0.17} \cdot D^{1.9}$$

[kNm]

where:

$D_{limit} = 1.8 \cdot H_{ice}$ [m]

n shall be taken as in 3.5.6.1.

For CP propellers, the propeller pitch $P_{0.7}$ is correspond to MCR in bollard condition. If not known, $P_{0.7}$ is to be taken as $0.7 \cdot P_{0.7n}$, where $P_{0.7n}$ is the propeller pitch at MCR in free running condition.

3.5.6.3 Ice torque excitation for open and ducted propellers

The given excitations are used to estimate the maximum torque likely to be experienced once during the service life of the ship. The following load cases are intended to reflect the operational loads on the propulsion system when the propeller interacts with ice and the corresponding reaction of the complete system. The ice impact and system response cause loads in the individual shaft line components. The ice torque Q_{max} may be taken as a constant value in the complete speed range. When considerations at specific shaft speeds are performed a relevant Q_{max} may be calculated using the relevant speed.

Diesel engine plants without an elastic coupling is to be calculated at the least favourable phase angle for ice versus engine excitation, when calculated in time domain. The engine firing pulses is to be included in the calculations and their standard steady state harmonics can be used. A phase angle between ice and gas force excitation does not need to be regarded in frequency domain analysis. Misfiring does not need to be considered.

If there is a blade order resonance just above MCR speed, calculations are to cover the rotational speeds up to 105% of MCR speed.

See also Guidelines for calculations given in 3.5.7.

3.5.6.3.1 Excitation for the time domain calculation

The propeller ice torque excitation for shaft line transient dynamic analysis (time domain) is defined as a sequence of blade impacts which are of half sine shape and occur at the blade. The torque due to a single blade ice impact as a function of the propeller rotation angle is then defined as:

$$Q(\varphi) = C_q \cdot Q_{\max} \cdot \sin(\varphi(180/\alpha_i))$$

when φ rotates from 0 to α_i plus integer revolutions.

$$Q(\varphi) = 0$$

when φ rotates from α_i to 360 plus integer revolutions.

Where

Φ = rotation angle starting when the first impact occurs

C_q and α_i parameters are given in the Table 3.5.6.3.1 below. α_i is the duration of propeller blade/ice interaction expressed in propeller rotation angle.

Table 3.5.6.3.1 : Ice impact magnification and duration factors for different blade numbers

Torque excitation	Propeller/ ice interaction	C_q	α_i [deg]			
			Z=3	Z=4	Z=5	Z=6
Excitation case 1	Single ice block	0.75	90	90	72	60
Excitation case 2	Single ice block	1.0	135	135	135	135
Excitation case 3	Two ice blocks (phase shift 360/(2·Z) deg.)	0.5	45	45	36	30
Excitation case 4	Single ice block	0.5	45	45	36	30

The total ice torque is obtained by summing the torque of single blades, taking into account the phase shift 360 deg./Z.

At the beginning and at the end of the milling sequence (within calculated duration) linear ramp functions are to be used to increase C_q to its maximum within one propeller revolution and vice versa to decrease it to zero (see examples for different Z numbers in the appendix).

The number of propeller revolutions during a milling sequence is to be obtained from the formula:

$$N_Q = 2 \cdot H_{ice}$$

The number of impacts is $Z \cdot N_Q$ for blade order excitation.

An illustration of all excitation cases for different blade numbers is given in the Appendix.

The dynamic simulation is to be performed for all excitation cases starting at MCR nominal, MCR bollard condition and just above all resonance speeds (1st engine and 1st blade harmonic), so that the resonant vibration responses can be obtained. For a fixed pitch propeller plant the dynamic simulation is to cover bollard pull condition with a corresponding speed assuming maximum possible output of the engine.

If a speed drop occurs down to stand still of the main engine, it indicates that the engine may not be sufficiently powered for the intended service task. For the consideration of loads, the maximum occurring torque during the speed drop process is to be applied. On these cases, the excitation is to follow the shaft speed.

3.5.6.3.2 Frequency domain excitation

For frequency domain calculations the following torque excitation may be used. The excitation has been derived so that the time domain half sine impact sequences have been assumed to be continuous and the Fourier series components for blade order and twice the blade order components have been derived. The frequency domain analysis is generally considered as conservative compared to the time domain simulation provided there is a first blade order resonance in the considered speed range.

$$Q_F(\varphi) = Q_{max} \cdot (C_{q0} + C_{q1} \cdot sin(Z \cdot E_0 \cdot \varphi + \alpha_1) + C_{q2} \cdot sin(2 \cdot Z \cdot E_0 \cdot \varphi + \alpha_2)) \quad \text{[kNm]}$$

where :

C_{q0} = mean torque component
C_{q1} = first blade order excitation amplitude
C_{q2} = second blade order excitation amplitude
Φ = angle of rotation
$\alpha_{1,2}$ = phase angle of excitation component
Z = number of blades

Table 3.5.6.3.2 : Coefficients for simplified excitation torque estimation

Torque excitation	Z=3					
	C_{q0}	C_{q1}	α_1	C_{q2}	α_2	E_0
Excitation case 1	0.375	0.375	-90	0	0	1
Excitation case 2	0.7	0.33	-90	0.05	-45	1
Excitation case 3	0.25	0.25	-90	0	0	2
Excitation case 4	0.2	0.25	0	0.05	-90	1
Torque excitation	Z=4					
	C_{q0}	C_{q1}	α_1	C_{q2}	α_2	E_0
Excitation case 1	0.45	0.36	-90	0.06	-90	1
Excitation case 2	0.9375	0	-90	0.0625	-90	1
Excitation case 3	0.25	0.251	-90	0	0	2
Excitation case 4	0.2	0.25	0	0.05	-90	1
Torque excitation	Z=5					
	C_{q0}	C_{q1}	α_1	C_{q2}	α_2	E_0
Excitation case 1	0.45	0.36	-90	0.06	-90	1
Excitation case 2	1.19	0.17	-90	0.02	-90	1
Excitation case 3	0,3	0.25	-90	0.048	-90	2
Excitation case 4	0,2	0.25	0	0.05	-90	1
Torque excitation	Z=6					
	C_{q0}	C_{q1}	α_1	C_{q2}	α_2	E_0
Excitation case 1	0.45	0.375	-90	0.05	-90	1
Excitation case 2	1.435	0.1	-90	0	0	1
Excitation case 3	0.3	0.25	-90	0.048	-90	2
Excitation case 4	0.2	0.25	0	0.05	-90	1

Torsional vibration responses are to be calculated for all excitation cases.

The results of the relevant excitation cases at the most critical rotational speeds are to be used in the following way:

The highest response torque (between the various lumped masses in the system) is in the following referred to as peak torque Q_{peak}.

The highest torque amplitude during a sequence of impacts is to be determined as half of the range from max to min torque and is referred to as Q_{Amax}.

An illustration of Q_{Amax} is given in Fig 3.5.6.3.2. It can be determined by

$$Q_{Amax} = \left(\frac{\max(Q_r(time)) - \min(Q_r(time))}{2}\right) \quad \text{[kNm]}$$

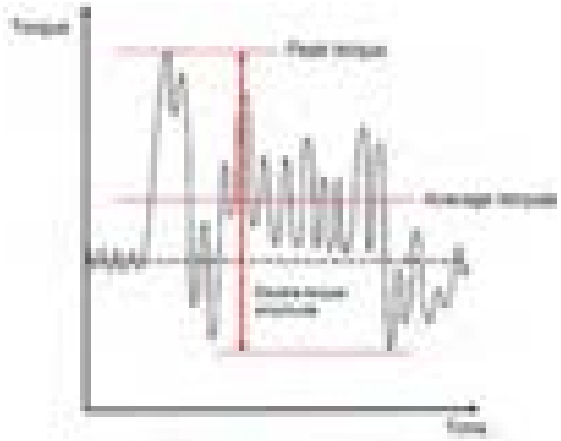

Fig 3.5.6.3.2 : Interpretation of different torques in a measured curve, as example

3.5.6.4 Design torque along shaft line

a) If there is no relevant first order propeller torsional resonance in the range 20% (of n_n) above and 20% below the maximum operating speed in bollard condition (see Table 8), the following estimation of the maximum response torque can be used to calculate the design torque along the propeller shaft line.

$$Q_r = Q_{e\max} + Q_{vib} + Q_{\max} \cdot \frac{I}{I_t} \quad \text{[kNm]}$$

The above equation is to be applied for directly coupled two stroke Diesel engines without flexible coupling.

For all other plants:

$$Q_r = Q_{e\max} + Q_{\max} \cdot \frac{I}{I_t} \quad \text{[kNm]}$$

where:
- I = equivalent mass moment of inertia of all parts on engine side of component under consideration and
- I_t is equivalent mass moment of inertia of the whole propulsion system.

All the torques and the inertia moments are to be reduced to the rotation speed of the component being examined.

If the maximum torque, Q_{emax}, is not known, it is to be taken as follows:

Propeller type	Q_{emax}
Propellers driven by electric motor	Q_{motor}
CP propellers not driven by electric motor	Q_n
FP propellers driven by turbine	Q_n
FP propellers driven by diesel engine	0.75 Q_n

Here Q_{motor} is the electric motor peak torque.

b) If there is a first blade order torsional resonance in the range 20% (of n_n) above and 20% below the maximum operating speed(bollard condition), the design torque (Q_r) of the shaft component is to be determined by means of a dynamic torsional vibration analysis of the entire propulsion line in the time domain or alternatively in the frequency domain. It is then assumed that the plant is sufficiently designed to avoid harmful operation in barred speed range.

3.5.7 Guideline for torsional vibration calculation

The aim of torsional vibration calculations is to estimate the torsional loads for individual shaft line components over the life time in order to determine scantlings for safe operation. The model can be taken from the normal lumped mass elastic torsional vibration model (frequency domain) including the damping. Standard harmonics may be used to consider the gas forces. The engine torque - speed curve of the actual plant is to be applied.

For time domain analysis the model should include the ice excitation at propeller, the mean torques provided by the prime mover and the hydrodynamic mean torque produced by the propeller as well as any other relevant excitations. The calculations should cover the variation of phase between the ice excitation and prime mover excitation. This is extremely relevant for propulsion lines with direct driven combustion engines.

For frequency domain calculations the load should be estimated as a Fourier component analysis of the continuous sequence of half sine load peaks. The first and second order blade components should be used for excitation. The calculation should cover the whole relevant shaft speed range. The analysis of the responses at the relevant torsional vibration resonances may be performed for open water (without ice excitation) and ice excitation separately. The resulting maximum torque can be obtained for directly coupled plants by the following superposition:

$$Q_{peak} = Q_{emax} + Q_{opw} + Q_{ice} \quad \text{[kNm]}$$

where:

Q_{emax} is the maximum engine torque at considered rotational speed

Q_{opw} is the maximum open water response of engine excitation at considered shaft speed and determined by frequency domain analysis

Q_{ice} is the calculated torque using frequency domain analysis for the relevant shaft speeds, ice excitation cases 1-4, resulting in the maximum response torque due to ice excitation

3.6 Design

3.6.1 Design Principle

The propulsion line is to be designed according to the pyramid strength principle in terms of its strength. This means that the loss of the propeller blade is not to cause any significant damage to other propeller shaft line components.

The propulsion line components are to withstand maximum and fatigue operational loads with the relevant safety margin. The loads do not need to be considered for shaft alignment or other calculations of normal operational conditions.

3.6.2 Fatigue design in general

The design loads are to be based on the ice excitation and where necessary (shafting) dynamic analysis, described as a sequence of blade impacts (3.5.6.3.1). The shaft response torque is to be determined according 3.5.6.4.

The propulsion line components are to be designed so as to prevent accumulated fatigue failure when considering the relevant loads using the linear elastic Miner's rule as defined below.

$$D = \frac{n_1}{N_1} + \frac{n_2}{N_2} + \cdots + \frac{n_k}{N_k} \leq 1$$

Or

$$D = \sum_{J=1}^{j=k} \frac{n_j}{N_j} \leq 1$$

Where:

k is the number of stress levels

$N_{1...k}$ is the number of load cycles to failure of the individual stress level class

$n_{1...k}$ is the accumulated number of load cycles of the case under consideration, per class

D Miners damage sum

Guidance:

The stress distribution should be divided into a frequency load spectrum having minimum 10 stress blocks (every 10 % of the load). Calculation with 5 stress blocks has been found to be too conservative. The maximum allowable load is limited by $\sigma_{ref\,2}$ for propeller blades and yield strength for all other components. The load distribution (spectrum) should be in accordance with the Weibull distribution.

3.6.3 Propeller blades

3.6.3.1 Calculation of blade stresses due to static loads

The blade stresses (equivalent and principal stresses) are to be calculated for the design loads given in 3.5.3. Finite element analysis (FEA) is to be used for stress analysis as part of the final approval for all propeller blades. The von Mises stresses, taken as σ_{st}, is to comply with equation in 3.6.3.2. Alternatively, the following simplified equation can be used in estimating the blade stresses for all propellers in the root area (r/R < 0.5) for final approval

$$\sigma_{st} = C_1 \frac{M_{BL}}{100 \cdot ct^2} \quad \text{[MPa]}$$

Where:

constant C_1 is the ratio of actual stress to stress obtained with beam equation. If the actual value is not available, C_1 is to be taken as 1.6.

- $M_{BL} = (0.75 - r/R) \cdot R \cdot F$, for relative radius r/R < 0.5

- F is the maximum of F_b and F_f, whichever is greater.

3.6.3.2 Acceptability criterion for static loads

The following criterion for calculated blade stresses shall be fulfilled:

$$\frac{\sigma_{ref2}}{\sigma_{st}} \geq 1.3$$

where:

σ_{st} = calculated stress for the design loads. If FE analysis is used in estimating the stresses, von Mises stresses are to be used.

3.6.3.3 Fatigue design of propeller blade

3.6.3.3.1 General

For materials with a two slope S-N curve (Fig 3.6.3.3.1 a) the fatigue calculations defined in this chapter are not required if the following criterion is fulfilled.

$$\sigma_{\exp} \geq B_1 \cdot \sigma_{ref\,2}{}^{B_2} \cdot \log(N_{ice})^{B_3}$$

where:

B1, B2 and B3 are coefficients for open and ducted propellers, given in the Table 3.6.3.3.1 below.

Table 3.6.3.3.1 : Coefficients to check a dispense from fatigue calculation

	Open propeller	**Ducted propeller**
B1	0.00328	0.00223
B2	1.0076	1.0071
B3	2.101	2.471

Where the above criterion is not fulfilled the fatigue requirements defined below is to be applied:
The fatigue design of the propeller blade is based on an estimated load distribution for the service life of the ship and the S-N curve for the blade material. An equivalent stress σ_{fat} that produces the same fatigue damage as the expected load distribution is to be calculated according to Miner's rule and the acceptability criterion for fatigue should be fulfilled as given in this section. The equivalent stress is normalised for 100 million cycles.
The blade stresses at various selected load levels for fatigue analysis are to be taken proportional to the stresses calculated for maximum loads given in section 3.5.3.
The peak principal stresses σ_f and σ_b are determined from F_f and F_b using FEA. The peak stress range $\Delta\sigma_{max}$ and the maximum stress amplitude σ_{Amax} are determined on the basis of load cases 1 and 3, 2 and 4.

$$\Delta\sigma_{\max} = 2 \cdot \sigma_{A\max} = \left|(\sigma_{ice})_{f\max}\right| + \left|(\sigma_{ice})_{b\max}\right|$$

The load spectrum for backward loads is normally expected to have a lower number of cycles than the load spectrum for forward loads. Taking this into account in a fatigue analysis introduces complications that are not justified considering all uncertainties involved.

For the calculation of equivalent stress two types of S-N curves are available.

Two slope S-N curve (slopes 4.5 and 10), see Fig 3.6.3.3.1 a) .

One slope S-N curve (the slope can be chosen), see Figure 3.6.3.3.1 b).

The type of the S-N-curve is to be selected to correspond with the material properties of the blade. If the S-N-curve is not known the two slope S-N curve is to be used.

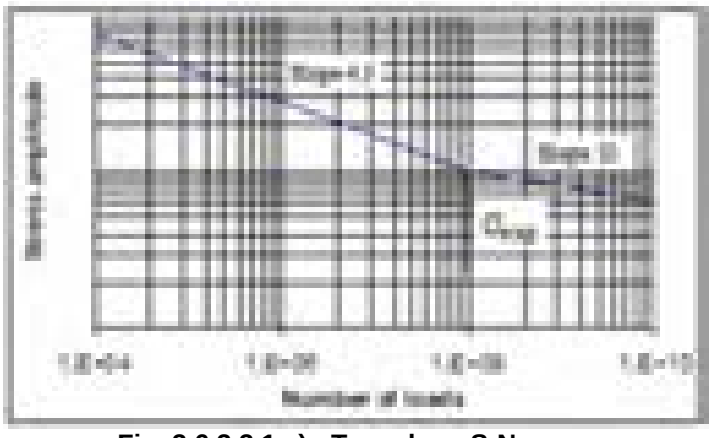

Fig 3.6.3.3.1 a) : Two-slope S-N curve

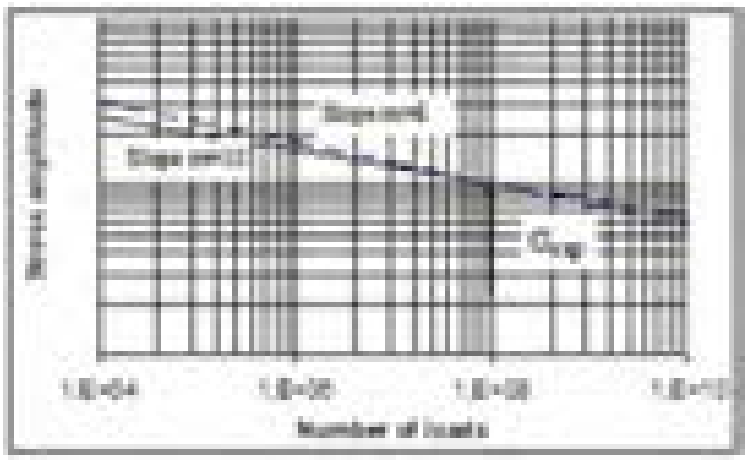

Fig 3.6.3.3.1 b) : Constant-slope S-N curve.

3.6.3.3.2 Equivalent fatigue stress

Note: A more general method of determining the equivalent fatigue stress of propeller blades is described in 3.6.5, where the principal stresses are considered according to 3.5.3 using the Miner's rule. For a total number of load blocks $n_{bl} > 100$, both methods deliver the same result. Therefore, they are regarded as equivalent. The equivalent fatigue stress for 10^8 cycles which produces the same fatigue damage as the load distribution is:

$$\sigma_{fat} = \rho \cdot (\sigma_{ice})_{max}$$

Where:

$$(\sigma_{ice})_{\max} = 0.5 \cdot \left((\sigma_{ice})_{f\max} - (\sigma_{ice})_{b\max}\right)$$

$(\sigma_{ice})_{\max}$ = mean value of the principal stress amplitudes resulting from design forward and backward blade forces at the location being studied.

$(\sigma_{ice})_{f\max}$ = principal stress resulting from forward load

$(\sigma_{ice})_{b\max}$ = principal stress resulting from backward load

In the calculation of $(\sigma_{ice})_{max}$, case 1 and case 3 or case 2 and case 4 are considered as pairs for $(\sigma_{ice})_{fmax}$, and $(\sigma_{ice})_{bmax}$ calculations. Case 5 is excluded from the fatigue analysis.

Calculation of parameter ρ for two-slope S-N curve

The error of the following method to determine the parameter ρ is sufficiently small, if the number of load cycles N_{ice} is in the range

$$5 \cdot 10^6 \le N_{ice} \le 10^8$$

The parameter ρ relates the maximum ice load to the distribution of ice loads according to the regression formula:

$$\rho = C_1 \cdot (\sigma_{ice})_{\max}^{C_2} \cdot \sigma_{fl}^{C_3} \cdot \log(N_{ice})^{C_4}$$

Where:

$\sigma_{fl} = \gamma_{\varepsilon 1} \cdot \gamma_{\varepsilon 2} \cdot \gamma_v \cdot \gamma_m \cdot \sigma_{\exp}$ is the blade material fatigue strength at 10^8 load cycles, see 3.6.3.3.3

The coefficients C_1, C_2, C_3 and C_4 are given in Table 3.6.3.3.2 a).

Table 3.6.3.3.2 a) : Coefficients to evaluate material fatigue strength

	Open propeller	**Ducted propeller**
C_1	0.000747	0.000534
C_2	0.0645	0.0533
C_3	-0.0565	-0.0459
C_4	2.22	2.584

Calculation of parameter ρ for constant-slope S-N curve. For materials with a constant-slope S-N curve, see Fig 3.6.3.3.1 b), - the factor ρ is to be calculated from the following formula:

$$\rho = \left(G \frac{N_{ice}}{N_R} \right)^{1/m} (\ln(N_{ice}))^{-1/k}$$

where:

k = shape parameter of the Weibull distribution

k = 1.0 for ducted propellers and

k = 0.75 for open propellers

N_R= reference number of load cycles (=10^8)

Values for the parameter G are given in Table 3.6.3.3.2 b) below. Linear interpolation may be used to calculate the value of G for m/k ratios other than those given in the Table 3.6.3.3.2 b).

Table 3.6.3.3.2 b) : Value for the parameter G for different m/k ratios

m/k	G	m/k	G	m/k	G
3	6	5.5	287.9	8	40320
3.5	11.6	6	720	8.5	119292
4	24	6.5	1871	9	362880
4.5	52.3	7	5040	9.5	1.133×10^6
5	120	7.5	14034	10	3.623×10^6

3.6.3.3.3 Acceptability criterion for fatigue

The equivalent fatigue stress σ_{fat} at all locations on the blade is to fulfil the following acceptability criterion:

$$\frac{\sigma_{fl}}{\sigma_{fat}} \geq 1.5$$

Where:

$$\sigma_{fl} = \gamma_{\varepsilon 1} \cdot \gamma_{\varepsilon 2} \cdot \gamma_v \cdot \gamma_m \cdot \sigma_{\exp}$$

$\gamma_{\varepsilon 1}$ = reduction factor due to scatter (equal to one standard deviation)

$\gamma_{\varepsilon 2}$ = reduction factor for test specimen size effect

γ_v = reduction factor for variable amplitude loading.

γ_m = reduction factor for mean stress.

$\sigma_{\exp}$ = mean fatigue strength of the blade material at 10^8 cycles to failure in seawater

$\sigma_{\exp}$ in Table 15 has been defined from the results of constant amplitude loading fatigue tests at 10^7 load cycles and 50% survival probability and has been extended to 10^8 load cycles.

Fatigue strength values and correction factors other than those given in Table 3.6.3.3.3 may be used, provided the values are determined under conditions approved by IRS.

The S-N curve characteristics are based on two slopes, the first slope 4.5 is from 1000 to 10^8 load cycles; the second slope 10 is above 10^8 load cycles. The maximum allowable stress for one or low number of cycles is limited to σ_{ref2}/S, with S=1.3 for static loads. The fatigue strength σ_{fat} is the fatigue limit at 100 million load cycles.

The geometrical size factor ($\gamma_{\varepsilon 2}$) is:

$$\gamma_{\varepsilon 2} = 1 - a \cdot \ln\left(\frac{t}{0.025}\right)$$

The following values is to be used for the reduction factors if actual values are not available: $\gamma_{\varepsilon 1}$ = 0.85, γ_v = 0.75, and γ_m = 0.75.

Table 3.6.3.3.3 : Mean fatigue strength σ_{exp} for different material types at 10^8 load cycles and stress ratio R = -1 with a survival probability of 50%.

Mean fatigue strength σ_{exp} for different material types at 10^8 load cycles			
Bronze and brass (a=0.10)		Stainless steel (a=0.05)	
Mn-Bronze, CU1 (high tensile brass)	84 MPa	Ferritic (12Cr 1Ni)	144[1] MPa
Mn-Ni-Bronze, CU2 (high tensile brass)	84 MPa	Martensitic (13Cr 4Ni/13Cr 6Ni)	156 MPa
Ni-Al-Bronze, CU3	120 MPa	Martensitic (16Cr 5Ni)	168 MPa
Mn-Al-Bronze, CU4	113 MPa	Austenitic (19Cr 10Ni)	132 MPa

Note:
1. This value may be used, provided a perfect galvanic protection is active. Otherwise a reduction of about 30 MPa is to be applied.

3.6.4 Blade bolts, propeller hub and CP mechanism

3.6.4.1 General

The blade bolts, CP mechanism, propeller boss and the fitting of the propeller to the propeller shaft is to be designed to withstand the maximum static and fatigue design loads (as applicable), as defined in 3.5.3 and 3.6.3. The safety factor S against yielding due to static loads and against fatigue is to be greater than 1.5, if not stated otherwise. The safety factor S for loads, resulting from propeller blade failure as defined in 3.5.4 is to be greater than 1.0 against yielding.

Provided that calculated stresses duly considering local stress, concentrations are less than yield strength, or maximum of 70% of σ_u of respective materials, detailed fatigue analysis is not required. In all other cases components are to be analysed for cumulative fatigue. An approach similar to that used for shafting assessment may be applied (3.6.5).

3.6.4.2 Blade bolts

Blade bolts are to withstand the following bending moment considered around a tangent on bolt pitch circle, or any other relevant axis for non-circular joints, parallel to considered root section:

$$M_{bolt} = S \cdot F_{ex}(0.8\frac{D}{2} - r_{bolt}) \quad \text{[kNm]}$$

Where:
r_{bolt} = radius to the bolt plane [m]
S = 1.0 safety factor

Blade bolt pre-tension is to be sufficient to avoid separation between mating surfaces when the maximum forward and backward ice loads defined in 3.5.3 (open and ducted propellers respectively) are applied. For conventional arrangements, the following formula may be applied:

$$\mathbf{d_{bb} = 41 \cdot \sqrt[2]{\frac{F_{ex} \cdot (0.8 \cdot D - d) \cdot S \cdot \alpha}{\sigma_{0.2} \cdot z_{bb} \cdot PCD}}} \quad \text{[mm]}$$

where:
α = 1.6 torque guided tightening
= 1.3 elongation guided
= 1.2 angle guided
= 1.1 elongated by other additional means other factors may be used, if evidence is demonstrated

d_{bb}- effective diameter of blade bolt in way of thread [mm]

z_{bb}- number of blade bolts

S= 1.0 safety factor

3.6.4.3 CP mechanism

Separate means, e.g., dowel pins, are to be provided in order to withstand the spindle torque resulting from blade failure Q_{sex} (3.5.4.2) or ice interaction Q_{smax} (3.5.3.7), whichever is greater. Other components of the CP mechanism is not to be damaged by the maximum spindle torques (Q_{smax}, Q_{sex}). One third of the spindle torque is assumed to be consumed by friction, if not otherwise documented trough further analysis.

The diameter of fitted pins d_{fp} between the blade and blade carrier can be calculated using the formula:

$$d_{fp} = 66 \cdot \sqrt{\frac{(Q_s - Q_{fr})}{PCD \cdot z_{pin} \cdot \sigma_{0.2}}} \quad \text{[mm]}$$

where:

Q_s= max(S•Q_{smax}; S•Q_{sex}) [kNm]

S = 1.3 for Q_{smax} and

= 1.0 for Q_{sex}

Q_{fr}= friction between connected surfaces= 0.33·Q_s

IRS may approve alternative Q_{fr} calculation according to reaction forces due to F_{ex}, or F_f, F_b whichever is relevant, utilising a friction coefficient = 0.15.

The stress in the actuating pin can be estimated by

$$\sigma_{vMises} := \sqrt{\left[\frac{\left(F \cdot \frac{h_{pin}}{2}\right)}{\frac{\pi \cdot d_{pin}^{3}}{32}}\right]^2 + 3 \cdot \left(\frac{F}{\frac{\pi}{4} \cdot d_{pin}^{2}}\right)^2}$$

[MPa]

Where:

$$F = \frac{(Q_s - Q_{fr})}{l_m} \quad \text{[kN]}$$

l_m = distance pitching centre of blade – axis of pin [m]
h_{pin} = height of actuating pin [mm]
d_{pin} = diameter of actuating pin [mm]
Q_{fr} = friction torque in blade bearings acting on the blade palm and caused by the reaction forces due to F_{ex}, or F_f, F_b whichever is relevant; taken to one third of spindle torque Q_s

The blade failure spindle torque Q_{sex} is not to lead to any consequential damage. Fatigue strength is to be considered for parts transmitting the spindle torque from the blade to a servo system considering the ice spindle torque acting on one blade. The maximum amplitude Q_{samax} is defined as:

$$Q_{samax} = \frac{Q_{sb} + Q_{sf}}{2} \quad \text{[kNm]}$$

where:

Q_{sb} = spindle torque due to IF_bI [kNm]
Q_{sf} = spindle torque due to IF_fI [kNm]

3.6.4.4 Servo pressure

The design pressure for the servo system is to be taken as the pressure caused by Q_{smax} or, Q_{sex} when not protected by relief valves on the hydraulic actuator side, reduced by relevant friction losses in bearings caused by the respective ice loads. The design pressure is, in any case, not to be less than relief valve set pressure.

3.6.5 Propulsion line components

The ultimate load resulting from total blade failure F_{ex} as defined in 3.5.4, is to consist of combined axial and bending load components, wherever this is significant. The minimum safety factor against yielding is to be 1.0 for all shaft line components.

The shafts and shafting components, such as bearings, couplings and flanges are to be designed to withstand the operational propeller/ice interaction loads as given in 3.5. The given loads are not intended to be used for shaft alignment calculation. Cumulative fatigue calculations shall be conducted according to the Miner's rule. A fatigue calculation is not necessary, if the maximum stress is below fatigue strength at 10^8 load cycles.

The torque and thrust amplitude distribution (spectrum) in the propulsion line is to be taken as (because Weibull exponent k = 1):

$$Q_A(N) = Q_{Amax} \cdot \left\{1 - \frac{\log(N)}{\log(Z \cdot N_{ice})}\right\}$$

This is illustrated by the example in the Fig 3.6.5 a).

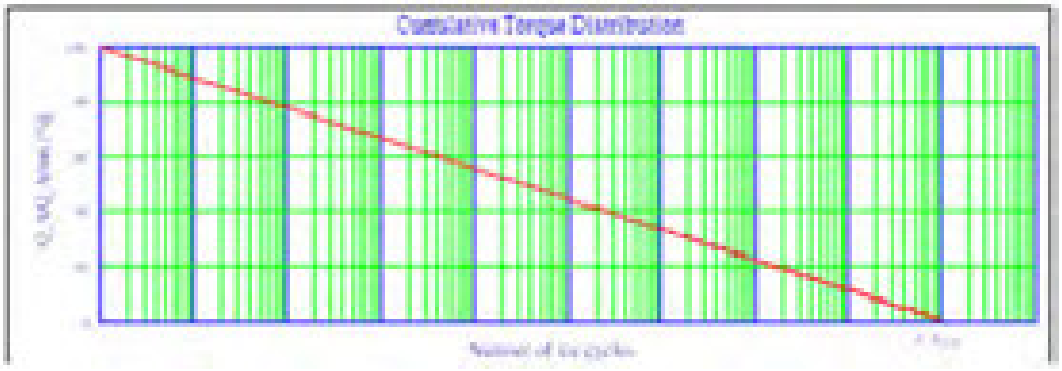

Fig 3.6.5 a) : Cumulative torque distribution

The number of load cycles in the load spectrum is defined as $Z \cdot N_{ice}$. The Weibull exponent should be considered as k = 1.0 for both open and ducted propeller torque and bending forces. The load distribution is an accumulated load spectrum, and the load spectrum should be divided into a minimum of ten load blocks when using the Miner summation method. The load spectrum used counts the number of cycles for 100% load to be the number of cycles above the next step, e.g., 90 % load. This ensures that the calculation is on the conservative side. Consequently, the fewer stress blocks used the more conservative the calculated safety margin.

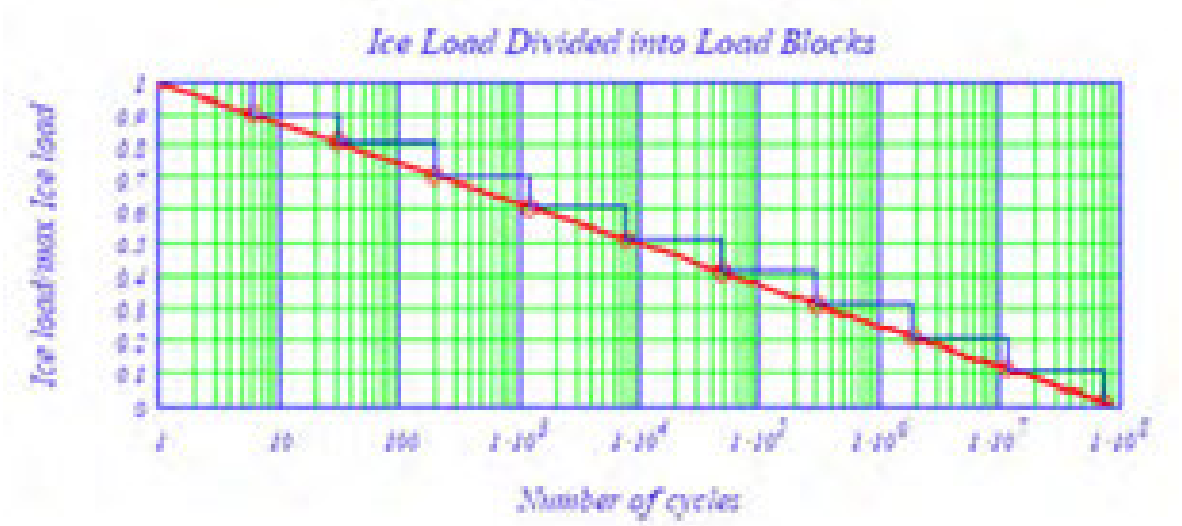

Figure 3.6.5 b): Example of ice load distribution (spectrum) for the shafting (k = 1).

The load spectrum is divided into n_{bl}-number of load blocks for the Miner summation method. The following formula can be used for calculation of the number of cycles for each load block.

$$n_i = N_{ice}^{1-\left(1-\frac{i}{n_{bl}}\right)^k} - \sum_{i=1}^{i} n_{i-1}$$

Where:

i = single load block i and n_{bl} is the number of load blocks

3.6.5.1 Propeller fitting to the shaft

3.6.5.1.1 Keyless cone mounting

The friction capacity (at 0° C) is to be at least S = 2.0 times the highest peak torque Q_{peak} as determined in 3.5.6 without exceeding the permissible hub stresses.

The necessary surface pressure $p_{0°C}$ can be determined as:

$$p_{0°C} = \frac{2 \cdot S \cdot Q_{peak}}{\pi \cdot \mu \cdot D_S^2 \cdot L \cdot 10^3} \quad \text{[MPa]}$$

where:
μ = 0.15 for steel-steel,
= 0.13 for steel-bronze
D_S = is the shrinkage diameter at the mid-length of the taper [m]

L = is the effective length of taper [m]

Above friction coefficients may be increased by 0.04 if glycerine is used in wet mounting.

3.6.5.1.2 Key mounting

Key mounting is not permitted.

3.6.5.1.3 Flange mounting

The flange thickness is to be at least 25% of the required aft end shaft diameter (*Pt.4, Ch.4, Sec.6, 6.13*). Any additional stress raisers such as recesses for bolt heads is not to interfere with the flange fillet unless the flange thickness is increased correspondingly. The flange fillet radius is to be at least 10% of the required shaft diameter. The diameter of shear pins are to be calculated according to the following equation:

$$d_{pin} = 66 \cdot \sqrt[2]{\frac{Q_{peak} \cdot S}{PCD \cdot z_{pin} \cdot \sigma_{0.2}}} \quad \text{[mm]}$$

Where

z_{pin} - number of shear pins
S = 1.3 safety factor

The bolts are to be designed so that the blade failure load F_{ex} (3.5.4) in backward direction does not cause yielding of the bolts. The following equation is to be applied:

$$d_b = 41 \cdot \sqrt{\frac{F_{ex} \cdot (0.8 \cdot D / PCD + 1) \cdot \alpha}{\sigma_{0.2} \cdot z_b}}$$

[mm]

where:
α = 1.6 torque guided tightening
= 1.3 elongation guided
= 1.2 angle guided
= 1.1 elongated by other additional means
other factors may be used, if evidence is demonstrated
d_b - diameter flange bolt [mm]
z_b - number of flange bolts

3.6.5.2 Propeller shaft

The propeller shaft is to be designed to fulfil the following:

3.6.5.2.1 The blade failure load F_{ex} (3.5.4) applied parallel to the shaft (forward or backwards) is not to cause yielding. The bending moment need not to be combined with any other loads. The diameter d_p in way of the aft stern tube bearing is not to be less than:

$$d_p = 160 \cdot \sqrt[3]{\frac{F_{ex} \cdot D}{\sigma_{0.2} \cdot \left(1 - \frac{d_i^4}{d_p^4}\right)}} \quad \text{[mm]}$$

where:
d_p = propeller shaft diameter [mm]
d_i = propeller shaft inner diameter [mm]

Forward from the aft stern tube bearing the shaft diameter may be reduced based on direct calculation of the actual bending moment, or by the assumption that the bending moment caused by F_{ex} is linearly reduced to 25% at the next bearing and in front of this linearly to zero at third bearing. Bending due to maximum blade forces F_b and F_f have been disregarded since the resulting stress levels are much lower than the stresses caused by the blade failure load.

3.6.5.2.2 The stresses due to the peak torque Q_{peak} are to have a minimum safety factor of S=1.5 against yielding in plain sections and S=1.0 in way of stress concentrations in order to avoid bent shafts.

Minimum diameter of:

plain shaft:

$$d_p = 210 \cdot \sqrt[3]{\frac{Q_{peak} \cdot S}{\sigma_{0.2} \cdot \left(1 - \frac{d_i^4}{d^4}\right)}} \quad \text{[mm]}$$

notched shaft:

$$d_p = 210 \cdot \sqrt[3]{\frac{Q_{peak} \cdot S \cdot \alpha_t}{\sigma_{0.2} \cdot \left(1 - \frac{d_i^4}{d^4}\right)}} \quad \text{[mm]}$$

where:
α_t = local stress concentration factor in torsion.
Notched shaft diameter is, in any case, not to be less than the required plain shaft diameter.

3.6.5.2.3 The torque amplitudes (3.5.6.4) with the corresponding number of load cycles are to be used in an accumulated fatigue evaluation where the safety factor is S_{fat}=1.5. If the plant has high engine excited torsional vibrations (e.g. direct coupled 2-stroke engines), this is to be considered.

3.6.5.2.4 The fatigue strengths σ_F and τ_F (3 million cycles) of shaft materials may be assessed on the basis of the material's yield or 0.2% proof strength as:

$$\sigma_F = 0.436 \cdot \sigma_{0.2} + 77 = \tau_F \cdot \sqrt{3} \quad \text{[MPa]}$$

This is valid for small polished specimens (no notch) and reversed stresses. The high cycle fatigue (HCF) is to be assessed based on the above fatigue strengths, notch factors (i.e. geometrical stress concentration factors and notch sensitivity), size factors, mean stress influence and the required safety factor of 1.6 at 3 million cycles increasing to 1.8 at 10^9 cycles. The low cycle fatigue (LCF) representing 10^4 cycles is to be based on the smaller value of yield or 0.7 of tensile strength/√3. The criterion utilises a safety factor of 1.25. The LCF and HCF as given above represent the upper and lower knees in a stress-cycle diagram. Since the required safety factors are included in these values, a Miner sum of unity is acceptable.

3.6.5.3 Intermediate shafts

The intermediate shafts are to be designed to fulfil 3.6.5.2.2 to 3.6.5.2.4.

3.6.5.4 Shaft connections

3.6.5.4.1 Shrink fit couplings (keyless)

See 3.6.5.1.1. A safety factor of S= 1.8 shall be applied.

3.6.5.4.2 Key mounting

Key mounting is not permitted.

3.6.5.4.3 Flange mounting

The flange thickness is to be at least 20% of the required shaft diameter (*Pt.4, Ch.4, Sec.6, 6.13*).

Any additional stress raisers such as recesses for bolt heads is not to interfere with the flange fillet unless the flange thickness is increased correspondingly.

The flange fillet radius is to be at least 8% of the shaft diameter (*Pt.4, Ch.4, Sec.6, 6.13*).

The diameter of ream fitted (light press fit) bolts are to be chosen so that the peak torque is transmitted with a safety factor of 1.9. This accounts for a prestress. Pins are to transmit the peak torque with a safety factor of 1.5 against yielding (see equation for d_{pin} in 3.6.5.1.3). The bolts are to be designed so that the blade failure load (3.5.4) in backward direction does not cause yielding.

3.6.5.4.4 Splined shaft connections

Splined shaft connections can be applied where no axial or bending loads occur. A safety factor of S = 1.5 against allowable contact and shear stress resulting from Q_{peak} is to be applied.

3.6.5.4.5 Gear transmissions

3.6.5.4.6 Shafts

Shafts in gear transmissions are to meet the same safety level as intermediate shafts, but where relevant, bending stresses and torsional stresses are to be combined (e.g., by von Mises for static loads). Maximum permissible deflection in order to maintain sufficient tooth contact pattern to be considered for the relevant parts of the gear shafts.

3.6.5.4.7 Gearing

The gearing is to fulfil following three acceptance criteria:

- Tooth root stresses
- Pitting of flanks
- Scuffing

In addition to above 3 criteria subsurface fatigue may need to be considered.

Common for all criteria is the influence of load distribution over the face width. All relevant parameters are to be considered, such as elastic deflections (of mesh, shafts and gear bodies), accuracy tolerances, helix modifications, and working positions in bearings (especially for multiple input single output gears).

The load spectrum (see 3.6.5) may be applied in such a way that the numbers of load cycles for the output wheel are multiplied by a factor of (number of pinions on the wheel / number of propeller blades Z). For pinions and wheels operating at higher speeds the numbers of load cycles are found by multiplication with the gear ratios. The peak torque (Q_{peak}) is also to be considered during calculations.

Cylindrical gears can be assessed on the basis of the international standard ISO 6336 series (i.e. ISO 6336-1:2019, ISO 6336-2:2019, ISO 6336-3:2019, ISO 6336-4:2019, ISO 6336-5:2016 and ISO 6336-6:2019), provided that "method B" is used. Standards within the classification societies can also be applied provided that they are considered equivalent to the above-mentioned ISO 6336.

For Bevel Gears the methods or standards used or acknowledged by the classification society can be applied provided that they are properly calibrated.

Tooth root safety is to be assessed against the peak torque, torque amplitudes (with the pertinent average torque) as well as the ordinary loads (open water free running) by means of accumulated fatigue analyses. The resulting factor of safety is to be at least 1.5. (Ref ISO 6336 Pt 1, 3 and 6 and IRS Classification Note "*Marine Gears - Calculation of load capacity of involute parallel axis spur and helical gears*")

The safety against pitting is to be assessed in the same way as tooth root stresses, but with a minimum resulting safety factor of 1.2. (Ref ISO 6336-1:2019, ISO 6336-2:2019 and ISO 6336-6:2019 as well as IRS Classification Note "*Marine Gears - Calculation of load capacity of involute parallel axis spur and helical gears*").

The scuffing safety (flash temperature method – ref. ISO/TR 13989-1:2000 and ISO/TR 13989-2:2000) based on the peak torque is to be at least 1.2 when the FZG class of the oil is assumed one stage below specification.

The safety against subsurface fatigue of flanks for surface hardened gears (oblique fracture from active flank to opposite root) is to be assessed. (It is to be noted that high overloads can initiate subsurface fatigue cracks that may lead to a premature failure. In lieu of analyses UT inspection intervals may be used.)

3.6.5.4.8 Bearings

See section 3.6.5.8.

3.6.5.4.9 Gear wheel shaft connections

The torque capacity is to be at least 1.8 times the highest peak torque Q_{peak} (at considered rotational speed) as determined in 3.6.5 without exceeding the permissible hub stresses of 80% yield.

3.6.5.5 Clutches

Clutches are to have a static friction torque of at least 1.3 times the peak torque Q_{peak} and dynamic friction torque 2/3 of the static. Emergency operation of clutch after failure of e.g. operating pressure is to be made possible within reasonably short time. If this is arranged by bolts, it is to be on the engine side of the clutch in order to ensure access to all bolts by turning the engine.

3.6.5.6 Elastic couplings

There is to be a separation margin of at least 20% between the peak torque and the torque where any twist limitation is reached.

$$Q_{peak} < 0.8 \cdot T_{kmax} \ (N = 1) \quad \text{[kNM]}$$

There is to be a separation margin of at least 20% between the maximum response torque Q_{peak} (see Fig 3.5.6.3.2) and the torque where any mechanical twist limitation and/or the permissible maximum torque of the elastic coupling, valid for at least a single load cycle (N=1), is reached.

A sufficient fatigue strength is to be demonstrated at design torque level Q_r(N=x) and Q_A(N=x). This may be demonstrated by interpolation in a Weibull torque distribution (similar to Figure 7):

$$\frac{\boldsymbol{Q_r\,(N = x)}}{\boldsymbol{Q_r\,(N = 1)}} = \mathbf{1} - \frac{\boldsymbol{\log(x)}}{\boldsymbol{log(Z * N_{ICE})}}$$

respectively

$$\frac{\boldsymbol{Q_A(N = x)}}{\boldsymbol{Q_A(N = 1)}} = \mathbf{1} - \frac{\boldsymbol{\log(x)}}{\boldsymbol{log(Z * N_{ICE})}}$$

Where Q_r (N=1) corresponds to Q_{peak} and Q_A (N=1) to Q_{Amax}.

$Q_r(N=5E4) \cdot S < T_{Kmax}\ (N=5E4)$ [kNm]
$Q_r(N=1E6) \cdot S < T_{KV}$ [kNm]
$Q_A(N=5E4) \cdot S < \Delta T_{max}\ (N=5E4)$ [kNm]

S is the general safety factor for fatigue, equal to 1.5.
See illustration in below Fig 3.6.5.6 a), Fig 3.6.5.6 b) and Fig 3.6.5.6 c) .

The torque amplitude (or range Δ) is not to lead to fatigue cracking, i.e. exceeding the permissible vibratory torque. The permissible torque may be determined by interpolation in a

Weibull torque distribution where T_{Kmax1} respectively ΔT_{Kmax} refer to 50000 cycles and T_{KV} refer to 10^6 cycles. See illustration in below Fig 3.6.5.6 a), Fig 3.6.5.6 b) and Fig 3.6.5.6 c) .

$T_{kmax1} \geq Q_r \; at \; 5 \cdot 10^4$ load cycles [kNm]

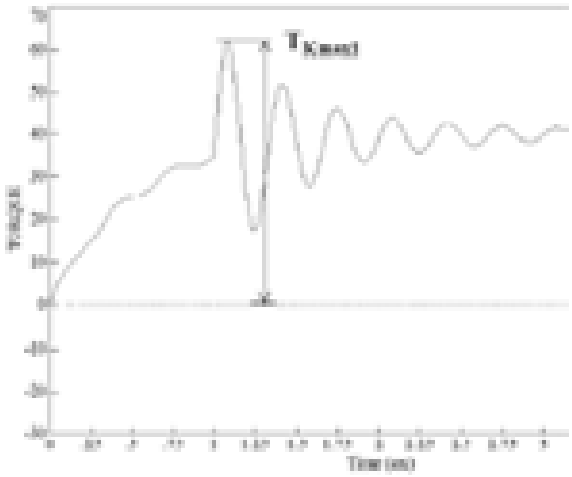

Fig 3.6.5.6 a)

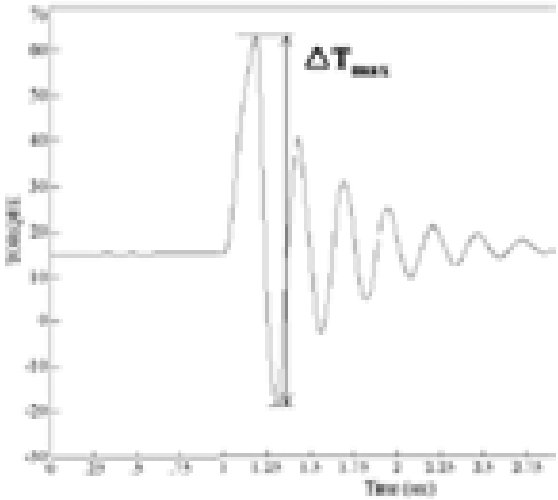

Fig 3.6.5.6 b)

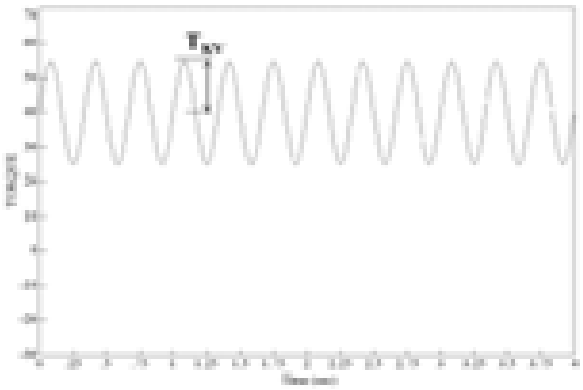

Fig 3.6.5.6 c)

3.6.5.7 Crankshafts

Special considerations apply for plants with large inertia (e.g. flywheel, tuning wheel or PTO) in the non-driving end front of the engine (opposite to main power take off).

3.6.5.8 Bearings

The aft stern tube bearing as well as the next shaft line bearing are to withstand F_{ex} as given in 3.5.4, in such a way that the ship can maintain operational capability. Rolling bearings are to have an L_{10a} lifetime of at least 40000 hours according to ISO 281:2007. Thrust bearings and their housings are to be designed to withstand with a safety factor S = 1.0 the maximum response thrust 3.5.5 and the axial force resulting from the blade failure load F_{ex} in 3.5.4. For the purpose of calculation, except for F_{ex}, the shafts are assumed to rotate at rated speed. For pulling propellers special consideration is to be given to loads from ice interaction on the propeller hub.

3.6.5.9 Seals

Seals are to prevent egress of pollutants and be suitable for the operating temperatures. Contingency plans for preventing the egress of pollutants under failure conditions are to be documented.

Seals installed are to be suitable for the intended application. The manufacturer is to provide service experience in similar applications and/or testing results for consideration.

3.6.6 Azimuthing main propulsors

In addition to the above requirements, special consideration is to be given to those loading cases which are extraordinary for propulsion units when compared with conventional propellers. The estimation of load cases are to reflect the way the thrusters are intended to operate on the specific ship. In this respect, for example, the loads caused by the impacts of ice blocks on the propeller hub of a pulling propeller is to be considered. Furthermore, loads resulting from the thrusters operating at an oblique angle to the flow is to be considered. The steering mechanism, the fitting of the unit, and the body of the thruster is to be designed to withstand the loss of a blade without damage. The loss of a blade is to be considered for the propeller blade orientation which causes the maximum load on the component being studied. Typically, top-down blade orientation places the maximum bending loads on the thruster body. Azimuth thrusters are to be designed for estimated loads caused by thruster body/ice interaction. The thruster body is to withstand the loads obtained when the maximum ice blocks, which are given in section 3.5.2, strike the thruster body when the ship is at a typical ice operating speed. In addition, the design situation in which an ice sheet glides along the ship's hull and presses against the thruster body should be considered. The thickness of the sheet should be taken as the thickness of the maximum ice block entering the propeller, as defined in section 3.5.2.

3.7 Prime Movers

3.7.1 Propulsion engines

Engines are to be capable of being started and running the propeller in bollard condition.

Propulsion plants with CP propeller are to be capable being operated even when the CP system is at full pitch as limited by mechanical stoppers.

3.7.2 Starting arrangements

The capacity of the air receivers are to be sufficient to provide, without recharging, not less than 12 consecutive starts of the propulsion engine, if this has to be reversed for going astern or 6 consecutive starts if the propulsion engine does not have to be reversed for going astern.

If the air receivers serve any other purposes than starting the propulsion engine, they are to have additional capacity sufficient for these purposes.

The capacity of the air compressors are to be sufficient for charging the air receivers from atmospheric to full pressure in one (1) hour, except for a ship with the ice class PC6 to PC1, if its propulsion engine has to be reversed for going astern, in which case the compressor is to be able to charge the receivers in half an hour.

3.7.3 Emergency power units

Provisions are to be made for heating arrangements to ensure ready starting from cold of the emergency power units at an ambient temperature applicable to the Polar Class of the ship.

Emergency power units are to be equipped with starting devices with a stored energy capability of at least three consecutive starts at the above-mentioned temperature. The source of stored energy is to be protected to preclude critical depletion by the automatic starting system, unless a second independent mean of starting is provided. A second source of energy is to be provided for an additional three starts within 30 min., unless manual starting can be demonstrated to be effective.

3.8 Equipment fastening loading accelerations

3.8.1 General

Essential equipment and supports are to be suitable for the accelerations as indicated in the following paragraphs. Accelerations are to be considered as acting independently.

3.8.2 Longitudinal Impact Accelerations, a_l

Maximum longitudinal impact acceleration at any point along the hull girder,

$$a_l = \left(F_{IB}/\Delta\right)\left\{\left[1.1\cdot\tan\left(\gamma+\phi\right)\right]+\left[7\cdot\frac{H}{L}\right]\right\}$$

[m/s^2]

3.8.3 Vertical acceleration, a_v

Combined vertical impact acceleration at any point along the hull girder,

$$a_v = 2.5\cdot\left(F_{IB}/\Delta\right)\cdot F_X \quad [\text{m/s}^2]$$

F_X = 1.3 at FP
= 0.2 at midships
= 0.4 at AP
= 1.3 at AP for vessels conducting ice breaking astern

Intermediate values to be interpolated linearly.

3.8.4 Transverse impact acceleration, a_t

Combined transverse impact acceleration at any point along hull girder,

$$a_t = 3F_i \frac{F_X}{\Delta} \quad [m/s^2]$$

F_X = 1.5 at FP
= 0.25 at midships
= 0.5 at AP
= 1.5 at AP for vessels conducting ice breaking astern

Intermediate values to be interpolated linearly.

where:

φ = maximum friction angle between steel and ice, normally taken as 10 [degrees]

γ = bow stem angle at waterline [degrees]

Δ = displacement

L = length between perpendiculars [m]

H = distance in meters from the water line to the point being considered [m]

FIB = vertical impact force, defined in Sec.2, 2.13.2.1.

Fi = total force normal to shell plating in the bow area due to oblique ice impact, defined in Sec.2, 2.3.2.1.

3.9 Auxiliary systems

3.9.1 Machinery is to be protected from the harmful effects of ingestion or accumulation of ice or snow. Where continuous operation is necessary, means are to be provided to purge the system of accumulated ice or snow.

3.9.2 Means are to be provided to prevent damage, to tanks containing liquids due to freezing.

3.9.3 Vent pipes, intake and discharge pipes and associated systems are to be designed to prevent blockage due to freezing or ice and snow accumulation.

3.10 Sea inlets and Cooling Water Systems

3.10.1 Cooling water systems for machinery that is essential for the propulsion and safety of the vessel, including sea chest inlets, are to be designed for the environmental conditions applicable to the ice class.

3.10.2 At least two sea chests are to be arranged as ice boxes (sea chests for water intake in severe ice conditions) for ice class PC1 to PC5 inclusive. The calculated volume for each of the ice boxes is to be at least 1 m^3 for every 750 [kW] of the totally installed power. For PC6 and PC7 there is to be at least one ice box located preferably near center line.

3.10.3 Ice boxes are to be designed for effective separation of ice and venting of air.

3.10.4 Sea inlet valves are to be secured directly to the ice boxes. The valves are to be of full bore type.

3.10.5 Ice boxes and sea bays are to have vent pipes and are to have shut off valves connected directly to the shell.

3.10.6 Means are to be provided to prevent freezing of sea bays, ice boxes, ship side valves and fittings above the load water line.

3.10.7 Efficient means are to be provided to re-circulate cooling seawater to the ice box. Total sectional area of the circulating pipes is not to be less than the area of the cooling water discharge pipe.

3.10.8 Detachable gratings or manholes are to be provided for ice boxes. Manholes are to be located above the deepest load line. Access is to be provided to the ice box from above.

3.10.9 Openings in ship sides for ice boxes are to be fitted with gratings or holes or slots in shell plates. The net area through these openings is to be not less than 5 times he area of the inlet pipe. The diameter of holes and width of slot in shell plating is to be not less than 20 [mm]. Gratings of the ice boxes are to be provided with a means of clearing. The means of clearing is to be of a type using low pressure steam. Clearing pipes are to be provided with screw-down type non-return valves.

3.11 Ballast Tanks

3.11.1 Efficient means are to be provided to prevent freezing in fore and after peak tanks and wing tanks located above the water line and where otherwise found necessary.

3.12 Ventilation Systems

3.12.1 The air intakes for machinery and accommodation ventilation are to be located on both sides of the ship at locations where manual de-icing is possible. Anti-icing protection of the air inlets may be accepted as an equivalent solution to location on both sides of the ship and manual de-icing. Notwithstanding the above, multiple air intakes are to be provided for the emergency generating set and are to be as far apart as possible.

3.12.2 The temperature of the inlet air is to be suitable for:
- the safe operation of the machinery; and
- the thermal comfort in the accommodation.

Accommodation and ventilation air intakes are to be provided with means of heating, if needed.

3.13 Steering Systems

3.13.1 Rudder stops are to be provided. The design ice force on rudder is to be transmitted to the rudder stops without damage to the steering system. An ice knife is to in general be fitted to protect the rudder in centre position. The ice knife is to extend below BWL. Design forces are to be determined according to the Sec2, 2.15.

3.13.2 The rudder actuator is to comply with the following requirements 3.13.2.1 and 3.13.2.2:

3.13.2.1 The rudder actuator is to be designed for a holding torque obtained by multiplying the open water torque resulting from the application of SOLAS Reg. II-1 / 29.3.2 (considering however a maximum speed of 18 knots, by following factors:

Table 3.13.2.1 : Ice class factors for steering gear	
Ice class	**Factor**
PC1	5
PC2	5
PC3	3
PC4	3
PC5	3
PC6	1.5
PC7	1.5

3.13.2.2 The design pressure for calculations to determine the scantlings of the rudder actuator is to be at least 1.25 times the maximum working pressure corresponding to the holding torque defined in 3.13.2.1 (Derived from SOLAS Reg. II-1 / 29.2.2).

3.13.3 The rudder actuator is to be protected by torque relief arrangements, assuming the following turning speeds [deg/s] without an undue pressure rise (ref *Pt.4, Ch.6, Steering Gear* for undue pressure rise):

Table 3.13.3 : Steering gear turning speeds			
Ice Class	**PC1 and PC2**	**PC3 to PC5**	**PC6 and PC7**
Turning speeds [deg/s]	10	7.5	6

If the rudder and actuator design can withstand such rapid loads, this special relief arrangement is not necessary and a conventional one may be used instead (*Pt.4, Ch.6, Steering Gear*).

3.13.4 Additionally for icebreakers, fast-acting torque relief arrangements are to be fitted in order to provide effective protection of the rudder actuator in case of the rudder being pushed rapidly hard over against the stops.

For hydraulically operated steering gear, the fast-acting torque relief arrangement is to be so designed that the pressure cannot exceed 115% of the set pressure of the safety valves when the rudder is being forced to move at the speed indicated in Table 3.13.4, also when taking into account the oil viscosity at the lowest expected ambient temperature in the steering gear compartment.

For alternative steering systems the fast-acting torque relief arrangement is to demonstrate an equivalent degree of protection to that required for hydraulically operated arrangements.

Table 3.13.4 : Steering gear turning speeds for icebreakers

Ice Class	**PC1 and PC2**	**PC3 to PC5**	**PC6 and PC7**
Turning speeds [deg/s]	40	20	15

The arrangement is to be designed such that steering capacity can be speedily regained.

3.14 Alternative design

3.14.1 As an alternative – a comprehensive design study may be submitted and validated by an agreed test programme.

A P P E N D I X

The following illustrations show the excitation torque for all torsional load cases given in section 3 for different blade numbers (Z). The plots have been made using data for PC7 (H_{ice} = 1.5)

Section 1

General

1.1 Application

1.1.1 The rules in this chapter apply to vessels which are arranged and equipped for stimulation of wells for production of oil and or gas. The requirements are supplementary to those given for assignment of main class.

1.2 Classification and Class Notations

1.2.1 Vessels built and equipped according to the rules in this chapter may be given the additional class notation "**WELL STIMULATION VESSEL"**.

1.2.2 Well Stimulation Vessels transporting and handling hazardous and noxious liquid substances in bulk are to comply with the OSV Chemical Code (IMO Resolution A.1122(30) and will be eligible to be assigned class notation "**OCC**".

1.2.3 Any additional requirements of the Flag Administration and/or the Coastal State are also to be complied with.

1.3 Definitions

1.3.1 Well Stimulation Systems
Well stimulation is a type of well intervention performed on an oil or gas well to increase production by improving the flow of hydrocarbons from the drainage area into the wellbore. Well stimulation systems are the facilities installed on vessels for the purpose of stimulation of wells to improve their productivity of oil and/or gas. Well stimulation systems may include acidizing equipment, fracturing blenders, pumping units, hydration and chemical additive systems, supporting equipment such as coiled tubing, lifting equipment, well control equipment, pressure vessels, piping, electrical components and control systems.

1.3.2 Lining

Lining is an acid-resistant material that is applied to the tank or piping system in a solid state with a defined elasticity property.

1.4 Scope of Classification

1.4.1 The following matters are covered by classification :

a) Position keeping, intact and damage stability of the vessel.

b) Tanks, pumping and piping arrangement, equipment and instrumentation related to the storage and handling of well stimulation fluids.
c) Personnel protective equipment.

1.5 Plans and Documentation

1.5.1 In addition to plans listed in Part 1, Ch 1, Sec 3, plans/documents given in 1.5.2 to

1.5.6, are to be submitted for information/ approval, as appropriate:

1.5.2 The following drawings are to be submitted for information :

General arrangement plan of well stimulation equipment including hazardous area/zone classification and chemical storage area definition, as well as decontamination and eye-washing facilities, and location of personnel protective equipment.

1.5.3 Arrangement and Equipment Plans.

The following plans/ documentation are to be submitted for approval:

i) Arrangement of all integral and independent tanks, including support and stays of independent tanks

ii) Structural drawings of acid tanks including vent arrangements, information on non-destructive testing of welds, strength and tightness testing, and specification of protective linings

iii) Documentation for liquid nitrogen tanks (plans required for liquefied gas carriers are to be referred Part 5, Ch 4)

iv) Pumping arrangement including diagrams of piping for acid, nitrogen and liquid additives, details of flange connections and pipe clamping/securing as well as specification and data on high pressure flexible hoses with end connections.

v) Mechanical ventilation arrangements of closed and semi-closed spaces containing acid tanks, pipes, pumps, mixers and blenders

vi) Drawings showing location of all electrical equipment in areas containing installations for uninhibited acid

vii) Electrical diagrams of well stimulation systems including single line diagram for intrinsically safe circuits, control and monitoring systems for cargo tank level gauging, overflow protection and emergency shutdown, as well as indication equipment for hydrogen, hydrogen chloride and oxygen

viii) List of explosion protected equipment together with certificates and references to specific diagrams and/or plans

ix) Drawings of pumps and mixers/blenders.

x) Drawings and particulars of nitrogen vaporizer and heat exchangers.

xi) Scope and type of Personnel protective equipment intended to be provided.

1.5.4 The following calculations/ analyses are to be submitted for approval :

i) Stability Calculations.

ii) Calculations demonstrating adequacy of propulsion power required for the vessel to maintain station during well stimulation operations.

iii) Stress analysis of supporting structure in way of flexible hose storage reel(s).

iv) Stress analysis of liquid nitrogen piping and heat exchangers.

v) Stress analysis of high pressure piping.

1.5.5 Documentation for the control and monitoring systems for the following is to be submitted for approval:

i) Cargo tank level measurement system.

ii) Cargo tank overflow protection system.

iii) Emergency shut-down system.

iv) Hydrogen indication equipment.

v) Hydrogen chloride indication equipment.

vi) Oxygen indication equipment.

1.5.6 The values of all design loads for Burner/ Flare Booms, where provided, are to be submitted.

1.6 Operation Manual

1.6.1 Operation manual for well stimulation procedure is to be submitted for approval and the same are to be readily available on board. The manual is to provide instructions and information on safety aspects related to well stimulation processing.

1.6.2 The operation manual is to include details of :

a) protective equipment
b) storage and handling of fluids and dry additives
c) transfer operations
d) emergency shut-down and dis-connection.

Section 2

Position Keeping and Stability

2.1 Position Keeping

2.1.1 It is essential that well stimulation vessels are capable of maintaining their positions safely during well stimulation operations. The means to maintain position may be a mooring system with anchors or dynamic positioning system.

2.1.2 If position mooring is undertaken with anchors, they are to fulfill the requirements for position keeping systems in Ch 10 of the *Rules and Regulations for Construction and Classification of Mobile Offshore Drilling Units*. Precautions are to be taken to prevent damage to seabed equipment and installations by anchors.

2.1.3. Dynamic positioning systems, where used to maintain the vessel's position during well stimulation operations, are to comply with the requirements for the class notation **DP (2)** or **DP (3)**.

2.2 Stability

2.2.1 Intact stability of the vessel should be in accordance with the Guidelines for the Design and Construction of Offshore Supply Vessels 2006 (Res. MSC.235 (82)).

2.2.2 The maximum aggregate quantity of hazardous and noxious liquids normally permitted to be carried is as indicated in the following:

a) 800 [m^3] or
b) a volume in cubic meters equal to 40% of the vessel's deadweight calculated at a cargo density of 1.0, whichever is the lesser.

2.2.3 The Administration may permit carriage of more than the maximum amount specified above.

2.2.4 Well stimulation vessels which are permitted to carry more than the maximum amount specified in 2.2.2 are to comply with the requirements for intact stability and damage stability requirements in Res. MSC. 235(82) with damage assumption given in 3.2.1 of Res. MSC. 235(82).

Section 3

Well Stimulation Equipment and Systems

3.1 General

3.1.1 The design of well stimulation equipment is to be carried out in accordance with Recognized National/International Standards, acceptable to IRS and the same are to be specified by the designer. The equipment and systems used only for well stimulation operations are in general not subject to classification by IRS, unless requested by the client. Manufacturer's certificate affirming compliance with applicable recognized standards is to be submitted to IRS. Their installations and onboard testing are to be supervised in the aspects of operational safety as to reduce to a minimum

any danger to persons on board and marine pollution, due regard to be paid to moving parts, hot surfaces and other hazards. Consequences of failure of systems and equipment essential to the safety of the vessel are to be considered.

3.1.2 Classified areas related to the installation of well stimulation equipment are to be described in accordance with IEC61892-7 and *Rules and Regulations for Construction and Classification of Mobile Offshore Drilling Units, Ch 13.*

3.1.3 The equipment class of vessel chosen for any particular operation should be agreed between the owner of the vessel and the customer based upon a risk analysis of the consequence of loss of position

3.2 Tanks and Piping Arrangement

3.2.1 Tanks for acid(s) and liquefied nitrogen are to be located at a minimum distance of 760 [mm] from the vessel's side and bottom. In sides the distance is to be measured perpendicularly inboard from the vessel's side to the centerline at the level of the summer load line.

3.2.2 Cargoes that react with other cargoes in hazardous manner are to be segregated by means of cofferdam, void space, cargo pump room, empty tank or fuel oil tank. Tanks used for other purposes (except for fresh water and lubricating oils) may be accepted as cofferdams.

3.2.3 For access to all spaces, the minimum spacing between cargo tank boundaries and adjacent ship's structure is to be 600 [mm].

Independent tanks installed in otherwise empty holds or stowed on deck are considered satisfactory in terms of segregation requirements.

3.2.4 The design of tanks and pumping arrangements is to cater for their segregation from machinery spaces, propeller shaft tunnels, dry cargo spaces, accommodation and service spaces, as well as from drinking water and stores for human consumption. The segregation may be achieved by means of cofferdam, void space, cargo pump room, empty tank, oil fuel tank or similar arrangements.

3.2.5 Piping Systems for the well stimulation processing plant are not to pass through any accommodation, service or machinery space other than cargo pump-room or pump-rooms and are to be separated from the machinery and ship piping systems.

3.2.6 Cargo piping is to be joined by welding except as allowed in Part 5, Ch 3, Sec 5.2. Storage tanks, pumps, valves, gaskets and piping for uninhibited acids are to be of corrosion resistant material or to have internal lining of corrosion resistant material. (Also Refer to Section 4, 4.1.3).

3.2.7 Each well injection line is to be provided with a check valve located at a flow-head or a test tree.

3.2.8 Tanks and pumping arrangements for liquid additives having flashpoint below 60°C are to comply with relevant requirements of Part 5 Chapter 3.
Arrangement of pump room for LFL (low flashpoint liquids) substances adjacent to the LFL tanks and without separating cofferdams may be specially considered in each case.

3.2.9 Requirements for tanks and pumping arrangements for chemicals other than acids will be considered in each case with due regard to the properties of the chemicals and applicable requirements of Part 5, Ch 3, Sec 15.

3.2.10 The well stimulation processing plant is to be remotely controlled from a position outside the area where the well stimulation systems are located.

3.3 Tank Venting

3.3.1 Outlets from safety valves of nitrogen tanks are to be led to open deck. Outlet pipes are to be arranged and supported in order to allow thermal expansion/contraction during release of cold gas. Deck/bulkhead penetrations are to be such that the structures are thermally isolated from the cold pipes.

3.3.2 Vent outlets from acid tanks are to be led to open deck. The outlets are to have a minimum height of 4 m above the deck and located at a minimum horizontal distance of 5 m from openings to accommodation and service spaces.

3.3.3 Vent outlets from acid tanks are to have pressure/vacuum valves and be provided with flame screens.

3.4 Access Openings

3.4.1 Access to enclosed spaces containing tanks, piping, pumps and blenders for uninhibited acid is to be direct from open deck or through air locks from other spaces. The air lock is to have independent mechanical ventilation.

3.4.2 For access through hatches, manholes or horizontal openings, the dimensions are to be sufficient to allow a person wearing a self contained breathing apparatus and protective equipment to ascend or descend any ladder without obstruction and also to provide a clear opening to facilitate the hoisting of an injured person from the bottom of a space.

3.4.3 Minimum clear opening for horizontal access is not to be less than 600 [mm] x 600 [mm] and for vertical openings is not to be less than 600 [mm] x 800 [mm] at a height of not more than 600 [mm] from the bottom shell plating unless gratings or other footholds are provided.

3.5 Ventilation

3.5.1 Ventilation of spaces for acid storage and handling:

i) The spaces containing uninhibited acid are to have independent mechanical ventilation with a capacity of minimum 30 air changes per hour, while those containing inhibited acid a minimum of 20 air changes per hour.

ii) Spaces for acid storage and handling are to be preferably ventilated by local exhaust. Spaces containing acetic acid are to be ventilated by explosion proof electrical equipment.

iii) The discharge suctions are to be located both, at floor and ceiling levels of the space concerned.

3.5.2 Ventilation of other spaces containing equipment for well stimulation:

i) Spaces containing installations for liquid nitrogen are to have a mechanical ventilation system (independent of the ventilation systems for accommodation) with a minimum capacity of 20 air changes per hour.

3.5.3 Ventilation of spaces for additive storage and handling:

i) Ventilation of spaces for storage and handling of dry and liquid additives will be considered in each case depending on the flammability, toxicity and reactivity properties of the additives to be used.

3.6 Spill Protection

3.6.1 A lining of corrosion resistant material extending up to a minimum height of 500 [mm] on the surrounding bulkheads and coaming is to be provided for protection of floors or decks under acid storage tanks, pumps and piping for uninhibited acid. Watertight coaming is to be provided for hatches or other openings in way of such decks with a minimum height of 500 [mm]. The coaming is to be protected by suitable lining or an acid resistant coating. Height requirement for coamings may be waived where this height is not practicable.

3.6.2 In order to keep deck spill away from accommodation and service areas, a permanent coaming of 150 [mm] height is to be provided on deck.

3.6.3 Flanges or other detachable pipe connections are to be covered by spray shields.

3.6.4 Portable shield covers for connecting flanges of loading manifold are to be provided. Drip trays of acid resistant material are to be provided under loading manifold for acid.

3.6.5 Manifolds transferring liquefied gases and other flanged connections in the system are to be provided with drip trays resistant to cryogenic temperatures. The issue of cold cracking of the ship structure, in the event of a liquid nitrogen spill, is to be addressed and mitigation measures provided.

3.7 Drainage

3.7.1 Drainage arrangements for acids are to be of acid resistant materials.

3.7.2 The drainage systems for spaces housing tanks, pumping and piping for acids or

additives are to be separate and not to be connected to the drainage system for other areas. These are to be of corrosion resistant materials. These drainage arrangements are to be located within the well stimulation processing area.

3.7.3 Drainage arrangements for void spaces, double bottom tanks and ballast tanks which are not separated from tanks containing well stimulation substances or their residues by a double bulkhead, are to be situated within the processing area.

3.8 Electrical Equipment

3.8.1 Electrical equipment or other ignition sources used in enclosed spaces containing acid tanks and acid pumping arrangements are to be certified as safe for operation in hydrogen/air atmosphere and are to be explosion proof.

3.9 Control and Monitoring Systems

3.9.1 A system of automatic and manual controls together with process shutdown and operating procedures are to be provided. System design is to cater for normal manning during well stimulation operations, accessibility of manual controls and switchover between manual and automatic operations.

3.9.2 Vapour and Gas Detection

i) Vapour detection and alarm systems for hydrogen or hydrogen chloride gas are to be provided in enclosed or semi-enclosed spaces containing installations for uninhibited acid.

ii) Spaces containing tanks and piping for liquid nitrogen are to be equipped with oxygen deficiency monitoring systems.

3.9.3 Gauging and Level Detection

i) Tanks containing liquefied nitrogen are to have gauging and level detection arrangements in accordance with Part 5, Ch 4, Sec.13.

ii) Tanks containing hydrochloric acid are to have a closed gauging system. A high level alarm is to be provided and the alarm is to be activated by a level sensing device, independent of the gauging system.

iii) Spaces containing equipment and storage tanks for the well stimulation system are to be provided with suitable detection and alarm system for liquid leakage.

3.9.4 Emergency Shutdown

i) Emergency stop of all pumps in the oil well stimulation system is to be arranged from one or more positions, outside the area where the system is located.

ii) Liquid nitrogen outlet lines from each nitrogen tank are to be provided with Emergency shut-off valves. These valves are to be remotely controlled from one or more positions outside the area where the oil well stimulation system is located.

iii) Emergency depressurizing and disconnection of the transfer hose are to be arranged from the central control position and from the bridge.

iv) At least one emergency shutdown panel capable of closing all barrier elements of blowout preventer and disconnecting connector for subsea blowout preventer sections is to be provided at a safe and readily accessible location, where applicable.

3.9.5 Electrical power supply is to be from a main power system and from a monitored uninterrupted power supply (UPS). The UPS is to be powered from both the main and emergency power systems and capable of continuously operating for at least 30 minutes upon loss of power from the main source. A reliable power supply is to be provided wherever auxiliary energy is required for functionality of emergency control and shutdown,

3.9.6 Where hydraulic and/or pneumatic power supply is used for actuation of emergency control and shutdown, duplication arrangements are to be made in accordance with the requirements in Part 4, Ch 7 Sec 2. Power supply circuits are to be connected to the main and emergency power sources separately where driving power for hydraulic and/or pneumatic pumps is electric.

3.9.7 A hardwired means for voice communications is to be provided between the central control station for well stimulation

operation and the vessel's position keeping control stations.

3.10 Flare / Burner Boom (where provided)

3.10.1 Design Loads

3.10.1.1 The loads to be considered in the design of a boom structure are to include, as applicable:

a) Dead weight of structure, piping, fittings, rigging, snow and ice, walkways, guard rails, etc.

b) Wind loads

c) Thermal and impulsive loads resulting from the use of the flare

d)Vessel motion-induced loads

3.10.1.2 Loads resulting from vessel motions may be estimated as per Pt 3, Ch 4 and wind loads may be established as per *Rules and Regulations for Construction and Classification of Mobile Offshore Drilling Units, Ch 4*.

3.10.1.3 The derivation of loading conditions to be used in the design is to give due account of the operational requirements of the Owner/Operator, and are to reflect both the operational and stowed modes of the boom.

3.10.2 The completed burner assembly is to be pressure-tested from the flexible line connection flange to the burner head. The adequacy of the boom's slewing and topping gear is to be demonstrated by testing after the boom's installation on the drilling unit. The details of the test procedure are to be agreed upon with IRS and witnessed by a Surveyor.

Section 4

Acid and Liquid Nitrogen Systems

4.1 Acid

4.1.1 Materials

4.1.1.1 Part 5 Ch 3, Sec 6 is applicable in general.

4.1.1.2 Storage tanks, pumping and piping for uninhibited acid are to be of corrosion resistant material or are to have internal lining of corrosion resistant material.

4.1.2 Storage Tanks

4.1.2.1 Scantling of integral tanks are to be in accordance with the requirements of Pt 3.

4.1.2.2 Scantlings of independent tanks, constructed mainly of plane surfaces, are to be in accordance with relevant requirements given in Pt.3.Tanks of pressure vessel configuration type (cylinders, spheres etc.) are to be in accordance with the requirements given in Pt 5, Ch.3 Sec.4.

4.1.3 Pumping and Piping

4.1.3.1 The rules in Pt 5, Ch. 3 will apply to pumping and piping systems.

4.1.3.2 The flexible hoses with end connectors are to be in accordance with a recognized standard.

4.2 Liquid Nitrogen

4.2.1 Materials

4.2.1.1 The materials are to be in accordance with the requirements of Pt. 5, Ch.4,Sec. 6.

4.2.2 Storage tank

4.2.2.1 The relevant requirements of Pt. 5, Ch. 4, Sec. 4 are to be applied.

4.2.3 Piping

4.2.3.1 The relevant requirements of Pt. 5, Ch. 4, Sec. 5 are to be applied.

4.2.4 Pressure/temperature control

4.2.4.1 The relevant requirements of Pt. 5, Ch. 4, Sec. 7 are to be applied.

4.2.5 Venting Arrangement

4.2.5.1 The relevant requirements of Pt. 5, Ch. 4, Sec. 8 are to be applied.

4.2.6 Personnel Protection

4.2.6.1 The relevant requirements of Pt. 5, Ch. 4, Sec. 14 are to be applied.

4.2.7 Liquid nitrogen is generally kept at atmospheric pressure within temperature range of -210 [˚C] to -196 [˚C]. Where the working temperature of liquid nitrogen is below -165 [˚C] the selection of structural materials is to be undertaken in consultation with IRS.

4.2.8 Where the working temperature is below -110 [˚C], a complete stress analysis is to be submitted for approval accounting for the weight of pipes, acceleration loads induced by hogging and sagging of the ship, for each branch of the piping system.

Section 5

Personnel and Fire Protection

5.1 Decontamination Showers and Eye Washes

5.1.1 A suitably marked decontamination shower and eyewashes are to be available on deck in a convenient location. The shower and eyewash are to be operable in all ambient conditions. Temperature control of water is to be provided in order to avoid excessive temperature.

5.2 Personnel Protective Equipment

5.2.1 Protective equipment are to be kept onboard in suitable locations as required by Part 5 Chapter 3 for carriage of hydrochloric acid.

5.3 Fire Protection

5.3.1 The arrangement of firefighting stations, fixed fire extinguishing systems and portable fire extinguishers are to be in accordance with Pt 6 and Pt 5, Ch 3, Sec 11.

End of Chapter

Chapter 34

Oil Recovery Vessels

Section	Contents
1	*General*
2	*Ship Structure*
3	*Pumping, Piping and Ventilation Systems*
4	*Electrical Installations*
5	*Fire Detection, Protection and Fighting*

Section 1

General

1.1 Application

1.1.1 This Chapter gives additional requirements for ships which are equipped to recover oil from the sea surface at a safe distance, handle, store and transport the recovered oil.

1.1.2 A ship complying with the applicable requirements of this chapter will be eligible for an appropriate class notation, as given in 1.2, and which will be entered in the Register Book.

1.1.3 Additional requirements may be imposed by the National Administration with whom the ship is registered and/or by the Administration within whose territorial jurisdiction the ship is intended to operate for oil recovery.

1.2 Classification and Class Notations

1.2.1 The Class Notations that may be assigned are as follows:

a) **OIL RECOVERY VESSEL**: A ship designed and constructed primarily for oil recovery duties. The scantlings of recovered oil storage tanks will be specially considered based on the requirements of Pt 5, Ch.2;

b) **OIL RECOVERY**: A ship equipped for carrying out oil recovery in addition to other duties and complying with the applicable requirements of this Chapter;

c) **FP 60C**: A ship designed and equipped to recover polluted water in the event of spills of oils which have, at the time of recovery, a flash point higher than 60 degree Celsius (closed cup test).
The notation is not to be assigned to oil recovery ships carrying recovered oils at a temperature within 15 degree Celsius of its flash point.

1.3 Scope of Classification

1.3.1 The following aspects of vessels related to oil recovery are covered by classification

a) Construction

b) Ship equipment and operation

c) Safety against fire and explosion during handling, storage and transportation of oil recovered from a spill

d) Supporting structures for oil recovery equipment

e) Stability and floatability in all relevant operating conditions

f) Available power for supply to equipment used during oil recovery operations

1.4 Definitions

1.4.1 **Oil Recovery Vessel**: A ship specially equipped with a fixed installation and /or mobile equipment for the removal of oil from the sea surface at a safe distance (see Cl 1.7 also) and its retention on board, carriage and subsequent unloading.

1.4.2 **Recovered Oil**: The top layers of oil polluted water collected by means of skimmers, rotating disk, floating pumps or equivalent systems, with sweeping arms, booms or similar devices.

1.4.3 **Oil recovery Tank**: A tank intended for the retention and transportation of recovered oil.

1.4.4 **Oil Recovery Pump Room**: A space containing the pumps and their accessories for handling of recovered oil.

1.4.5 **Oil Recovery Area**: The oil recovery areas are those parts of the ship which contain the following:

a) oil recovery tanks;
b) oil recovery pump rooms;
c) cofferdams;
d) ballast or void spaces surrounding the integral tanks and hold spaces in which independent tanks are located;
e) deck areas such as :
    i) area above the oil recovery tanks;
    ii) In addition, the deck area extending transversely and longitudinally from the oil recovery tanks over a distance of 3[m], where the rule length of the vessel is 50[m] and over.

1.4.6 **Hazardous Areas**: The areas in which an explosive atmosphere is, or may be, expected to be present in quantities such as to require special precautions for the construction, installation and use of electrical apparatus (See Cl 4.3).

1.4.7 **Gas-safe areas**: The gas areas which are not defined as hazardous.

1.5 Assumptions

1.5.1 The classification of the vessel is based upon the following assumptions:

a) The vessel would carry out oil recovery operations in accordance with the approved operating manual (see Cl 1.7 also);

b) The oil recovery operations would take place in moderate sea conditions

1.6 Submission of Plans

1.6.1 The following plans and/ or information are to be submitted in addition to the supporting documentation required for classification as specified elsewhere in this Chapter :

1.6.1.1 For Approval:

i) Arrangement plan indicating the location of oil recovery and handling equipment including portable ones and tanks utilized for recovered oil;

ii) Structural support in way of oil recovery equipment and loads in way of their foundations;

iii) Structural arrangement of tanks designed for storage of recovered oil including access to those tanks;

iv) Stability calculations for all operating conditions including ballasted condition (See also Cl. 1.9.2);

v) Piping system diagrams for handling recovered oil accompanied by details like size, wall thickness, maximum working pressure and material of all pipes; and the type, size, pressure rating and material of valves and fittings;

vi) Recovered oil tank venting arrangements including position of vent outlets;

vii) Arrangement of openings to hazardous areas and adjacent compartments, self closing doors and their direction of opening;

viii) Ventilation systems for all hazardous areas with details including number of air changes per hour, capacities of fans, air flows, areas subject to positive or

negative pressure, location and details of machinery exhaust outlets;

ix) Electrical equipment fitted in hazardous areas, including portable electric equipment connected during oil recovery operations (if any). Other details like model name/ number, manufacturer and certification of explosion proof, intrinsically safe, pressurized equipment are also to be submitted;

x) Wiring diagrams, installation instructions and restrictions imposed by certifying agency for intrinsically safe systems;

xi) Power supply, electrical protection and cabling for oil recovery equipment;

xii) Electrical load schedule considering the use of oil recovery equipment during operations;

xiii) Structural fire protection arrangements, controls and particulars of fixed fire extinguishing systems and portable fire safety equipment;

xiv) Diagrammatic plan of recovered oil heating systems, if installed.

1.6.1.2 For Review/ Information:

i) Specifications of gas detection equipment;

ii) Operating Manual

1.7 Operating Manual

1.7.1 The Operating manual is to be submitted in order to verify that the information included within is consistent with the design information and limitations considered in the vessel's classification.

The following information/ procedures are in general to be included in an operating manual to be available on board:

(a) Guidelines regarding safe distance from an oil spill source including specifying conditions when to withdraw the vessel;

(b) Information regarding the safe use of the ship with respect to, preparing for and conducting oil recovery and subsequent operations;

(c) Establishing and maintaining a safe atmosphere in any space(s) liable to become hazardous during oil recovery and subsequent operations;

(d) Isolation, where necessary, of electrical equipment in zones or spaces considered hazardous during oil recovery and subsequent operations, or on failure of, the measures required to establish and maintain a safe atmosphere;

(e) Gas measurements during operation including hydrogen sulphide gas (on open deck and in spaces where gas might accumulate). Actions to be taken in case of gas detection;

(f) Cleaning and gas freeing of tanks and pipes;

(g) Stability in all the relevant operational conditions;

(h) Firefighting;

(j) Maintenance procedures.

1.8 Testing and Trials

1.8.1 During ship trials, the transfer procedures to oil recovery mode of operation are to be simulated to verify that the vessel will be able to operate, as intended.

1.8.2 Testing of Oil Recovery Equipment: Tests are to be carried out according to an approved trial protocol, in order to check the proper operation of the oil recovery equipment. These tests may be performed during dock and/ or sea trials.

1.9 Intact Stability

1.9.1 Intact stability is to be as per the requirements of Chapters 1, 2 and 3 of Part A of the International Code on Intact Stability, 2008 (Resolution MSC 267(85)), as amended.

1.9.2 The following cases are also to be included in the trim and stability booklet for ships intended to carry out Oil Recovery Operations.

a) Ship in the fully loaded departure condition to the oil recovery spot having all the oil recovery equipment installed on board;

b) Ship in the worst anticipated operating condition during oil recovery operation; the worst operating condition regarding free surface effects when the equipment is fitted in the most unfavorable condition (for example, swiping arm extended).

Section 2

Ship Structure

2.1 General

2.1.1 The vessel is to be provided with:

a) a suitable working deck for use in oil recovery operation;

b) storage tanks for recovered oil;

c) permanently installed pumping and piping arrangement for transfer and discharge of recovered oil.

2.1.2 The visibility from the manoeuvring station is to be such that the Master can easily monitor oil recovery operations both on deck and in the water.

2.1.3 Accommodation areas are to be located as far away as possible from the oil tanks and the deck area, where the recovery operations are performed.

2.1.4 Oil handling areas and equipment on deck are to be provided with a coaming around all pumps, transfer flanges and other connections where leakage may be expected.

2.1.5 The coaming is to have a height of at least 150 [mm]. Each coaming is to be adequately sized to contain deck spills and prevent recovered oil from entering accommodation, machinery, control and service spaces or passing overboard.

2.1.6 Where drains are provided for the coaming, closing devices for these drains are to be permanently attached.

2.1.7 Spill coamings may be of the removable type. Removable coamings are to be constructed of rigid, non oil-absorbent material, leak proof, and may be temporarily fixed to the vessel's structure.

2.1.8 Exhaust outlets from machinery are to be located as high as practicable above the deck and are to be fitted with spark arresters.

2.2 General Arrangement

2.2.1 Tank arrangement

2.2.1.1 Oil recovery tanks are to be separated from machinery spaces of category A, propeller shaft tunnels, dry cargo spaces, accommodations, control stations and service spaces and from drinking water and stores for human consumption by means of a cofferdam or equivalent space.

2.2.1.2 For easy access to all parts, the cofferdams are to have a minimum width of 600 [mm]. Fuel oil tanks, tanks for ballast water, tanks for liquids used for oil treatment, tanks for anti-pollution liquids, storerooms for oil removal equipment and pump-rooms are considered as spaces equivalent to a cofferdam.

2.2.1.3 When this cofferdam is impracticable, oil recovery tanks adjacent to the engine room may be accepted provided that:

a) the boundary bulkheads are accessible for inspection;

b) the boundary bulkheads are connected to adjoining structure by full penetration welding ;

c) the tanks are pressure tested at each renewal survey.

2.2.1.4 In ships not exclusively used for oil recovery operations, the following may be used as oil recovery tanks:

a) tanks in supply vessels complying with LHNS guidelines;

b) tanks in Well Stimulation Vessels, if designed for a cargo mass density of, at least, 1.025 [t/m^3];

c) water ballast tanks;

d) fuel oil tanks;

e) hoppers spaces;

f) liquid mud tanks.

In all cases, the tanks, their associated equipment and piping are to comply with the requirements for oil recovery tanks.

2.2.1.5 Oil recovery tanks are to be located abaft the collision bulkhead.

2.2.1.6 The coating used in recovered oil tanks is to be of an oil and dispersion resistant type.

2.2.1.7 The height of tanks for recovered oil is not to be less than 1.5 [m].

2.2.1.8 Internal obstructions in tanks for recovered oil are to be provided with adequate openings to allow full flow of oil. The openings are to be so arranged that the tanks can be effectively drained. The area of one single opening is not to be less than twice the sectional area of the discharge pipe.

2.2.2 Accommodation, control station, service and machinery spaces

2.2.2.1 Accommodation or service spaces, control stations or machinery spaces of category A are to be located outside the oil recovery area.

2.2.2.2 Entrances, air inlets and openings to accommodation, service and machinery spaces of category A and control stations are not to face the oil recovery area unless they are spaced at least 7 [m] away from the oil recovery area.

2.2.2.3 Doors to spaces not having access to accommodation, service and machinery spaces and control stations, such as oil recovery control stations, storerooms or equipment rooms, may be permitted within the 7 [m] zone specified above, provided the boundaries of these spaces are insulated to A-60 standard.

2.2.2.4 The requirements of 2.2.2.2 and 2.2.2.3 are not applicable to vessels with class notation **FP 60C**.

2.2.3 Access to spaces in oil recovery area

2.2.3.1 Access hatches (at least 600 mm x 600 mm of clear opening) within the oil recovery area are to be direct from the open deck. Such accesses are to be suitable for cleaning and gas-freeing.

2.2.4 Oil recovery tank construction

2.2.4.1 A cargo density of 1.025 [t/m^3] is to be considered for calculating the internal pressures and forces in cargo tanks according to Pt. 3.

2.2.4.2 All tank openings and connections to the tank are to terminate above the weather deck and are to be located on the top of the tanks.

2.2.4.3 The structural design of the tanks is to take into account the temperature of recovered oil. Additional strength calculations may be required in case of risk of sloshing induced loads. (refer Pt. 3).

2.2.4.4 All tanks exceeding a breadth of 0.56B or a length of 0.1L or 12m whichever is the greater, are normally to be provided with wash bulkheads to reduce sloshing in partially filled tanks.

2.2.5 Supporting structures for oil recovery equipment

2.2.5.1 The supporting structures for oil recovery equipment are to be designed appropriately and submitted to IRS for approval.

2.2.6 Access openings between non hazardous and hazardous spaces (See Cl 4.3 also)

2.2.6.1 Normally, access doors or other openings between non hazardous spaces (such as accommodation, service spaces, machinery spaces, control stations and similar spaces) and hazardous spaces are not permitted.

2.2.6.2 Access (other than access between oil recovery pump room and machinery spaces category A) may be accepted between such spaces and hazardous areas provided that:

.1 The non-hazardous room is to have overpressure ventilation with 20 air changes per hour in relation to the hazardous area.

.2 The doors are to be gastight.

.3 The doors are to be self-closing and preferably arranged to swing into the non-hazardous space so that they are kept closed by the overpressure. Water tight sliding doors are not acceptable.

.4 If a door cannot be made self-closing, a second self-closing door in accordance with 2.2.6.2.2 and 2.2.6.2.3 above is to be arranged (air lock). The doors are to be arranged with sufficient spacing to allow for safe passage.

.5 Self-closing doors may be used for passage, but are not to remain open during oil recovery operations. Signboards are to be fitted to this effect.

.6 Emergency escape hatches to open deck that cannot be made self-closing need not be arranged with an air lock, but they can only be used for emergency escape purpose during oil recovery operations. Signboards are to be fitted to this effect.

Section 3

Pumping, Piping and Ventilation Systems

3.1 Pumping system, piping system and pump-rooms intended for recovered oil

3.1.1 The requirements of Pt 5, Ch.2 Sec.6 to 11 and Pt 4, Ch.2 and 3 are to be complied with, as applicable.

3.1.2 Piping systems for handling recovered oil are not to pass through:

a) accommodation spaces;
b) service spaces;
c) control stations;
d) machinery spaces of category A. (except for vessels with notation **FP 60C**).

3.1.3 Pumping and piping systems intended for recovered oil are to be independent from the other pumping and piping systems of the ship, except in the following cases:

a) Sections of the cargo system of supply vessels (in compliance with LHNS guidelines) or Well Stimulation Vessels used for oil recovery or if fuel oil tanks are used, means are provided to isolate the oil recovery system from any other system from which it may be connected. The connection between the cargo system and the recovered oil transfer piping may consist of movable pipe sections.

b) If water ballast tanks are used as oil recovery tanks when the ship is in oil recovery mode, the water ballast piping is blanked-off at the nearest position at the tank before starting the oil recovery operation. The connection between the oil recovery piping and the water ballast tanks is to be done by means of detachable spool pieces.

3.1.4 Piping intended for recovered oil and located below the main deck may run from the tank it serves and penetrate tank bulkheads or boundaries common to longitudinally or transversely adjacent oil recovery tanks, ballast tanks, empty tanks, pump-rooms or oil recovery pump-rooms, provided that, it is fitted with a stop-valve operable from the weather deck inside the tank, it serves. As an alternative, where an oil recovery tank is adjacent to an oil recovery pump-room, the stop valve operable from the weather deck may be situated on the tank bulkhead on the oil recovery pump-room side, provided an additional valve is fitted between the bulkhead valve and the oil recovery pump. A totally enclosed hydraulically operated valve located outside the oil recovery tank may also be accepted, provided that the valve is:

a) fitted on the bulkhead of the oil recovery tank it serves;
b) suitably protected against mechanical damage;
c) fitted at a distance from the shell as required for damage protection; and
d) operable from the weather deck.

3.1.5 Transfer of recovered oil through hatches by means of flexible hoses or moving piping is not permitted (except for vessels with notation **FP 60C**).

3.2 Oil Recovery Pumps

3.2.1 Oil recovery pumps are to comply with the requirements of cargo pumps for oil tankers; (see Pt. 5, Ch. 2, Sec. 6).

3.2.2 Oil recovery pumps are to be capable of being remotely shutdown from a location which is manned during oil recovery operations and from at least one other location outside the oil recovery area.

3.2.3 If an oil recovery pump serves more than one tank, a stop valve is to be fitted in the line of each tank.

3.2.4 Oil recovery pumps are to be so designed as to minimize the danger of sparking.

3.2.5 For ships not exclusively dedicated to oil recovery operations, the use of portable pumps or pumps serving cargo systems may be permitted, subject to special consideration by the IRS.

3.3 Pump Rooms for Oil Recovery Operations

3.3.1 Pump-rooms containing the pumps for handling the recovered oil are to be provided with a fixed fire-extinguishing system suitable for machinery spaces of category A (except for vessels with notation **FP 60 C**).

3.3.2 Means are to be provided to deal with drainage and any possible leakage from oil recovery pumps and valves in the oil recovery pump-room.

3.3.3 Bilge pumping arrangement is to be situated entirely within the oil recovery area. The bilge system is to be operable from outside the oil recovery pump-room.

3.3.4 Oil recovery pumps may also be used for bilge pumping provided they are connected to the oil recovery pump-room bilge piping through a shut-off valve and a non-return valve arranged in series.

3.3.5 For ventilation of oil recovery transfer pump-rooms, see 3.10.

3.4 Vent Pipes in Oil Recovery Tanks

3.4.1 Vent pipes of oil recovery tanks are to lead to the open at least 2.4 [m] above the weather deck.

3.4.2 Vent pipes are to be located at a distance of at least 5 [m] measured horizontally from the nearest air intake or opening to accommodations, control stations, service and machinery spaces of category A and other gas-safe spaces and from ignition sources.

3.4.3 Openings of vent pipes are to be directed to open deck and fitted with:

i) flameproof wire gauze made of corrosion resistant material easily removable for cleaning, and
ii) closing appliances complying with the provisions of Pt 3, Ch.13, Sec.3

3.4.4 For ships, not used exclusively for oil recovery operations, portable vent pipes may be accepted, subject to special consideration by IRS.

3.5 Level Gauging and Overfilling Control of Oil Recovery tanks

3.5.1 Oil recovery tanks are to be fitted with sounding pipes or other level gauging devices of a type approved by IRS.

3.5.2 Oil recovery tanks are to be fitted with a high level alarm or an overflow control system.

3.5.3 The high level alarm is to be of a type approved by the IRS and is to give an audible and visual alarm.

3.6 Heating systems in Oil recovery tanks

3.6.1 Heating systems fitted in oil recovery tanks are to comply with the requirements of Pt.5, Ch.2, Sec.10.

3.7 Sea Water Cooling System

3.7.1 One of the suctions serving the sea water cooling system is to be located in the lower part of the hull

3.8 Fire Pumps

3.8.1 Sea suctions serving the fire water pumps are to be located as low as possible.

3.9 Exhaust Systems

3.9.1 Exhaust lines from engines, gas turbines, boilers and incinerators are to be led outside any hazardous area above the deck and are to be fitted with a spark arrester.

3.9.2 Where the distance between the exhaust lines of engines and the hazardous areas is less than 3 [m], the ducts are to be fitted in a position:

i) near the waterline, if cooled by water injection; or

ii) below the waterline, in the other cases.

3.10 Ventilation System

3.10.1 The ventilation systems for hazardous and non-hazardous spaces are to be independent.

3.10.2 Ventilation of oil recovery pump rooms

3.10.2.1 Oil recovery pump rooms are to be provided with a mechanical ventilation system of the extraction type capable of giving at least 20 air changes per hour.

3.10.2.2 Ventilation intakes are to be so arranged as to minimize the possibility of recycling hazardous vapours from ventilation discharge openings.

3.10.2.3 Ventilation exhaust ducts are to discharge upwards to a gas-safe area on the weather deck in locations at least 3 [m] from any ventilation intake and opening to accommodations, service and machinery spaces, control stations and other spaces outside the oil recovery area.

3.10.2.4 Protection screens of not more than 13 [mm] square mesh are to be fitted on ventilation duct intakes and outlets.

3.10.2.5 Ventilation fans are to be of non-sparking construction.

3.10.2.6 The ventilation system is to be capable of being controlled from outside the oil recovery pump-room.

3.10.2.7 Provision is to be made to ventilate such spaces prior to entering the compartment and operating the equipment and a warning notice requiring the use of such ventilation is to be placed outside the compartment.

3.10.2.8 Ventilation ducts are not to lead through accommodations, service and machinery spaces or other similar spaces.

3.10.3 Ventilation of enclosed spaces normally entered during oil recovery operation other than recovery oil pump rooms

3.10.3.1 Enclosed spaces normally entered within the oil recovery area are to be provided with a mechanical ventilation system of the extraction type capable of giving at least 8 air changes per hour.

3.10.3.2 Ventilation intakes are to be located at a distance of not less than 3 [m] from the ventilation outlets of oil recovery pump-rooms.

Section 4

Electrical Installations

4.1 General

4.1.1 Electrical installations are to comply with the relevant requirements of Pt.4, Ch.8, as applicable.

4.2 Supply and Distribution Systems

4.2.1 The following systems of generation and distribution of electrical energy are acceptable:

i) DC Supply:
   a) two-wire insulated

ii) AC Supply:
   a) single-phase,two-wire insulated
   b) three-phase, three-wire insulated.

4.2.2 Earthed systems with hull return are not permitted, with the following exceptions subject to acceptance by IRS. :

i) impressed current cathodic protective systems;

ii) limited and locally earthed systems, such as starting and ignition systems of internal combustion engines, provided that any possible resulting current does not flow directly through any hazardous area;

iii) insulation level monitoring devices, provided that the circulation current of the devices does not exceed 30 [mA] under the most unfavourable conditions.

4.2.3 Earthed systems without hull return are not permitted, except for the following:

i) earthed intrinsically safe circuits and the following other systems subject to acceptance by IRS ;

ii) power supplies, control circuits and instrumentation circuits in non-hazardous areas where technical or safety reasons preclude the use of a system with no connection to earth, provided the current in the hull is limited to not more than 5 A in both normal and fault conditions; or

iii) earthed systems, provided that any possible resulting hull current does not flow directly through any hazardous area; or

iv) isolating transformers or other adequate means, to be provided if the distribution system is extended to areas remote from the machinery space.

4.2.4 No current carrying part is to be earthed in insulated distribution systems, other than the following:

i) through an insulation level monitoring device;
ii) through components used for the suppression of interference in radio circuits.

4.2.5 The devices intended to continuously monitor the insulation level of all distribution systems are also to monitor all circuits, other than intrinsically safe circuits, connected to apparatus in hazardous areas or passing through such areas.

4.2.6 An audible and visual alarm is to be given, at a manned position, in the event of an abnormally low level of insulation.

4.3 Hazardous Zones and Spaces

4.3.1 In order to facilitate the selection of appropriate electrical installations, hazardous areas are classified into zones. The following zones or spaces are regarded as hazardous during and on completion of oil recovery operations, until proven gas-safe:(Refer to 4.3.3 for hazardous zones in vessels with class notation **FP 60C**)

4.3.1.1 Hazardous Areas Zone 0:

i) Interiors of tanks intended for the storage of recovered oil;

ii) Interiors of piping systems intended for the handling of recovered oil including venting arrangement;

iii) Equipment containing recovered oil;

iv) Cofferdams and voids adjacent to recovered oil tanks, containing recovered oil pipe flanges, valves or other sources of release.

4.3.1.2 Hazardous Areas Zone 1:

i) Zones on open deck or semi-enclosed spaces on open deck within 3 [m] of any oil recovery tank outlet, oil recovery manifold valve, oil recovery valve, oil recovery pipe flange and oil recovery hatches;

ii) Oil Recovery Pump Rooms;

iii) Spaces in which oil contaminated equipment for handling the recovered oil is located and oil handling areas;

iv) Enclosed or semi enclosed spaces in which recovered oil pipe flanges, valves or other sources of release are located;

v) Areas on the open deck within a 3 [m] radius of any entrance or ventilation opening to any hazardous area zone 1 space;

vi) Areas on the open deck within a 3 [m] radius of any oil recovery equipment. Equipment includes but is not limited to skimmers, containment booms and reels, and separators;

vii) Areas on open deck within spillage coaming surrounding oil recovery manifold valves and 3 [m] beyond the coaming up to a height of 2.4 [m] above the deck.

4.3.1.3 Hazardous areas zone 2:

i) Enclosed spaces immediately adjacent to recovered oil tanks in any direction, not containing recovered oil pipe flanges, valves, or other sources of release;

ii) Enclosed or semi-enclosed spaces having a direct access or opening to any hazardous area;

iii) Air lock spaces between Zone 1 and non-hazardous space;

iv) Areas on the open deck within 1.5 [m] radius of any entrance or ventilation opening to any hazardous area zone 2 space excluding tanks adjacent to recovered oil tanks not containing recovered oil pipe flanges, valves, or other sources of release.

4.3.2 Hazardous areas are not to contain the following:

i) Internal combustion engines;
ii) Steam turbines and steam piping with a steam temperature in excess of 200 [C];
iii) Other piping system and heat exchangers with surface temperature exceeding 200 [C];
iv) Any other source of ignition.

4.3.3 Hazardous Zones for vessels with class notation **FP 60C**

i) Hazardous Area Zone 2:

a) Interiors of tanks intended for the storage of recovered oil;

b) Interiors of piping systems intended for the handling of recovered oil including venting arrangement;

c) Equipment containing recovered oil;

d) Cofferdams and voids adjacent to recovered oil tanks, containing recovered oil pipe flanges, valves or other sources of release.

4.4 Selection of electrical equipment for installation in hazardous areas

4.4.1 The types of electrical equipment permitted, depending on zones where they are installed are indicated in Pt 4, Ch 8, Sec. 11.

Section 5

Fire Detection, Protection and Fighting

5.1 Vapor Detector

5.1.1 At least one type approved portable gas detection instrument capable of measuring flammable vapour concentrations in air and an equipment for oil flashpoint measurements are to be provided on board.

5.1.2 Alternatively, instead of a portable gas detection instrument, a fixed system may be accepted provided that the sample is drawn from a point within 6 [m] from the waterline.

5.2 Structural Fire protection

5.2.1 Structural Fire Protection requirements as provided in Part 6 are to be complied with, as applicable. In addition, the following special requirements are to be complied with (not applicable for vessels with class notation **FP 60C**) :

5.2.1.1 Unless they are located at least 7 [m] from the nearest oil recovery area, exterior boundaries of the superstructures and deckhouses enclosing accommodation and including any overhanging decks which support such accommodation are to be insulated to A-60 standard for the whole of the portions which face the oil recovery areas up to the underside of the navigation bridge deck and for a distance of 3 [m] aft or forward of such areas.

5.2.1.2 As an alternative to A-60 insulation, a fixed water-spraying system capable of delivering water at a rate of 10 [litre/m^2/min] may be accepted. This system is to comply with the requirements listed in Pt. 5, Ch. 25, Cl. 2.7, except that the only protected area is to be the exterior boundaries of the superstructures and deckhouses enclosing accommodations and including any overhanging decks which support such accommodations facing the oil recovery area. The sea suctions are to be at safe locations sufficiently below the waterline to prevent floating oil from entering the system.

5.2.1.3 Windows and side scuttles fitted within 7 [m] from the nearest oil recovery area are to have the same fire integrity as the bulkhead on which they are fitted. If they have a lower fire rating because they are protected by the fixed water-spraying system mentioned in 5.2.1.2, the windows and side scuttles are to be fitted with inside covers of steel or other equivalent material having a thickness equal to the bulkhead on which they are fitted. Where they are not of the fixed type, they are to be such as to ensure an efficient gastight closure.

5.3 Fire-fighting

5.3.1 Firefighting arrangements are to be provided in accordance with the requirements of Part 6, as applicable. In addition, the following requirements are to be complied with:

.1 For the protection of the oil recovery area, the following fire-fighting equipment is to be provided near the working area:

a) two dry powder fire extinguishers, each with a capacity of at least 50 [kg] or equivalent
b) at least one portable foam extinguishing applicator complying with Pt. 6, Ch. 8, Cl. 4.2.2.

Introduction

IR1.0 General

IR1.1 These Rules have been prepared to ensure that ships using natural gas or other low flash point fuel as fuel built with a view to classification with IRS, will also comply with the requirements of IMO International Code of Safety for Ships Using Gases or Other Low-Flashpoint Fuels (IGF Code).

IR1.2 Responsibility for interpretation of the IGF Code requirements for the purpose of issuing Safety Construction Certificate lies with the statutory authority of the country where the ship is to be registered.

IR1.3 The IGF code contains requirements for operational matters which are not within the scope of classification requirements and IRS does not require these to be investigated for the purpose of classification. However, these matters will be considered for issuing the Safety Construction Certificate on behalf of the Administration

IR1.4 Where for the purpose of issuing a Safety Construction Certificate, an Administration has specifically accepted an equivalent under the terms of the IGF code or has adopted an interpretation different from that agreed to by IRS, individual consideration will be given to the acceptance of the equivalent or interpretation concerned for the purpose of classification.

IR 1.5 This chapter addresses the requirements of the IGF code relevant to the Classification of ships. IGF Code Parts C-1 and D related to Drills and Emergency exercises, Operation and Training matters are not covered in the Rules.

While Sections 1 to 4 of this chapter covers the general requirements for gas and other low flash point fuels, specific requirements for natural gas fuelled ships are given in Section 5 to 16 and Annex-1. Requirements for other low flash point fuelled ships are presently addressed through alternative design principle.

IR2.0 Application

IR 2.1 The chapter is applicable to ships to which Reg. SOLAS II-1/56 (as adopted by MSC.392(95)) is applicable.

IR 2.2 This chapter is not applicable to any gas carriers using their cargoes as fuel and complying with the requirements of IGC Code (Pt 5 Ch 4).

IR3.0 Classification and class notations

IR3.1 The general requirements for classification and the assignment of class notations are given in Pt.1 of the Rules, to which reference is to be made.

IR3.2 In general, an additional class notation "**LFPF**" would be assigned, where the vessel is designed and constructed primarily for using low-flash point fuel.

IR3.3 Following additional qualifier will be added to the above mentioned class notation:

(NG) – Ship using natural gas as fuel, complying with the requirements of this Chapter.

(EG) - Ship using Ethane gas as fuel, complying with the alternative design requirements in 2.3 of this Chapter.

(LPG) - Ship using Liquid Petroleum gas as fuel complying with the requirements of IRS Guidelines on "*LPG Fuelled Vessels*" or complying with the alternative design requirements in 2.3 of this Chapter.

(ML) - Ship using Methanol as fuel, complying with the requirements of IRS Guidelines on "*Methanol Fueled Vessels"* or complying with the alternative design requirements in 2.3 of this Chapter.

(EL) – Ships using Ethanol as fuel and complying with the relevant and applicable requirements for Ethanol in the IRS Guidelines on "*Methanol Fueled Vessels*" or complying with the alternative design requirements in 2.3 of this Chapter.

(AM) - Ships using Ammonia as fuel, complying with the requirements of IRS Guidelines on "*Ammonia Fueled Vessels*" or complying with the alternative design requirements in 2.3 of this Chapter.

(SFE) – Ships with single fuel engines using natural gas or other low flash point fuel.

(DFE) – Ship using dual fuel engines

Example:

1) Following additional notation will be assigned to ship with single fuel engine, using natural gas as fuel complying with the requirements of this chapter:

LFPF (NG) (SFE)

2) Following additional notation will be assigned to ship with dual fuel engine, using natural gas as fuel complying with the requirements of this chapter:

LFPF (NG) (DFE)

Section 1

Preamble (to the IGF Code)

1.1 The purpose of IGF Code is to provide an international standard for ships using low-flashpoint fuel, other than ships covered by the IGC Code.

1.2 The basic philosophy of IGF Code is to provide mandatory provisions for the arrangement, installation, control and monitoring of machinery, equipment and systems using low-flashpoint fuel to minimize the risk to the ship, its crew and the environment, having regard to the nature of the fuels involved.

1.3 Throughout the development of IGF Code it was recognized that it must be based upon sound naval architectural and engineering principles and the best understanding available of current operational experience, field data and research and development. Due to the rapidly evolving new fuels technology, IMO will periodically review IGF Code, taking into account both experience and technical developments.

1.4 IGF Code addresses all areas that need special consideration for the usage of the low-flashpoint fuel. The basic philosophy of the IGF Code considers the goal based approach (MSC.1/Circ.1394). Therefore, goals and functional requirements were specified for each section forming the basis for the design, construction and operation.

1.5 The current version of IGF Code includes regulations to meet the functional requirements for natural gas fuel. Regulations for other low-flashpoint fuels will be added to IGF Code as, and when, they are developed by the Organization.

1.6 In the meantime, for other low-flashpoint fuels, compliance with the functional requirements of IGF Code must be demonstrated through alternative design.

Section 2

General

2.1 Application

2.1.1 Unless expressly provided otherwise this Chapter applies to ships to which part G of SOLAS chapter II-1 applies.

2.1.2 *Fuel* in the context of the requirements in this chapter means natural gas, either in its liquefied or gaseous state. It should be recognized that the composition of natural gas may vary depending on the source of natural gas and the processing of the gas.

2.2 Definitions

2.2.1 Unless otherwise stated below, definitions are as defined in SOLAS chapter II-2.

2.2.1.1 *Accident* means an uncontrolled event that may entail the loss of human life, personal injuries, environmental damage or the loss of assets and financial interests.

2.2.1.2 *Breadth (B)* means the greatest moulded breadth of the ship at or below the deepest draught (summer load line draught) (refer to SOLAS regulation II-1/2.8).

2.2.1.3 *Bunkering* means the transfer of liquid or gaseous fuel from land based or floating facilities into a ship's permanent tanks or connection of portable tanks to the fuel supply system.

2.2.1.4 *Certified safe type* means electrical equipment that is certified safe by the relevant authorities recognized by the IRS/Administration for operation in a flammable atmosphere based on a recognized standard.*

Note:

**Refer to IEC 60079 series, Explosive atmospheres and IEC 60092-502:1999 Electrical Installations in Ships – Tankers – Special Features.*

2.2.1.5 *CNG* means compressed natural gas (see also 2.2.1.26).

2.2.1.6 *Control station* means those spaces defined in SOLAS chapter II-2 and additionally for this Chapter, the engine control room.

2.2.1.7 *Design temperature* for selection of materials is the minimum temperature at which liquefied gas fuel may be loaded or transported in the liquefied gas fuel tanks.

2.2.1.8 *Design vapour pressure "P_0"* is the maximum gauge pressure, at the top of the tank, to be used in the design of the tank.

2.2.1.9 *Double block and bleed valve* means a set of two valves in series in a pipe and a third valve enabling the pressure release from the pipe between those two valves. The arrangement may also consist of a two-way valve and a closing valve instead of three separate valves.

2.2.1.10 *Dual fuel engines* means engines that employ fuel covered by this Chapter (with pilot fuel) and oil fuel. Oil fuels may include distillate and residual fuels.

2.2.1.11 *Enclosed space* means any space within which, in the absence of artificial ventilation, the ventilation will be limited and any explosive atmosphere will not be dispersed naturally.*

Note:

**See also definition in IEC 60092-502:1999.*

2.2.1.12 *ESD* means emergency shutdown.

2.2.1.13 *Explosion* means a deflagration event of uncontrolled combustion.

2.2.1.14 *Explosion pressure relief* means measures provided to prevent the explosion pressure in a container or an enclosed space exceeding the maximum overpressure the container or space is designed for, by releasing the overpressure through designated openings.

2.2.1.15 *Fuel containment system* is the arrangement for the storage of fuel including tank connections. It includes where fitted, a primary and secondary barrier, associated insulation and any intervening spaces, and adjacent structure if necessary for the support of these elements. If the secondary barrier is part of the hull structure it may be a boundary of the fuel storage hold space. The spaces around the fuel tank are defined as follows:

.1 *Fuel storage hold space* is the space enclosed by the ship's structure in which a fuel containment system is situated. If tank connections are located in the fuel storage hold space, it will also be a tank connection space;

.*2 Interbarrier space* is the space between a primary and a secondary barrier, whether or not completely or partially occupied by insulation or other material; and

.*3 Tank connection space* is a space surrounding all tank connections and tank valves that is required for tanks with such connections in enclosed spaces.

IR.3.1 A tank connection space may be required also for tanks on open deck. This may apply for ships where restriction of hazardous areas is safety critical. A tank connection space may also be necessary in order to provide environmental protection for essential

safety equipment related to the gas fuel system like tank valves, safety valves and instrumentation.

IR .3.2 A tank connection space may also contain equipment such as vaporizers or heat exchangers. Such equipment is considered to only contain potential sources of release, but not sources of ignition.

2.2.1.16 *Filling limit (FL)* means the maximum liquid volume in a fuel tank relative to the total tank volume when the liquid fuel has reached the reference temperature.

2.2.1.17 *Fuel preparation room* means any space containing pumps, compressors and/or vaporizers for fuel preparation purposes.

IR 2.2.1.17 A tank connection space which has equipment such as vaporizers or heat exchangers installed inside is not regarded as a fuel preparation room.

2.2.1.18 *Gas* means a fluid having a vapour pressure exceeding 0.28 [MPa] absolute at a temperature of 37.8 [°C].

2.2.1.19 *Gas consumer* means any unit within the ship using gas as a fuel.

2.2.1.20 *Gas only engine* means an engine capable of operating only on gas, and not able to switch over to operation on any other type of fuel.

2.2.1.21 *Hazardous area* means an area in which an explosive gas atmosphere is or may be expected to be present, in quantities such as to require special precautions for the construction, installation and use of equipment.

2.2.1.22 *High pressure* means a maximum working pressure greater than 1.0 [MPa].

2.2.1.23 *Independent tanks* are self-supporting, do not form part of the ship's hull and are not essential to the hull strength.

2.2.1.24 *LEL* means the lower explosive limit.

2.2.1.25 *Length (L)* is the length as defined in the International Convention on Load Lines in force.

2.2.1.26 *LNG* means liquefied natural gas.

2.2.1.27 *Loading limit (LL)* means the maximum allowable liquid volume relative to the tank volume to which the tank may be loaded.

2.2.1.28 *Low-flashpoint fuel* means gaseous or liquid fuel having a flashpoint lower than otherwise permitted under paragraph 2.1.1 of SOLAS regulation II-2/4.

2.2.1.29 *MARVS* means the maximum allowable relief valve setting.

2.2.1.30 *MAWP* means the maximum allowable working pressure of a system component or tank.

2.2.1.31 *Membrane tanks* are non-self-supporting tanks that consist of a thin liquid and gas tight layer (membrane) supported through insulation by the adjacent hull structure.

2.2.1.32 *Multi-fuel engines* means engines that can use two or more different fuels that are separate from each other.

2.2.1.33 *Non-hazardous area* means an area in which an explosive gas atmosphere is not expected to be present in quantities such as to require special precautions for the construction, installation and use of equipment.

2.2.1.34 *Open deck* means a deck having no significant fire risk that at least is open on both ends/sides, or is open on one end and is provided with adequate natural ventilation that is effective over the entire length of the deck through permanent openings distributed in the side plating or deckhead.

2.2.1.35 *Risk i*s an expression for the combination of the likelihood and the severity of the consequences.

2.2.1.36 *Reference temperature* means the temperature corresponding to the vapour pressure of the fuel in a fuel tank at the set pressure of the pressure relief valves (PRVs).

2.2.1.37 *Secondary barrier* is the liquid-resisting outer element of a fuel containment system designed to afford temporary containment of any envisaged leakage of liquid fuel through the primary barrier and to prevent the lowering of the temperature of the ship's structure to an unsafe level.

2.2.1.38 *Semi-enclosed space* means a space where the natural conditions of ventilation are notably different from those on open deck due to the presence of structure such as roofs, windbreaks and bulkheads and which are so arranged that dispersion of gas may not occur.*

Note:

**Refer also to IEC 60092-502:1999 Electrical Installations in Ships – Tankers – Special Features.*

2.2.1.39 *Source of release* means a point or location from which a gas, vapour, mist or liquid may be released into the atmosphere so that an explosive atmosphere could be formed.

2.2.1.40 *Unacceptable loss of power* means that it is not possible to sustain or restore normal operation of the propulsion machinery in the event of one of the essential auxiliaries becoming inoperative, in accordance with SOLAS regulation II-1/26.3.

2.2.1.41 *Vapour pressure* is the equilibrium pressure of the saturated vapour above the liquid, expressed in [MPa] absolute at a specified temperature.

2.3 Alternative design

2.3.1 IGF Code contains functional requirements for all appliances and arrangements related to the usage of low-flashpoint fuels.

2.3.2 Fuels, appliances and arrangements of low-flashpoint fuel systems may either:

.1 deviate from those set out in this IGF Code, or

.2 be designed for use of a fuel not specifically addressed in IGF Code.

Such fuels, appliances and arrangements can be used provided that these meet the intent of the goal and functional requirements concerned and provide an equivalent level of safety of the relevant chapters.

2.3.3 The equivalence of the alternative design is to be demonstrated as specified in SOLAS regulation II-1/55 and approved by the Administration. However, the Administration would not allow operational methods or procedures to be applied as an alternative to a particular fitting, material, appliance, apparatus, item of equipment, or type thereof which is prescribed by IGF Code.

IR 2.4 Documentation Requirements

IR 2.4.1 For a ship with natural gas-fuelled engine installations, plans and documents are to be submitted for approval as listed in the following:

IR 2.4.1.1 Arrangement plan of the ship indicating the following:

a) machinery and boiler spaces, accommodation spaces, service spaces and control stations.

b) fuel containment systems

c) fuel preparation rooms

d) ventilating pipes, door and openings to fuel preparation rooms and other hazardous areas

e) entrances, air inlets and openings to accommodation spaces, service spaces and control stations.

f) Air lock arrangements

IR 2.4.1.2 Plans and documents of the gas fuel tanks covering the following details:

a) tank structure

b) supports and stays

c) secondary barriers

d) Insulations

e) marking plates

f) tank connection space arrangement

g) tank hatches, pipes and any openings to the gas tanks

h) safety relief valves and associated vent piping

i) gas freeing and purging system, Including vent lines for safety relief valves or similar piping and ducts for gas pipes.

j) capacity analysis of safety relief valves and associated piping, including back pressure.

k) fabrication details of tanks including Building tolerances, NDT Plan and Welding procedures (WPS)

l) Cooling down procedure of tanks

m)Specification of safety relief valves and associated vent piping.

IR 2.4.1.3 Documentation for Control and Monitoring system of the gas fuel including safety system.

IR2.4.1.4 Testing procedure for safety shut downs.

IR2.4.1.5 Plans and documentation showing arrangement and details of piping systems covering the following:

a) Vent mast, including location and details of outlets from the fuel tanks safety relief valves.

b) Fuel gas drip trays

c) vent lines for safety relief valves or similar piping and ducts for gas pipes.

d) fuel gas cooling system

e) fuel gas heating system

f) exhaust gas system, including arrangement of explosion relief

g) ventilation systems for gas fuel system spaces, including capacity and location of fans and their motors. Detailed drawing of rotating parts and casing for fans and portable ventilators for gas fuel system spaces.

h) Functional testing procedure of all piping systems including valves, fittings and associated equipment for handling fuel.

i) Control and monitoring system documentation for ventilation systems.

IR2.4.1.6 Hazardous area Classification plan

IR2.4.1.7 Electrical schematic drawing, including single line diagrams for all intrinsically safe circuits including explosion protection details of components.

IR2.4.1.8 Plans and Documentation for Fire safety as listed in the following:

a) Hydrocarbon gas detection and alarm system

b) Fire detection and alarm system

c) Fire extinguishing equipment

d) Structural fire protection plan

e) Control and monitoring system documentation for:

- Hydrocarbon gas detection and alarm system
- Fire detection and alarm system

f) Fixed fire extinguishing system documentation, containing details on:

- External surface protection water spraying system
- Bunkering station fire extinguishing system

Section 3

Goal and Functional Requirements

3.1 Goal

3.1.1 The goal of this Chapter is to provide for safe and environmentally-friendly design, construction and operation of ships and in particular their installations of systems for propulsion machinery, auxiliary power generation machinery and/or other purpose machinery using gas or low-flashpoint fuel as fuel.

3.2 Functional requirements

3.2.1 The safety, reliability and dependability of the systems are to be equivalent to that achieved with new and comparable conventional oil-fuelled main and auxiliary machinery.

3.2.2 The probability and consequences of fuel-related hazards is to be limited to a minimum through arrangement and system design, such as ventilation, detection and safety actions. In the event of gas leakage or failure of the risk reducing measures, necessary safety actions is to be initiated.

3.2.3 The design philosophy is to ensure that risk reducing measures and safety actions for the gas fuel installation do not lead to an unacceptable loss of power.

3.2.4 Hazardous areas are to be restricted, as far as practicable, to minimize the potential risks that might affect the safety of the ship, persons on board, and equipment.

3.2.5 Equipment installed in hazardous areas is to be minimized to that required for operational purposes and is to be suitably and appropriately certified.

3.2.6 Unintended accumulation of explosive, flammable or toxic gas concentrations is to be prevented.

3.2.7 System components are to be protected against external damages.

3.2.8 Sources of ignition in hazardous areas are to be minimized to reduce the probability of explosions.

3.2.9 It is to be arranged for safe and suitable fuel supply, storage and bunkering arrangements capable of receiving and containing the fuel in the required state without leakage. Other than when necessary for safety reasons, the system is to be designed to prevent venting under all normal operating conditions including idle periods.

3.2.10 Piping systems, containment and over-pressure relief arrangements that are of suitable design, construction and installation for their intended application are to be provided.

3.2.11 Machinery, systems and components are to be designed, constructed, installed, operated, maintained and protected to ensure safe and reliable operation.

3.2.12 Fuel containment system and machinery spaces containing source that might release gas into the space is to be arranged and located such that a fire or explosion in either will not lead to an unacceptable loss of power or render equipment in other compartments inoperable.

3.2.13 Suitable control, alarm, monitoring and shutdown systems are to be provided to ensure safe and reliable operation.

3.2.14 Fixed gas detection suitable for all spaces and areas concerned are to be arranged.

3.2.15 Fire detection, protection and extinction measures appropriate to the hazards concerned are to be provided.

3.2.16 Commissioning, trials and maintenance of fuel systems and gas utilization machinery shall satisfy the goal in terms of safety, availability and reliability.

3.2.17 The technical documentation is to permit an assessment of the compliance of the system and its components with the applicable rules, guidelines, design standards used and the principles related to safety, availability, maintainability and reliability.

3.2.18 A single failure in a technical system or component is not to lead to an unsafe or unreliable situation.

Section 4

General Requirements

4.1 Goal

4.1.1 The goal of this section is to ensure that the necessary assessments of the risks involved are carried out in order to eliminate or mitigate any adverse effect to the persons on board, the environment or the ship.

4.2 Risk assessment

4.2.1 A risk assessment is to be conducted to ensure that risks arising from the use of low-flashpoint fuels affecting persons on board, the environment, the structural strength or the integrity of the ship are addressed. Consideration is to be given to the hazards associated with physical layout, operation and maintenance, following any reasonably foreseeable failure.

4.2.2 For ships using natural gas as fuel, the risk assessment required by 4.2.1 need only be conducted where explicitly required by paragraphs 5.10.5, 5.12.3, 6.4.1.1, 6.4.15.4.7.2, 8.3.1.1, 13.4.1, 13.7 and 15.8.1.10 as well as by paragraphs 4.4 and 6.8 of the Annex-1.

4.2.3 The risks is to be analysed using acceptable and recognized risk analysis techniques, and loss of function, component damage, fire, explosion and electric shock shall as a minimum be considered. The analysis shall ensure that risks are eliminated wherever possible. Risks which cannot be eliminated are to be mitigated as necessary. Details of risks, and the means by which they are mitigated, is to be documented to the satisfaction of the IRS/Administration.

4.3 Limitation of explosion consequences

4.3.1 An explosion in any space containing any potential sources of release* and potential ignition sources shall not :

.1 cause damage to or disrupt the proper functioning of equipment/systems located in any space other than that in which the incident occurs;

.2 damage the ship in such a way that flooding of water below the main deck or any progressive flooding occur;

.3 damage work areas or accommodation in such a way that persons who stay in such areas under normal operating conditions are injured;

.4 disrupt the proper functioning of control stations and switchboard rooms necessary for power distribution;

.5 damage life-saving equipment or associated launching arrangements;

.6 disrupt the proper functioning of firefighting equipment located outside the explosion-damaged space;

.7 affect other areas of the ship in such a way that chain reactions involving, inter alia, cargo, gas and bunker oil may arise; or

.8 prevent persons access to life-saving appliances or impede escape routes.

Note:

**Double wall fuel pipes are not considered as potential sources of release.*

Section 5

Ship Design and Arrangement

5.1 Goal

5.1.1 The goal of this section is to provide for safe location, space arrangements and mechanical protection of power generation equipment, fuel storage systems, fuel supply equipment and refuelling systems.

5.2 Functional requirements

5.2.1 This section is related to functional requirements in 3.2.1 to 3.2.3, 3.2.5, 3.2.6, 3.2.8, 3.2.12 to 3.2.15 and 3.2.17. In particular the following apply:

.1 the fuel tank(s) is to be located in such a way that the probability for the tank(s) to be damaged following a collision or grounding is reduced to a minimum taking into account the safe operation of the ship and other hazards that may be relevant to the ship;

.2 fuel containment systems, fuel piping and other fuel sources of release is to be so located and arranged that released gas is led to a safe location in the open air;

.3 the access or other openings to spaces containing fuel sources of release is to be so arranged that flammable, asphyxiating or toxic gas cannot escape to spaces that are not designed for the presence of such gases

.4 fuel piping is to be protected against mechanical damage;
.5 the propulsion and fuel supply system is to be so designed that safety actions after any gas leakage do not lead to an unacceptable loss of power; and

.6 the probability of a gas explosion in a machinery space with gas or low-flashpoint fuelled machinery is to be minimized.

5.3 General

5.3.1 Fuel storage tanks are to be protected against mechanical damage.

5.3.2 Fuel storage tanks and/or equipment located on open deck are to be located to ensure sufficient natural ventilation, so as to prevent accumulation of escaped gas.

5.3.3 The fuel tank(s) is to be protected from external damage caused by collision or grounding in the following way:

.1 The fuel tanks are to be located at a minimum distance of B/5 or 11.5 [m], whichever is less, measured inboard from the ship side at right angles to the centreline at the level of the summer load line draught;

where:

B is the greatest moulded breadth of the ship at or below the deepest draught (summer load line draught) (refer to SOLAS regulation II-1/2.8).

.2 The boundaries of each fuel tank are to be taken as the extreme outer longitudinal, transverse and vertical limits of the tank structure including its tank valves.

.3 For independent tanks the protective distance is to be measured to the tank shell (the primary barrier of the tank containment system). For membrane tanks the distance is to be measured to the bulkheads surrounding the tank insulation.

.4 In no case shall the boundary of the fuel tank be located closer to the shell plating or aft terminal of the ship than as follows:

.1 For passenger ships: B/10 but in no case less than 0.8 [m]. However, this distance

need not be greater than B/15 or 2 [m] whichever is less where the shell plating is located inboard of B/5 or 11.5 [m], whichever is less, as required by 5.3.3.1.

.2 For cargo ships:

.1 for V_c below or equal 1000 [m^3], 0.8 [m];

.2 for 1000 [m^3]< V_c < 5000 [m^3], 0.75 + V_c x 0.2/4000 [m];

.3 for 5000 [m^3] ≤ V_c < 30000 [m^3], 0.8 + V_c/25000 [m]; and

.4 for V_c ≥ 30000 [m^3], 2 [m],

where:

V_c corresponds to 100% of the gross design volume of the individual fuel tank at 20 [°C], including domes and appendages.

.5 The lowermost boundary of the fuel tank(s) is to be located above the minimum distance of B/15 or 2.0 [m, whichever is less, measured from the moulded line of the bottom shell plating at the centreline.

.6 For multihull ships the value of B may be specially considered.

.7 The fuel tank(s) is to be abaft a transverse plane at 0.08L measured from the forward perpendicular in accordance with SOLAS regulation II-1/8.1 for passenger ships, and abaft the collision bulkhead for cargo ships.

where:

L is the length as defined in the International Convention on Load Lines (refer to SOLAS regulation II-1/2.5).

.8 For ships with a hull structure providing higher collision and/or grounding resistance, fuel tank location requirements may be specially considered in accordance with section 2.3.

5.3.4 As an alternative to 5.3.3 above, the following calculation method may be used to determine the acceptable location of the fuel tanks:

.1 The value f_{CN} calculated as described in the following is to be less than 0.02 for passenger ships and 0.04 for cargo ships.*

Note :

**The value f_{CN} accounts for collision damages that may occur within a zone limited by the longitudinal projected boundaries of the fuel tank only, and cannot be considered or used as the probability for the fuel tank to become damaged given a collision. The real probability will be higher when accounting for longer damages that include zones forward and aft of the fuel tank.*

.2 The f_{CN} is calculated by the following formulation:

$$f_{CN} = f_l \times f_t \times f_v$$

where:

f_l is calculated by use of the formulations for factor p contained in SOLAS regulation II-1/7-1.1.1.1. The value of x1 shall correspond to the distance from the aft terminal to the aftmost boundary of the fuel tank and the value of x2 shall correspond to the distance from the aft terminal to the foremost boundary of the fuel tank.

f_t is calculated by use of the formulations for factor r contained in SOLAS regulation II-1/7-1.1.2, and reflects the probability that the damage penetrates beyond the outer boundary of the fuel tank. The formulation is:

$$f_t = 1 - r(x1, x2, b) *$$

Note:

** When the outermost boundary of the fuel tank is outside the boundary given by the deepest subdivision waterline the value of b should be taken as 0.*

f_v is calculated by use of the formulations for factor v contained in SOLAS regulation II-1/7-2.6.1.1 and reflects the probability that the damage is extending vertically above the lowermost boundary of the fuel tank. The formulations to be used are:

f_v=1.0−0.8 (($H-d$)/7.8),
if ($H-d$) is less than or equal to 7.8 [m]. f_v is not to be taken greater than 1.

f_v=0.2−(0.2 (($H-d$)−7.8)/4.7),
in all other cases f_v is not to be taken less than 0.

where:

H is the distance from baseline, in metres, to the lowermost boundary of the fuel tank; and

d is the deepest draught (summer load line draught).

.3 The boundaries of each fuel tank are to be taken as the extreme outer longitudinal, transverse and vertical limits of the tank structure including its tank valves.

.4 For independent tanks the protective distance is to be measured to the tank shell (the primary barrier of the tank containment system). For membrane tanks the distance is to be measured to the bulkheads surrounding the tank insulation.

.5 In no case shall the boundary of the fuel tank be located closer to the shell plating or aft terminal of the ship than as follows:

.1 For passenger ships: B/10 but in no case less than 0.8 [m]. However, this distance need not be greater than B/15 or 2 [m] whichever is less where the shell plating is located inboard of B/5 or 11.5 [m], whichever is less, as required by 5.3.3.1.

.2 For cargo ships:

.1 for V_c below or equal 1000 [m^3], 0.8 [m];

.2 for 1000 [m^3] < V_c < 5000 [m^3], 0.75+ V_c x 0.2/4000 [m];

.3 for 5000 [m^3] ≤ V_c < 30000 [m^3], 0.8 + V_c/25000 [m]; and

.4 for V_c ≥ 30000 [m^3], 2 [m],

where:

V_c corresponds to 100% of the gross design volume of the individual fuel tank at 20 [°C], including domes and appendages.

.6 In case of more than one non-overlapping fuel tank located in the longitudinal direction, f_{CN} is to be calculated in accordance with paragraph 5.3.4.2 for each fuel tank separately. The value used for the complete fuel tank arrangement is the sum of all values for f_{CN} obtained for each separate tank.

.7 In case the fuel tank arrangement is unsymmetrical about the centreline of the ship, the calculations of f_{CN} is to be calculated on both starboard and port side and the average value is to be used for the assessment. The minimum distance as set forth in paragraph 5.3.4.5 is to be met on both sides.

.8 For ships with a hull structure providing higher collision and/or grounding resistance, fuel tank location requirements may be specially considered in accordance with section 2.3.

5.3.5 When fuel is carried in a fuel containment system requiring a complete or partial secondary barrier:

.1 fuel storage hold spaces is to be segregated from the sea by a double bottom; and

.2 the ship is to also have a longitudinal bulkhead forming side tanks.

5.4 Machinery space concepts

5.4.1 In order to minimize the probability of a gas explosion in a machinery space with gas-fuelled machinery one of these two alternative concepts may be applied:

.1 Gas safe machinery spaces:

Arrangements in machinery spaces are such that the spaces are considered gas safe under all conditions, normal as well as abnormal conditions, i.e. inherently gas safe.

In a gas safe machinery space a single failure cannot lead to release of fuel gas into the machinery space.

.2 ESD-protected machinery spaces:

Arrangements in machinery spaces are such that the spaces are considered non-hazardous under normal conditions, but under certain abnormal conditions may have the potential to become hazardous. In the event of abnormal conditions involving gas hazards, emergency shutdown (ESD) of non-safe equipment (ignition sources) and machinery is to be automatically executed while equipment or machinery in use or active during these conditions is to be of a certified safe type.

In an ESD protected machinery space a single failure may result in a gas release into the space. Venting is designed to accommodate a probable maximum leakage scenario due to technical failures.

Failures leading to dangerous gas concentrations, e.g. gas pipe ruptures or blow out of gaskets are covered by explosion pressure relief devices and ESD arrangements.

IR 5.4.1 Premixed engines using fuel gas mixed with air before the turbocharger should be located in ESD protected machinery spaces.

5.5 Gas safe machinery space

5.5.1 A single failure within the fuel system is not to lead to a gas release into the machinery space.

5.5.2 All fuel piping within machinery space boundaries is to be enclosed in a gas tight enclosure in accordance with 9.6.

5.6 ESD-protected machinery spaces

5.6.1 ESD protection is to be limited to machinery spaces that are certified for periodically unattended operation.

5.6.2 Measures are to be applied to protect against explosion, damage of areas outside of the machinery space and ensure redundancy of power supply. The following arrangement is to be provided but may not be limited to:

.1 gas detector;

.2 shutoff valve;

.3 redundancy; and

.4 efficient ventilation.

5.6.3 Gas supply piping within machinery spaces may be accepted without a gastight external enclosure on the following conditions:

.1 Engines for generating propulsion power and electric power are to be located in two or more machinery spaces not having any common boundaries unless it can be documented that a single casualty will not affect both spaces.

.2 The gas machinery space is to contain only a minimum of such necessary equipment, components and systems as are required to ensure that the gas machinery maintains its function.

.3 A fixed gas detection system arranged to automatically shutdown the gas supply, and disconnect all electrical equipment or installations not of a certified safe type, is to be fitted.

5.6.4 Distribution of engines between the different machinery spaces is to be such that shutdown of fuel supply to any one machinery space does not lead to an unacceptable loss of power.

5.6.5 ESD protected machinery spaces separated by a single bulkhead shall have sufficient strength to withstand the effects of a local gas explosion in either space, without affecting the integrity of the adjacent space and equipment within that space.

5.6.6 ESD protected machinery spaces is to be designed to provide a geometrical shape that will minimize the accumulation of gases or formation of gas pockets.

5.6.7 The ventilation system of ESD-protected machinery spaces is to be arranged in accordance with 13.5.

5.7 Location and protection of fuel piping

5.7.1 Fuel pipes are not to be located less than 800 [mm] from the ship's side.

5.7.2 Fuel piping is not to be led directly through accommodation spaces, service spaces, electrical equipment rooms or control stations as defined in the SOLAS Convention.

5.7.3 Fuel pipes led through ro-ro spaces, special category spaces and on open decks are to be protected against mechanical damage.

5.7.4 Gas fuel piping in ESD protected machinery spaces is to be located as far as practicable from the electrical installations and tanks containing flammable liquids.

5.7.5 Gas fuel piping in ESD protected machinery spaces is to be protected against mechanical damage.

5.8 Fuel preparation room design

5.8.1 Fuel preparation rooms are to be located on an open deck, unless those rooms are arranged and fitted in accordance with the requirements of this Chapter for tank connection spaces.

IR 5.8.1.1 Fuel preparation rooms, regardless of location, should be arranged to safely contain cryogenic leakages.

IR 5.8.1.2 The material of the boundaries of the fuel preparation room is to have a design temperature corresponding with the lowest temperature it can be subject to in a probable maximum leakage scenario unless the boundaries of the space, i.e. bulkheads and decks, are provided with suitable thermal protection.

IR 5.8.1.3 The fuel preparation room is to be arranged to prevent surrounding hull structure from being exposed to unacceptable cooling, in case of leakage of cryogenic liquids.

IR 5.8.1.4 The fuel preparation room is to be designed to withstand the maximum pressure build up during such a leakage. Alternatively, pressure relief venting to a safe location (mast) can be provided.

5.9 Bilge systems

5.9.1 Bilge systems installed in areas where fuel covered by this Chapter can be present are to be segregated from the bilge system of spaces where fuel cannot be present.

5.9.2 Where fuel is carried in a fuel containment system requiring a secondary barrier, suitable drainage arrangements for dealing with any leakage into the hold or insulation spaces through the adjacent ship structure is to be provided. The bilge system is not to lead to pumps in safe spaces. Means of detecting such leakage is to be provided.

5.9.3 The hold or interbarrier spaces of type A independent tanks for liquid gas is to be provided with a drainage system suitable for handling liquid fuel in the event of fuel tank leakage or rupture.

5.10 Drip trays

5.10.1 Drip trays are to be fitted where leakage may occur which can cause damage to the ship structure or where limitation of the

area which is effected from a spill is necessary.

5.10.2 Drip trays are to be made of suitable material.

5.10.3 The drip tray is to be thermally insulated from the ship's structure so that the surrounding hull or deck structures are not exposed to unacceptable cooling, in case of leakage of liquid fuel.

5.10.4 Each tray is to be fitted with a drain valve to enable rain water to be drained over the ship's side.

5.10.5 Each tray is to have a sufficient capacity to ensure that the maximum amount of spill according to the risk assessment can be handled.

5.11 Arrangement of entrances and other openings in enclosed spaces

5.11.1 Direct access is not to be permitted from a non-hazardous area to a hazardous area. Where such openings are necessary for operational reasons, an airlock which complies with 5.12 is to be provided.

5.11.2 If the fuel preparation room is approved located below deck, the room is to, as far as practicable, have an independent access direct from the open deck. Where a separate access from deck is not practicable, an airlock which complies with 5.12 is to be provided.

5.11.3 Unless access to the tank connection space is independent and direct from open deck it is to be arranged as a bolted hatch. The space containing the bolted hatch will be a hazardous space.

5.11.4 If the access to an ESD-protected machinery space is from another enclosed space in the ship, the entrances are to be arranged with an airlock which complies with 5.12.

5.11.5 For inerted spaces, access arrangements are to be such that unintended entry by personnel is prevented. If access to such spaces is not from an open deck, sealing arrangements shall ensure that leakages of inert gas to adjacent spaces are prevented.

5.12 Airlocks

5.12.1 An airlock is a space enclosed by gastight bulkheads with two substantially gastight doors spaced at least 1.5 [m] and not more than 2.5 [m] apart. Unless subject to the requirements of the International Convention on Load Lines, the door sill is not to be less than 300 [mm] in height. The doors are to be self-closing without any holding back arrangements.

5.12.2 Airlocks are to be mechanically ventilated at an overpressure relative to the adjacent hazardous area or space.

5.12.3 The airlock is to be designed in a way that no gas can be released to safe spaces in case of the most critical event in the gas dangerous space separated by the airlock. The events are to be evaluated in the risk analysis according to 4.2.

5.12.4 Airlocks are to have a simple geometrical form. They are to provide free and easy passage, and are to have a deck area not less than 1.5 [m^2]. Airlocks are not to be used for other purposes, for instance as store rooms.

5.12.5 An audible and visual alarm system to give a warning on both sides of the airlock is to be provided to indicate if more than one door is moved from the closed position.

5.12.6 For non-hazardous spaces with access from hazardous spaces below deck where the access is protected by an airlock, upon loss of underpressure in the hazardous space access to the space is to be restricted until the ventilation has been reinstated. Audible and visual alarms are to be given at a manned location to indicate both loss of pressure and opening of the airlock doors when pressure is lost.

5.12.7 Essential equipment required for safety is not to be de-energized and is to be of a certified safe type. This may include lighting, fire detection, public address, general alarms systems.

Section 6

Fuel Containment System

6.1 Goal

6.1.1 The goal of this section is to provide that gas storage is adequate so as to minimize the risk to personnel, the ship and the environment to a level that is equivalent to a conventional oil fuelled ship.

6.2 Functional requirements

6.2.1 This section relates to functional requirements in 3.2.1, 3.2.2, 3.2.5 and 3.2.8 to 3.2.17. In particular the following apply:

.1 the fuel containment system is to be so designed that a leak from the tank or its connections does not endanger the ship, persons on board or the environment. Potential dangers to be avoided include:

.1 exposure of ship materials to temperatures below acceptable limits; (Also refer to IR 5.8.1.1 to 5.8.1.4)

.2 flammable fuels spreading to locations with ignition sources;

.3 toxicity potential and risk of oxygen deficiency due to fuels and inert gases;

.4 restriction of access to muster stations, escape routes and life-saving appliances (LSA); and

.5 reduction in availability of LSA.

.2 the pressure and temperature in the fuel tank is to be kept within the design limits of the containment system and possible carriage requirements of the fuel;

.3 the fuel containment arrangement is to be so designed that safety actions after any gas leakage do not lead to an unacceptable loss of power; and

.4 if portable tanks are used for fuel storage, the design of the fuel containment system is to be equivalent to permanent installed tanks as described in this section.

6.3 General

6.3.1 Natural gas in a liquid state may be stored with a maximum allowable relief valve setting (MARVS) of up to 1.0 [MPa].

6.3.2 The Maximum Allowable Working Pressure (MAWP) of the gas fuel tank is not to exceed 90% of the Maximum Allowable Relief Valve Setting (MARVS).

6.3.3 A fuel containment system located below deck is to be gas tight towards adjacent spaces.

6.3.4 All tank connections, fittings, flanges and tank valves must be enclosed in gas tight tank connection spaces, unless the tank connections are on open deck. The space is to be able to safely contain leakage from the tank in case of leakage from the tank connections.

6.3.5 Pipe connections to the fuel storage tank is to be mounted above the highest liquid level in the tanks, except for fuel storage tanks of type C. Connections below the highest liquid level may however also be accepted for other tank types after special consideration by the IRS/Administration.

6.3.6 Piping between the tank and the first valve which release liquid in case of pipe failure is to have equivalent safety as the type C tank, with dynamic stress not exceeding the values given in 6.4.15.3.1.2.

6.3.7 The material of the bulkheads of the tank connection space is to have a design temperature corresponding with the lowest temperature it can be subject to in a probable maximum leakage scenario. The tank connection space is to be designed to withstand the maximum pressure build up during such a leakage. Alternatively, pressure relief venting to a safe location (mast) can be provided.

6.3.8 The probable maximum leakage into the tank connection space is to be determined based on detail design, detection and shutdown systems.

6.3.9 If piping is connected below the liquid level of the tank it has to be protected by a secondary barrier up to the first valve.

6.3.10 If liquefied gas fuel storage tanks are located on open deck the ship steel is to be protected from potential leakages from tank connections and other sources of leakage by use of drip trays. The material is to have a design temperature corresponding to the temperature of the fuel carried at atmospheric pressure. The normal operation pressure of the tanks is to be taken into consideration for protecting the steel structure of the ship.

IR 6.3.10 Whether a drip tray is needed or not is to be in accordance with the following:

.1 When the tank is located on the open deck, drip trays are to be provided to protect the deck from leakages from tank connections and other sources of leakage.

.2 When the tank is located below the open deck but the tank connections are on the open deck, drip trays are to be provided to protect the deck from leakages from tank connections and other sources of leakage.

.3 When the tank and the tank connections are located below the deck, all tank connections are to be located in a tank connection space. Drip trays in this case are not required.

6.3.11 Means are to be provided whereby liquefied gas in the storage tanks can be safely emptied.

6.3.12 It is to be possible to empty, purge and vent fuel storage tanks with fuel piping systems. Instructions for carrying out these procedures must be available on board. Inerting is to be performed with an inert gas prior to venting with dry air to avoid an explosion hazardous atmosphere in tanks and fuel pipes. See detailed requirements in 6.10.

6.4 Liquefied gas fuel containment

6.4.1 General

6.4.1.1 The risk assessment required in 4.2 is to include evaluation of the ship's liquefied gas fuel containment system, and may lead to additional safety measures for integration into the overall vessel design.

6.4.1.2 The design life of fixed liquefied gas fuel containment system is not to be less than the design life of the ship or 20 years, whichever is greater.

6.4.1.3 The design life of portable tanks is not to be less than 20 years.

6.4.1.4 Liquefied gas fuel containment systems is to be designed in accordance with North Atlantic environmental conditions and relevant long-term sea state scatter diagrams for unrestricted navigation. Less demanding environmental conditions, consistent with the expected usage, may be accepted by the Administration for liquefied gas fuel containment systems used exclusively for restricted navigation. More demanding environmental conditions may be required for liquefied gas fuel containment systems operated in conditions more severe than the North Atlantic environment.*
Note:

**Refer to IACS Rec No. 34. North Atlantic Environmental conditions refer to wave conditions. Assumed Temperatures are used for determining qualities with respect to design temperatures and is another matter not intended to be covered in 6.4.1.4*

6.4.1.5 Liquefied gas fuel containment systems are to be designed with suitable safety margins:

.1 to withstand, in the intact condition, the environmental conditions anticipated for the liquefied gas fuel containment system's design life and the loading conditions appropriate for them, which is to include full homogeneous and partial load conditions and partial filling to any intermediate levels; and

.2 being appropriate for uncertainties in loads, structural modelling, fatigue, corrosion, thermal effects, material variability, aging and construction tolerances.

IR6.4.1.5 Guidance: Safety Margins

IR6.4.1.5.1 The Safety Margins to be used for design are specified in the sections as mentioned below:

Independent Type A Tank:	Section 6.4.15.1
Independent Type B Tank:	Section 6.4.15.2
Independent Type C Tank	Section 6.4.15.3
Membrane Tank:	Section 6.4.15.4
Integral Tank	Section 6.4.15.5

IR6.4.1.5.2 Notwithstanding IR6.4.1.5.1, the safety margin is to be taken not less than 2 for membrane tanks. IRS may specially consider lower safety margins provided they are accompanied with satisfactory technical justification which may include detailed analyses, calculations, experimental and model tests, records of satisfactory service history etc. If the flag Administration specifies a more stringent margin of safety, then the same is to be utilized.

6.4.1.6 The liquefied gas fuel containment system structural strength is to be assessed against failure modes, including but not limited to plastic deformation, buckling and fatigue. The specific design conditions that are to be considered for the design of each liquefied gas fuel containment system are given in 6.4.15. There are three main categories of design conditions:

.1 Ultimate Design Conditions – The liquefied gas fuel containment system structure and its structural components are to withstand loads liable to occur during its construction, testing and anticipated use in service, without loss of structural integrity. The design is to take into account proper combinations of the following loads:

.1 internal pressure;

.2 external pressure;

.3 dynamic loads due to the motion of the ship in all loading conditions;

.4 thermal loads;

.5 sloshing loads;

.6 loads corresponding to ship deflections;

.7 tank and liquefied gas fuel weight with the corresponding reaction in way of supports;

.8 insulation weight;

.9 loads in way of towers and other attachments; and

.10 test loads.

.2 Fatigue Design Conditions – The liquefied gas fuel containment system structure and its structural components are not to fail under accumulated cyclic loading.

.3 Accidental Design Conditions – The liquefied gas fuel containment system is to meet each of the following accident design conditions (accidental or abnormal events), addressed in this chapter:

.1 Collision – The liquefied gas fuel containment system is to withstand the collision loads specified in 6.4.9.5.1 without deformation of the supports or the tank structure in way of the supports likely to endanger the tank and its supporting structure.

.2 Fire – The liquefied gas fuel containment systems are to sustain without rupture the rise in internal pressure specified in 6.7.3.1 under the fire scenarios envisaged therein.

.3 Flooded compartment causing buoyancy on tank – the anti-flotation arrangements are to sustain the upward force, specified in 6.4.9.5.2 and there is to be no endangering plastic

deformation to the hull. Plastic deformation may occur in the fuel containment system provided it does not endanger the safe evacuation of the ship.

6.4.1.7 Measures are to be applied to ensure that scantlings required meet the structural strength provisions and are maintained throughout the design life. Measures may include, but are not limited to, material selection, coatings, corrosion additions, cathodic protection and inerting.

6.4.1.8 An inspection/survey plan for the liquefied gas fuel containment system is to be developed and approved by the IRS/Administration. The inspection/survey plan shall identify aspects to be examined and/or validated during surveys throughout the liquefied gas fuel containment system's life and, in particular, any necessary in-service survey, maintenance and testing that was assumed when selecting liquefied gas fuel containment system design parameters. The inspection/survey plan may include specific critical locations as per 6.4.12.2.8 or 6.4.12.2.9.

6.4.1.9 Liquefied gas fuel containment systems are to be designed, constructed and equipped to provide adequate means of access to areas that need inspection as specified in the inspection/survey plan. Liquefied gas fuel containment systems, including all associated internal equipment are to be designed and built to ensure safety during operations, inspection and maintenance.

6.4.2 Liquefied gas fuel containment safety principles

6.4.2.1 The containment systems are to be provided with a complete secondary liquid-tight barrier capable of safely containing all potential leakages through the primary barrier and, in conjunction with the thermal insulation system, of preventing lowering of the temperature of the ship structure to an unsafe level.

6.4.2.2 The size and configuration or arrangement of the secondary barrier may be reduced or omitted where an equivalent level of safety can be demonstrated in accordance with 6.4.2.3 to 6.4.2.5 as applicable.

6.4.2.3 Liquefied gas fuel containment systems for which the probability for structural failures to develop into a critical state has been determined to be extremely low but where the possibility of leakages through the primary barrier cannot be excluded, is to be equipped with a partial secondary barrier and small leak protection system capable of safely handling and disposing of the leakages (a critical state means that the crack develops into unstable condition). The arrangements are to comply with the following:

.1 failure developments that can be reliably detected before reaching a critical state (e.g. by gas detection or inspection) are to have a sufficiently long development time for remedial actions to be taken; and

.2 failure developments that cannot be safely detected before reaching a critical state are to have a predicted development time that is much longer than the expected lifetime of the tank.

6.4.2.4 No secondary barrier is required for liquefied gas fuel containment systems, e.g. type C independent tanks, where the probability for structural failures and leakages through the primary barrier is extremely low and can be neglected.

6.4.2.5 For independent tanks requiring full or partial secondary barrier, means for safely disposing of leakages from the tank is to be arranged.

6.4.3 Secondary barriers in relation to tank types

6.4.3.1 Secondary barriers in relation to the tank types defined in 6.4.15 are to be provided in accordance with the following table.

Basic tank type	Secondary barrier requirements
Membrane	Complete secondary barrier
Independent Type A	Complete secondary barrier
Independent Type B	Partial secondary barrier
Independent Type C	No secondary barrier required

6.4.4 Design of secondary barriers

6.4.4.1 The design of the secondary barrier, including spray shield if fitted, is to be such that:

.1 it is capable of containing any envisaged leakage of liquefied gas fuel for a period of 15 days unless different criteria apply for particular voyages, taking into account the load spectrum referred to in 6.4.12.2.6;

.2 physical, mechanical or operational events within the liquefied gas fuel tank that could cause failure of the primary barrier is not to impair the due function of the secondary barrier, or vice versa;

.3 failure of a support or an attachment to the hull structure will not lead to loss of liquid tightness of both the primary and secondary barriers;

.4 it is capable of being periodically checked for its effectiveness by means of a visual inspection or other suitable means acceptable to Administration/ IRS;

.5 the methods required in 6.4.4.1.4 is to be approved by the Administration/ IRS and is to include, as a minimum:

.1 details on the size of defect acceptable and the location within the secondary barrier, before its liquid tight effectiveness is compromised;

.2 accuracy and range of values of the proposed method for detecting defects in .1 above;

.3 scaling factors to be used in determining the acceptance criteria if full-scale model testing is not undertaken; and

.4 effects of thermal and mechanical cyclic loading on the effectiveness of the proposed test.

.6 the secondary barrier is to fulfill its functional requirements at a static angle of heel of 30°.

6.4.5 Partial secondary barriers and primary barrier small leak protection system

6.4.5.1 Partial secondary barriers as permitted in 6.4.2.3 are to be used with a small leak protection system and meet all the requirements in 6.4.4. The small leak protection system is to include means to detect a leak in the primary barrier, provision such as a spray shield to deflect any liquefied gas fuel down into the partial secondary barrier, and means to dispose of the liquid, which may be by natural evaporation.

6.4.5.2 The capacity of the partial secondary barrier is to be determined, based on the liquefied gas fuel leakage corresponding to the extent of failure resulting from the load spectrum referred to in 6.4.12.2.6, after the initial detection of a primary leak. Due account may be taken of liquid evaporation, rate of leakage, pumping capacity and other relevant factors.

6.4.5.3 The required liquid leakage detection may be by means of liquid sensors, or by an effective use of pressure, temperature or gas detection systems, or any combination thereof.

6.4.5.4 For independent tanks for which the geometry does not present obvious locations for leakage to collect, the partial secondary barrier is also to fulfill its functional requirements at a nominal static angle of trim.

6.4.6 Supporting arrangements

6.4.6.1 The liquefied gas fuel tanks is to be supported by the hull in a manner that prevents bodily movement of the tank under the static and dynamic loads defined in 6.4.9.2 to 6.4.9.5, where applicable, while allowing contraction and expansion of the tank under temperature variations and hull deflections without undue stressing of the tank and the hull.

6.4.6.2 Anti-flotation arrangements are to be provided for independent tanks and capable of withstanding the loads defined in 6.4.9.5.2 without plastic deformation likely to endanger the hull structure.

6.4.6.3 Supports and supporting arrangements are to withstand the loads defined in 6.4.9.3.3.8 and 6.4.9.5, but these loads need not be combined with each other or with wave-induced loads.

6.4.7 Associated structure and equipment

6.4.7.1 Liquefied gas fuel containment systems are to be designed for the loads imposed by associated structure and equipment. This includes pump towers, liquefied gas fuel domes, liquefied gas fuel pumps and piping, stripping pumps and piping, nitrogen piping, access hatches, ladders, piping penetrations, liquid level gauges, independent level alarm gauges, spray nozzles, and instrumentation systems (such as pressure, temperature and strain gauges).

6.4.8 Thermal insulation

6.4.8.1 Thermal insulation is to be provided as required to protect the hull from temperatures below those allowable (see 6.4.13.1.1) and limit the heat flux into the tank to the levels that can be maintained by the pressure and temperature control system applied in 6.9.

6.4.9 Design loads

6.4.9.1 General

6.4.9.1.1 This sub-section defines the design loads that are to be considered with regard to 6.4.10 to 6.4.12. This includes load categories (permanent, functional, environmental and accidental) and the description of the loads.

6.4.9.1.2 The extent to which these loads are to be considered depends on the type of tank, and is more fully detailed in the following paragraphs.

6.4.9.1.3 Tanks, together with their supporting structure and other fixtures, is to be designed taking into account relevant combinations of the loads described below.

6.4.9.2 Permanent loads

6.4.9.2.1 Gravity loads

6.4.9.2.1.1 The weight of tank, thermal insulation, loads caused by towers and other attachments are to be considered.

6.4.9.2.2 Permanent external loads

6.4.9.2.2.1 Gravity loads of structures and equipment acting externally on the tank are to be considered.

6.4.9.3 Functional loads

6.4.9.3.1 Loads arising from the operational use of the tank system are to be classified as functional loads.

6.4.9.3.2 All functional loads that are essential for ensuring the integrity of the tank system, during all design conditions, are to be considered.

6.4.9.3.3 As a minimum, the effects from the following criteria, as applicable, are to be considered when establishing functional loads:

(a) internal pressure

(b) external pressure

(c) thermally induced loads

(d) vibration

(e) interaction loads

(f) loads associated with construction and installation

(g) test loads

(h) static heel loads

(i) weight of liquefied gas fuel

(j) sloshing

(k) wind impact, wave impacts and green sea effect for tanks installed on open deck.

6.4.9.3.3.1 Internal pressure

.1 In all cases, including 6.4.9.3.3.1.2, P_0 is not to be less than MARVS.

.2 For liquefied gas fuel tanks where there is no temperature control and where the pressure of the liquefied gas fuel is dictated only by the ambient temperature, P_0 is not to be less than the gauge vapour pressure of the liquefied gas fuel at a temperature of 45 [°C] except as follows:

.1 Lower values of ambient temperature may be accepted by the IRS/Administration for ships operating in restricted areas. Conversely, higher

values of ambient temperature may be required.

.2 For ships on voyages of restricted duration, P_0 may be calculated based on the actual pressure rise during the voyage and account may be taken of any thermal insulation of the tank.

.3 Subject to special consideration by the IRS/Administration and to the limitations given in 6.4.15 for the various tank types, a vapour pressure P_h higher than P_0 may be accepted for site specific conditions (harbour or other locations), where dynamic loads are reduced.

.4 Pressure used for determining the internal pressure is to be:

.1 $(P_{gd})\max$ is the associated liquid pressure determined using the maximum design accelerations.
.2 $(P_{gd\ site})\max$ is the associated liquid pressure determined using site specific accelerations.

.3 P_{eq} to be the greater of P_{eq1} and P_{eq2} calculated as follows:

$$P_{eq1} = P_0 + (P_{gd})max \quad \text{[MPa]}$$

$$P_{eq2} = P_h + (P_{gd_site})max \quad \text{[MPa]}$$

.5 The internal liquid pressures are those created by the resulting acceleration of the centre of gravity of the liquefied gas fuel due to the motions of the ship referred to in 6.4.9.4.1.1. The value of internal liquid pressure P_{gd} resulting from combined effects of gravity and dynamic accelerations is to be calculated as follows:

$$P_{gd} = \alpha_\beta Z_\beta (\rho/(1.02 \times 10^5)) \text{ [MPa]}$$

where:

α_β = dimensionless acceleration (i.e. relative to the acceleration of gravity), resulting from gravitational and dynamic loads, in an arbitrary direction β; (see Fig.6.4.1).

For large tanks, an acceleration ellipsoid, taking account of transverse vertical and longitudinal accelerations, should be used.

Z_β = largest liquid height [m] above the point where the pressure is to be determined measured from the tank shell in the β direction (see Fig.6.4.2).

Tank domes considered to be part of the accepted total tank volume is to be taken into account when determining Z_β unless the total volume of tank domes V_d does not exceed the following value:

$$V_d = V_t \left(\frac{100 - FL}{FL}\right)$$

where:

V_t = tank volume without any domes; and
F_L = filling limit according to 6.8.

ρ = maximum liquefied gas fuel density [kg/m^3] at the design temperature.

The direction that gives the maximum value $(P_{gd})max$ or $(P_{gd\ site})max$ is to be considered. Where acceleration components in three directions need to be considered, an ellipsoid is to be used instead of the ellipse in Fig.6.4.1. The above formula applies only to full tanks.

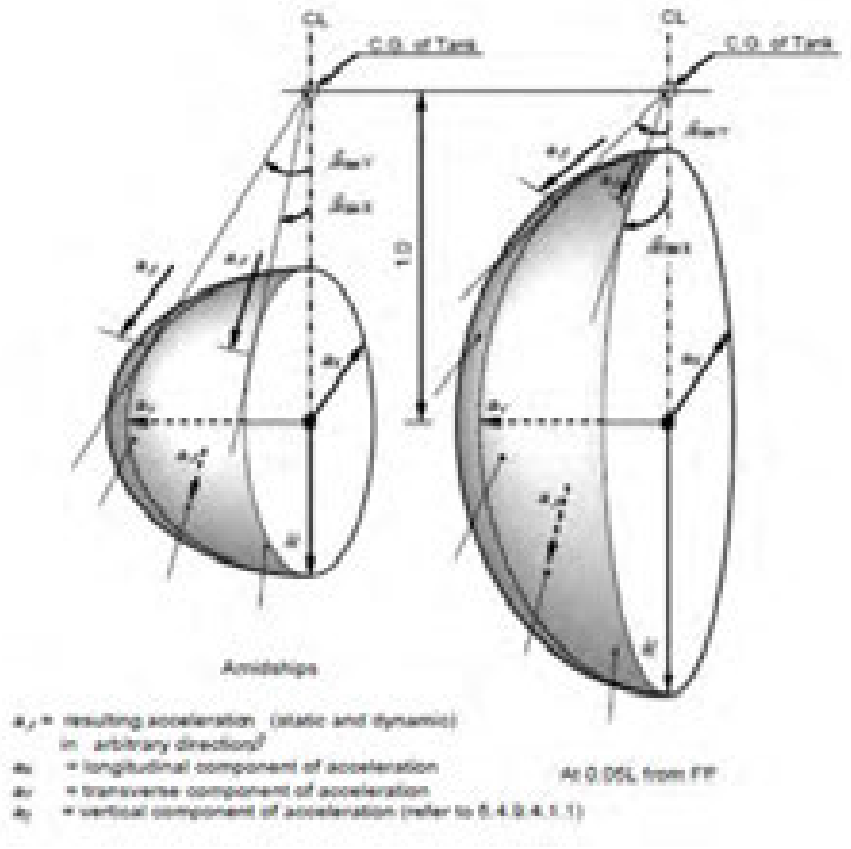

Fig.6.4.1 : Acceleration ellipsoid

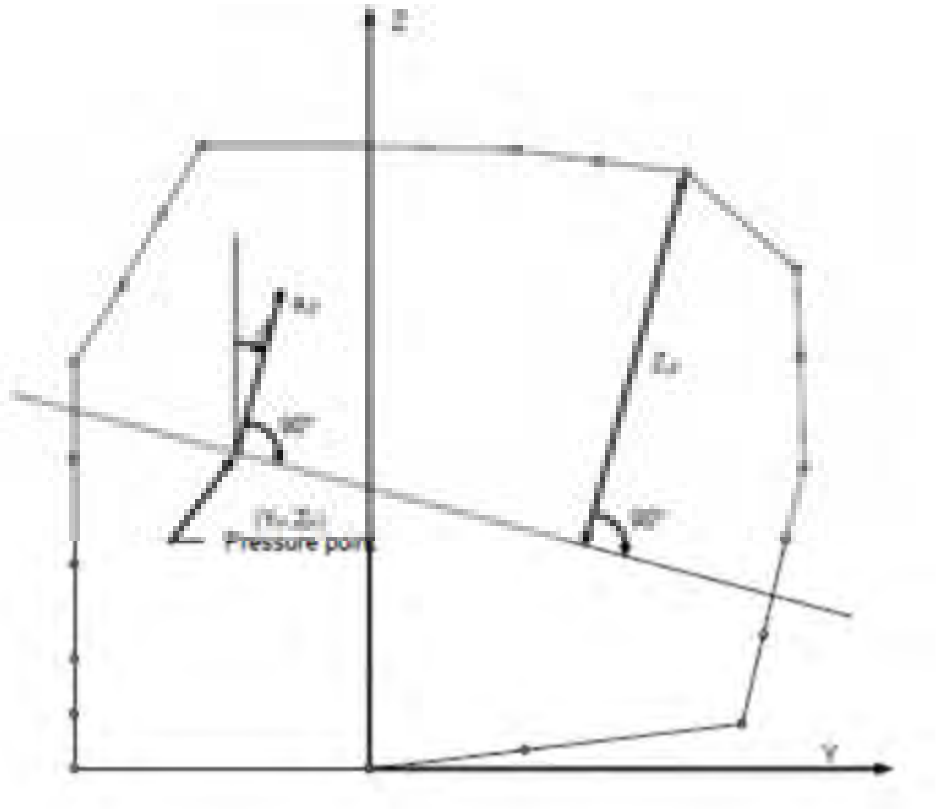

Fig.6.4.2 : Determination of internal pressure heads

6.4.9.3.3.2 External pressure

6.4.9.3.3.2.1 External design pressure loads are to be based on the difference between the minimum internal pressure and the maximum external pressure to which any portion of the tank may be simultaneously subjected.

6.4.9.3.3.3 Thermally induced loads

6.4.9.3.3.3.1 Transient thermally induced loads during cooling down periods are to be considered for tanks intended for liquefied gas fuel temperatures below minus 55 [°C].

6.4.9.3.3.3.2 Stationary thermally induced loads are to be considered for liquefied gas fuel containment systems where the design supporting arrangements or attachments and operating temperature may give rise to significant thermal stresses (see paragraph 6.9.2).

6.4.9.3.3.4 Vibration

6.4.9.3.3.4.1 The potentially damaging effects of vibration on the liquefied gas fuel containment system are to be considered.

6.4.9.3.3.5 Interaction loads

6.4.9.3.3.5.1 The static component of loads resulting from interaction between liquefied gas fuel containment system and the hull structure, as well as loads from associated structure and equipment, is to be considered.

6.4.9.3.3.6 Loads associated with construction and installation

6.4.9.3.3.6.1 Loads or conditions associated with construction and installation are to be considered, e.g. lifting.

6.4.9.3.3.7 Test loads

6.4.9.3.3.7.1 Account is to be taken of the loads corresponding to the testing of the liquefied gas fuel containment system referred to in 16.5.

6.4.9.3.3.8 Static heel loads

6.4.9.3.3.8.1 Loads corresponding to the most unfavourable static heel angle within the range 0° to 30° are to be considered.

6.4.9.3.3.9 Other loads

6.4.9.3.3.9.1 Any other loads not specifically addressed, which could have an effect on the liquefied gas fuel containment system, are to be taken into account.

6.4.9.4 Environmental loads

6.4.9.4.1 Environmental loads are defined as those loads on the liquefied gas fuel containment system that are caused by the surrounding environment and that are not otherwise classified as a permanent, functional or accidental load.

6.4.9.4.1.1 Loads due to ship motion

6.4.9.4.1.1.1 The determination of dynamic loads is to take into account the long-term distribution of ship motion in irregular seas, which the ship will experience during its operating life. Account may be taken of the reduction in dynamic loads due to necessary speed reduction and variation of heading. The ship's motion shall include surge, sway, heave, roll, pitch and yaw. The accelerations acting on tanks are to be estimated at their centre of gravity and include the following components:

.1 vertical acceleration: motion accelerations of heave, pitch and, possibly roll (normal to the ship base);

.2 transverse acceleration: motion accelerations of sway, yaw and roll and gravity component of roll; and

.3 longitudinal acceleration: motion accelerations of surge and pitch and gravity component of pitch.

Methods to predict accelerations due to ship motion are to be proposed and approved by the IRS/Administration.*

Ships for restricted service may be given special consideration.

Note:

**Refer to 4.28.2.1 of Part5, Ch 4 for guidance formulae for acceleration components.*

6.4.9.4.1.2 Dynamic interaction loads

6.4.9.4.1.2.1 Account is to be taken of the dynamic component of loads resulting from interaction between liquefied gas fuel containment systems and the hull structure,

including loads from associated structures and equipment.

6.4.9.4.1.3 Sloshing loads

6.4.9.4.1.3.1 The sloshing loads on a liquefied gas fuel containment system and internal components are to be evaluated for the full range of intended filling levels.

6.4.9.4.1.4 Snow and ice loads

6.4.9.4.1.4.1 Snow and icing is to be considered, if relevant.

6.4.9.4.1.5 Loads due to navigation in ice

6.4.9.4.1.5.1 Loads due to navigation in ice are to be considered for ships intended for such service.

6.4.9.4.1.6 Green sea loading

6.4.9.4.1.6.1 Account is to be taken to loads due to water on deck.

6.4.9.4.1.7 Wind loads

6.4.9.4.1.7.1 Account is to be taken to wind generated loads as relevant.

6.4.9.5 Accidental loads

6.4.9.5.1 Accidental loads are defined as loads that are imposed on a liquefied gas fuel containment system and it's supporting arrangements under abnormal and unplanned conditions.

6.4.9.5.1 Collision load

6.4.9.5.1.1 The collision load is to be determined based on the fuel containment system under fully loaded condition with an inertial force corresponding to "a" in the Table below in forward direction and "a/2" in the aft direction, where "g" is gravitational acceleration.

Ship length (L)	Design acceleration (a)
L > 100 m	0.5 g
60 < L ≤ 100 m	$\left(2-\frac{3(L-60)}{80}\right)g$
L ≤ 60 m	2g

Special consideration should be given to ships with Froude number (Fn) > 0.4.

6.4.9.5.2 Loads due to flooding on ship

6.4.9.5.2.1 For independent tanks, loads caused by the buoyancy of a fully submerged empty tank are to be considered in the design of anti-flotation chocks and the supporting structure in both the adjacent hull and tank structure.

6.4.10 Structural integrity

6.4.10.1 General

6.4.10.1.1 The structural design is to ensure that tanks have an adequate capacity to sustain all relevant loads with an adequate margin of safety. This is to take into account the possibility of plastic deformation, buckling, fatigue and loss of liquid and gas tightness.

6.4.10.1.2 The structural integrity of liquefied gas fuel containment systems can be demonstrated by compliance with 6.4.15, as appropriate for the liquefied gas fuel containment system type.

6.4.10.1.3 For other liquefied gas fuel containment system types, that are of novel design or differ significantly from those covered by 6.4.15, the structural integrity is to be demonstrated by compliance with 6.4.16.

6.4.11 Structural analysis

6.4.11.1 Analysis

6.4.11.1.1 The design analyses are to be based on accepted principles of statics, dynamics and strength of materials.

6.4.11.1.2 Simplified methods or simplified analyses may be used to calculate the load effects, provided that they are conservative. Model tests may be used in combination with, or instead of, theoretical calculations. In cases where theoretical methods are inadequate, model or full-scale tests may be required.

6.4.11.1.3 When determining responses to dynamic loads, the dynamic effect is to be taken into account where it may affect structural integrity.

6.4.11.2 Load scenarios

6.4.11.2.1 For each location or part of the liquefied gas fuel containment system to be considered and for each possible mode of failure to be analysed, all relevant combinations of loads that may act simultaneously are to be considered.

6.4.11.2.2 The most unfavourable scenarios for all relevant phases during construction, handling, testing and in service conditions are to be considered.

6.4.11.2.3 When the static and dynamic stresses are calculated separately and unless other methods of calculation are justified, the total stresses are to be calculated according to:

$$\sigma_x = \sigma_{x.st} \pm \sqrt{\sum \left(\sigma_{x.dyn}\right)^2}$$

$$\sigma_y = \sigma_{y.st} \pm \sqrt{\sum \left(\sigma_{y.dyn}\right)^2}$$

$$\sigma_z = \sigma_{z.st} \pm \sqrt{\sum \left(\sigma_{z.dyn}\right)^2}$$

$$\tau_{xy} = \tau_{xy.st} \pm \sqrt{\sum \left(\tau_{xy.dyn}\right)^2}$$

$$\tau_{xz} = \tau_{xz.st} \pm \sqrt{\sum \left(\tau_{xz.dyn}\right)^2}$$

$$\tau_{yz} = \tau_{yz.st} \pm \sqrt{\sum \left(\tau_{yz.dyn}\right)^2}$$

where:

$\sigma_{x,st}$, $\sigma_{y,st}$, $\sigma_{z,st}$, $\tau_{xy,st}$, $\tau_{xz,\,st}$, and $\tau_{yz,st}$, are static stresses; and

$\sigma_{x,dyn}$, $\sigma_{y,dyn}$, $\sigma_{z,dyn}$, $\tau_{xy,dyn}$, $\tau_{xz,\,dyn}$, and $\tau_{yz,dyn}$, are dynamic stresses,

each is to be determined separately from acceleration components and hull strain components due to deflection and torsion.

6.4.12 Design conditions

All relevant failure modes are to be considered in the design for all relevant load scenarios and design conditions. The design conditions are given in the earlier part of this chapter, and the load scenarios are covered by 6.4.11.2.

6.4.12.1 Ultimate design condition

6.4.12.1.1 Structural capacity may be determined by testing, or by analysis, taking into account both the elastic and plastic material properties, by simplified linear elastic analysis or by the provisions of this Chapter:

.1 Plastic deformation and buckling are to be considered.

.2 Analysis is to be based on characteristic load values as follows:

Permanent loads	Expected values
Functional loads	Specified values
Environmental loads	For wave loads: most probable largest load encountered during 10^8 wave encounters

.3 For the purpose of ultimate strength assessment the following material parameters apply:

.1 R_e = specified minimum yield stress at room temperature [N/mm^2]. If the stress-strain curve does not show a defined yield stress, the 0.2% proof stress applies.

.2 R_m = specified minimum tensile strength at room temperature [N/mm^2].

For welded connections where under-matched welds, i.e. where the weld metal has lower tensile strength than the parent metal, are unavoidable, such as in some aluminium alloys, the respective R_e and R_m of the welds, after any applied heat treatment, is to be used. In such cases the transverse weld tensile strength is not to be less than the actual yield strength of the parent metal. If this cannot be achieved, welded structures made from such materials are not to be incorporated in liquefied gas fuel containment systems.

The above properties shall correspond to the minimum specified mechanical properties of the material, including the weld metal in the as fabricated condition. Subject to special consideration by the

IRS/Administration, account may be taken of the enhanced yield stress and tensile strength at low temperature.

.4 The equivalent stress σ_c (von Mises, Huber) is to be determined by:

$$\sigma_c = \sqrt{\sigma_x^2 + \sigma_y^2 + \sigma_z^2 - \sigma_x\sigma_y - \sigma_x\sigma_z - \sigma_y\sigma_z + 3\left(\tau_{xy}^2 + \tau_{xz}^2 + \tau_{yz}^2\right)}$$

where:

σ_x = total normal stress in x-direction;
σ_y = total normal stress in y-direction;
σ_z = total normal stress in z-direction;
τ_{xy} = total shear stress in x-y plane;
τ_{xz} = total shear stress in x-z plane; and
τ_{yz} = total shear stress in y-z plane.

The above values are to be calculated as described in 6.4.11.2.3.

.5 Allowable stresses for materials other than those covered by 7.4 is to be subject to approval by the Administration in each case.

.6 Stresses may be further limited by fatigue analysis, crack propagation analysis and buckling criteria.

6.4.12.2 Fatigue Design Condition

6.4.12.2.1 The fatigue design condition is the design condition with respect to accumulated cyclic loading.

6.4.12.2.2 Where a fatigue analysis is required the cumulative effect of the fatigue load shall comply with:

$$\sum \frac{n_i}{N_i} + \frac{n_{Loading}}{N_{Loading}} \leq C_w$$

where:

n_i = number of stress cycles at each stress level during the life of the tank;

N_i = number of cycles to fracture for the respective stress level according to the Wohler (S-N) curve;

$n_{Loading}$ = number of loading and unloading cycles during the life of the tank not to be less than 1000. Loading and unloading cycles include a complete pressure and thermal cycle;

$N_{Loading}$ = number of cycles to fracture for the fatigue loads due to loading and unloading; and

C_w = maximum allowable cumulative fatigue damage ratio.

The fatigue damage is to be based on the design life of the tank but not less than 10^8 wave encounters.

6.4.12.3 Where required, the liquefied gas fuel containment system is to be subject to fatigue analysis, considering all fatigue loads and their appropriate combinations for the expected life of the liquefied gas fuel containment system. Consideration is to be given to various filling conditions.

6.4.12.4 Design S-N curves used in the analysis is to be applicable to the materials and weldments, construction details, fabrication procedures and applicable state of the stress envisioned.

The S-N curves are to be based on a 97.6% probability of survival corresponding to the mean-minus-two-standard-deviation curves of relevant experimental data up to final failure. Use of S-N curves derived in a different way requires adjustments to the acceptable Cw values specified in 6.4.12.2.7 to 6.4.12.2.9.

6.4.12.5 Analysis is to be based on characteristic load values as follows:

Permanent loads	Expected values
Functional loads	Specified values or specified history
Environmental loads	Expected load history, but not less than 10^8 cycles

If simplified dynamic loading spectra are used for the estimation of the fatigue life, those are to be specially considered by the IRS/Administration.

6.4.12.6 Where the size of the secondary barrier is reduced, as is provided for in 6.4.2.3, fracture mechanics analyses of fatigue crack growth is to be carried out to determine:

.1 crack propagation paths in the structure, where necessitated by 6.4.12.2.7 to 6.4.12.2.9, as applicable;

.2 crack growth rate;

.3 the time required for a crack to propagate to cause a leakage from the tank;

.4 the size and shape of through thickness cracks; and

.5 the time required for detectable cracks to reach a critical state after penetration through the thickness.

The fracture mechanics are in general based on crack growth data taken as a mean value plus two standard deviations of the test data. Methods for fatigue crack growth analysis and fracture mechanics is to be based on recognized standards.

In analysing crack propagation the largest initial crack not detectable by the inspection method applied is to be assumed, taking into account the allowable non-destructive testing and visual inspection criterion as applicable.

Crack propagation analysis specified in 6.4.12.2.7 the simplified load distribution and sequence over a period of 15 days may be used. Such distributions may be obtained as indicated in Fig.6.4.3. Load distribution and sequence for longer periods, such as in 6.4.12.2.8 and 6.4.12.2.9 is to be approved by the IRS/Administration.

The arrangements are to comply with 6.4.12.2.7 to 6.4.12.2.9 as applicable.

6.4.12.2.7 For failures that can be reliably detected by means of leakage detection:

C_w is to be less than or equal to 0.5.

Predicted remaining failure development time, from the point of detection of leakage till reaching a critical state, is not to be less than 15 days unless different regulations apply for ships engaged in particular voyages.

6.4.12.2.8 For failures that cannot be detected by leakage but that can be reliably detected at the time of in-service inspections:

C_w is to be less than or equal to 0.5.

Predicted remaining failure development time, from the largest crack not detectable by in-service inspection methods until reaching a critical state, is not to be less than three (3) times the inspection interval.

6.4.12.2.9 In particular locations of the tank where effective defect or crack development detection cannot be assured, the following, more stringent, fatigue acceptance criteria is to be applied as a minimum:

C_w is to be less than or equal to 0.1.

Predicted failure development time, from the assumed initial defect until reaching a critical state, is not to be less than three (3) times the lifetime of the tank.

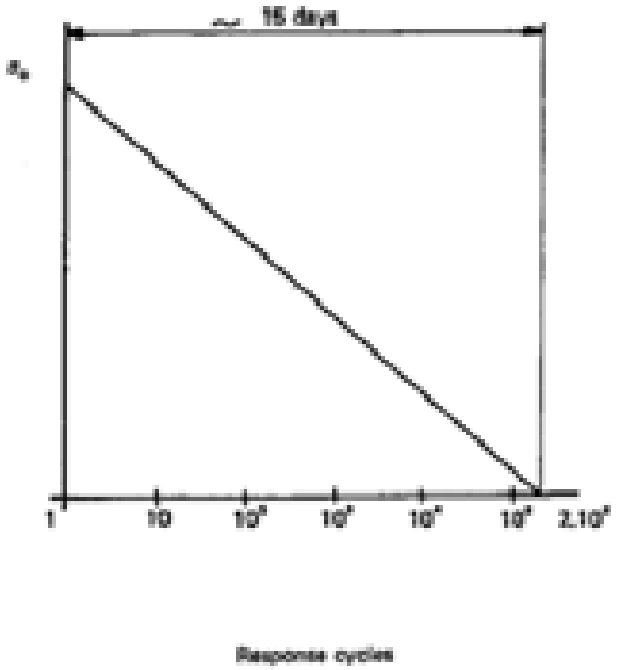
6.4.12.3 Accidental design condition

6.4.12.3.1 The accidental design condition is a design condition for accidental loads with extremely low probability of occurrence.

6.4.12.3.2 Analysis is to be based on the characteristic values as follows:

Permanent loads	Expected values
Functional loads	Specified values
Environmental loads	Specified values
Accidental loads	Specified values or expected values

Loads mentioned in 6.4.9.3.3.8 and 6.4.9.5 need not be combined with each other or with wave-induced loads.



σ_0 = most probable maximum stress over the life of the ship

Response cycle scale is logarithmic; the value of 2.10^8 is given as an example of estimate.

Fig.6.4.3 : Simplified load distribution

6.4.13 Materials and construction

6.4.13.1 Materials

6.4.13.1.1 Materials forming ship structure

6.4.13.1.1.1 To determine the grade of plate and sections used in the hull structure, a temperature calculation is to be performed for all tank types. The following assumptions are to be made in this calculation:

.1 The primary barrier of all tanks is to be assumed to be at the liquefied gas fuel temperature.

.2 In addition to .1 above, where a complete or partial secondary barrier is required it is to be assumed to be at the liquefied gas fuel temperature at atmospheric pressure for any one tank only.

.3 For worldwide service, ambient temperatures is to be taken as 5 [°C] for air and 0 [°C] for seawater. Higher values may be accepted for ships operating in restricted areas and conversely, lower values may be imposed by the IRS/Administration for ships trading to areas where lower temperatures are expected during the winter months.

.4 Still air and sea water conditions are to be assumed, i.e. no adjustment for forced convection.

.5 Degradation of the thermal insulation properties over the life of the ship due to factors such as thermal and mechanical ageing, compaction, ship motions and tank vibrations as defined in 6.4.13.3.6 and 6.4.13.3.7 is to be assumed.

.6 The cooling effect of the rising boil-off vapour from the leaked liquefied gas fuel is to be taken into account where applicable.

.7 Credit for hull heating may be taken in accordance with 6.4.13.1.1.3, provided the heating arrangements are in compliance with 6.4.13.1.1.4.

.8 No credit is to be given for any means of heating, except as described in 6.4.13.1.1.3.

.9 For members connecting inner and outer hulls, the mean temperature may be taken for determining the steel grade.

6.4.13.1.1.2 The materials of all hull structures for which the calculated temperature in the design condition is below 0 [°C], due to the influence of liquefied gas fuel temperature, is to be in accordance with Table 7.5. This includes hull structure supporting the liquefied gas fuel tanks, inner bottom plating, longitudinal bulkhead plating, transverse bulkhead plating, floors, webs, stringers and all attached stiffening members.

6.4.13.1.1.3 Means of heating structural materials may be used to ensure that the material temperature does not fall below the minimum allowed for the grade of material specified in Table 7.5. In the calculations required in 6.4.13.1.1.1, credit for such heating may be taken in accordance with the following principles:

.1 for any transverse hull structure;

.2 for longitudinal hull structure referred to in 6.4.13.1.1.2 where colder ambient temperatures are specified, provided the material remains suitable for the ambient temperature conditions of plus 5[°C] for air and 0[°C] for seawater with no credit taken in the calculations for heating; and

.3 as an alternative to 6.4.13.1.1.3.2, for longitudinal bulkhead between liquefied gas fuel tanks, credit may be taken for heating provided the material remain suitable for a minimum design temperature of minus 30[°C], or a temperature 30[°C] lower than that determined by 6.4.13.1.1.1 with the heating considered, whichever is less. In this case, the ship's longitudinal strength shall comply with SOLAS regulation II-1/3-1 for both when those bulkhead(s) are considered effective and not.

6.4.13.1.1.4 The means of heating referred to in 6.4.13.1.1.3 is to comply with the following:

.1 the heating system is to be arranged so that, in the event of failure in any part of the system, standby heating can be maintained equal to no less than 100% of the theoretical heat requirement;

.2 the heating system is to be considered as an essential auxiliary. All electrical components of at least one of the systems provided in accordance with 6.4.13.1.1.3.1 is to be supplied from the emergency source of electrical power; and

.3 the design and construction of the heating system is to be included in the approval of the containment system by the IRS/Administration.

6.4.13.2 Materials of primary and secondary barriers

6.4.13.2.1 Metallic materials used in the construction of primary and secondary barriers not forming the hull, is to be suitable for the design loads that they may be subjected to, and be in accordance with Table 7.1, 7.2 or 7.3.

6.4.13.2.2 Materials, either non-metallic or metallic but not covered by Tables 7.1, 7.2 and 7.3, used in the primary and secondary barriers may be approved by the Administration considering the design loads that they may be subjected to, their properties and their intended use.

6.4.13.2.3 Where non-metallic materials, including composites, are used for or incorporated in the primary or secondary barriers, they is to be tested for the following properties, as applicable, to ensure that they are adequate for the intended service:

.1 compatibility with the liquefied gas fuels;

.2 ageing;

.3 mechanical properties;

.4 thermal expansion and contraction;

.5 abrasion;

.6 cohesion;

.7 resistance to vibrations;

.8 resistance to fire and flame spread; and

.9 resistance to fatigue failure and crack propagation.

6.4.13.2.4 The above properties, where applicable, is to be tested for the range between the expected maximum temperature in service and 5[°C] below the minimum design temperature, but not lower than -196[°C].

6.4.13.2.5 Where non-metallic materials, including composites, are used for the primary and secondary barriers, the joining processes shall also be tested as described above.

6.4.13.2.6 Consideration may be given to the use of materials in the primary and secondary barrier, which are not resistant to fire and flame spread, provided they are protected by a suitable system such as a permanent inert gas environment, or are provided with a fire retardant barrier.

6.4.13.3 Thermal insulation and other materials used in liquefied gas fuel containment systems

6.4.13.3.1 Load-bearing thermal insulation and other materials used in liquefied gas fuel containment systems are to be suitable for the design loads.

6.4.13.3.2 Thermal insulation and other materials used in liquefied gas fuel containment systems shall have the following properties, as applicable, to ensure that they are adequate for the intended service:

.1 compatibility with the liquefied gas fuels;

.2 solubility in the liquefied gas fuel;

.3 absorption of the liquefied gas fuel;

.4 shrinkage;

.5 ageing;

.6 closed cell content;

.7 density;

.8 mechanical properties, to the extent that they are subjected to liquefied gas fuel and other loading effects, thermal expansion and contraction;

.9 abrasion;

.10 cohesion;

.11 thermal conductivity;

.12 resistance to vibrations;

.13 resistance to fire and flame spread; and

.14 resistance to fatigue failure and crack propagation.

6.4.13.3.3 The above properties, where applicable, is to be tested for the range between the expected maximum temperature in service and 5[°C] below the minimum design temperature, but not lower than -196[°C].

6.4.13.3.4 Due to location or environmental conditions, thermal insulation materials are to have suitable properties of resistance to fire and flame spread and is to be adequately protected against penetration of water vapour and mechanical damage. Where the thermal insulation is located on or above the exposed deck, and in way of tank cover penetrations, it shall have suitable fire resistance properties in accordance with a recognized standard or be covered with a material having low flame spread characteristics and forming an efficient approved vapour seal.

6.4.13.3.5 Thermal insulation that does not meet recognized standards for fire resistance may be used in fuel storage hold spaces that are not kept permanently inerted, provided its surfaces are covered with material with low flame spread characteristics and that forms an efficient approved vapour seal.

6.4.13.3.6 Testing for thermal conductivity of thermal insulation is to be carried out on suitably aged samples.

6.4.13.3.7 Where powder or granulated thermal insulation is used, measures are to be taken to reduce compaction in service and to maintain the required thermal conductivity and also prevent any undue increase of pressure on the liquefied gas fuel containment system.

6.4.14 Construction processes

6.4.14.1 Weld joint design

6.4.14.1.1 All welded joints of the shells of independent tanks are to be of the in-plane butt weld full penetration type. For dome-to-shell connections only, tee welds of the full penetration type may be used depending on the results of the tests carried out at the approval of the welding procedure. Except for small penetrations on domes, nozzle welds are also to be designed with full penetration.

6.4.14.1.2 Welding joint details for type C independent tanks, and for the liquid-tight primary barriers of type B independent tanks primarily constructed of curved surfaces, is to be as follows:

.1 All longitudinal and circumferential joints is to be of butt welded, full penetration, double vee or single vee type. Full penetration butt welds is to be obtained by double welding or by the use of backing rings. If used, backing rings is to be removed except from very small process pressure vessels*. Other edge preparations may be permitted, depending on the results of the tests carried out at the approval of the welding procedure. For connections of tank shell to a longitudinal bulkhead of type C bilobe tanks, tee welds of the full penetration type may be accepted.

Note:

** For vacuum insulated tanks without manhole, the longitudinal and circumferential joints should meet the aforementioned requirements, except for the erection weld joint of the outer shell, which may be a one-side welding with backing ring.*

.2 The bevel preparation of the joints between the tank body and domes and between domes and relevant fittings is to be designed according to a standard acceptable to the Administration. All welds connecting nozzles, domes or other penetrations of the vessel and all welds connecting flanges to the vessel or nozzles is to be full penetration welds.

6.4.14.2 Design for gluing and other joining processes

6.4.14.2.1 The design of the joint to be glued (or joined by some other process except welding) shall take account of the strength characteristics of the joining process.

6.4.15 Tank types

6.4.15.1 Type A independent tanks

6.4.15.1.1 Design basis

6.4.15.1.1.1 Type A independent tanks are tanks primarily designed using classical ship-structural analysis procedures in accordance with the requirements of the IRS/Administration. Where such tanks are primarily constructed of plane surfaces, the design vapour pressure P_0 is to be less than 0.07 [MPa].

6.4.15.1.1.2 A complete secondary barrier is required as defined in 6.4.3. The secondary barrier is to be designed in accordance with 6.4.4.

6.4.15.1.2 Structural analysis

6.4.15.1.2.1 A structural analysis is to be performed taking into account the internal pressure as indicated in 6.4.9.3.3.1, and the interaction loads with the supporting and keying system as well as a reasonable part of the ship's hull.

6.4.15.1.2.2 For parts, such as structure in way of supports, not otherwise covered by the requirements in this chapter, stresses is to be determined by direct calculations, taking into account the loads referred to in 6.4.9.2 to 6.4.9.5 as far as applicable, and the ship deflection in way of supports.

6.4.15.1.2.3 The tanks with supports are to be designed for the accidental loads specified in 6.4.9.5. These loads need not be combined with each other or with environmental loads.

6.4.15.1.3 Ultimate design condition

6.4.15.1.3.1 For tanks primarily constructed of plane surfaces, the nominal membrane stresses for primary and secondary members (stiffeners, web frames, stringers, girders), when calculated by classical analysis procedures, shall not exceed the lower of Rm/2.66 or Re/1.33 for nickel steels, carbon-manganese steels, austenitic steels and aluminium alloys, where Rm and Re are defined in 6.4.12.1.1.3. However, if detailed calculations are carried out for the primary members, the equivalent stress σ_c, as defined

in 6.4.12.1.1.4, may be increased over that indicated above to a stress acceptable to the IRS/Administration. Calculations are to take into account the effects of bending, shear, axial and torsional deformation as well as the hull/liquefied gas fuel tank interaction forces due to the deflection of the hull structure and liquefied gas fuel tank bottoms.

6.4.15.1.3.2 Tank boundary scantlings are to meet at least the requirements of the IRS/Administration for deep tanks taking into account the internal pressure as indicated in 6.4.9.3.3.1 and any corrosion allowance required by 6.4.1.7.

6.4.15.1.3.3 The liquefied gas fuel tank structure is to be reviewed against potential buckling.

6.4.15.1.4 Accidental design condition

6.4.15.1.4.1 The tanks and the tank supports are to be designed for the accidental loads and design conditions specified in 6.4.9.5 and 6.4.1.6.3 as relevant.

6.4.15.1.4.2 When subjected to the accidental loads specified in 6.4.9.5, the stress is to comply with the acceptance criteria specified in 6.4.15.1.3, modified as appropriate taking into account their lower probability of occurrence.

6.4.15.2 Type B independent tanks

6.4.15.2.1 Design basis

6.4.15.2.1.1 Type B independent tanks are tanks designed using model tests, refined analytical tools and analysis methods to determine stress levels, fatigue life and crack propagation characteristics. Where such tanks are primarily constructed of plane surfaces (prismatic tanks) the design vapour pressure P_0 is to be less than 0.07 [MPa].

6.4.15.2.1.2 A partial secondary barrier with a protection system is required as defined in 6.4.3. The small leak protection system is to be designed according to 6.4.5.

6.4.15.2.2 Structural analysis

6.4.15.2.2.1 The effects of all dynamic and static loads are to be used to determine the suitability of the structure with respect to:

.1 plastic deformation;

.2 buckling;

.3 fatigue failure; and

.4 crack propagation.

Finite element analysis or similar methods and fracture mechanics analysis or an equivalent approach, is to be carried out.

6.4.15.2.2.2 A three-dimensional analysis is to be carried out to evaluate the stress levels, including interaction with the ship's hull. The model for this analysis is to include the liquefied gas fuel tank with its supporting and keying system, as well as a reasonable part of the hull.

6.4.15.2.2.3 A complete analysis of the particular ship accelerations and motions in irregular waves, and of the response of the ship and its liquefied gas fuel tanks to these forces and motions is to be performed unless the data is available from similar ships.

6.4.15.2.3 Ultimate design condition

6.4.15.2.3.1 Plastic deformation

For type B independent tanks, primarily constructed of bodies of revolution, the allowable stresses are not to exceed:

σ_m	$\leq f$
σ_L	$\leq 1.5f$
σ_b	$\leq 1.5F$
$\sigma_L+\sigma_b$	$\leq 1.5F$
$\sigma_m+\sigma_b$	$\leq 1.5F$
$\sigma_m+\sigma_b+\sigma_g$	$\leq 3.0F$
$\sigma_L+\sigma_b+\sigma_g$	$\leq 3.0F$

where:

σ_m = equivalent primary general membrane stress;

σ_L = equivalent primary local membrane stress;

σ_b = equivalent primary bending stress;

σ_g = equivalent secondary stress;

f = the lesser of (R_m / A) or (R_e / B); and

F = the lesser of (R_m / C) or (R_e / D),

with R_m and R_e as defined in 6.4.12.1.1.3. With regard to the stresses σ_m, σ_L, σ_g and σ_b see

also the definition of stress categories in 6.4.15.2.3.6.

The values A and B are to have at least the following minimum values:

	Nickel steels and carbon manganese steel	**Austenitic steel**	**Aluminium alloys**
A	3	3.5	4
B	2	1.6	1.5
C	3	3	3
D	1.5	1.5	1.5

The above figures may be altered considering the design condition considered in acceptance with the IRS/Administration. For type B independent tanks, primarily constructed of plane surfaces, the allowable membrane equivalent stresses applied for finite element analysis is not to exceed:

.1 for nickel steels and carbon-manganese steels, the lesser of R_m /2 or R_e /1.2;

.2 for austenitic steels, the lesser of R_m /2.5 or R_e /1.2; and

.3 for aluminium alloys, the lesser of R_m /2.5 or R_e /1.2.

The above figures may be amended considering the locality of the stress, stress analysis methods and design condition considered in acceptance with the IRS/Administration.

The thickness of the skin plate and the size of the stiffener shall not be less than those required for type A independent tanks.

6.4.15.2.3.2 Buckling

.1 Buckling strength analyses of liquefied gas fuel tanks subject to external pressure and other loads causing compressive stresses is to be carried out in accordance with recognized standards. The method is to adequately account for the difference in theoretical and actual buckling stress as a result of plate edge misalignment, lack of straightness or flatness, ovality and deviation from true circular form over a specified arc or chord length, as applicable.

6.4.15.2.3.3 Fatigue design condition

6.4.15.2.3.3.1 Fatigue and crack propagation assessment is to be performed in accordance with the provisions of 6.4.12.2. The acceptance criteria shall comply with 6.4.12.2.7, 6.4.12.2.8 or 6.4.12.2.9, depending on the detectability of the defect.

6.4.15.2.3.3.2 Fatigue analysis is to consider construction tolerances.

6.4.15.2.3.3.3 Where deemed necessary by the IRS/Administration, model tests may be required to determine stress concentration factors and fatigue life of structural elements.

6.4.15.2.3.4 Accidental design condition

6.4.15.2.3.4.1 The tanks and the tank supports are to be designed for the accidental loads and design conditions specified in 6.4.9.5 and 6.4.1.6.3, as relevant.

6.4.15.2.3.4.2 When subjected to the accidental loads specified in 6.4.9.5, the stress shall comply with the acceptance criteria specified in 6.4.15.2.3, modified as appropriate, taking into account their lower probability of occurrence.

6.4.15.2.3.5 Marking

.1 Any marking of the pressure vessel is to be achieved by a method that does not cause unacceptable local stress raisers.

6.4.15.2.3.6 Stress categories

For the purpose of stress evaluation, stress categories are defined in this section as follows:

.1 Normal stress is the component of stress normal to the plane of reference.

.2 Membrane stress is the component of normal stress that is uniformly distributed and equal to the average value of the stress across the thickness of the section under consideration.

.3 Bending stress is the variable stress across the thickness of the section

under consideration, after the subtraction of the membrane stress.

.4 Shear stress is the component of the stress acting in the plane of reference.

.5 Primary stress is a stress produced by the imposed loading, which is necessary to balance the external forces and moments. The basic characteristic of a primary stress is that it is not self-limiting. Primary stresses that considerably exceed the yield strength will result in failure or at least in gross deformations.

.6 Primary general membrane stress is a primary membrane stress that is so distributed in the structure that no redistribution of load occurs as a result of yielding.

.7 Primary local membrane stress arises where a membrane stress produced by pressure or other mechanical loading and associated with a primary or a discontinuity effect produces excessive distortion in the transfer of loads for other portions of the structure. Such a stress is classified as a primary local membrane stress, although it has some characteristics of a secondary stress. A stress region may be considered as local, if:

$S_1 \leq 0.5\sqrt{Rt}$; and

$S_1 \geq 2.5\sqrt{Rt}$

where:

S_1 = distance in the meridional direction over which the equivalent stress exceeds $1.1f$;

S_2 = distance in the meridional direction to another region where the limits for primary general membrane stress are exceeded;

R = mean radius of the vessel;

t = wall thickness of the vessel at the location where the primary general membrane stress limit is exceeded; and

f = allowable primary general membrane stress.

.8 *Secondary stress* is a normal stress or shear stress developed by constraints of adjacent parts or by self-constraint of a structure. The basic characteristic of a secondary stress is that it is self-limiting. Local yielding and minor distortions can satisfy the conditions that cause the stress to occur.

6.4.15.3 Type C independent tanks

6.4.15.3.1 Design basis

6.4.15.3.1.1 The design basis for type C independent tanks is based on pressure vessel criteria modified to include fracture mechanics and crack propagation criteria. The minimum design pressure defined in 6.4.15.3.1.2 is intended to ensure that the dynamic stress is sufficiently low so that an initial surface flaw will not propagate more than half the thickness of the shell during the lifetime of the tank.

6.4.15.3.1.2 The design vapour pressure is not to be less than:

$$P_0 = 0.2 + AC(\rho_r)^{1.5} \text{ [MPa]}$$

where:

$$A = 0.00185\left(\frac{\sigma_m}{\Delta\sigma_A}\right)^2$$

with:

σ_m = design primary membrane stress;
$\Delta\sigma_A$ = allowable dynamic membrane stress (double amplitude at probability level Q = 10^{-8}) and equal to:

- 55 [N/mm^2] for ferritic-perlitic, martensitic and austenitic steel;

- 25 [N/mm^2] for aluminium alloy (5083-O);

C = a characteristic tank dimension to be taken as the greatest of the following:

h, 0.75*b* or 0.*45ℓ,*

with:

h = height of tank (dimension in ship's vertical direction) (m);

b = width of tank (dimension in ship's transverse direction) (m);

ℓ = length of tank (dimension in ship's longitudinal direction) (m);

ρ_r = the relative density of the cargo (ρ_r = 1 for fresh water) at the design temperature.

6.4.15.3.2 Shell thickness

6.4.15.3.2.1 In considering the shell thickness the following apply:

.1 for pressure vessels, the thickness calculated according to 6.4.15.3.2.4 is to be considered as a minimum thickness after forming, without any negative tolerance;

.2 for pressure vessels, the minimum thickness of shell and heads including corrosion allowance, after forming, shall not be less than 5 [mm] for carbon manganese steels and nickel steels, 3 [mm] for austenitic steels or 7 [mm] for aluminium alloys; and

.3 the welded joint efficiency factor to be used in the calculation according to 6.4.15.3.2.4 is to be 0.95 when the inspection and the non-destructive testing referred to in 16.3.6.4 are carried out. This figure may be increased up to 1 when account is taken of other considerations, such as the material used, type of joints, welding procedure and type of loading. For process pressure vessels IRS/Administration may accept partial non-destructive examinations, but not less than those of 16.3.6.4, depending on such factors as the material used, the design temperature, the nil ductility transition temperature of the material as fabricated and the type of joint and welding procedure, but in this case an efficiency factor of not more than 0.85 is to be adopted. For special materials the above-mentioned factors is to be reduced, depending on the specified mechanical properties of the welded joint.

6.4.15.3.2.2 The design liquid pressure defined in 6.4.9.3.3.1 is to be taken into account in the internal pressure calculations.

6.4.15.3.2.3 The design external pressure P_e, used for verifying the buckling of the pressure vessels, is not to be less than that given by:

$$P_e = P_1+P_2+P_3+P_4 \text{ [MPa]}$$

where:

P_1 = setting value of vacuum relief valves. For vessels not fitted with vacuum relief valves P_1 is to be specially considered, but shall not in general be taken as less than 0.025 [MPa].

P_2 = the set pressure of the pressure relief valves (PRVs) for completely closed spaces containing pressure vessels or parts of pressure vessels; elsewhere P_2 = 0.

P_3 = compressive actions in or on the shell due to the weight and contraction of thermal insulation, weight of shell including corrosion allowance and other miscellaneous external pressure loads to which the pressure vessel may be subjected. These include, but are not limited to, weight of domes, weight of towers and piping, effect of product in the partially filled condition, accelerations and hull deflection. In addition, the local effect of external or internal pressures or both is to be taken into account.

P_4 = external pressure due to head of water for pressure vessels or part of pressure vessels on exposed decks; elsewhere P_4 = 0.

6.4.15.3.2.4 Scantlings based on internal pressure are to be calculated as follows:

The thickness and form of pressure-containing parts of pressure vessels, under internal pressure, as defined in 6.4.9.3.3.1, including flanges, is to be determined. These calculations shall in all cases be based on accepted pressure vessel design theory. Openings in pressure-containing parts of pressure vessels are to be reinforced in accordance with a recognized standard acceptable to IRS/Administration.

6.4.15.3.2.5 Stress analysis in respect of static and dynamic loads is to be performed as follows:

.1 pressure vessel scantlings are to be determined in accordance with 6.4.15.3.2.1 to 6.4.15.3.2.4 and 6.4.15.3.3;

.2 calculations of the loads and stresses in way of the supports and the shell attachment of the support are to be made. Loads referred to in 6.4.9.2 to 6.4.9.5 are to be used, as applicable. Stresses in way of the supports are to be to a recognized standard acceptable to the Administration. In special cases a fatigue analysis may be required by the Administration; and

.3 if required by IRS/Administration, secondary stresses and thermal stresses is to be specially considered.

6.4.15.3.3 Ultimate design condition

6.4.15.3.3.1 Plastic deformation

For type C independent tanks, the allowable stresses are not to exceed:

$\sigma_m \leq f$
$\sigma_L \leq 1.5f$
$\sigma_b \leq 1.5f$
$\sigma_L+\sigma_b \leq 1.5f$
$\sigma_m+\sigma_b \leq 1.5f$
$\sigma_m+\sigma_b+\sigma_g \leq 3.0f$
$\sigma_L+\sigma_b+\sigma_g \leq 3.0f$

where:

σ_m = equivalent primary general membrane stress;

σ_L = equivalent primary local membrane stress;

σ_b = equivalent primary bending stress;

σ_g = equivalent secondary stress; and

f = the lesser of R_m /A or R_e /B,

with R_m and R_e as defined in 6.4.12.1.1.3. With regard to the stresses σ_m, σ_L, σ_g and σ_b see also the definition of stress categories in 6.4.15.2.3.6. The values A and B are to have at least the following minimum values:

	Nickel steels and carbon-manganese steel	**Austenitic steel**	**Aluminium alloys**
A	3	3.5	4
B	1.5	1.5	1.5

6.4.15.3.3.2 Buckling criteria is to be as follows:

.1 The thickness and form of pressure vessels subject to external pressure and other loads causing compressive stresses is to be based on calculations using accepted pressure vessel buckling theory and is to adequately account for the difference in theoretical and actual buckling stress as a result of plate edge misalignment, ovality and deviation from true circular form over a specified arc or chord length.

6.4.15.3.4 Fatigue design condition

6.4.15.3.4.1 For type C independent tanks where the liquefied gas fuel at atmospheric pressure is below minus 55[°C], IRS/Administration may require additional verification to check their compliance with 6.4.15.3.1.1, regarding static and dynamic stress depending on the tank size, the configuration of the tank and arrangement of its supports and attachments.

6.4.15.3.4.2 For vacuum insulated tanks, special attention is to be made to the fatigue strength of the support design and special considerations is also to be made to the limited inspection possibilities between the inside and outer shell.

6.4.15.3.5 Accidental design condition

6.4.15.3.5.1 The tanks and the tank supports are to be designed for the accidental loads and design conditions specified in 6.4.9.5 and 6.4.1.6.3, as relevant.

6.4.15.3.5.2 When subjected to the accidental loads specified in 6.4.9.5, the stress is to comply with the acceptance criteria specified in 6.4.15.3.3.1, modified as appropriate taking into account their lower probability of occurrence.

6.4.15.3.6 Marking

The required marking of the pressure vessel is to be achieved by a method that does not cause unacceptable local stress raisers.

6.4.15.4 Membrane tanks

6.4.15.4.1 Design basis

6.4.15.4.1.1 The design basis for membrane containment systems is that thermal and other expansion or contraction is compensated for without undue risk of losing the tightness of the membrane.

6.4.15.4.1.2 A systematic approach, based on analysis and testing, is to be used to demonstrate that the system will provide its intended function in consideration of the identified in service events as specified in 6.4.15.4.2.1.

6.4.15.4.1.3 A complete secondary barrier is required as defined in 6.4.3. The secondary barrier is to be designed according to 6.4.4.

6.4.15.4.1.4 The design vapour pressure P_0 is not normally exceed 0.025 [MPa]. If the hull scantlings are increased accordingly and consideration is given, where appropriate, to the strength of the supporting thermal insulation, P_0 may be increased to a higher value but less than 0.070 [MPa].

6.4.15.4.1.5 The definition of membrane tanks does not exclude designs such as those in which non-metallic membranes are used or where membranes are included or incorporated into the thermal insulation.

6.4.15.4.1.6 The thickness of the membranes is normally not exceed 10 [mm].

6.4.15.4.1.7 The circulation of inert gas throughout the primary and the secondary insulation spaces, in accordance with 6.11.1 is to be sufficient to allow for effective means of gas detection.

6.4.15.4.2 Design considerations

6.4.15.4.2.1 Potential incidents that could lead to loss of fluid tightness over the life of the membranes are to be evaluated. These include, but are not limited to:

.1 Ultimate design events:

.1 tensile failure of membranes;

.2 compressive collapse of thermal insulation;

.3 thermal ageing;

.4 loss of attachment between thermal insulation and hull structure;

.5 loss of attachment of membranes to thermal insulation system;

.6 structural integrity of internal structures and their associated supporting structures; and

.7 failure of the supporting hull structure.

.2 Fatigue design events:

.1 fatigue of membranes including joints and attachments to hull structure;

.2 fatigue cracking of thermal insulation;

.3 fatigue of internal structures and their associated supporting structures; and

.4 fatigue cracking of inner hull leading to ballast water ingress.

.3 Accident design events:

.1 accidental mechanical damage (such as dropped objects inside the tank while in service);

.2 accidental over pressurization of thermal insulation spaces;

.3 accidental vacuum in the tank; and

.4 water ingress through the inner hull structure.

Designs where a single internal event could cause simultaneous or cascading failure of both membranes are unacceptable.

6.4.15.4.2.2 The necessary physical properties (mechanical, thermal, chemical, etc.) of the materials used in the construction of the liquefied gas fuel containment system is to be established during the design development in accordance with 6.4.15.4.1.2.

6.4.15.4.3 Loads, load combinations

Particular consideration is to be paid to the possible loss of tank integrity due to either an overpressure in the interbarrier space, a possible vacuum in the liquefied gas fuel tank, the sloshing effects, to hull vibration effects, or any combination of these events.

6.4.15.4.4 Structural analyses

6.4.15.4.4.1 Structural analyses and/or testing for the purpose of determining the ultimate strength and fatigue assessments of the liquefied gas fuel containment and associated structures and equipment noted in 6.4.7 is to be performed. The structural analysis shall provide the data required to assess each failure mode that has been identified as critical for the liquefied gas fuel containment system.

6.4.15.4.4.2 Structural analyses of the hull shall take into account the internal pressure as indicated in 6.4.9.3.3.1. Special attention is to be paid to deflections of the hull and their compatibility with the membrane and associated thermal insulation.

6.4.15.4.4.3 The analyses referred to in 6.4.15.4.4.1 and 6.4.15.4.4.2 is to be based on the particular motions, accelerations and response of ships and liquefied gas fuel containment systems.

6.4.15.4.5 Ultimate design condition

6.4.15.4.5.1 The structural resistance of every critical component, sub-system, or assembly, is to be established, in accordance with 6.4.15.4.1.2, for in-service conditions.

6.4.15.4.5.2 The choice of strength acceptance criteria for the failure modes of the liquefied gas fuel containment system, its attachments to the hull structure and internal tank structures, are to reflect the consequences associated with the considered mode of failure.

6.4.15.4.5.3 The inner hull scantlings are to meet the requirements for deep tanks, taking into account the internal pressure as indicated in 6.4.9.3.3.1 and the specified appropriate requirements for sloshing load as defined in 6.4.9.4.1.3.

6.4.15.4.6 Fatigue design condition

6.4.15.4.6.1 Fatigue analysis is to be carried out for structures inside the tank, i.e. pump towers, and for parts of membrane and pump tower attachments, where failure development cannot be reliably detected by continuous monitoring.

6.4.15.4.6.2 The fatigue calculations are to be carried out in accordance with 6.4.12.2, with relevant requirements depending on:

.1 the significance of the structural components with respect to structural integrity; and

.2 availability for inspection.

6.4.15.4.6.3 For structural elements for which it can be demonstrated by tests and/or analyses that a crack will not develop to cause simultaneous or cascading failure of both membranes, *Cw* is to be less than or equal to 0.5.

6.4.15.4.6.4 Structural elements subject to periodic inspection, and where an unattended fatigue crack can develop to cause simultaneous or cascading failure of both membranes, shall satisfy the fatigue and fracture mechanics requirements stated in 6.4.12.2.8.

6.4.15.4.6.5 Structural element not accessible for in-service inspection, and where a fatigue crack can develop without warning to cause simultaneous or cascading failure of both membranes, is to satisfy the fatigue and fracture mechanics requirements stated in 6.4.12.2.9.

6.4.15.4.7 Accidental design condition

6.4.15.4.7.1 The containment system and the supporting hull structure are to be designed for the accidental loads specified in 6.4.9.5. These loads need not be combined with each other or with environmental loads.

6.4.15.4.7.2 Additional relevant accidental scenarios are to be determined based on a

risk analysis. Particular attention is to be paid to securing devices inside of tanks.

6.4.16 Limit state design for novel concepts

6.4.16.1 Fuel containment systems that are of a novel configuration that cannot be designed using section 6.4.15 is to be designed using this section and 6.4.1 to 6.4.14, as applicable. Fuel containment system design according to this section is to be based on the principles of limit state design which is an approach to structural design that can be applied to established design solutions as well as novel designs. This more generic approach maintains a level of safety similar to that achieved for known containment systems as designed using 6.4.15.

6.4.16.2.1 The limit state design is a systematic approach where each structural element is evaluated with respect to possible failure modes related to the design conditions identified in 6.4.1.6. A limit state can be defined as a condition beyond which the structure, or part of a structure, no longer satisfies the requirements.

6.4.16.2.2 For each failure mode, one or more limit states may be relevant. By consideration of all relevant limit states, the limit load for the structural element is found as the minimum limit load resulting from all the relevant limit states. The limit states are divided into the three following categories:

.1 Ultimate limit states (ULS), which correspond to the maximum load-carrying capacity or, in some cases, to the maximum applicable strain or deformation; under intact (undamaged) conditions.

.2 Fatigue limit states (FLS), which correspond to degradation due to the effect of time varying (cyclic) loading.

.3 Accident limit states (ALS), which concern the ability of the structure to resist accidental situations.

6.4.16.3 The procedure and relevant design parameters of the limit state design are to comply with the Standards for the Use of limit state methodologies in the design of fuel containment systems of novel configuration (LSD Standard), as set out in the Annex 1.

6.5 Portable liquefied gas fuel tanks

6.5.1 The design of the tank is to comply with 6.4.15.3. The tank support (container frame or truck chassis) is to be designed for the intended purpose.

6.5.2 Portable fuel tanks are to be located in dedicated areas fitted with:

.1 mechanical protection of the tanks depending on location and cargo operations;

.2 if located on open deck: spill protection and water spray systems for cooling; and

.3 if located in an enclosed space: the space is to be considered as a tank connection space.

6.5.3 Portable fuel tanks are to be secured to the deck while connected to the ship systems. The arrangement for supporting and fixing the tanks is to be designed for the maximum expected static and dynamic inclinations, as well as the maximum expected values of acceleration, taking into account the ship characteristics and the position of the tanks.

6.5.4 Consideration is to be given to the strength and the effect of the portable fuel tanks on the ship's stability.

6.5.5 Connections to the ship's fuel piping systems are to be made by means of approved flexible hoses or other suitable means designed to provide sufficient flexibility.

6.5.6 Arrangements are to be provided to limit the quantity of fuel spilled in case of inadvertent disconnection or rupture of the non-permanent connections.

6.5.7 The pressure relief system of portable tanks is to be connected to a fixed venting system.

6.5.8 Control and monitoring systems for portable fuel tanks is to be integrated in the ship's control and monitoring system. Safety system for portable fuel tanks is to be integrated in the ship's safety system (e.g. shutdown systems for tank valves, leak/gas detection systems).

6.5.9 Safe access to tank connections for the purpose of inspection and maintenance is to be ensured.

6.5.10 After connection to the ship's fuel piping system,

.1 with the exception of the pressure relief system in 6.5.6 each portable tank is to be capable of being isolated at any time;

.2 isolation of one tank shall not impair the availability of the remaining portable tanks; and

.3 the tank shall not exceed its filling limits as given in 6.8.

6.6 CNG fuel containment

6.6.1 The storage tanks to be used for CNG are to be certified and approved by IRS/Administration.

6.6.2 Tanks for CNG are to be fitted with pressure relief valves with a set point below the design pressure of the tank and with outlet located as required in 6.7.2.7 and 6.7.2.8.

6.6.3 Adequate means is to be provided to depressurize the tank in case of a fire which can affect the tank.

6.6.4 Storage of CNG in enclosed spaces is normally not acceptable, but may be permitted after special consideration and approval by Administration/ IRS provided the following is fulfilled in addition to 6.3.4 to 6.3.6:

.1 adequate means are provided to depressurize and inert the tank in case of a fire which can affect the tank;

.2 all surfaces within such enclosed spaces containing the CNG storage are provided with suitable thermal protection against any lost high-pressure gas and resulting condensation unless the bulkheads are designed for the lowest temperature that can arise from gas expansion leakage; and

.3 a fixed fire-extinguishing system is installed in the enclosed spaces containing the CNG storage. Special consideration should be given to the extinguishing of jet-fires.

6.7 Pressure relief system

6.7.1 General

6.7.1.1 All fuel storage tanks are to be provided with a pressure relief system appropriate to the design of the fuel containment system and the fuel being carried. Fuel storage hold spaces, interbarrier spaces and tank connection spaces , which may be subject to pressures beyond their design capabilities, are also be provided with a suitable pressure relief system. Pressure control systems specified in 6.9 are to be independent of the pressure relief systems.

6.7.1.2 Fuel storage tanks which may be subject to external pressures above their design pressure is to be fitted with vacuum protection systems.

6.7.2 Pressure relief systems for liquefied gas fuel tanks

6.7.2.1 If fuel release into the vacuum space of a vacuum insulated tank cannot be excluded, the vacuum space is to be protected by a pressure relief device which is to be connected to a vent system if the tanks are located below deck. On open deck a direct release into the atmosphere may be accepted by IRS/Administration for tanks not exceeding the size of a 40 ft container if the released gas cannot enter safe areas.

6.7.2.2 Liquefied gas fuel tanks is to be fitted with a minimum of 2 pressure relief valves (PRVs) allowing for disconnection of one PRV in case of malfunction or leakage.

6.7.2.3 Interbarrier spaces are to be provided with pressure relief devices*. For membrane systems, the designer is to demonstrate adequate sizing of interbarrier space PRVs.

Note:

** Refer to Pt 5, Ch 4, IR 8.5*

6.7.2.4 The setting of the PRVs is not to be higher than the vapour pressure that has been used in the design of the tank. Valves comprising not more than 50% of the total relieving capacity may be set at a pressure up to 5% above MARVS to allow sequential lifting, minimizing unnecessary release of vapour.

6.7.2.5 The following temperature requirements apply to PRVs fitted to pressure relief systems:

.1 PRVs on fuel tanks with a design temperature below 0[^{o}C] is to be designed and arranged to prevent their becoming inoperative due to ice formation;

.2 the effects of ice formation due to ambient temperatures is to be considered in the construction and arrangement of PRVs;

.3 PRVs is to be constructed of materials with a melting point above 925[°C]. Lower melting point materials for internal parts and seals may be accepted provided that fail-safe operation of the PRV is not compromised; and

.4 sensing and exhaust lines on pilot operated relief valves are to be of suitably robust construction to prevent damage.

6.7.2.6 In the event of a failure of a fuel tank PRV a safe means of emergency isolation is to be available.

.1 procedures is to be provided and included in the operation manual (refer to Section 18);

.2 the procedures are to allow only one of the installed PRVs for the liquefied gas fuel tanks to be isolated, physical interlocks is to be included to this effect; and

.3 isolation of the PRV is to be carried out under the supervision of the master. This action is to be recorded in the ship's log, and at the PRV.

6.7.2.7 Each pressure relief valve installed on a liquefied gas fuel tank is to be connected to a venting system, which is to be:

.1 so constructed that the discharge will be unimpeded and normally be directed vertically upwards at the exit;

.2 arranged to minimize the possibility of water or snow entering the vent system; and

.3 arranged such that the height of vent exits is normally not be less than B/3 or 6 [m], whichever is the greater, above the weather deck and 6 [m] above working areas and walkways. However, vent mast height could be limited to lower value according to special consideration by IRS/Administration.

6.7.2.8 The outlet from the pressure relief valves is normally to be located at least 10 [m] from the nearest:

.1 air intake, air outlet or opening to accommodation, service and control spaces, or other non-hazardous area; and

.2 exhaust outlet from machinery installations.

6.7.2.9 All other fuel gas vent outlets are also to be arranged in accordance with 6.7.2.7 and 6.7.2.8. Means is to be provided to prevent liquid overflow from gas vent outlets, due to hydrostatic pressure from spaces to which they are connected.

6.7.2.10 In the vent piping system, means for draining liquid from places where it may accumulate is to be provided. The PRVs and piping is to be arranged so that liquid can, under no circumstances, accumulate in or near the PRVs.

6.7.2.11 Suitable protection screens of not more than 13 [mm] square mesh is to be fitted on vent outlets to prevent the ingress of foreign objects without adversely affecting the flow.

6.7.2.12 All vent piping is to be designed and arranged not to be damaged by the temperature variations to which it may be exposed, forces due to flow or the ship's motions.

6.7.2.13 PRVs is to be connected to the highest part of the fuel tank. PRVs is to be positioned on the fuel tank so that they will remain in the vapour phase at the filling limit (FL) as given in 6.8, under conditions of 15° list and 0.015L trim, where L is defined in 2.2.25.

6.7.3 Sizing of pressure relieving system

6.7.3.1 Sizing of pressure relief valves

6.7.3.1.1 PRVs are to have a combined relieving capacity for each liquefied gas fuel tank to discharge the greater of the following,

with not more than a 20% rise in liquefied gas fuel tank pressure above the MARVS:

1 the maximum capacity of the liquefied gas fuel tank inerting system if the maximum attainable working pressure of the liquefied gas fuel tank inerting system exceeds the MARVS of the liquefied gas fuel tanks; or

.2 vapours generated under fire exposure computed using the following formula:

$$Q=FGA^{0.82}\ [m^3/s]$$

where:

Q = minimum required rate of discharge of air at standard conditions of 273.15 Kelvin (K) and 0.1013 [MPa].

F = fire exposure factor for different liquefied gas fuel types:

F = 1.0 for tanks without insulation located on deck;
F = 0.5 for tanks above the deck when insulation is approved by the IRS/Administration. (Approval will be based on the use of a fireproofing material, the thermal conductance of insulation, and its stability under fire exposure);

F = 0.5 for uninsulated independent tanks installed in holds;

F = 0.2 for insulated independent tanks in holds (or uninsulated independent tanks in insulated holds);

F = 0.1 for insulated independent tanks in inerted holds (or uninsulated independent tanks in inerted, insulated holds); and

F = 0.1 for membrane tanks.

For independent tanks partly protruding through the weather decks, the fire exposure factor is to be determined on the basis of the surface areas above and below deck.

G = gas factor according to formula:

$$G=\frac{12.4}{LD}\sqrt{\frac{ZT}{M}}$$

where:

T = temperature in Kelvin at relieving conditions, i.e. 120% of the pressure at which the pressure relief valve is set;

L = latent heat of the material being vaporized at relieving conditions, in kJ/kg;

D = a constant based on relation of specific heats *k* and is calculated as follows:

$$D=\sqrt{k\left(\frac{2}{k+1}\right)^{\frac{k+1}{k-1}}}$$

where:

k = ratio of specific heats at relieving conditions, and the value of which is between 1.0 and 2.2. If *k* is not known, *D* = 0.606 is to be used;

Z = compressibility factor of the gas at relieving conditions; if not known, *Z* = 1.0 is to be used;

M = molecular mass of the product.

The gas factor of each liquefied gas fuel to be carried is to be determined and the highest value is to be used for PRV sizing.

A = external surface area of the tank (m^2).Indicative examples of different tank types are given in Fig.6.7.1

IR 6.7.3.1.1.2 For Prismatic Tanks:

.1 L_{min} , for non-tapered tanks, is the smaller of the horizontal dimensions of the flat bottom of the tank. For tapered tanks,

as would be used for the forward tank, L_{min} is the smaller of the length and the average width.

.2 For prismatic tanks whose distance between the flat bottom of the tank and bottom of the hold space is equal to or less than $L_{min}/10$:

A=external surface area minus flat bottom surface area

.3 For prismatic tanks whose distance between the flat bottom of the tank and bottom of the hold space is greater than $L_{min}/10$:

A= external surface area.

6.7.3.1.2 For vacuum insulated tanks in fuel storage hold spaces and for tanks in fuel storage hold spaces separated from potential fire loads by coffer dams or surrounded by ship spaces with no fire load the following applies:

If the pressure relief valves have to be sized for fire loads the fire factors according may be reduced to the following values:

F = 0.5 to F = 0.25

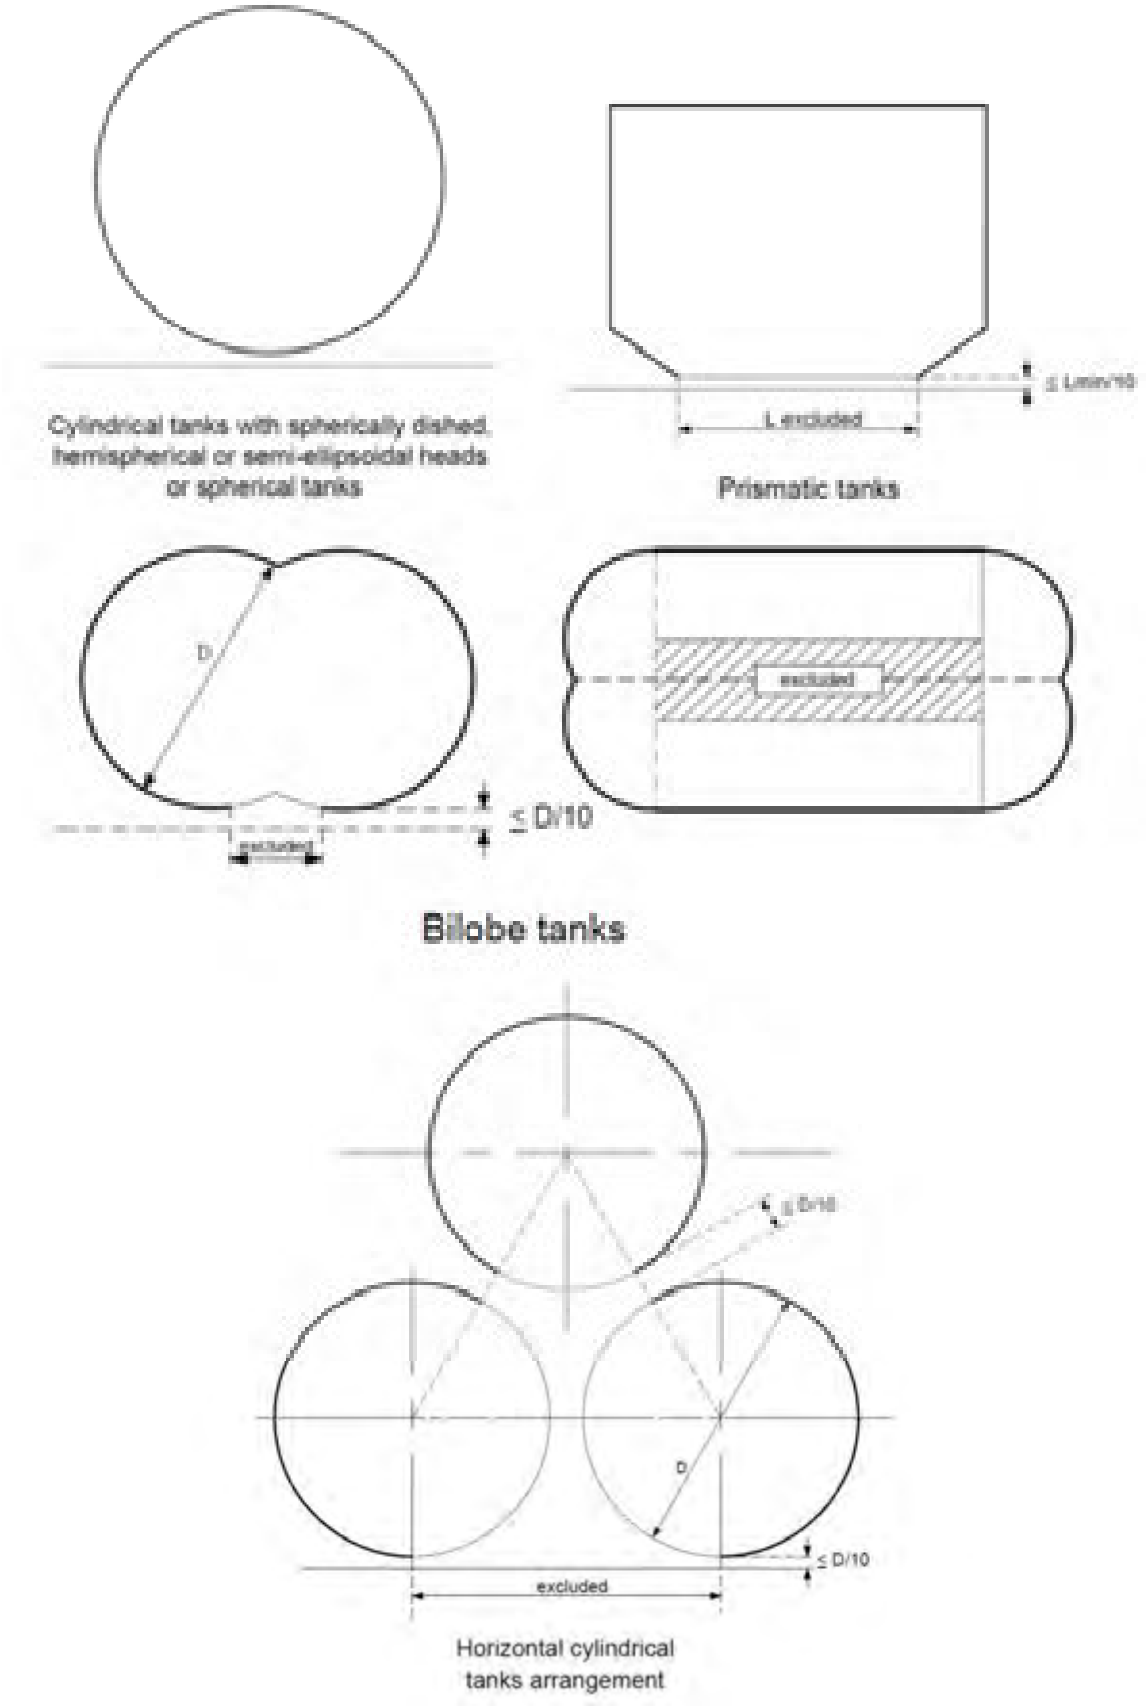
F = 0.2 to F = 0.1

The minimum fire factor is F= 0.1

6.7.3.1.3 The required mass flow of air at relieving conditions is given by:

$$M_{air} = Q\ \rho_{air} \text{ (kg/s)}$$

where density of air (ρ_{air}) = 1.293 [kg/m^3] (air at 273.15 [K], 0.1013 [MPa]).



Cylindrical tanks with spherically dished, hemispherical or semi-ellipsoidal heads or spherical tanks
L excluded

Fig.6.7.1

6.7.3.2 Sizing of vent pipe system

6.7.3.2.1 Pressure losses upstream and downstream of the PRVs, is to be taken into account when determining their size to ensure the flow capacity required by 6.7.3.1.

6.7.3.2.2 Upstream pressure losses

.1 the pressure drop in the vent line from the tank to the PRV inlet shall not exceed 3% of the valve set pressure at the calculated flow rate, in accordance with 6.7.3.1;

.2 pilot-operated PRVs is to be unaffected by inlet pipe pressure losses when the pilot senses directly from the tank dome; and

.3 pressure losses in remotely sensed pilot lines is to be considered for flowing type pilots.

6.7.3.2.3 Downstream pressure losses

.1 Where common vent headers and vent masts are fitted, calculations are to include flow from all attached PRVs.

.2 The built-up back pressure in the vent piping from the PRV outlet to the location of discharge to the atmosphere, and including any vent pipe interconnections that join other tanks, shall not exceed the following values:

.1	for unbalanced PRVs	10% of MARVS
.2	for balanced PRVs	30% of MARVS; and
.3	for pilot operated PRVs	50% of MARVS.

Alternative values provided by the PRV manufacturer may be accepted.

6.7.3.2.4 To ensure stable PRV operation, the blow-down is not to be less than the sum of the inlet pressure loss and 0.02 MARVS at the rated capacity.

6.8 Loading limit for liquefied gas fuel tanks

6.8.1 Storage tanks for liquefied gas are not to be filled to more than a volume equivalent to 98% full at the reference temperature as defined in 2.2.36.

A loading limit curve for actual fuel loading temperatures is to be prepared from the following formula:

$$LL = FL\ \rho_R/\rho_L$$

where:

LL = loading limit as defined in 2.2.27, expressed in per cent;

FL = filling limit as defined in 2.2.16 expressed in per cent, here 98%;

ρ_R = relative density of fuel at the reference temperature; and

ρ_L = relative density of fuel at the loading temperature.

6.8.2 In cases where the tank insulation and tank location make the probability very small for the tank contents to be heated up due to an external fire, special considerations may be made to allow a higher loading limit than calculated using the reference temperature, but never above 95%. This also applies in cases where a second system for pressure maintenance is installed, (refer to 6.9). However, if the pressure can only be maintained / controlled by fuel consumers, the loading limit as calculated in 6.8.1 is to be used.

IR 6.8.2 The alternative loading limit option given under 6.8.2 is understood to be an alternative to 6.8.1 and should only be applicable when the calculated loading limit using the formulae in 6.8.1 gives a lower value than 95%.

6.8.3 In lieu of 6.8.2, for ships constructed on or after 1 January 2024, in cases where the tank insulation and tank location make the probability very small for the tank contents to be heated up due to an external fire, special considerations may be made to allow a higher loading limit than calculated using the reference temperature, but never above 95%.

6.9 Maintenance of fuel storage condition

6.9.1 Control of tank pressure and temperature

6.9.1.1 With the exception of liquefied gas fuel tanks designed to withstand the full gauge vapour pressure of the fuel under conditions of the upper ambient design temperature, liquefied gas fuel tanks' pressure and temperature is to be maintained at all times within their design range by means acceptable to IRS/Administration, e.g. by one of the following methods:

.1 reliquefaction of vapours;

.2 thermal oxidation of vapours;

.3 pressure accumulation; or

.4 liquefied gas fuel cooling.

The method chosen is to be capable of maintaining tank pressure below the set pressure of the tank pressure relief valves for a period of 15 days assuming full tank at normal service pressure and the ship in idle condition, i.e. only power for domestic load is generated.

6.9.1.2 Venting of fuel vapour for control of the tank pressure is not acceptable except in emergency situations.

IR 6.9.1.3 Liquefied gas fuel tank’s pressure and temperature is to be controlled and maintained within the design range at all times including after activation of the safety system required in 15.2.2 for a period of minimum 15 days. The activation of the safety system alone is not deemed as an emergency situation.

6.9.2 Design of systems

6.9.2.1 For worldwide service, the upper ambient design temperature is to be sea 32[ºC] and air 45[ºC]. For service in particularly hot or cold zones, these design temperatures is to be increased or decreased, to the satisfaction of IRS/Administration.

6.9.2.2 The overall capacity of the system is to be such that it can control the pressure within the design conditions without venting to atmosphere.

6.9.3 Reliquefaction systems

6.9.3.1 The reliquefaction system is to be designed and calculated according to 6.9.3.2. The system has to be sized in a sufficient way also in case of no or low consumption.

6.9.3.2 The reliquefaction system is to be arranged in one of the following ways:

.1 a direct system where evaporated fuel is compressed, condensed and returned to the fuel tanks;

.2 an indirect system where fuel or evaporated fuel is cooled or condensed by refrigerant without being compressed;

.3 a combined system where evaporated fuel is compressed and condensed in a fuel/refrigerant heat exchanger and returned to the fuel tanks; or

.4 if the reliquefaction system produces a waste stream containing methane during pressure control operations within the design conditions, these waste gases shall, as far as reasonably practicable, be disposed of without venting to atmosphere.

6.9.4 Thermal oxidation systems

6.9.4.1 Thermal oxidation can be done by either consumption of the vapours according to the requirements for consumers described in this Chapter or in a dedicated gas combustion unit (GCU). It is to be demonstrated that the capacity of the oxidation system is sufficient to consume the required quantity of vapours. In this regard, periods of slow steaming and/or no consumption from propulsion or other services of the ship is to be considered.

6.9.5 Compatibility

6.9.5.1 Refrigerants or auxiliary agents used for refrigeration or cooling of fuel is to be compatible with the fuel they may come in contact with (not causing any hazardous reaction or excessively corrosive products). In addition, when several refrigerants or agents are used, these is to be compatible with each other.

6.9.6 Availability of systems

6.9.6.1 The availability of the system and its supporting auxiliary services is to be such that in case of a single failure (of mechanical non-static component or a component of the control systems) the fuel tank pressure and

temperature can be maintained by another service/system.

6.9.6.2 Heat exchangers that are solely necessary for maintaining the pressure and temperature of the fuel tanks within their design ranges shall have a standby heat exchanger unless they have a capacity in excess of 25% of the largest required capacity for pressure control and they can be repaired on board without external sources.

6.10 Atmospheric control within the fuel containment system

6.10.1 A piping system is to be arranged to enable each fuel tank to be safely gas-freed, and to be safely filled with fuel from a gas-free condition. The system is to be arranged to minimize the possibility of pockets of gas or air remaining after changing the atmosphere.

6.10.2 The system is to be designed to eliminate the possibility of a flammable mixture existing in the fuel tank during any part of the atmosphere change operation by utilizing an inerting medium as an intermediate step.

6.10.3 Gas sampling points is to be provided for each fuel tank to monitor the progress of atmosphere change.

6.10.4 Inert gas utilized for gas freeing of fuel tanks may be provided externally to the ship.

6.11 Atmosphere control within fuel storage hold spaces (Fuel containment systems other than type C independent tanks)

6.11.1 Interbarrier and fuel storage hold spaces associated with liquefied gas fuel containment systems requiring full or partial secondary barriers is to be inerted with a suitable dry inert gas and kept inerted with make-up gas provided by a shipboard inert gas generation system, or by shipboard storage, which is to be sufficient for normal consumption for at least 30 days. Shorter periods may be considered by IRS/Administration depending on the ship's service.

6.11.2 Alternatively, the spaces referred to in 6.11.1 requiring only a partial secondary barrier may be filled with dry air provided that the ship maintains a stored charge of inert gas or is fitted with an inert gas generation system sufficient to inert the largest of these spaces, and provided that the configuration of the spaces and the relevant vapour detection systems, together with the capability of the inerting arrangements, ensures that any leakage from the liquefied gas fuel tanks will be rapidly detected and inerting effected before a dangerous condition can develop. Equipment for the provision of sufficient dry air of suitable quality to satisfy the expected demand is to be provided.

6.12 Environmental control of spaces surrounding type C independent tanks

6.12.1 Spaces surrounding liquefied gas fuel tanks is to be filled with suitable dry air and be maintained in this condition with dry air provided by suitable air drying equipment. This is only applicable for liquefied gas fuel tanks where condensation and icing due to cold surfaces is an issue.

6.13 Inerting

6.13.1 Arrangements to prevent back-flow of fuel vapour into the inert gas system are to be provided as specified below.

6.13.2 To prevent the return of flammable gas to any non-hazardous spaces, the inert gas supply line is to be fitted with two shutoff valves in series with a venting valve in between (double block and bleed valves). In addition, a closable non-return valve is to be installed between the double block and bleed arrangement and the fuel system. These valves are to be located outside non-hazardous spaces.

6.13.3 Where the connections to the fuel piping systems are non-permanent, two non-return valves may be substituted for the valves required in 6.13.2.

6.13.4 The arrangements are to be such that each space being inerted can be isolated and the necessary controls and relief valves, etc. is to be provided for controlling pressure in these spaces.

6.13.5 Where insulation spaces are continually supplied with an inert gas as part of a leak detection system, means is to be provided to monitor the quantity of gas being supplied to individual spaces.

6.14 Inert gas production and storage on board

6.14.1 The equipment is to be capable of producing inert gas with oxygen content at no time greater than 5% by volume. A continuous-reading oxygen content meter is to be fitted to the inert gas supply from the equipment and is to be fitted with an alarm set at a maximum of 5% oxygen content by volume.

6.14.2 An inert gas system is to have pressure controls and monitoring arrangements appropriate to the fuel containment system.

6.14.3 Where a nitrogen generator or nitrogen storage facilities are installed in a separate compartment outside of the engine-room, the separate compartment is to be fitted with an independent mechanical extraction ventilation system, providing a minimum of 6 air changes per hour. A low oxygen alarm is to be fitted.

6.14.4 Nitrogen pipes are only to be led through well ventilated spaces. Nitrogen pipes in enclosed spaces shall:

- be fully welded;

- have only a minimum of flange connections as needed for fitting of valves; and

- be as short as possible.

Section 7

Material and General Pipe Design

7.1 Goal

7.1.1 The goal of this section is to ensure the safe handling of fuel, under all operating conditions, to minimize the risk to the ship, personnel and to the environment, having regard to the nature of the products involved.

7.2 Functional requirements

7.2.1 This section relates to functional requirements in 3.2.1, 3.2.5, 3.2.6, 3.2.8, 3.2.9 and 3.2.10. In particular the following apply:

7.2.1.1 Fuel piping is to be capable of absorbing thermal expansion or contraction caused by extreme temperatures of the fuel without developing substantial stresses.

7.2.1.2 Provision is to be made to protect the piping, piping system and components and fuel tanks from excessive stresses due to thermal movement and from movements of the fuel tank and hull structure.

7.2.1.3 If the fuel gas contains heavier constituents that may condense in the system, means for safely removing the liquid is to be fitted.

7.2.1.4 Low temperature piping is to be thermally isolated from the adjacent hull structure, where necessary, to prevent the temperature of the hull from falling below the design temperature of the hull material.

7.3 General pipe design

7.3.1 General

7.3.1.1 Fuel pipes and all the other piping needed for a safe and reliable operation and maintenance is to be colour marked in accordance with a standard at least equivalent to those acceptable to the IMO*.

Note :

** Refer to EN ISO 14726:2008 Ships and marine technology – identification colours for the content of piping systems*

7.3.1.2 Where tanks or piping are separated from the ship's structure by thermal isolation, provision is to be made for electrically bonding to the ship's structure both the piping and the tanks. All gasketed pipe joints and hose connections is to be electrically bonded.

7.3.1.3 All pipelines or components which may be isolated in a liquid full condition are to be provided with relief valves.

7.3.1.4 Pipework, which may contain low temperature fuel, is to be thermally insulated

to an extent which will minimize condensation of moisture.

7.3.1.5 Piping other than fuel supply piping and cabling may be arranged in the double wall piping or duct provided that they do not create a source of ignition or compromise the integrity of the double pipe or duct. The double wall piping or duct shall only contain piping or cabling necessary for operational purposes.

7.3.2 Wall thickness

7.3.2.1 The minimum wall thickness is to be calculated as follows:

$$t = (t_0 + b + c) / (1 - a/100) \text{ [mm]}$$

where:

t_0 = theoretical thickness

$t_0 = PD / (2Ke + P)$ [mm]

with:

P = design pressure [MPa] referred to in 7.3.3;

D = outside diameter [mm];

K = allowable stress [N/mm²] referred to in 7.3.4; and

e = efficiency factor equal to 1.0 for seamless pipes and for longitudinally or spirally welded pipes, delivered by approved manufacturers of welded pipes, that are considered equivalent to seamless pipes when non-destructive testing on welds is carried out in accordance with recognized standards. In other cases an efficiency factor of less than 1.0, in accordance with recognized standards, may be required depending on the manufacturing process;

b = allowance for bending [mm]. The value of b is to be chosen so that the calculated stress in the bend, due to internal pressure only, does not exceed the allowable stress. Where such justification is not given, b is to be:

$$b = D \cdot t_0 / 2.5r \text{ [mm]}$$

with:

r = mean radius of the bend [mm];

c = corrosion allowance [mm]. If corrosion or erosion is expected the wall thickness of the piping is to be increased over that required by other design requirements. This allowance is to be consistent with the expected life of the piping; and

a = negative manufacturing tolerance for thickness [%].

7.3.2.2 The absolute minimum wall thickness is to be in accordance with a standard acceptable to IRS/Administration.

7.3.3 Design condition

7.3.3.1 The greater of the following design conditions is to be used for piping, piping system and components as appropriate*, **:

.1 for systems or components which may be separated from their relief valves and which contain only vapour at all times, vapour pressure at 45[°C] assuming an initial condition of saturated vapour in the system at the system operating pressure and temperature; or

.2 the MARVS of the fuel tanks and fuel processing systems; or

.3 the pressure setting of the associated pump or compressor discharge relief valve; or

.4 the maximum total discharge or loading head of the fuel piping system; or

.5 the relief valve setting on a pipeline system.

Note:

** Lower values of ambient temperature regarding design condition in 7.3.3.1.1 may be accepted by Administration/ IRS for ships operating in restricted areas. Conversely, higher values of ambient temperature may be required.*

*** For ships on voyages of restricted duration, P_0 may be calculated based*

on the actual pressure rise during the voyage and account may be taken of any thermal insulation of the tank. Reference is made to the " Application of amendments to gas carrier codes concerning type C tank loading limits" (SIGTTO/IACS).

7.3.3.2 Piping, piping systems and components shall have a minimum design pressure of 1 [MPa] except for open ended lines where it is not to be less than 0.5 [MPa].

7.3.4 Allowable stress

7.3.4.1 For pipes made of steel including stainless steel, the allowable stress to be considered in the formula of the strength thickness in 7.3.2.1 is to be the lower of the following values:

R_m/2.7 or R_e/1.8

where:

R_m = specified minimum tensile strength at room temperature [N/mm²]; and

R_e = specified minimum yield stress at room temperature [N/mm²]. If the stress strain curve does not show a defined yield stress, the 0.2% proof stress applies.

7.3.4.2 Where necessary for mechanical strength to prevent damage, collapse, excessive sag or buckling of pipes due to superimposed loads, the wall thickness is to be increased over that required by 7.3.2 or, if this is impracticable or would cause excessive local stresses, these loads is to be reduced, protected against or eliminated by other design methods. Such superimposed loads may be due to; supports, ship deflections, liquid pressure surge during transfer operations, the weight of suspended valves, reaction to loading arm connections, or otherwise.

7.3.4.3 For pipes made of materials other than steel, the allowable stress is to be considered by the IRS/Administration.

7.3.4.4 High pressure fuel piping systems is to have sufficient constructive strength. This is to be confirmed by carrying out stress analysis and taking into account:

.1 stresses due to the weight of the piping system;

.2 acceleration loads when significant; and

.3 internal pressure and loads induced by hog and sag of the ship.

7.3.4.5 When the design temperature is minus 110 [°C] or colder, a complete stress analysis, taking into account all the stresses due to weight of pipes, including acceleration loads if significant, internal pressure, thermal contraction and loads induced by hog and sag of the ship is to be carried out for each branch of the piping system.

7.3.5 Flexibility of piping

7.3.5.1 The arrangement and installation of fuel piping is to provide the necessary flexibility to maintain the integrity of the piping system in the actual service situations, taking potential for fatigue into account.

7.3.6 Piping fabrication and joining details

7.3.6.1 Flanges, valves and other fittings are to comply with a standard acceptable to the IRS/Administration, taking into account the design pressure defined in 7.3.3.1. For bellows and expansion joints used in vapour service, a lower minimum design pressure than defined in 7.3.3.1 may be accepted.

7.3.6.2 All valves and expansion joints used in high pressure fuel piping systems are to be approved according to a standard acceptable to IRS/Administration.

7.3.6.3 The piping system is to be joined by welding with a minimum of flange connections. Gaskets are to be protected against blow-out.

IR 7.3.6.3 In the piping system for fuel transfer, there is to be, no single common flange or other component where one single failure itself may overcome both primary and secondary barriers and may result in a gas leak into the surrounding area causing danger to the persons on board, the environment or the ship. A single common flange (with two sealing systems) may be accepted at the fuel connection to the gas consumers including GCUs, boilers and components on the engine, such as gas regulating units.

7.3.6.4 Piping fabrication and joining details are to comply with the following:

7.3.6.4.1 Direct connections

.1 Butt-welded joints with complete penetration at the root may be used in all applications. For design temperatures colder than minus 10[°C], butt welds is to be either double welded or equivalent to a double welded butt joint. This may be accomplished by use of a backing ring, consumable insert or inert gas back-up on the first pass. For design pressures in excess of 1 [MPa] and design temperatures of minus 10[°C] or colder, backing rings is to be removed.

.2 Slip-on welded joints with sleeves and related welding, having dimensions in accordance with recognized standards, are only to be used for instrument lines and open-ended lines with an external diameter of 50 [mm] or less and design temperatures not colder than minus 55[°C].

.3 Screwed couplings complying with recognized standards are only to be used for accessory lines and instrumentation lines with external diameters of 25 [mm] or less.

7.3.6.4.2 Flanged connections

.1 Flanges in flange connections is to be of the welded neck, slip-on or socket welded type; and

.2 For all piping except open ended, the following restrictions apply:

.1 For design temperatures colder than minus 55[°C], only welded neck flanges is to be used; and

.2 For design temperatures colder than minus 10[°C], slip-on flanges are not to be used in nominal sizes above 100 [mm] and socket welded flanges are not to be used in nominal sizes above 50 [mm].

7.3.6.4.3 Expansion joints

Where bellows and expansion joints are provided in accordance with 7.3.6.1 the following apply:

.1 if necessary, bellows is to be protected against icing;

.2 slip joints are not to be used except within the liquefied gas fuel storage tanks; and

.3 bellows are normally not to be arranged in enclosed spaces.

7.3.6.4.4 Other connections

Piping connections are to be joined in accordance with 7.3.6.4.1 to 7.3.6.4.3 but for other exceptional cases IRS/Administration may consider alternative arrangements.

7.4 Materials

7.4.1 Metallic materials

7.4.1.1 Materials for fuel containment and piping systems are to comply with the minimum requirements given in the following Tables:

Table 7.1: Plates, pipes (seamless and welded), sections and forgings for fuel tanks and process pressure vessels for design temperatures not lower than 0[°C].

Table 7.2: Plates, sections and forgings for fuel tanks, secondary barriers and process pressure vessels for design temperatures below 0[°C] and down to minus 55[°C].

Table 7.3: Plates, sections and forgings for fuel tanks, secondary barriers and process pressure vessels for design temperatures below minus 55[°C] and down to minus 165[°C].

Table 7.4: Pipes (seamless and welded), forgings and castings for fuel and process piping for design temperatures below 0[°C] and down to minus 165[°C].

Table 7.5: Plates and sections for hull structures required by 6.4.13.1.1.2.

IR7.4.1.1 High Manganese Austenitic Steel may also be used for cargo and fuel tanks of LNG fueled ships. IRS '*Guidelines on Approval of High Manganese Austenitic Steel for Cryogenic Service'* may be referred for manufacturing approval of such steels.

Table : 7.1		
PLATES, PIPES (SEAMLESS AND WELDED)[See note 1 and note 2], SECTIONS AND FORGINGS FOR FUEL TANKS AND PROCESS PRESSURE VESSELS FOR DESIGN TEMPERATURES NOT LOWER THAN 0 [˚C]		
CHEMICAL COMPOSITION AND HEAT TREATMENT		
• Carbon-manganese steel		
• Fully killed fine grain steel		
• Small additions of alloying elements by agreement with the Administration/ IRS		
• Composition limits to be approved by the Administration/ IRS		
• Normalized, or quenched and tempered [See note 4]		
TENSILE AND TOUGHNESS (IMPACT) TEST REQUIREMENTS		
Sampling Frequency		
• Plates	Each "piece" to be tested	
• Sections and forgings	Each "batch" to be tested	
Mechanical properties		
• Tensile properties	Specified minimum yield stress not to exceed 410 [N/mm^2][See note 2 & 5]	
Toughness (Charpy V-notch test)		
• Plates	Transverse test pieces. Minimum average energy value (KV) 27J	
• Sections and forgings	Longitudinal test pieces. Minimum average energy (KV) 41J	
• Test temperature	Thickness t (mm)	Test temperature (˚C)
	t < 20	0
	20 < t ≤ 40 [See note 3]	-20

Notes

1 For seamless pipes and fittings normal practice applies. The use of longitudinally and spirally welded pipes is to be specially approved by the Administration or IRS. .

2 Charpy V-notch impact tests are not required for pipes.

3 This table is generally applicable for material thicknesses up to 40 [mm].

4 A controlled rolling procedure or TMCP may be used as an alternative.

5 Materials with specified minimum yield stress exceeding 410 [N/mm^2] may be approved by the Administration or IRS. For these materials, particular attention is to be given to the hardness of the welded and heat affected zones.

In addition to Table 7.1 above, for design temperature not lower than 0°C, the following applies:

Table 7.1.1		
Plates, pipes (seamless and welded), sections and forgings for fuel tanks and process pressure vessels for design temperatures not lower than 0°C.		
CHARPY V-NOTCH IMPACT TEST REQUIREMENTS		
TEST TEMPERATURE	Thickness t (mm)	Test temperature (°C)
	40 < t ≤ 50 (1)	-20 (2)
	40 < t ≤ 50 (1)	-30 (3)
NOTES:		
(1) A further set of impact test at mid thickness for products with t>40mm is required except rolled steels specified in Part 2, Chapter 3, Section 2 to 4.		
(2) Applies to type C independent tanks and process pressure vessels. In addition, post-weld stress relief heat treatment is to be performed. Exemption to post-weld stress relief heat treatment based on alternative approach (e.g. Engineering Critical Assessment) is to be approved by IRS or is to be in accordance with recognized standards.		
(3) Applies to fuel tank other than type C.		

Table 7.2					
PLATES, SECTIONS AND FORGINGS See note 1 FOR FUEL TANKS, SECONDARY BARRIERS AND PROCESS PRESSURE VESSELS FOR DESIGN TEMPERATURES BELOW 0 [°C] AND DOWN TO MINUS 55 [°C] MAXIMUM THICKNESS 25 [mm] see note 2					
CHEMICAL COMPOSITION AND HEAT TREATMENT					
• Carbon-manganese steel					
• Fully killed, aluminium treated fine grain steel					
• Chemical composition (ladle analysis)					
C	Mn	Si	S	P	
0.16%max see note 3	0.7 – 1.60 %	0.1 – 0.50 %	0.025% max	0.025% max	
Optional additions: Alloys and grain refining elements may be generally in accordance with the following:					
Ni	Cr	Mo	Cu	Nb	V
0.8% max	0.25% max	0.08% max	0.35% max	0.05% max	0.1% max
Al content total 0.02% min (Acid soluble 0.015% min)					
• Normalized, or quenched and tempered See note 4					
TENSILE AND TOUGHNESS (IMPACT) TEST REQUIREMENTS					
Sampling frequency					
• Plates	Each “piece” to be tested				
• Sections and forgings	Each “ batch” to be tested				
Mechanical properties					
• Tensile properties	Specified minimum yield stress not to exceed 410 [N/mm^2] See note 5				

Toughness (Charpy V-notch test)	
• Plates	Transverse test pieces. Minimum average energy value (KV) 27J
• Sections and forgings	Longitudinal test pieces. Minimum average energy (KV) 41J
• Test temperature	5 [˚C] below the design temperature or -20 [˚C], whichever is lower

Notes

1 The Charpy V-notch and chemistry requirements for forgings may be specially considered by the Administration/ IRS.

2 For material thickness of more than 25 [mm], Charpy V-notch tests is to be conducted as follows:

Material Thickness [mm]	Test temperature [˚C]
25 < t ≤ 30	10 [˚C] below design temperature or -20[˚C], whichever is lower
30 < t ≤ 35	15 [˚C] below design temperature or -20[˚C], whichever is lower
35 < t ≤ 40	20 [˚C] below design temperature
40 < t	Temperature approved by Administration/ IRS

The impact energy value is to be in accordance with the table for the applicable type of test specimen.

Materials for tanks and parts of tanks which are completely thermally stress relieved after welding may be tested at a temperature 5 [°C] below design temperature or -20 [°C], whichever is lower.

For thermally stress relieved reinforcements and other fittings, the test temperature is to be the same as that required for the adjacent tank-shell thickness.

3 By special agreement with the Administration/ IRS, the carbon content may be increased to 0.18% maximum, provided the design temperature is not lower than -40 [°C].

4 A controlled rolling procedure or TMCP may be used as an alternative.

5 Materials with specified minimum yield stress exceeding 410 [N/mm^2] may be approved by Administration/IRS. For these materials, particular attention is to be given to the hardness of the welded and heat affected zones.

Guidance:
For materials exceeding 25 [mm] in thickness for which the test temperature is -60 [°C] or lower, the application of specially treated steels or steels in accordance with Table 7.3 may be necessary.

In addition to Table 7.2 above, the following applies:

Table 7.2.1		
Plates, sections and forgings for fuel tanks, secondary barriers and process pressure vessels for design temperatures below 0°C and down to -10°C		
CHARPY V-NOTCH IMPACT TEST REQUIREMENTS		
TEST TEMPERATURE	Thickness t (mm)	Test temperature (°C)
	40 < t ≤ 50 (1)	5°C below design temperature or –20°C, whichever is lower (2)
	40 < t ≤ 45 (1)	25 °C below design temperature (3)
	45 < t ≤ 50 (1)	30 °C below design temperature (3)
NOTES:		
(1) A further set of impact test at mid thickness for products with t>40mm is required except rolled steels specified in Part 2, Chapter 3, Section 2 to 4. (2) Applies to type C independent tanks and process pressure vessels. In addition, post-weld stress relief heat treatment is to be performed. Exemption to post-weld stress relief heat treatment based on alternative approach (e.g. Engineering Critical Assessment) is to be approved by IRS or is to be accordance with recognized standards. (3) Applies to fuel tank other than type C.		

Table 7.2.2		
Plates, sections and forgings for fuel tanks, secondary barriers and process pressure vessels for design temperatures below -10°C and down to -55°C		
CHARPY V-NOTCH IMPACT TEST REQUIREMENTS		
TEST TEMPERATURE	Thickness t (mm)	Test temperature (°C)
	40 < t ≤ 50 (1)	5°C below design temperature or –20°C, whichever is lower
	40 < t ≤ 45 (1)	25 °C below design temperature (2)
	45 < t ≤ 50 (1)	30 °C below design temperature (2)
NOTES:		
(1) A further set of impact test at mid thickness for products with t>40mm is required except rolled steels specified in Part 2, Chapter 3, Section 2 to 4. (2) Applies to fuel tank other than type C.		

Table 7.3

PLATES, SECTIONS AND FORGINGS See note 1 FOR FUEL TANKS, SECONDARY BARRIERS AND PROCESS PRESSURE VESSELS FOR DESIGN TEMPERATURES BELOW MINUS 55 [°C] AND DOWN TO MINUS 165 [°C] See note 2 MAXIMUM THICKNESS 25 [mm] see note 3 and note 4

Minimum design temperature [˚C]	Chemical composition See note 5 and heat treatment	Impact test temperature [˚C]
-60	1.5% nickel steel – normalized or normalized and tempered or quenched and tempered or TMCP See note 6	-65
-65	2.25% nickel steel – normalized or normalized and tempered or quenched and tempered or TMCP See note 6 and 7	-70
-90	3.5% nickel steel – normalized or normalized and tempered or quenched and tempered or TMCP See note 6 and 7	-95
-105	5% nickel steel – normalized or normalized and tempered or quenched and tempered See note 6,7and 8	-110
-165	9% nickel steel – double normalized and tempered or quenched and tempered See note 6	-196
-165	Austenitic steels, such as types 304, 304L, 316, 316L, 321 and 347 solution treated See note 9	-196
-165	Aluminium alloys; such as type 5083 annealed	Not required
-165	Austenitic Fe-Ni alloy (36% nickel). Heat treatment as agreed.	Not required

TENSILE AND TOUGHNESS (IMPACT) TEST REQUIREMENTS

Sampling frequency	
• Plates	Each “piece” to be tested
• Sections and forgings	Each “ batch” to be tested
Toughness (Charpy V-notch test)	
• Plates	Transverse test pieces. Minimum average energy value (KV) 27J
• Sections and forgings	Longitudinal test pieces. Minimum average energy (KV) 41J

Notes

1 The impact test required for forgings used in critical application is to be subject to special consideration by the Administration/ IRS.

2 The requirements for design temperatures below -165[°C] are to be specially agreed with the Administration/ IRS.

3 For materials 1.5% Ni, 2.25% Ni, 3.5% Ni and 5% Ni, with thicknesses greater than 25 [mm], the impact tests are to be conducted as follows:

Material Thickness [mm]	Test temperature [˚C]
25 < t ≤ 30	10 [˚C] below design temperature
30 < t ≤ 35	15 [˚C] below design temperature
35 < t ≤ 40	20 [˚C] below design temperature

The energy value is to be in accordance with the table for the applicable type of test specimen. For material thickness of more than 40 [mm], the Charpy V-notch values is to be specially considered.

4 For 9% Ni steels, austenitic stainless steels and aluminium alloys, thickness greater than 25 [mm] may be used.

5 The chemical composition limits are to be in accordance with recognized standards.

6 TMCP nickel steels will be subject to acceptance by the Administration/ IRS.

7 A lower minimum design temperature for quenched and tempered steels may be specially agreed with the Administration/ IRS.

8 A specially heat treated 5% nickel steel, for example triple heat treated 5% nickel steel, may be used down to -165 [°C], provided that the impact tests are carried out at -196 [°C].

9 The impact test may be omitted, subject to agreement with the Administration/ IRS.

In addition to Table 7.3 above, the following applies:

Table 7.3.1	
Plates, sections and forgings for fuel tanks, secondary barriers and process pressure vessels for design temperatures below -55°C and down to -165°C.	
CHARPY V-NOTCH IMPACT TEST REQUIREMENTS	
40 < t ≤ 45 mm (1)	25°C below design temperature
45 < t ≤ 50 mm (1)	30°C below design temperature
(1) A further set of impact test at mid thickness for products with t>40mm is required except rolled steels specified in Part 2, Chapter 3, Section 2 to 4.

• Each “batch” to be tested			

Toughness (Charpy V-notch test)
• Impact test: Longitudinal test pieces
Notes 1 The use of longitudinally or spirally welded pipes is to be specially approved by the Administration/ IRS. 2 The requirements for forgings and castings may be subject to special consideration by the Administration/ IRS. 3 The requirements for design temperatures below -165 [°C] are to be specially agreed with the Administration/ IRS. 4 The test temperature is to be 5 [°C] below the design temperature or -20 [°C], whichever is lower. 5 The composition limits are to be in accordance with recognized standards. 6 A lower design temperature may be specially agreed with the Administration/ IRS for quenched and tempered materials. 7 This chemical composition is not suitable for castings. 8 Impact tests may be omitted, subject to agreement with the Administration/ IRS.

Table 7.5

PLATES AND SECTIONS FOR HULL STRUCTURES REQUIRED BY 6.4.13.1.1.2

Minimum design temperature of hull structure (°C)	**Maximum thickness (mm) for steel grades**							
	A	**B**	**D**	**E**	**AH**	**DH**	**EH**	**FH**
0 and above	Recognized Standards							
down to -5	15	25	30	50	25	45	50	50
down to -10	x	20	25	50	20	40	50	50
down to -20	x	x	20	50	x	30	50	50
down to -30	x	x	x	40	x	20	40	50
Below -30	In accordance with Table 7.2 except that the thickness limitation given in Table 7.2 and in footnote 2 of that table does not apply							
Notes 'x' means steel grade not to be used.								

7.4.1.2 Materials having a melting point below 925 [°C] are not to be used for piping outside the fuel tanks.

7.4.1.3 For CNG tanks, the use of materials not covered above may be specially considered by the IRS/Administration.

7.4.1.4 Where required the outer pipe or duct containing high pressure gas in the inner pipe shall as a minimum fulfill the material requirements for pipe materials with design temperature down to minus 55[°C] in Table 7.4.

7.4.1.5 The outer pipe or duct around liquefied gas fuel pipes shall as a minimum fulfill the material requirements for pipe materials with design temperature down to minus 165[°C] in Table 7.4.

Section 8

Bunkering

8.1 Goal

8.1.1 The goal of this section is to provide for suitable systems on board the ship to ensure that bunkering can be conducted without causing danger to persons, the environment or the ship.

8.2 Functional requirements

8.2.1 This section relates to functional requirements in 3.2.1 to 3.2.11 and 3.2.13 to 3.2.17. In particular the following apply:

8.2.1.1 The piping system for transfer of fuel to the storage tank is to be designed such that any leakage from the piping system cannot cause danger to personnel, the environment or the ship.

8.3 Bunkering station

8.3.1 General

8.3.1.1 The bunkering station is to be located on open deck so that sufficient natural ventilation is provided. Closed or semi-enclosed bunkering stations are to be subject to special consideration within the risk assessment.

IR 8.3.1.1 The special consideration should as a minimum include, but not be restricted to, the following design features:

- segregation towards other areas on the ship
- hazardous area plans for the ship
- requirements for forced ventilation
- requirements for leakage detection (e.g. gas detection and low temperature detection)
- safety actions related to leakage detection (e.g. gas detection and low temperature detection)
- access to bunkering station from non-hazardous areas through airlocks
- monitoring of bunkering station by direct line of sight or by CCTV.

8.3.1.2 Connections and piping are to be so positioned and arranged that any damage to the fuel piping does not cause damage to the ship's fuel containment system resulting in an uncontrolled gas discharge.

8.3.1.3 Arrangements are to be made for safe management of any spilled fuel.

8.3.1.4 Suitable means are to be provided to relieve the pressure and remove liquid contents from pump suctions and bunker lines. Liquid is to be discharged to the liquefied gas fuel tanks or other suitable location.

8.3.1.5 The surrounding hull or deck structures shall not be exposed to unacceptable cooling, in case of leakage of fuel.

8.3.1.6 For CNG bunkering stations, low temperature steel shielding is to be considered to determine if the escape of cold jets impinging on surrounding hull structure is possible.

8.3.2 Ship’s fuel hoses

8.3.2.1 Liquid and vapour hoses used for fuel transfer are to be compatible with the fuel and suitable for the fuel temperature.

8.3.2.2 Hoses subject to tank pressure, or the discharge pressure of pumps or vapour compressors, are to be designed for a bursting pressure not less than five times the maximum pressure the hose can be subjected to during bunkering.

8.4 Manifold

8.4.1 The bunkering manifold is to be designed to withstand the external loads during bunkering. The connections at the bunkering station is to be of dry-disconnect type equipped with additional safety dry break-away coupling/ self-sealing quick release. The couplings are to be of a standard type.

8.5 Bunkering system

8.5.1 An arrangement for purging fuel bunkering lines with inert gas is to be provided.

8.5.2 The bunkering system is to be so arranged that no gas is discharged to the atmosphere during filling of storage tanks.

8.5.3 A manually operated stop valve and a remote operated shutdown valve in series, or a combined manually operated and remote valve are to be fitted in every bunkering line close to the connecting point. It is to be possible to operate the remote valve in the control location for bunkering operations and/or from another safe location.

8.5.4 Means are to be provided for draining any fuel from the bunkering pipes upon completion of operation.

8.5.5 Bunkering lines are to be arranged for inerting and gas freeing. When not engaged in bunkering, the bunkering pipes are to be free of gas, unless the consequences of not gas freeing are evaluated and approved.

8.5.6 In case bunkering lines are arranged with a cross-over it is to be ensured by suitable isolation arrangements that no fuel is transferred inadvertently to the ship side not in use for bunkering.

8.5.7 A ship-shore link (SSL) or an equivalent means for automatic and manual ESD communication to the bunkering source is to be fitted.

8.5.8 If not demonstrated to be required at a higher value due to pressure surge considerations a default time as calculated in accordance with 16.7.3.7 from the trigger of the alarm to full closure of the remote operated valve required by 8.5.3 is to be adjusted.

Section 9

Fuel Supply to Consumers

9.1 Goal

9.1.1 The goal of this section is to ensure safe and reliable distribution of fuel to the consumers.

9.2 Functional requirements

9.2.1 This section is related to functional requirements in 3.2.1 to 3.2.6, 3.2.8 to 3.2.11 and 3.2.13 to 3.2.17. In particular the following apply:

.1 the fuel supply system is to be so arranged that the consequences of any release of fuel will be minimized, while providing safe access for operation and inspection;

.2 the piping system for fuel transfer to the consumers is to be designed in a way that a failure of one barrier cannot lead to a leak from the piping system into the surrounding area causing danger to the persons on board, the environment or the ship; and

.3 fuel lines outside the machinery spaces are to be installed and protected so as to minimize the risk of injury to personnel and damage to the ship in case of leakage.

IR 9.2.1 To comply with 9.2.1.2 above, two independent safety barriers are to be in place, while, as far as practicable, using a minimum of flange connections. There is to be, no single common flange or other component where one single failure itself may overcome both primary and secondary barriers and may result in a gas leak into the surrounding area causing danger to the persons on board, the environment or the ship. A single common flange (with two sealing systems) may be accepted at the fuel connection to the gas consumers including GCUs, boilers and components on the engine, such as gas regulating units.

9.3 Redundancy of fuel supply

9.3.1 For single fuel installations the fuel supply system are to be arranged with full

redundancy and segregation all the way from the fuel tanks to the consumer, so that a leakage in one system does not lead to an unacceptable loss of power.

9.3.2 For single fuel installations, the fuel storage is to be divided between two or more tanks. The tanks are to be located in separate compartments.

9.3.3 For type C tank only, one tank may be accepted if two completely separate tank connection spaces are installed for the one tank.

9.4 Safety functions of gas supply system

9.4.1 Fuel storage tank inlets and outlets are to be provided with valves located as close to the tank as possible. Valves required to be operated during normal operation* which are not accessible is to be remotely operated. Tank valves whether accessible or not are to be automatically operated when the safety system required in 15.2.2 is activated.

Note:

** Normal operation in this context is when gas is supplied to consumers and during bunkering operation.*

9.4.2 The main gas supply line to each gas consumer or set of consumers is to be equipped with a manually operated stop valve and an automatically operated "master gas fuel valve" coupled in series or a combined manually and automatically operated valve. The valves are to be situated in the part of the piping that is outside the machinery space containing gas consumers, and placed as near as possible to the installation for heating the gas, if fitted. The master gas fuel valve is to automatically cut off the gas supply when activated by the safety system required in 15.2.2.

9.4.3 The automatic master gas fuel valve is to be operable from safe locations on escape routes inside a machinery space containing a gas consumer, the engine control room, if applicable; outside the machinery space, and from the navigation bridge.

9.4.4 Each gas consumer is to be provided with "double block and bleed" valves arrangement. These valves are to be arranged as outlined in .1 or .2 so that when the safety system required in 15.2.2 is activated this will cause the shutoff valves that are in series to close automatically and the bleed valve to open automatically and:

.1 the two shutoff valves are to be in series in the gas fuel pipe to the gas consuming equipment. The bleed valve is to be in a pipe that vents to a safe location in the open air that portion of the gas fuel piping that is between the two valves in series; or

.2 the function of one of the shutoff valves in series and the bleed valve can be incorporated into one valve body, so arranged that the flow to the gas utilization unit will be blocked and the ventilation opened.

9.4.5 The two valves are to be of the fail-to-close type, while the ventilation valve is to be fail-to-open.

9.4.6 The double block and bleed valves are also to be used for normal stop of the engine.

9.4.7 In cases where the master gas fuel valve is automatically shutdown, the complete gas supply branch downstream of the double block and bleed valve is to be automatically ventilated assuming reverse flow from the engine to the pipe.

9.4.8 There is to be one manually operated shutdown valve in the gas supply line to each engine upstream of the double block and bleed valves to assure safe isolation during maintenance on the engine.

9.4.9 For single-engine installations and multi-engine installations, where a separate master valve is provided for each engine, the master gas fuel valve and the double block and bleed valve functions can be combined.

9.4.10 For each main gas supply line entering an ESD protected machinery space, and each gas supply line to high pressure installations means are to be provided for rapid detection of a rupture in the gas line in the engine-room. When rupture is detected a valve is to be automatically shut off*. This valve is to be located in the gas supply line before it enters the engine-room or as close as possible to the point of entry inside the engine-room. It can be a separate valve or combined with other functions, e.g. the master valve.

Note:

** The shutdown is to be time delayed to prevent shutdown due to transient load variations.*

9.5 Fuel distribution outside of machinery space

9.5.1 Where fuel pipes pass through enclosed spaces in the ship, they are to be protected by a secondary enclosure. This enclosure can be a ventilated duct or a double wall piping system. The duct or double wall piping system is to be mechanically underpressure ventilated with 30 air changes per hour, and gas detection as required in 15.8 is to be provided. Other solutions providing an equivalent safety level may also be accepted by IRS/Administration.

9.5.2 The requirement in 9.5.1 need not be applied for fully welded fuel gas vent pipes led through mechanically ventilated spaces.

9.5.3 The requirements in 9.5.4 to 9.5.6 are to apply to ships constructed on or after 1 January 2024 in lieu of the requirements in 9.5.1 and 9.5.2.

9.5.4 Where gaseous fuel pipes pass through enclosed spaces in the ship, they are to be protected by a secondary enclosure. This enclosure can be a ventilated duct or a double wall piping system. The duct or double wall piping system is to be mechanically under pressure ventilated with 30 air changes per hour, and gas detection as required in 15.8 is to be provided. Other solutions providing an equivalent safety level may also be accepted by the Administration.

9.5.5 The requirement in 9.5.4 need not be applied for fully welded fuel gas vent pipes led through mechanically ventilated spaces.

9.5.6 Liquefied fuel pipes are to be protected by a secondary enclosure able to contain leakages. If the piping system is in a fuel preparation room or a tank connection space, the Administration may waive this requirement. Where gas detection as required in 15.8.1.2 is not fit for purpose, the secondary enclosures around liquefied fuel pipes are to be provided with leakage detection by means of pressure or temperature monitoring systems, or any combination thereof. The secondary enclosure is to be able to withstand the maximum pressure that may build up in the enclosure in case of leakage from the fuel piping. For this purpose, the secondary enclosure may need to be arranged with a pressure relief system that prevents the enclosure from being subjected to pressures above their design pressures.

9.6 Fuel supply to consumers in gas-safe machinery spaces

9.6.1 Fuel piping in gas-safe machinery spaces is to be completely enclosed by a double pipe or duct fulfilling one of the following conditions:

.1 the gas piping is to be a double wall piping system with the gas fuel contained in the inner pipe. The space between the concentric pipes is to be pressurized with inert gas at a pressure greater than the gas fuel pressure. Suitable alarms are to be provided to indicate a loss of inert gas pressure between the pipes. When the inner pipe contains high pressure gas, the system is to be so arranged that the pipe between the master gas valve and the engine is automatically purged with inert gas when the master gas valve is closed; or

.2 the gas fuel piping is to be installed within a ventilated pipe or duct. The air space between the gas fuel piping and the wall of the outer pipe or duct is to be equipped with mechanical underpressure ventilation having a capacity of at least 30 air changes per hour. This ventilation capacity may be reduced to 10 air changes per hour provided automatic filling of the duct with nitrogen upon detection of gas is arranged for. The fan motors are to comply with the required explosion protection in the installation area. The ventilation outlet is to be covered by a protection screen and placed in a position where no flammable gas-air mixture may be ignited; or

.3 other solutions providing an equivalent safety level may also be accepted by the IRS/Administration.

IR 9.6.1 To comply with 9.6.1 above, two independent safety barriers are to be in place, while, as far as practicable, using a minimum of flange connections. There is to be, no single common flange or other component where one

single failure itself may overcome both primary and secondary barriers and may result in a gas leak into the surrounding area causing danger to the persons on board, the environment or the ship. A single common flange (with two sealing systems) may be accepted at the fuel connection to the gas consumers including GCUs, boilers and components on the engine, such as gas regulating units.

9.6.2 The connecting of gas piping and ducting to the gas injection valves are to be completely covered by the ducting. The arrangement is to facilitate replacement and/or overhaul of injection valves and cylinder covers. The double ducting is also required for all gas pipes on the engine itself, until gas is injected into the chamber*.

Note:
** If gas is supplied into the air inlet directly on each individual cylinder during air intake to the cylinder on a low pressure engine, such that a single failure will not lead to release of fuel gas into the machinery space, double ducting may be omitted on the air inlet pipe.*

9.7 Gas fuel supply to consumers in ESD-protected machinery spaces

9.7.1 The pressure in the gas fuel supply system is not to exceed 1 [MPa].

9.7.2 The gas fuel supply lines are to have a design pressure not less than 1 [MPa].

9.8 Design of ventilated duct, outer pipe against inner pipe gas leakage

9.8.1 The design pressure of the outer pipe or duct of fuel systems is not to be less than the maximum working pressure of the inner pipe. Alternatively for fuel piping systems with a working pressure greater than 1 [MPa], the design pressure of the outer pipe or duct is not to be less than the maximum built-up pressure arising in the annular space considering the local instantaneous peak pressure in way of any rupture and the ventilation arrangements.

9.8.2 For high-pressure fuel piping the design pressure of the ducting is to be taken as the higher of the following:

.1 the maximum built-up pressure: static pressure in way of the rupture resulting from the gas flowing in the annular space;

.2 local instantaneous peak pressure in way of the rupture: this pressure is to be taken as the critical pressure given by the following expression:

$$p=p_0(2/k+1)^{(k/k-1)}$$

where:

p_0 = maximum working pressure of the inner pipe

$k = C_p/C_v$ constant pressure specific heat divided by the constant volume specific heat

$k = 1.31$ *for* CH_4

The tangential membrane stress of a straight pipe is not to exceed the tensile strength divided by 1.5 (Rm/1.5) when subjected to the above pressures. The pressure ratings of all other piping components shall reflect the same level of strength as straight pipes.

As an alternative to using the peak pressure from the above formula, the peak pressure found from representative tests can be used. Test reports shall then be submitted.

9.8.3 Verification of the strength is to be based on calculations demonstrating the duct or pipe integrity. As an alternative to calculations, the strength can be verified by representative tests.

9.8.4 For low pressure fuel piping the duct is to be dimensioned for a design pressure not less than the maximum working pressure of the fuel pipes. The duct is to be pressure tested to show that it can withstand the expected maximum pressure at fuel pipe rupture.

9.9 Compressors and pumps

9.9.1 If compressors or pumps are driven by shafting passing through a bulkhead or deck,the bulkhead penetration is to be of gastight type.

9.9.2 Compressors and pumps are to be suitable for their intended purpose. All equipment and machinery is to be such as to be adequately tested to ensure suitability for use within a marine environment. Such items

to be considered would include, but not be limited to:

.1 environmental;

.2 shipboard vibrations and accelerations;

.3 effects of pitch, heave and roll motions, etc.; and

.4 gas composition.

9.9.3 Arrangements are to be made to ensure that under no circumstances liquefied gas can be introduced in the gas control section or gas-fuelled machinery, unless the machinery is designed to operate with gas in liquid state.

9.9.4 Compressors and pumps are to be fitted with accessories and instrumentation necessary for efficient and reliable function.

Section 10

Power Generation including Propulsion and other Gas Consumers

10.1 Goal

10.1.1 The goal of this section is to provide safe and reliable delivery of mechanical, electrical or thermal energy.

10.2 Functional requirements

10.2.1 This section is related to functional requirements in 3.2.1, 3.2.11, 3.2.13, 3.2.16 and 3.2.17. In particular the following apply:

.1 the exhaust systems are to be configured to prevent any accumulation of un-burnt gaseous fuel;

.2 unless designed with the strength to withstand the worst case over pressure due to ignited gas leaks, engine components or systems containing or likely to contain an ignitable gas and air mixture are to be fitted with suitable pressure relief systems. Dependent on the particular engine design this may include the air inlet manifolds and scavenge spaces;

.3 the explosion venting is to be led away from where personnel may normally be present; and

.4 all gas consumers are to have a separate exhaust system.

10.3 Internal combustion engines of piston type

10.3.1 General

10.3.1.1 The exhaust system is to be equipped with explosion relief ventilation sufficiently dimensioned to prevent excessive explosion pressures in the event of ignition failure of one cylinder followed by ignition of the unburned gas in the system.

10.3.1.1.1 For ships constructed on or after 1 January 2024, the exhaust system is to be equipped with explosion relief systems unless designed to accommodate the worst case overpressure due to ignited gas leaks or justified by the safety concept of the engine. A detailed evaluation of the potential for unburnt gas in the exhaust system is to be undertaken covering the complete system from the cylinders up to the open end. This detailed evaluation is to be reflected in the safety concept of the engine.

10.3.1.2 For engines where the space below the piston is in direct communication with the crankcase a detailed evaluation regarding the hazard potential of fuel gas accumulation in the crankcase is to be carried out and reflected in the safety concept of the engine.

10.3.1.3 Each engine other than two-stroke crosshead diesel engines are to be fitted with vent systems independent of other engines for crankcases and sumps.

10.3.1.4 Where gas can leak directly into the auxiliary system medium (lubricating oil, cooling water), an appropriate means are to be fitted after the engine outlet to extract gas in order to prevent gas dispersion. The gas extracted from auxiliary systems media is to

be vented to a safe location in the atmosphere.

10.3.1.5 For engines fitted with ignition systems, prior to admission of gas fuel, correct operation of the ignition system on each unit is to be verified.

10.3.1.6 A means is to be provided to monitor and detect poor combustion or misfiring. In the event that it is detected, gas operation may be allowed provided that the gas supply to the concerned cylinder is shut off and provided that the operation of the engine with one cylinder cut-off is acceptable with respects to torsional vibrations.

10.3.1.7 For engines starting on fuels covered by this Chapter, if combustion has not been detected by the engine monitoring system within an engine specific time after the opening of the fuel supply valve, the fuel supply valve is to be automatically shut off. Means to ensure that any unburnt fuel mixture is purged away from the exhaust system is to be provided.

10.3.2 Dual fuel engines

10.3.2.1 In case of shutoff of the gas fuel supply, the engines are to be capable of continuous operation by oil fuel only without interruption.

10.3.2.2 An automatic system is to be fitted to change over from gas fuel operation to oil fuel operation and vice versa with minimum fluctuation of the engine power. Acceptable reliability is to be demonstrated through testing. In the case of unstable operation on engines when gas firing, the engine is to automatically change to oil fuel mode. Manual activation of gas system shutdown shall always be possible.

10.3.2.3 In case of a normal stop or an emergency shutdown, the gas fuel supply is to be shut off not later than the ignition source. It shall not be possible to shut off the ignition source without first or simultaneously closing the gas supply to each cylinder or to the complete engine.

10.3.3 Gas-only engines

10.3.3.1 In case of a normal stop or an emergency shutdown, the gas fuel supply is to be shut off not later than the ignition source. It shall not be possible to shut off the ignition source without first or simultaneously closing the gas supply to each cylinder or to the complete engine.

10.3.4 Multi-fuel engines

10.3.4.1 In case of shutoff of one fuel supply, the engines is to be capable of continuous operation by an alternative fuel with minimum fluctuation of the engine power.

10.3.4.2 An automatic system is to be fitted to change over from one fuel operation to an alternative fuel operation with minimum fluctuation of the engine power. Acceptable reliability is to be demonstrated through testing. In the case of unstable operation on an engine when using a particular fuel, the engine is to automatically change to an alternative fuel mode. Manual activation shall always be possible.

	GAS ONLY		**DUAL FUEL**	**MULTI FUEL**
IGNITION MEDIUM	Spark	Pilot fuel	Pilot fuel	N/A
MAIN FUEL	Gas	Gas	Gas and/or Oil fuel	Gas and/or Liquid

10.4 Main and auxiliary boilers

10.4.1 Each boiler is to have a dedicated forced draught system. A crossover between boiler force draught systems may be fitted for emergency use providing that any relevant safety functions are maintained.

10.4.2 Combustion chambers and uptakes of boilers are to be designed to prevent any accumulation of gaseous fuel.

10.4.3 Burners are to be designed to maintain stable combustion under all firing conditions.

10.4.4 On main/propulsion boilers an automatic system is to be provided to change from gas fuel operation to oil fuel operation without interruption of boiler firing.

10.4.5 Gas nozzles and the burner control system are to be configured such that gas fuel can only be ignited by an established oil fuel flame, unless the boiler and combustion equipment is designed and approved by the Administration to light on gas fuel.

10.4.6 There are to be arrangements to ensure that gas fuel flow to the burner is automatically cut off unless satisfactory ignition has been established and maintained.

10.4.7 On the fuel pipe of each gas burner a manually operated shutoff valve is to be fitted.

10.4.8 Provisions are to be made for automatically purging the gas supply piping to the burners, by means of an inert gas, after the extinguishing of these burners.

10.4.9 The automatic fuel changeover system required by 10.4.4 is to be monitored with alarms to ensure continuous availability.

10.4.10 Arrangements are to be made that, in case of flame failure of all operating burners, the combustion chambers of the boilers are automatically purged before relighting.

10.4.11 Arrangements are to be made to enable the boilers purging sequence to be manually activated.

10.5 Gas turbines

10.5.1 Unless designed with the strength to withstand the worst case over pressure due to ignited gas leaks, pressure relief systems are to be suitably designed and fitted to the exhaust system, taking into consideration of explosions due to gas leaks. Pressure relief systems within the exhaust uptakes are to be led to a safe location, away from personnel.

10.5.2 The gas turbine may be fitted in a gas-tight enclosure arranged in accordance with the ESD principle outlined in 5.6 and 9.7, however a pressure above 1 [MPa] in the gas supply piping may be accepted within this enclosure.

10.5.3 Gas detection systems and shutdown functions are to be as outlined for ESD protected machinery spaces.

10.5.4 Ventilation for the enclosure is to be as outlined in Section 13 for ESD protected machinery spaces, but shall in addition be arranged with full redundancy (2 x 100% capacity fans from different electrical circuits).

10.5.5 For other than single fuel gas turbines, an automatic system is to be fitted to change over easily and quickly from gas fuel operation to oil fuel operation and vice-versa with minimum fluctuation of the engine power.

10.5.6 Means are to be provided to monitor and detect poor combustion that may lead to unburnt fuel gas in the exhaust system during operation. In the event that it is detected, the fuel gas supply is to be shutdown.

10.5.7 Each turbine is to be fitted with an automatic shutdown device for high exhaust temperatures.

Section 11

Fire Safety

11.1 Goal

11.1.1 The goal of this section is to provide for fire protection, detection and fighting for all system components related to the storage, conditioning, transfer and use of natural gas as ship fuel.

11.2 Functional requirements

11.2.1 This section is related to functional requirements in 3.2.2, 3.2.4, 3.2.5, 3.2.7, 3.2.12, 3.2.14, 3.2.15 and 3.2.17.

11.3 Fire protection

11.3.1 Any space containing equipment for the fuel preparation such as pumps, compressors, heat exchangers, vaporizers and pressure vessels is to be regarded as a machinery space of category A for fire protection purposes.

IR 11.3.1.1 Fire protection in 11.3.1 means structural fire protection, not including means of escape.

IR 11.3.1.2. Enclosed spaces containing equipment for fuel preparation such as pumps or compressors or other potential ignition sources are to be provided with a fixed fire-extinguishing system complying with the provisions of Pt.6, Ch.3, 4.4.1.1 (SOLAS II-2/10.4.1.1) and Pt.6, Ch.8 (FSS Code) and taking into account the necessary concentrations / application rate required for extinguishing gas fires.

11.3.2 Any boundary of accommodation spaces, service spaces, control stations, escape routes and machinery spaces, facing fuel tanks on open deck, is to be shielded by A-60 class divisions. The A-60 class divisions are to extend up to the underside of the deck of the navigation bridge. In addition, fuel tanks are to be segregated from cargo in accordance with the requirements of the International Maritime Dangerous Goods (IMDG) Code where the fuel tanks are regarded as bulk packaging. For the purposes of the stowage and segregation requirements of the IMDG Code, a fuel tank on the open deck is to be considered a class 2.1 package.

11.3.3 The space containing the fuel containment system is to be separated from the machinery spaces of category A or other rooms with high fire risks. The separation is to be done by a cofferdam of at least 900 [mm] with insulation of A-60 class. When determining the insulation of the space containing fuel containment system from other spaces with lower fire risks, the fuel containment system is to be considered as a machinery space of category A, in accordance with SOLAS regulation II-2/9.For type C tanks, the fuel storage hold space may be considered as a cofferdam.

11.3.3.1 Notwithstanding the last sentence in 11.3.3, for ships constructed on or after 1 January 2024, the fuel storage hold space may be considered as a cofferdam provided that:

.1 the type C tank is not located directly above machinery spaces of category A or other rooms with high fire risk; and

.2 the minimum distance to the A-60 boundary from the outer shell of the type C tank or the boundary of the tank connection space, if any, is not less than 900 mm.

IR 11.3.3 The following "other rooms with high fire risk" should as a minimum be considered, but not be restricted to:

.1 cargo spaces except cargo tanks for liquids with flashpoint above 60°C and except cargo spaces exempted in accordance with Pt.6, Ch.3, 4.7.1.2 or 4.7.1.4 (SOLAS regulations II-2/10.7.1.2 or II-2/10.7.1.4);

.2 vehicle, ro-ro and special category spaces;

.3 service spaces (high risk): galleys, pantries containing cooking appliances, saunas, paint lockers and store-rooms having areas of 4 [m^2] or more, spaces for the storage of flammable liquids and workshops other than those forming part of the machinery space, as provided in Pt.6, Ch.3, 3.2.2.4, 3.2.3.3 and 3.2.4

(SOLAS regulations II-2/9.2.2.4, II-2/9.2.3.3 and II-2/9.2.4); and

.4 accommodation spaces of greater fire risk: saunas, sale shops, barber shops and beauty parlours and public spaces containing furniture and furnishing of other than restricted fire risk and having deck area of 50 [m^2] or more, as provided in Pt.6, Ch.3, 3.2.2.3 (SOLAS regulation II-2/9.2.2.3).

11.3.4 The fuel storage hold space is not to be used for machinery or equipment that may have a fire risk.

11.3.5 The fire protection of fuel pipes led through ro-ro spaces is to be subject to special consideration by the Administration depending on the use and expected pressure in the pipes.

11.3.6 The bunkering station is to be separated by A-60 class divisions towards machinery spaces of category A, accommodation, control stations and high fire risk spaces, except for spaces such as tanks, voids, auxiliary machinery spaces of little or no fire risk, sanitary and similar spaces where the insulation standard may be reduced to class A-0.

11.3.7 If an ESD protected machinery space is separated by a single boundary, the boundary is to be of A-60 class division.

11.4 Fire main

11.4.1 The water spray system required below may be part of the fire main system provided that the required fire pump capacity and working pressure are sufficient for the operation of both the required numbers of hydrants and hoses and the water spray system simultaneously.

11.4.2 When the fuel storage tank(s) is located on the open deck, isolating valves are to be fitted in the fire main in order to isolate damaged sections of the fire main. Isolation of a section of fire main is not to deprive the fire line ahead of the isolated section from the supply of water.

11.5 Water spray system

11.5.1 A water spray system is to be installed for cooling and fire prevention to cover exposed parts of fuel storage tank(s) located on open deck.

11.5.2 The water spray system is also to provide coverage for boundaries of the superstructures, compressor rooms, pump-rooms, cargo control rooms, bunkering control stations, bunkering stations and any other normally occupied deck houses that face the storage tank on open decks unless the tank is located 10 [m] or more from the boundaries.

11.5.3 The system is to be designed to cover all areas as specified above with an application rate of 10 [l/min/m^2] for the largest horizontal projected surfaces and 4 [l/min/m^2] for vertical surfaces.

11.5.4 Stop valves are to be fitted in the water spray application main supply line(s), at intervals not exceeding 40 [m], for the purpose of isolating damaged sections. Alternatively, the system may be divided into two or more sections that may be operated independently, provided the necessary controls are located together in a readily accessible position not likely to be inaccessible in case of fire in the areas protected.

11.5.5 The capacity of the water spray pump is to be sufficient to deliver the required amount of water to the hydraulically most demanding area as specified above in the areas protected.

11.5.6 If the water spray system is not part of the fire main system, a connection to the ship's fire main through a stop valve is to be provided.

11.5.7 Remote start of pumps supplying the water spray system and remote operation of any normally closed valves to the system is to be located in a readily accessible position which is not likely to be inaccessible in case of fire in the areas protected.

11.5.8 The nozzles are to be of an approved full bore type and they are to be arranged to ensure an effective distribution of water throughout the space being protected.

11.6 Dry chemical powder fire-extinguishing system

11.6.1 A permanently installed dry chemical powder fire-extinguishing system is to be installed in the bunkering station area to cover all possible leak points. The capacity is to be

atleast 3.5 [kg/s] for a minimum of 45 s. The system is to be arranged for easy manual release from a safe location outside the protected area.

11.6.2 In addition to any other portable fire extinguishers that may be required elsewhere in IMO instruments, one portable dry powder extinguisher of at least 5 kg capacity is to be located near the bunkering station.

11.7 Fire detection and alarm system

11.7.1 A fixed fire detection and fire alarm system complying with the Fire Safety Systems Code is to be provided for the fuel storage hold spaces and the ventilation trunk to the tank connection space and in the tank connection space and for all other rooms of the fuel gas system where fire cannot be excluded.

11.7.2 Smoke detectors alone are not to be considered sufficient for rapid detection of a fire.

11.8 Regulation for fuel preparation room fire-extinguishing systems

For ships constructed on or after 1 January 2024, fuel preparation rooms containing pumps, compressors or other potential ignition sources are to be provided with a fixed fire-extinguishing system complying with the provisions of Part 6, Chapter 3, Cl. 4.4.1.1 and taking into account the necessary concentrations/application rate required for extinguishing gas fires.

Section 12

Explosion Prevention

12.1 Goal

12.1.1 The goal of this section is to provide for the prevention of explosions and for the limitation of effects from explosion.

12.2 Functional requirements

12.2.1 This section is related to functional requirements in 3.2.2 to 3.2.5, 3.2.7, 3.2.8, 3.2.12 to 3.2.14 and 3.2.17. In particular the following apply:

The probability of explosions is to be reduced to a minimum by:

.1 reducing number of sources of ignition; and

.2 reducing the probability of formation of ignitable mixtures.

12.3 General

12.3.1 Hazardous areas on open deck and other spaces not addressed in this chapter is to be decided based on a recognized standard.* The electrical equipment fitted within hazardous areas is to be according to the same standard.

Note:

** Refer to IEC standard 60092-502, part 4.4: Tankers carrying flammable liquefied gases as applicable.*

12.3.2 Electrical equipment and wiring are in general not to be installed in hazardous areas unless essential for operational purposes based on a recognized standard.*

Note:

** Refer to IEC standard 60092-502: IEC 60092-502:1999 Electrical Installations in Ships – Tankers – Special Features and IEC 60079-10-1:2008 Explosive atmospheres – Part 10-1: Classification of areas – Explosive gas atmospheres, according to the area classification.*

12.3.3 Electrical equipment fitted in an ESD-protected machinery space is to fulfil the following:

.1 in addition to fire and gas hydrocarbon detectors and fire and gas alarms, lighting and ventilation fans are to be certified safe for hazardous area zone 1; and

.2 all electrical equipment in a machinery space containing gas-fuelled engines, and not certified for zone 1 are to be automatically disconnected, if gas concentration above 40% LEL is detected by two detectors in the space containing gas-fuelled consumers.

12.4 Area classification

12.4.1 Area classification is a method of analysing and classifying the areas where explosive gas atmospheres may occur. The object of the classification is to allow the selection of electrical apparatus able to be operated safely in these areas.

12.4.2 In order to facilitate the selection of appropriate electrical apparatus and the design of suitable electrical installations, hazardous areas are divided into zones 0, 1 and 2.*. (See also 12.5 below.)

Note:

** Refer to standards IEC 60079-10-1:2008 Explosive atmospheres part 10-1: Classification of areas – Explosive gas atmospheres and guidance and informative examples given in IEC 60092-502:1999, Electrical Installations in Ships – Tankers – Special Features for tankers.*

12.4.3 Ventilation ducts are to have the same area classification as the ventilated space.

12.5 Hazardous area zones

12.5.1 Hazardous area zone 0

12.5.1.1 This zone includes, but is not limited to the interiors of fuel tanks, any pipework for pressure-relief or other venting systems for fuel tanks, pipes and equipment containing fuel.

12.5.2 Hazardous area zone 1*

12.5.2.1 This zone includes, but is not limited to:

.1 tank connection spaces, fuel storage hold spaces** and interbarrier spaces;

IR.1 For the purposes of hazardous area classification, fuel storage hold spaces containing Type C tanks with all potential leakage sources in a tank connection space and having no access to any hazardous area, are to be considered non-hazardous. Where the fuel storage hold spaces include potential leak sources, e.g. tank connections, they are to be considered as hazardous area zone 1. Where the fuel storage hold spaces include bolted access to the tank connection space, they are to be considered as hazardous area zone 2.

.2 fuel preparation room arranged with ventilation according to 13.6;

.3 areas on open deck, or semi-enclosed spaces on deck, within 3 [m] of any fuel tank outlet, gas or vapour outlet,*** bunker manifold valve, other fuel valve, fuel pipe flange, fuel preparation room ventilation outlets and fuel tank openings for pressure release provided to permit the flow of small volumes of gas or vapour mixtures caused by thermal variation;

.4 areas on open deck or semi-enclosed spaces on deck, within 1.5 [m] of fuel preparation room entrances, fuel preparation room ventilation inlets and other openings into zone 1 spaces;

.5 areas on the open deck within spillage coamings surrounding gas bunker manifold valves and 3 [m] beyond these, up to a height of 2.4 [m] above the deck;

.6 enclosed or semi-enclosed spaces in which pipes containing fuel are located, e.g. ducts around fuel pipes, semi-enclosed bunkering stations;

.7 the ESD-protected machinery space is considered a non-hazardous area during normal operation, but will require equipment required to operate following detection of gas leakage to be certified as suitable for zone 1;

.8 a space protected by an airlock is considered as non-hazardous area during normal operation, but will require equipment required to operate following loss of differential pressure between the protected space and the

hazardous area to be certified as suitable for zone 1; and

.9 except for type C tanks, an area within 2.4 [m] of the outer surface of a fuel containment system where such surface is exposed to the weather.

Note:

** Instrumentation and electrical apparatus installed within these areas should be of a type suitable for zone 1.*

*** Fuel storage hold spaces for type C tanks are normally not considered as zone 1.*

**** Such areas are, for example, all areas within 3 [m] of fuel tank hatches, ullage openings or sounding pipes for fuel tanks located on open deck and gas vapour outlets.*

12.5.3 Hazardous area zone 2*

12.5.3.1 This zone includes, but is not limited to areas within 1.5 [m] surrounding open or semi-enclosed spaces of zone 1.

12.5.3.2 Space containing bolted hatch to tank connection space.

Note :

** Instrumentation and electrical apparatus installed within these areas should be of a type suitable for zone 2.*

Section 13

Ventilation

13.1 Goal

13.1.1 The goal of this section is to provide for the ventilation required for safe operation of gas-fuelled machinery and equipment.

13.2 Functional requirements

13.2.1 This section is related to functional requirements in 3.2.2, 3.2.5, 3.2.8, 3.2.10, 3.2.12 to 3.2.14 and 3.2.17.

13.3 General

13.3.1 Any ducting used for the ventilation of hazardous spaces is to be separate from that used for the ventilation of non-hazardous spaces. The ventilation is to function at all temperatures and environmental conditions the ship will be operating in.

13.3.2 Electric motors for ventilation fans are not to be located in ventilation ducts for hazardous spaces unless the motors are certified for the same hazard zone as the space served.

13.3.3 Design of ventilation fans serving spaces containing gas sources are to fulfil the following:

.1 Ventilation fans are not to produce a source of vapour ignition in either the ventilated space or the ventilation system associated with the space. Ventilation fans and fan ducts, in way of fans only, is to be of non-sparking construction defined as:

.1 impellers or housings of non-metallic material, due regard being paid to the elimination of static electricity;

.2 impellers and housings of non-ferrous metals;

.3 impellers and housings of austenitic stainless steel;

.4 impellers of aluminium alloys or magnesium alloys and a ferrous (including austenitic stainless steel) housing on which a ring of suitable thickness of non-ferrous materials is fitted in way of the impeller, due regard being paid to static electricity and corrosion between ring and housing; or

.5 any combination of ferrous (including austenitic stainless steel) impellers and housings with not less than 13 [mm] tip design clearance.

.2 In no case shall the radial air gap between the impeller and the casing be less than 0.1 of the diameter of the impeller shaft in way of the bearing but not less than 2 [mm]. The gap need not be more than 13 [mm].

.3 Any combination of an aluminium or magnesium alloy fixed or rotating component and a ferrous fixed or rotating component, regardless of tip clearance, is considered a sparking hazard and are not to be used in these places.

13.3.4 Ventilation systems required to avoid any gas accumulation are to consist of independent fans, each of sufficient capacity, unless otherwise specified in this Chapter.

13.3.5 Air inlets for hazardous enclosed spaces are to be taken from areas that, in the absence of the considered inlet, would be non-hazardous. Air inlets for non-hazardous enclosed spaces are to be taken from non-hazardous areas at least 1.5 [m] away from the boundaries of any hazardous area. Where the inlet duct passes through a more hazardous space, the duct is to be gas-tight and have over-pressure relative to this space.

13.3.6 Air outlets from non-hazardous spaces are to be located outside hazardous areas.

13.3.7 Air outlets from hazardous enclosed spaces are to be located in an open area that, in the absence of the considered outlet, would be of the same or lesser hazard than the ventilated space.

13.3.8 The required capacity of the ventilation plant is normally based on the total volume of the room. An increase in required ventilation capacity may be necessary for rooms having a complicated form.

13.3.9 Non-hazardous spaces with entry openings to a hazardous area are to be arranged with an airlock and be maintained at overpressure relative to the external hazardous area. The overpressure ventilation is to be arranged according to the following:

.1 During initial start-up or after loss of overpressure ventilation, before energizing any electrical installations not certified safe for the space in the absence of pressurization, it is to be required to:

.1 proceed with purging (at least 5 air changes) or confirm by measurements that the space is non-hazardous; and

.2 pressurize the space.

.2 Operation of the overpressure ventilation is to be monitored and in the event of failure of the overpressure ventilation:

.1 an audible and visual alarm is to be given at a manned location; and

.2 if overpressure cannot be immediately restored, automatic or programmed, disconnection of electrical installations according to a recognized standard* is to be required.

Note:

** Refer to IEC 60092-502:1999 Electrical Installations in Ships – Tankers – Special Features, table 5.*

13.3.10 Non-hazardous spaces with entry openings to a hazardous enclosed space are to be arranged with an airlock and the hazardous space is to be maintained at underpressure relative to the non-hazardous space. Operation of the extraction ventilation in the hazardous space is to be monitored and in the event of failure of the extraction ventilation:

.1 an audible and visual alarm is to be given at a manned location; and

.2 if underpressure cannot be immediately restored, automatic or programmed, disconnection of electrical installations according to a recognized standard in the non-hazardous space is to be required.

13.4 Tank connection space

13.4.1 The tank connection space is to be provided with an effective mechanical forced ventilation system of extraction type. A ventilation capacity of at least 30 air changes per hour is to be provided. The rate of air changes may be reduced if other adequate means of explosion protection are installed. The equivalence of alternative installations is to be demonstrated by a risk assessment.

13.4.2 Approved automatic fail-safe fire dampers are to be fitted in the ventilation trunk for the tank connection space.

13.5 Machinery spaces

13.5.1 The ventilation system for machinery spaces containing gas-fuelled consumers is to be independent of all other ventilation systems.

IR 13.5.1 Spaces enclosed in the boundaries of machinery spaces (such as purifier's room, engine-room workshops and stores) are considered an integral part of machinery spaces containing gas-fuelled consumers and, therefore, their ventilation system does not need to be independent of the one of machinery spaces.

13.5.2 ESD protected machinery spaces are to have ventilation with a capacity of at least 30 air changes per hour. The ventilation system is to ensure a good air circulation in all spaces, and in particular ensure that any formation of gas pockets in the room are detected. As an alternative, arrangements whereby under normal operation the machinery spaces are ventilated with at least 15 air changes an hour is acceptable provided that, if gas is detected in the machinery space, the number of air changes will automatically be increased to 30 an hour.

13.5.3 For ESD protected machinery spaces the ventilation arrangements are to provide sufficient redundancy to ensure a high level of ventilation availability as defined in a standard acceptable to IMO.*

Note:

**Refer to IEC 60079-10-1.*

13.5.4 The number and power of the ventilation fans for ESD protected engine-rooms and for double pipe ventilation systems for gas safe engine-rooms is to be such that the capacity is not reduced by more than 50% of the total ventilation capacity if a fan with a separate circuit from the main switchboard or emergency switchboard or a group of fans with common circuit from the main switchboard or emergency switchboard, is inoperable.

13.6 Fuel preparation room

13.6.1 Fuel preparation rooms, are to be fitted with effective mechanical ventilation system of the underpressure type, providing a ventilation capacity of at least 30 air changes per hour.

13.6.2 The number and power of the ventilation fans is to be such that the capacity is not reduced by more than 50%, if a fan with a separate circuit from the main switchboard or emergency switchboard or a group of fans with common circuit from the main switchboard or emergency switchboard, is inoperable.

13.6.3 Ventilation systems for fuel preparation rooms, are to be in operation when pumps or compressors are working.

13.7 Bunkering station

13.7.1 Bunkering stations that are not located on open deck are to be suitably ventilated to ensure that any vapour being released during bunkering operations will be removed outside. If the natural ventilation is not sufficient, mechanical ventilation is to be provided in accordance with the risk assessment required by 8.3.1.1.

13.8 Ducts and double pipes

13.8.1 Ducts and double pipes containing fuel piping is to be fitted with effective mechanical ventilation system of the extraction type, providing a ventilation capacity of at least 30 air changes per hour. This is not applicable to double pipes in the engine-room if fulfilling 9.6.1.1.

13.8.2 The ventilation system for double piping and for gas valve unit spaces in gas safe engine-rooms is to be independent of all other ventilation systems.

IR13.8.2 Double piping and gas valve unit spaces in gas safe engine-rooms are considered an integral part of the fuel supply systems and, therefore, their ventilation system does not need to be independent of

other fuel supply ventilation systems provided such fuel supply systems contain only gaseous fuel.

13.8.3 The ventilation inlet for the double wall piping or duct is always to be located in a non-hazardous area away from ignition sources. The inlet opening is to be fitted with a suitable wire mesh guard and protected from ingress of water.

IR 13.8.3 The ventilation inlet for the double wall piping or duct is to be always located in a non-hazardous area in open air away from ignition sources.

13.8.4 The capacity of the ventilation for a pipe duct or double wall piping may be below 30 air changes per hour if a flow velocity of minimum 3 [m/s] is ensured. The flow velocity is to be calculated for the duct with fuel pipes and other components installed.

Section 14

Electrical Installations

14.1 Goal

14.1.1 The goal of this section is to provide for electrical installations that minimize the risk of ignition in the presence of a flammable atmosphere.

14.2 Functional requirements

14.2.1 This section is related to functional requirements in 3.2.1, 3.2.2, 3.2.4, 3.2.7, 3.2.8, 3.2.11, 3.2.13 and 3.2.16 to 3.2.18. In particular the following apply:

.1 Electrical generation and distribution systems, and associated control systems, is to be designed such that a single fault will not result in the loss of ability to maintain fuel tank pressures and hull structure temperature within normal operating limits.

14.3 General

14.3.1 Electrical installations are to be in compliance with a standard at least equivalent to those acceptable to IMO .*

Note :

** Refer to IEC 60092 series standards, as applicable.*

14.3.2 Electrical equipment or wiring is not to be installed in hazardous areas unless essential for operational purposes or safety enhancement.

14.3.3 Where electrical equipment is installed in hazardous areas as provided in 14.3.2 it is to be selected, installed and maintained in accordance with standards at least equivalent to those acceptable to IMO.*

Equipment for hazardous areas is to be evaluated and certified or listed by an accredited testing authority or notified body recognized by the Administration.

Note:

** Refer to the recommendation published by the International Electrotechnical Commission, in particular to publication IEC 60092-502:1999.*

14.3.4 Failure modes and effects of single failure for electrical generation and distribution systems in 14.2 is to be analysed and documented to be at least equivalent to those acceptable to IMO.*

Note:

** Refer to IEC 60812.*

14.3.5 The lighting system in hazardous areas is to be divided between at least two branch circuits. All switches and protective devices are to interrupt all poles or phases and are to be located in a non-hazardous area.

14.3.6 The installation on board of the electrical equipment units is to be such as to ensure the safe bonding to the hull of the units themselves.

14.3.7 Arrangements are to be made to alarm in low-liquid level and automatically shutdown the motors in the event of low-low liquid level. The automatic shutdown may be accomplished by sensing low pump discharge pressure, low motor current, or low-liquid level. This shutdown shall give an audible and visual alarm on the navigation bridge, continuously manned central control station or onboard safety centre.

14.3.8 Submerged fuel pump motors and their supply cables may be fitted in liquefied gas fuel containment systems. Fuel pump motors is to be capable of being isolated from their electrical supply during gas-freeing operations.

14.3.9 For non-hazardous spaces with access from hazardous open deck where the access is protected by an airlock, electrical equipment which is not of the certified safe type is to be de-energized upon loss of overpressure in the space.

14.3.10 Electrical equipment for propulsion, power generation, manoeuvring, anchoring and mooring, as well as emergency fire pumps, that are located in spaces protected by airlocks, are to be of a certified safe type.

Section 15

Control, Monitoring and Safety Systems

15.1 Goal

15.1.1 The goal of this section is to provide for the arrangement of control, monitoring and safety systems that support an efficient and safe operation of the gas-fuelled installation as covered in the other chapters of this Chapter.

15.2 Functional requirements

This chapter is related to functional requirements in 3.2.1, 3.2.2, 3.2.11, 3.2.13 to 3.2.15, 3.2.17 and 3.2.18. In particular the following apply:

.1 the control, monitoring and safety systems of the gas-fuelled installation is to be so arranged that the remaining power for propulsion and power generation is in accordance with 9.3.1 in the event of single failure;

.2 a gas safety system is to be arranged to close down the gas supply system automatically, upon failure in systems as described in Table 1 and upon other fault conditions which may develop too fast for manual intervention;

.3 for ESD protected machinery configurations the safety system is to shutdown gas supply upon gas leakage and in addition disconnect all non-certified safe type electrical equipment in the machinery space;

.4 the safety functions are to be arranged in a dedicated gas safety system that is independent of the gas control system in order to avoid possible common cause failures. This includes power supplies and input and output signal;

.5 the safety systems including the field instrumentation are to be arranged to avoid spurious shutdown, e.g. as a result of a faulty gas detector or a wire break in a sensor loop; and

.6 where two or more gas supply systems are required to meet the requirements, each system is to be fitted with its own set of independent gas control and gas safety systems.

15.3 General

15.3.1 Suitable instrumentation devices are to be fitted to allow a local and a remote reading of essential parameters to ensure a safe management of the whole fuel-gas equipment including bunkering.

15.3.2 A bilge well in each tank connection space of an independent liquefied gas storage tank is to be provided with both a level

indicator and a temperature sensor. Alarm is to be given at high level in the bilge well. Low temperature indication shall activate the safety system.

IR 15.3.2 The "level indicator" required by 15.3.2 is understood to be required for the purposes of indicating an alarm status only; a level switch (float switch) is an instrument example considered to meet this requirement.

15.3.3 For tanks not permanently installed in the ship a monitoring system is to be provided as for permanently installed tanks.

15.4 Bunkering and liquefied gas fuel tank monitoring

15.4.1 Level indicators for liquefied gas fuel tanks

.1 Each liquefied gas fuel tank is to be fitted with liquid level gauging device(s), arranged to ensure a level reading is always obtainable whenever the liquefied gas fuel tank is operational. The device(s) is to be designed to operate throughout the design pressure range of the liquefied gas fuel tank and at temperatures within the fuel operating temperature range.

.2 Where only one liquid level gauge is fitted it is to be arranged so that it can be maintained in an operational condition without the need to empty or gas-free the tank.

.3 Liquefied gas fuel tank liquid level gauges may be of the following types:

.1 indirect devices, which determine the amount of fuel by means such as weighing or in-line flow metering; or

.2 closed devices, which do not penetrate the liquefied gas fuel tank, such as devices using radio-isotopes or ultrasonic devices;

15.4.2 Overflow control

.1 Each liquefied gas fuel tank is to be fitted with a high liquid level alarm operating independently of other liquid level indicators and giving an audible and visual warning when activated.

.2 An additional sensor operating independently of the high liquid level alarm shall automatically actuate a shutoff valve in a manner that will both avoid excessive liquid pressure in the bunkering line and prevent the liquefied gas fuel tank from becoming liquid full.

.3 The position of the sensors in the liquefied gas fuel tank is to be capable of being verified before commissioning. At the first occasion of full loading after delivery and after each dry-docking, testing of high level alarms is to be conducted by raising the fuel liquid level in the liquefied gas fuel tank to the alarm point.

IR.3 The expression “each dry docking” refers to:

- the survey of the outside of the ship’s bottom required for the renewal of the Cargo Ship Safety Construction Certificate and or that Cargo Ship Safety Certificate, for cargo ships.

- The survey of the outside of the ship’s bottom to be carried out every 60 months according to IMO Resolutions A.1104(29, paragraphs 5.10.1 and 5.10.2), for passenger ships.

.4 All elements of the level alarms, including the electrical circuit and the sensor(s), of the high, and overfill alarms, is to be capable of being functionally tested. Systems are to be tested prior to fuel operation in accordance with 18.4.3.

.5 Where arrangements are provided for overriding the overflow control system, they are to be such that inadvertent operation is prevented. When this override is operated continuous visual indication is to be provided at the navigation bridge, continuously manned central control station or onboard safety centre.

15.4.3 The vapour space of each liquefied gas fuel tank is to be provided with a direct reading gauge. Additionally, an indirect indication is to be provided on the navigation bridge, continuously manned central control station or onboard safety centre.

15.4.4 The pressure indicators are to be clearly marked with the highest and lowest pressure permitted in the liquefied gas fuel tank.

15.4.5 A high-pressure alarm and, if vacuum protection is required, a low-pressure alarm is to be provided on the navigation bridge and at a continuously manned central control station or onboard safety centre. Alarms are to be activated before the set pressures of the safety valves are reached.

15.4.6 Each fuel pump discharge line and each liquid and vapour fuel manifold is to be provided with at least one local pressure indicator.

15.4.7 Local-reading manifold pressure indicator is to be provided to indicate the pressure between ship's manifold valves and hose connections to the shore.

15.4.8 Fuel storage hold spaces and interbarrier spaces without open connection to the atmosphere are to be provided with pressure indicator.

15.4.9 At least one of the pressure indicators provided is to be capable of indicating throughout the operating pressure range.

15.4.10 For submerged fuel-pump motors and their supply cables, arrangements is to be made to alarm in low-liquid level and automatically shutdown the motors in the event of low-low liquid level. The automatic shutdown may be accomplished by sensing low pump discharge pressure, low motor current, or low-liquid level. This shutdown shall give an audible and visual alarm on the navigation bridge, continuously manned central control station or onboard safety centre.

15.4.11 Except for independent tanks of type C supplied with vacuum insulation system and pressure build-up fuel discharge unit, each fuel tank is to be provided with devices to measure and indicate the temperature of the fuel in at least three locations; at the bottom and middle of the tank as well as the top of the tank below the highest allowable liquid level.

15.5 Bunkering control

15.5.1 Control of the bunkering is to be possible from a safe location remote from the bunkering station. At this location the tank pressure, tank temperature if required by 15.4.11, and tank level is to be monitored. Remotely controlled valves required by 8.5.3 and 11.5.7 are to be capable of being operated from this location. Overfill alarm and automatic shutdown shall also be indicated at this location.

15.5.2 If the ventilation in the ducting enclosing the bunkering lines stops, an audible and visual alarm is to be provided at the bunkering control location, see also 15.8.

15.5.3 If gas is detected in the ducting around the bunkering lines an audible and visual alarm and emergency shutdown is to be provided at the bunkering control location.

15.6 Gas compressor monitoring

15.6.1 Gas compressors are to be fitted with audible and visual alarms both on the navigation bridge and in the engine control room. As a minimum the alarms shall include low gas input pressure, low gas output pressure, high gas output pressure and compressor operation.

15.6.2 Temperature monitoring for the bulkhead shaft glands and bearings is to be provided, which automatically give a continuous audible and visual alarm on the navigation bridge or in a continuously manned central control station.

15.7 Gas engine monitoring

15.7.1 In addition to the instrumentation provided in accordance with part C of SOLAS chapter II-1, indicators are to be fitted on the navigation bridge, the engine control room and the manoeuvring platform for:

.1 operation of the engine in case of gas-only engines; or

.2 operation and mode of operation of the engine in the case of dual fuel engines.

15.8 Gas detection

15.8.1 Permanently installed gas detectors are to be fitted in:

.1 the tank connection spaces;

.2 all ducts around fuel pipes;

.3 machinery spaces containing gas piping, gas equipment or gas consumers;

.4 compressor rooms and fuel preparation rooms;

.5 other enclosed spaces containing fuel piping or other fuel equipment without ducting;

.6 other enclosed or semi-enclosed spaces where fuel vapours may accumulate including interbarrier spaces and fuel storage hold spaces of independent tanks other than type C;

.7 airlocks;

.8 gas heating circuit expansion tanks;

.9 motor rooms associated with the fuel systems; and

.10 at ventilation inlets to accommodation and machinery spaces if required based on the risk assessment required in 4.2.

15.8.2 In each ESD-protected machinery space, redundant gas detection systems are to be provided.

15.8.3 The number of detectors in each space is to be considered taking into account the size, layout and ventilation of the space.

15.8.4 The detection equipment is to be located where gas may accumulate and in the ventilation outlets. Gas dispersal analysis or a physical smoke test is to be used to find the best arrangement.

15.8.5 Gas detection equipment is to be designed, installed and tested in accordance with a recognized standard such as IEC 60079-29-1.

15.8.6 An audible and visible alarm is to be activated at a gas vapour concentration of 20% of the lower explosion limit (LEL). The safety system is to be activated at 40% of LEL at two detectors (see footnote 1 in Table 1).

15.8.7 For ventilated ducts around gas pipes in the machinery spaces containing gas-fuelled engines, the alarm limit can be set to 30% LEL. The safety system is to be activated at 60% of LEL at two detectors (see footnote 1 in Table 1).

15.8.8 Audible and visible alarms from the gas detection equipment are to be located on the navigation bridge or in the continuously manned central control station.

15.8.9 Gas detection required by this section is to be continuous without delay.

15.9 Fire detection

15.9.1 Required safety actions at fire detection in the machinery space containing gas-fuelled engines and rooms containing independent tanks for fuel storage hold spaces are given in Table 1 below.

15.10 Ventilation

15.10.1 Any loss of the required ventilating capacity is to give an audible and visual alarm on the navigation bridge or in a continuously manned central control station or safety centre.

IR 15.10.1 Acceptable means to confirm that the ventilation system has the “required ventilating capacity” in operation are, but not limited to:

- Monitoring of the ventilation electric motor or fan operation combined with under pressure indication; or
- Monitoring of the ventilation electric motor or fan operation combined with ventilation flow indication; or
- Monitoring of ventilation flow rate to indicate that the required air flow rate is established.

15.10.2 For ESD protected machinery spaces the safety system is to be activated upon loss of ventilation in engine-room.

15.11 Safety functions of fuel supply systems

15.11.1 If the fuel supply is shut off due to activation of an automatic valve, the fuel supply is not to be opened until the reason for the disconnection is ascertained and the necessary precautions taken. A readily visible notice giving instruction to this effect is to be placed at the operating station for the shutoff valves in the fuel supply lines.

15.11.2 If a fuel leak leading to a fuel supply shutdown occurs, the fuel supply is not to be operated until the leak has been found and dealt with. Instructions to this effect are to be placed in a prominent position in the machinery space.

15.11.3 A caution placard or signboard is to be permanently fitted in the machinery space containing gas-fuelled engines stating that heavy lifting, implying danger of damage to the fuel pipes, is not to be done when the engine(s) is running on gas.

15.11.4 Compressors, pumps and fuel supply are to be arranged for manual remote emergency stop from the following locations as applicable:

.1 navigation bridge;
.2 cargo control room;
.3 onboard safety centre;
.4 engine control room;
.5 fire control station; and
.6 adjacent to the exit of fuel preparation rooms.

The gas compressor shall also be arranged for manual local emergency stop.

Table 1 : Monitoring of gas supply system to engines

Parameter	Alarm	Automatic shutdown of tank valve[6)]	Automatic shutdown of gas supply to machinery space containing gas-fuelled engines	Comments
Gas detection in tank connection space at 20% LEL	X			
Gas detection on two detectors[1)] in tank connection space at 40% LEL	X	X		
Fire detection in fuel storage hold space	X			
Fire detection in ventilation trunk to the tank connection space and in the tank connection space	X			
Bilge well high level in tank connection space	X			
Bilge well low temperature in tank connection space	X	X		
Gas detection in duct between tank and machinery space containing gas-fuelled engines at 20% LEL	X			

Table 1 : (Contd.)

Parameter	Alarm	Automatic shutdown of tank valve[6)]	Automatic shutdown of gas supply to machinery space containing gas-fuelled engines	Comments
Gas detection on two detectors[1)] in duct between tank and machinery space containing gas-fuelled engines at 40% LEL	X	X[2)]		
Gas detection in fuel preparation room at 20% LEL	X			
Gas detection on two detectors[1)] in fuel preparation room at 40% LEL	X	X[2)]		
Gas detection in duct inside machinery space containing gas-fuelled engines at 30% LEL	X			If double pipe fitted in machinery space containing gas-fuelled engines
Gas detection on two detectors[1)] in duct inside machinery space containing gas-fuelled engines at 60% LEL	X		X[3)]	If double pipe fitted in machinery space containing gas-fuelled engines
Gas detection in ESD protected machinery space containing gas-fuelled engines at 20% LEL	X			
Gas detection on two detectors[1)] in ESD protected machinery space containing gas-fuelled engines at 40% LEL	X		X	It shall also disconnect non certified safe electrical equipment in machinery space containing gas-fuelled engines
Loss of ventilation in duct between tank and machinery space containing gas-fuelled engines	X		X[2)]	
Loss of ventilation in duct inside machinery space containing gas-fuelled engines[5)]	X		X[3)]	If double pipe fitted in machinery space containing gas-fuelled engines

Table 1 : (Contd.)

Parameter	Alarm	Automatic shutdown of tank valve[6)]	Automatic shutdown of gas supply to machinery space containing gas-fuelled engines	Comments
Loss of ventilation in ESD protected machinery space containing gas-fuelled engines	X		X	
Fire detection in machinery space containing gas-fuelled engines	X			
Abnormal gas pressure in gas supply pipe	X			
Failure of valve control actuating medium	X		X[4)]	Time delayed as found necessary
Automatic shutdown of engine (engine failure)	X		X[4)]	
Manually activated emergency shutdown of engine	X		X	

1) Two independent gas detectors located close to each other are required for redundancy reasons. If the gas detector is of self-monitoring type the installation of a single gas detector can be permitted.

2) If the tank is supplying gas to more than one engine and the different supply pipes are completely separated and fitted in separate ducts and with the master valves fitted outside of the duct, only the master valve on the supply pipe leading into the duct where gas or loss of ventilation is detected shall close.

3) If the gas is supplied to more than one engine and the different supply pipes are completely separated and fitted in separate ducts and with the master valves fitted outside of the duct and outside of the machinery space containing gas-fuelled engines, only the master valve on the supply pipe leading into the duct where gas or loss of ventilation is detected shall close.

4) Only double block and bleed valves to close.

5) If the duct is protected by inert gas (see 9.6.1.1) then loss of inert gas overpressure shall lead to the same actions as given in this Table.

6) Valves referred to in 9.4.1.

Section 16

Manufacture, Workmanship and Testing

16.1 General

16.1.1 The manufacture, testing, inspection and documentation are to be in accordance with recognized standards and the requirements given in this Chapter.

16.1.2 Where post-weld heat treatment is specified or required, the properties of the base material is to be determined in the heat treated condition, in accordance with the applicable Tables of Section 7, and the weld properties is to be determined in the heat treated condition in accordance with 16.3. In cases where a post-weld heat treatment is applied, the test requirements may be modified at the discretion of the Administration/ IRS.

16.2 General test requirements and specifications

16.2.1 Tensile test

16.2.1.1 Tensile testing is to be carried out in accordance with recognized standards.

16.2.1.2 Tensile strength, yield stress and elongation are to be to the satisfaction of the IRS/Administration. For carbon-manganese steel and other materials with definitive yield points, consideration is to be given to the limitation of the yield to tensile ratio.

16.2.2 Toughness test

16.2.2.1 Acceptance tests for metallic materials are to include Charpy V-notch toughness tests unless otherwise specified by the IRS/Administration. The specified Charpy V-notch requirements are minimum average energy values for three full size (10 [mm] × 10 [mm]) specimens and minimum single energy values for individual specimens. Dimensions and tolerances of Charpy V-notch specimens is to be in accordance with recognized standards. The testing and requirements for specimens smaller than 5 [mm] in size is to be in accordance with recognized standards. Minimum average values for sub-sized specimens are to be:

Charpy V-notch specimen size (mm)	Minimum average energy of three specimens
10 x 10	KV
10 x 7.5	5/6 KV
10 x 5.0	2/3 KV

where:

KV = the energy values [J] specified in Tables 7.1 to 7.4.

Only one individual value may be below the specified average value, provided it is not less than 70% of that value.

16.2.2.2 For base metal, the largest size Charpy V-notch specimens possible for the material thickness is to be machined with the specimens located as near as practicable to a point midway between the surface and the centre of the thickness and the length of the notch perpendicular to the surface as shown in Fig.16.1.

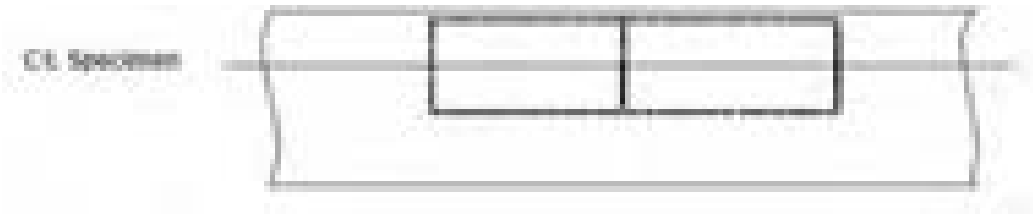

Fig.16.1: Orientation of base metal test specimen

16.2.2.3 For a weld test specimen, the largest size Charpy V-notch specimens possible for the material thickness is to be machined, with the specimens located as near as practicable to a point midway between the surface and the centre of the thickness. In all cases the distance from the surface of the material to the edge of the specimen is to be approximately 1 [mm] or greater. In addition, for double-V butt welds, specimens are to be machined closer to the surface of the second welded section. The specimens is to be taken generally at each of the following locations, as shown in Fig.16.2, on the centreline of the welds, the fusion line and 1 [mm], 3 [mm] and 5 [mm] from the fusion line.

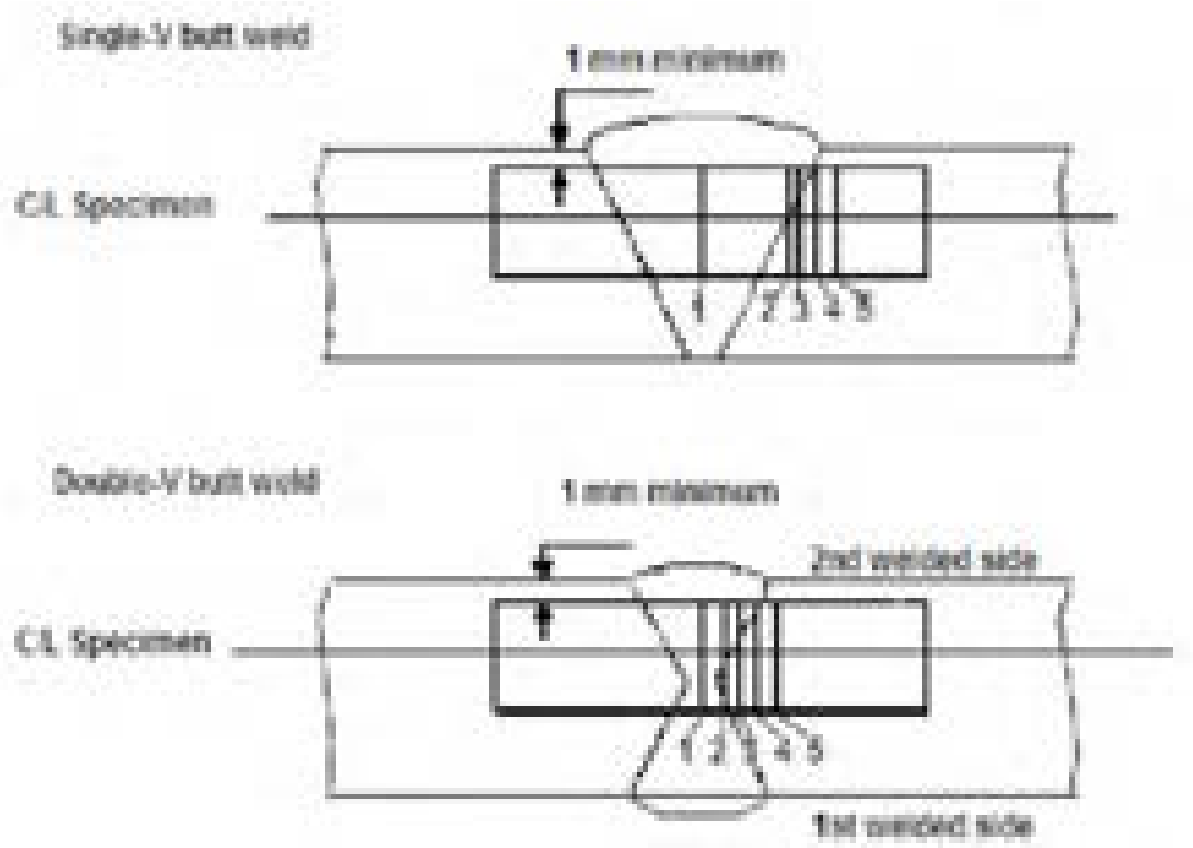

Fig.16.2 : Orientation of weld test specimen

Notch locations in Fig.16.2:

.1 centreline of the weld;

.2 on fusion line;

.3 in heat-affected zone (HAZ), 1 [mm] from fusion line;

.4 in HAZ, 3 [mm] from fusion line; and

.5 in HAZ, 5 [mm] from fusion line.

16.2.2.4 If the average value of the three initial Charpy V-notch specimens fails to meet the stated requirements, or the value for more than one specimen is below the required average value, or when the value for one specimen is below the minimum value permitted for a single specimen, three additional specimens from the same material may be tested and the results combined with those previously obtained to form a new average. If this new average complies with the requirements and if no more than two individual results are lower, than the required average and no more than one result is lower than the required value for a single specimen, the piece or batch may be accepted.

16.2.3 Bend test

16.2.3.1 The bend test may be omitted as a material acceptance test, but is required for weld tests. Where a bend test is performed, this is to be done in accordance with recognized standards.

16.2.3.2 The bend tests are to be transverse bend tests, which may be face, root or side bends at the discretion of the IRS/Administration. However, longitudinal bend tests may be required in lieu of transverse bend tests in cases where the base material and weld metal have different strength levels.

16.2.4 Section observation and other testing

16.2.4.1 Macrosection, microsection observations and hardness tests may also be required by the IRS/Administration, and they are to be carried out in accordance with recognized standards, where required.

16.3 Welding of metallic materials and non-destructive testing for the fuel containment system

16.3.1 General

16.3.1.1 This sub-section applicable to primary and secondary barriers only, including the inner hull where this forms the secondary barrier. Acceptance testing is specified for carbon, carbon-manganese, nickel alloy and stainless steels, but these tests may be adapted for other materials. At the discretion of the IRS/Administration, impact testing of stainless steel and aluminium alloy weldments may be omitted and other tests may be specially required for any material.

16.3.2 Welding consumables

16.3.2.1 Consumables intended for welding of fuel tanks are to be in accordance with recognized standards. Deposited weld metal tests and butt weld tests is to be required for all consumables. The results obtained from tensile and Charpy V-notch impact tests are to be in accordance with recognized standards. The chemical composition of the deposited weld metal is to be recorded for information.

16.3.3 Welding procedure tests for fuel tanks and process pressure vessels

16.3.3.1 Welding procedure tests for fuel tanks and process pressure vessels are required for all butt welds.

16.3.3.2 The test assemblies are to be representative of:

.1 each base material;

.2 each type of consumable and welding process; and

.3 each welding position.

16.3.3.3 For butt welds in plates, the test assemblies is to be so prepared that the rolling direction is parallel to the direction of welding. The range of thickness qualified by each welding procedure test is to be in accordance with recognized standards. Radiographic or ultrasonic testing may be performed at the option of the fabricator.

16.3.3.4 The following welding procedure tests for fuel tanks and process pressure vessels is to be done in accordance with 16.2 with specimens made from each test assembly:

.1 cross-weld tensile tests;

.2 longitudinal all-weld testing where required by the recognized standards;

.3 transverse bend tests, which may be face, root or side bends. However, longitudinal bend tests may be required in lieu of transverse bend tests in cases where the base material and weld metal have different strength levels;

.4 one set of three Charpy V-notch impacts, generally at each of the following locations, as shown in Fig.16.2:

.1 centreline of the welds;

.2 fusion line;

.3 1 [mm] from the fusion line;

.4 3 [mm] from the fusion line; and

.5 5 [mm] from the fusion line;

.5 macrosection, microsection and hardness survey may also be required.

16.3.3.5 Each test are to satisfy the following:

.1 Tensile tests: cross-weld tensile strength is not to be less than the specified minimum tensile strength for the appropriate parent materials. For materials such as aluminium alloys,

reference is to be made to 6.4.12.1.1.3 with regard to the requirements for weld metal strength of under-matched welds (where the weld metal has a lower tensile strength than the parent metal). In every case, the position of fracture is to be recorded for information;

.2 Bend tests: no fracture is acceptable after a 180° bend over a former of a diameter four times the thickness of the test pieces; and

.3 Charpy V-notch impact tests: Charpy V-notch tests is to be conducted at the temperature prescribed for the base material being joined. The results of weld metal impact tests, minimum average energy (KV), are to be no less than 27 [J]. The weld metal requirements for sub-size specimens and single energy values are to be in accordance with 16.2.2. The results of fusion line and heat affected zone impact tests are to show a minimum average energy (KV) in accordance with the transverse or longitudinal requirements of the base material, whichever is applicable, and for sub-size specimens, the minimum average energy (KV) is to be in accordance with 16.2.2. If the material thickness does not permit machining either full-size or standard sub-size specimens, the testing procedure and acceptance standards are to be in accordance with recognized standards.

16.3.3.6 Procedure tests for fillet welding is to be in accordance with recognized standards. In such cases, consumables are to be so selected that exhibit satisfactory impact properties.

16.3.4 Welding procedure tests for piping

16.3.4.1 Welding procedure tests for piping are to be carried out and are to be similar to those detailed for fuel tanks in 16.3.3.

16.3.5 Production weld tests

16.3.5.1 For all fuel tanks and process pressure vessels except membrane tanks, production weld tests are to generally be performed for approximately each 50 [m] of butt-weld joints and are to be representative of each welding position. For secondary barriers, the same type production tests as required for primary tanks are to be performed, except that the number of tests may be reduced subject to agreement with IRS/Administration. Tests, other than those specified in 16.3.5.2 to 16.3.5.5 may be required for fuel tanks or secondary barriers.

16.3.5.2 The production tests for types A and B independent tanks are to include bend tests and, where required for procedure tests, one set of three Charpy V-notch tests. The tests are to be made for each 50 [m] of weld. The Charpy V-notch tests are to be made with specimens having the notch alternately located in the centre of the weld and in the heat affected zone (most critical location based on procedure qualification results). For austenitic stainless steel, all notches are to be in the centre of the weld.

16.3.5.3 For type C independent tanks and process pressure vessels, transverse weld tensile tests are required in addition to the tests listed in 16.3.5.2. Tensile tests are to meet requirement 16.3.3.5.

16.3.5.4 The quality assurance/quality control (QA/QC) program are to ensure the continued conformity of the production welds as defined in the material manufacturers quality manual (QM).

16.3.5.5 The test requirements for membrane tanks are the same as the applicable test requirements listed in 16.3.3.

16.3.6 Non-destructive testing

16.3.6.1 All test procedures and acceptance standards are to be in accordance with recognized standards, unless the designer specifies a higher standard in order to meet design assumptions. Radiographic testing is to be used in principle to detect internal defects. However, an approved ultrasonic test procedure in lieu of radiographic testing may be conducted, but in addition supplementary radiographic testing at selected locations is to be carried out to verify the results. Radiographic and ultrasonic testing records are to be retained.

16.3.6.2 For type A independent tanks where the design temperature is below -20°C, and for type B independent tanks, regardless of temperature, all full penetration butt welds of the shell plating of fuel tanks are to be

subjected to non-destructive testing suitable to detect internal defects over their full length. Ultrasonic testing in lieu of radiographic testing may be carried out under the same conditions as described in 16.3.6.1.

16.3.6.3 In each case the remaining tank structure, including the welding of stiffeners and other fittings and attachments, are to be examined by magnetic particle or dye penetrant methods as considered necessary.

16.3.6.4 For type C independent tanks, the extent of non-destructive testing is to be total or partial according to recognized standards, but the controls to be carried out are not to be less than the following:

.1 Total non-destructive testing referred to in 6.4.15.3.2.1.3

Radiographic testing:

.1 all butt welds over their full length.

Non-destructive testing for surface crack detection:

.2 all welds over 10% of their length;

.3 reinforcement rings around holes, nozzles, etc. over their full length.

As an alternative, ultrasonic testing, as described in 16.3.6.1, may be accepted as a partial substitute for the radiographic testing. In addition, IRS/Administration may require total ultrasonic testing on welding of reinforcement rings around holes, nozzles, etc.

.2 Partial non-destructive testing referred to in 6.4.15.3.2.1.3:

Radiographic testing:

.1 all butt welded crossing joints and at least 10% of the full length of butt welds at selected positions uniformly distributed.

Non-destructive testing for surface crack detection:

.2 reinforcement rings around holes, nozzles, etc. over their full length.

Ultrasonic testing:

.3 as may be required by IRS/Administration in each instance.

16.3.6.5 The quality assurance/quality control (QA/QC) program is to ensure the continued conformity of the non-destructive testing of welds, as defined in the material manufacturer's quality manual (QM).

16.3.6.6 Inspection of piping is to be carried out in accordance with the requirements of Section 7.

16.3.6.7 The secondary barrier is to be non-destructive tested for internal defects as considered necessary. Where the outer shell of the hull is part of the secondary barrier, all sheer strake butts and the intersections of all butts and seams in the side shell is to be tested by radiographic testing.

16.4 Other requirements for construction in metallic materials

16.4.1 General

16.4.1.1 Inspection and non-destructive testing of welds are to be in accordance with requirements in 16.3.5 and 16.3.6. Where higher standards or tolerances are assumed in the design, they are also to be satisfied.

16.4.2 Independent tank

16.4.2.1 For type C tanks and type B tanks primarily constructed of bodies of revolution the tolerances relating to manufacture, such as out-of-roundness, local deviations from the true form, welded joints alignment and tapering of plates having different thicknesses, shall comply with recognized standards. The tolerances shall also be related to the buckling analysis referred to in 6.4.15.2.3.1 and 6.4.15.3.3.2.

16.4.3 Secondary barriers

16.4.3.1 During construction the requirements for testing and inspection of secondary barriers is to be approved or accepted by IRS/Administration (see also 6.4.4.5 and 6.4.4.6).

16.4.4 Membrane tanks

16.4.4.1 The quality assurance/quality control (QA/QC) program is to ensure the continued conformity of the weld procedure qualification, design details, materials, construction, inspection and production testing of components. These standards and procedures are to be developed during the prototype testing programme.

16.5 Testing

16.5.1 Testing and inspections during construction

16.5.1.1 All liquefied gas fuel tanks and process pressure vessels is to be subjected to hydrostatic or hydro-pneumatic pressure testing in accordance with 16.5.2 to 16.5.5, as applicable for the tank type.

16.5.1.2 All tanks are to be subject to a tightness test which may be performed in combination with the pressure test referred to in 16.5.1.1.

16.5.1.3 The gas tightness of the fuel containment system with reference to 6.3.3 is to be tested.

16.5.1.4 Regulations with respect to inspection of secondary barriers are to be decided by IRS/Administration in each case, taking into account the accessibility of the barrier (see also 6.4.4).

16.5.1.5 IRS/Administration may require that for ships fitted with novel type B independent tanks, or tanks designed according to 6.4.16 at least one prototype tank and its support is to be instrumented with strain gauges or other suitable equipment to confirm stress levels during the testing required in 16.5.1.1. Similar instrumentation may be required for type C independent tanks, depending on their configuration and on the arrangement of their supports and attachments.

16.5.1.6 The overall performance of the fuel containment system is to be verified for compliance with the design parameters during the first LNG bunkering, when steady thermal conditions of the liquefied gas fuel are reached, in accordance with the requirements of IRS/Administration. Records of the performance of the components and equipment, essential to verify the design parameters, are to be maintained on board and be available to IRS/Administration.

16.5.1.7 The fuel containment system is to be inspected for cold spots during or immediately following the first LNG bunkering, when steady thermal conditions are reached. Inspection of the integrity of thermal insulation surfaces that cannot be visually checked is to be carried out in accordance with the requirements of IRS/Administration.

16.5.1.8 Heating arrangements, if fitted in accordance with 6.4.13.1.1.3 and 6.4.13.1.1.4, are to be tested for required heat output and heat distribution.

16.5.2 Type A independent tanks

16.5.2.1 All type A independent tanks are to be subjected to a hydrostatic or hydro-pneumatic pressure testing. This test is to be performed such that the stresses approximate, as far as practicable, the design stresses, and that the pressure at the top of the tank corresponds at least to the MARVS. When a hydropneumatic test is performed, the conditions shall simulate, as far as practicable, the design loading of the tank and of its support structure including dynamic components, while avoiding stress levels that could cause permanent deformation.

16.5.3 Type B independent tanks

16.5.3.1 Type B independent tanks are to be subjected to a hydrostatic or hydro-pneumatic pressure testing as follows:

.1 The test is to be performed as required in 16.5.2 for type A independent tanks.

.2 In addition, the maximum primary membrane stress or maximum bending stress in primary members under test conditions shall not exceed 90% of the yield strength of the material (as fabricated) at the test temperature. To ensure that this condition is satisfied, when calculations indicate that this stress exceeds 75% of the yield strength the test of the first of a series of identical

tanks is to be monitored by the use of strain gauges or other suitable equipment.

16.5.4 Type C independent tanks and other pressure vessels

16.5.4.1 Each pressure vessel is to be subjected to a hydrostatic test at a pressure measured at the top of the tanks, of not less than 1.5 P_0. In no case during the pressure test shall the calculated primary membrane stress at any point exceed 90% of the yield strength of the material at the test temperature. To ensure that this condition is satisfied where calculations indicate that this stress will exceed 0.75 times the yield strength, the test of the first of a series of identical tanks is to be monitored by the use of strain gauges or other suitable equipment in pressure vessels other than simple cylindrical and spherical pressure vessels.

16.5.4.2 The temperature of the water used for the test is to be at least 30 [°C] above the nil-ductility transition temperature of the material, as fabricated.

16.5.4.3 The pressure is to be held for 2 hours per 25 [mm] of thickness, but in no case less than 2 hours.

16.5.4.4 Where necessary for liquefied gas fuel pressure vessels, a hydro-pneumatic test may be carried out under the conditions prescribed in 16.5.4.1 to 16.5.4.3.

16.5.4.5 Special consideration may be given to the testing of tanks in which higher allowable stresses are used, depending on service temperature. However, requirement in 16.5.4.1 is to be fully complied with.

16.5.4.6 After completion and assembly, each pressure vessel and its related fittings are to be subjected to an adequate tightness test, which may be performed in combination with the pressure testing referred to in 16.5.4.1 or 16.5.4.4 as applicable.

16.5.4.7 Pneumatic testing of pressure vessels other than liquefied gas fuel tanks are to be considered on an individual case basis. Such testing are only to be permitted for those vessels designed or supported such that they cannot be safely filled with water, or for those vessels that cannot be dried and are to be used in a service where traces of the testing medium cannot be tolerated.

16.5.5 Membrane tanks

16.5.5.1 Design development testing

16.5.5.1.1 The design development testing required in 6.4.15.4.1.2 is to include a series of analytical and physical models of both the primary and secondary barriers, including corners and joints, tested to verify that they will withstand the expected combined strains due to static, dynamic and thermal loads at all filling levels. This will culminate in the construction of a prototype scaled model of the complete liquefied gas fuel containment system. Testing conditions considered in the analytical and physical model are to represent the most extreme service conditions the liquefied gas fuel containment system will be likely to encounter over its life. Proposed acceptance criteria for periodic testing of secondary barriers required in 6.4.4 may be based on the results of testing carried out on the prototype scaled model.

16.5.5.1.2 The fatigue performance of the membrane materials and representative welded or bonded joints in the membranes are to be determined by tests. The ultimate strength and fatigue performance of arrangements for securing the thermal insulation system to the hull structure is to be determined by analyses or tests.

16.5.5.2 Testing

.1 In ships fitted with membrane liquefied gas fuel containment systems, all tanks and other spaces that may normally contain liquid and are adjacent to the hull structure supporting the membrane, are to be hydrostatically tested.

.2 All hold structures supporting the membrane are to be tested for tightness before installation of the liquefied gas fuel containment system.

.3 Pipe tunnels and other compartments that do not normally contain liquid need not be hydrostatically tested.

16.6 Welding, post-weld heat treatment and non-destructive testing

16.6.1 General

16.6.1.1 Welding is to be carried out in accordance with 16.3.

16.6.2 Post-weld heat treatment

16.6.2.1 Post-weld heat treatment is to be required for all butt welds of pipes made with carbon, carbon-manganese and low alloy steels. IRS/Administration may waive the requirements for thermal stress relieving of pipes with wall thickness less than 10 [mm] in relation to the design temperature and pressure of the piping system concerned.

16.6.3 Non-destructive testing

16.6.3.1 In addition to normal controls before and during the welding, and to the visual inspection of the finished welds, as necessary for proving that the welding has been carried out correctly and according to the requirements in this paragraph, the following tests are to be required:

.1 100% radiographic or ultrasonic inspection of butt-welded joints for piping systems with;

.1 design temperatures colder than minus 10[°C]; or

.2 design pressure greater than 1 [MPa]; or

.3 gas supply pipes in ESD protected machinery spaces; or

.4 inside diameters of more than 75 [mm]; or

.5 wall thicknesses greater than 10 [mm].

.2 When such butt welded joints of piping sections are made by automatic welding procedures approved by IRS/Administration, then a progressive reduction in the extent of radiographic or ultrasonic inspection can be agreed, but in no case to less than 10% of each joint. If defects are revealed the extent of examination is to be increased to 100% and is to include inspection of previously accepted welds. This approval can only be granted if well-documented quality assurance procedures and records are available to assess the ability of the manufacturer to produce satisfactory welds consistently.

.3 The radiographic or ultrasonic inspection requirement may be reduced to 10% for butt-welded joints in the outer pipe of double-walled fuel piping.

.4 For other butt-welded joints of pipes not covered by 16.6.3.1 and 16.6.3.3, spot radiographic or ultrasonic inspection or other non-destructive tests are to be carried out depending upon service, position and materials. In general, at least 10% of butt-welded joints of pipes are to be subjected to radiographic or ultrasonic inspection.

16.7 Testing requirements

16.7.1 Type testing of piping components

16.7.1.1 Valves

16.7.1.1.1 Each type of piping component intended to be used at a working temperature below minus 55[°C] is to be subject to the following type tests:

.1 Each size and type of valve is to be subjected to seat tightness testing over the full range of operating pressures and temperatures, at intervals, up to the rated design pressure of the valve. Allowable leakage rates are to be to the requirements of IRS/Administration During the testing satisfactory operation of the valve is to be verified.

.2 The flow or capacity is to be certified to a recognized standard for each size and type of valve.

.3 Pressurized components are to be pressure tested to at least 1.5 times the design pressure.

.4 For emergency shutdown valves, with materials having melting temperatures lower than 925[°C], the type testing is to include a fire test to a standard at least equivalent to those acceptable to IMO*

Note :

** Refer to the recommendations by the International Organization for Standardization, in particular publications:*

ISO 19921:2005, Ships and marine technology – Fire resistance of metallic pipe components with resilient and elastomeric seals – Test methods

ISO 19922:2005, Ships and marine technology – Fire resistance of metallic pipe components with resilient and elastomeric seals – Requirements imposed on the test bench

16.7.2 Expansion bellows

16.7.2.1 The following type tests are to be performed on each type of expansion bellows intended for use on fuel piping outside the fuel tank as found acceptable in 7.3.6.4.3.1.3 and where required by IRS/Administration, on those installed within the fuel tanks:

.1 Elements of the bellows, not pre-compressed, but axially restrained are to be pressure tested at not less than five times the design pressure without bursting. The duration of the test is not to be less than five minutes.

.2 A pressure test is to be performed on a type expansion joint, complete with all the accessories such as flanges, stays and articulations, at the minimum design temperature and twice the design pressure at the extreme displacement conditions recommended by the manufacturer without permanent deformation.

.3 A cyclic test (thermal movements) is to be performed on a complete expansion joint, which is to withstand at least as many cycles under the conditions of pressure, temperature, axial movement, rotational movement and transverse movement as it will encounter in actual service. Testing at ambient temperature is permitted when this testing is at least as severe as testing at the service temperature.

.4 A cyclic fatigue test (ship deformation, ship accelerations and pipe vibrations) is to be performed on a complete expansion joint, without internal pressure, by simulating the bellows movement corresponding to a compensated pipe length, for at least 2,000,000 cycles at a frequency not higher than 5 [Hz]. This test is only required when, due to the piping arrangement, ship deformation loads are actually experienced.

16.7.3 System testing requirements

16.7.3.1 The requirements for testing in this section apply to fuel piping inside and outside the fuel tanks. However, relaxation from these requirements for piping inside fuel tanks and open ended piping may be accepted by IRS/Administration.

16.7.3.2 After assembly, all fuel piping is to be subjected to a strength test with a suitable fluid. The test pressure is to be at least 1.5 times the design pressure for liquid lines and 1.5 times the maximum system working pressure for vapour lines. When piping systems or parts of systems are completely manufactured and equipped with all fittings, the test may be conducted prior to installation on board the ship. Joints welded on board are to be tested to at least 1.5 times the design pressure.

16.7.3.3 After assembly on board, the fuel piping system is to be subjected to a leak test using air, or other suitable medium to a pressure depending on the leak detection method applied.

16.7.3.4 In double wall fuel piping systems the outer pipe or duct is also to be pressure tested to show that it can withstand the expected maximum pressure at pipe rupture.

16.7.3.5 All piping systems, including valves, fittings and associated equipment for handling fuel or vapours, are to be tested under normal operating conditions not later than at the first bunkering operation, in accordance with the requirements of IRS/Administration.

16.7.3.6 Emergency shutdown valves in liquefied gas piping systems are to close fully and smoothly within 30 s of actuation. Information about the closure time of the

valves and their operating characteristics is to be available on board, and the closing time is to be verifiable and repeatable.

16.7.3.7 The closing time of the valve referred to in 8.5.8 and 15.4.2.2 (i.e. time from shutdown signal initiation to complete valve closure) is not to be greater than:

$$\frac{3600U}{BR} \quad (\text{second})$$

where:

U = ullage volume at operating signal level [m^3];

BR = maximum bunkering rate agreed between ship and shore facility [m^3/h]; or
5 seconds, whichever is the least.

The bunkering rate is to be adjusted to limit surge pressure on valve closure to an acceptable level, taking into account the bunkering hose or arm, the ship and the shore piping systems, where relevant.

ANNEX 1
Standard for the use of Limit State Methodologies in the Design of Fuel Containment Systems of Novel Configuration

1 GENERAL

1.1 The purpose of this standard is to provide procedures and relevant design parameters of limit state design of fuel containment systems of a novel configuration in accordance with section 6.4.16.

1.2 Limit state design is a systematic approach where each structural element is evaluated with respect to possible failure modes related to the design conditions identified in 6.4.1.6. A limit state can be defined as a condition beyond which the structure, or part of a structure, no longer satisfies the requirements.

1.3 The limit states are divided into the three following categories:

.1 Ultimate Limit States (ULS), which correspond to the maximum load-carrying capacity or, in some cases, to the maximum applicable strain, deformation or instability in structure resulting from buckling and plastic collapse; under intact (undamaged) conditions;

.2 Fatigue Limit States (FLS), which correspond to degradation due to the effect of cyclic loading; and

.3 Accident Limit States (ALS), which concern the ability of the structure to resist accident situations.

1.4 Section 6.4.1 through to section 6.4.14 is to be complied with as applicable depending on the fuel containment system concept.

2 DESIGN FORMAT

2.1 The design format in this standard is based on a Load and Resistance Factor Design format. The fundamental principle of the Load and Resistance Factor Design format is to verify that design load effects, L_d, do not exceed design resistances, R_d, for any of the considered failure modes in any scenario:

$L_d \leq R_d$

A design load F_{dk} is obtained by multiplying the characteristic load by a load factor relevant for the given load category:

$$F_{dk} = \gamma_f \, F_k$$

where:

γ_f is load factor; and

F_k is the characteristic load as specified in section 6.4.9 through to section 6.4.12.

A design load effect L_d (e.g. stresses, strains, displacements and vibrations) is the most unfavourable combined load effect derived from the design loads, and may be expressed by:

$L_d = q\ (F_{d1}, F_{d2}\ \ldots..\ F_{dN})$

Where q denotes the functional relationship between load and load effect determined by structural analyses.

The design resistance R_d is determined as follows:

$$R_d = \frac{R_k}{\gamma_R \gamma_C}$$

where:

R_k is the characteristic resistance. In case of materials covered by section 7, it may be, but not limited to, specified minimum yield stress, specified minimum tensile strength, plastic resistance of cross sections, and ultimate buckling strength;

γ_R is the resistance factor, defined as $\gamma_R = \gamma_m \gamma_s$

γ_m is the partial resistance factor to take account of the probabilistic distribution of the material properties (material factor);

γ_s is the partial resistance factor to take account of the uncertainties on the capacity of the structure, such as the quality of the construction, method considered for determination of the capacity including accuracy of analysis; and

γ_c is the consequence class factor, which accounts for the potential results of failure with regard to release of fuel and possible human injury.

2.2 Fuel containment design is to take into account potential failure consequences. Consequence classes are defined in Table 1, to specify the consequences of failure when the mode of failure is related to the Ultimate Limit State, the Fatigue Limit State, or the Accident Limit State.

Table 1 : Consequence Classes Consequence class

Consequence	**Definition**
Low	Failure implies minor release of the fuel.
Medium	Failure implies release of the fuel and potential for human injury.
High	Failure implies significant release of the fuel and high potential for human injury/fatality.

3 REQUIRED ANALYSES

3.1 Three-dimensional finite element analyses is to be carried out as an integrated model of the tank and the ship hull, including supports and keying system as applicable. All the failure modes is to be identified to avoid unexpected failures. Hydrodynamic analyses are to be carried out to determine the particular ship accelerations and motions in irregular waves, and the response of the ship and its fuel containment systems to these forces and motions.

3.2 Buckling strength analyses of fuel tanks subject to external pressure and other loads causing compressive stresses is to be carried out in accordance with recognized standards. The method shall adequately account for the difference in theoretical and actual buckling stress as a result of plate out of flatness, plate edge misalignment, straightness, ovality and deviation from true circular form over a specified arc or chord length, as relevant.

3.3 Fatigue and crack propagation analysis is to be carried out in accordance with paragraph 5.1 of this standard.

4 ULTIMATE LIMIT STATES

4.1 Structural resistance may be established by testing or by complete analysis taking account of both elastic and plastic material properties. Safety margins for ultimate strength are to be introduced by partial factors of safety taking account of the contribution of stochastic nature of loads and resistance (dynamic loads, pressure loads, gravity loads, material strength, and buckling capacities).

4.2 Appropriate combinations of permanent loads, functional loads and environmental loads including sloshing loads are to be considered in the analysis. At least two load combinations with partial load factors as given in Table 2 is to be used for the assessment of the ultimate limit states. The load factors for permanent and functional loads in load combination '*a*' are relevant for the normally well-controlled and/or specified loads applicable to fuel containment systems such as vapour pressure, fuel weight, system self-weight, etc. Higher load factors may be relevant for permanent and functional loads where the inherent variability and/or uncertainties in the prediction models are higher.

Table 2 : Partial load factors Load combination

Load combination	**Permanent loads**	**Functional loads**	**Environmental loads**
'a'	1.1	1.1	0.7
'b'	1.0	1.0	1.3

4.3 For sloshing loads, depending on the reliability of the estimation method, a larger load factor may be required by IRS/Administration.

4.4 In cases where structural failure of the fuel containment system are considered to imply high potential for human injury and significant release of fuel, the consequence class factor is to be taken as γ_C = 1.2. This value may be reduced if it is justified through risk analysis and subject to the approval by Administration/ IRS. The risk analysis is to take account of factors including, but not limited to, provision of full or partial secondary barrier to protect hull structure from the leakage and less hazards associated with intended fuel. Conversely, higher values may be fixed by Administration/ IRS, for example, for ships carrying more hazardous or higher pressure fuel. The consequence class factor in any case is not to be less than 1.

4.5 The load factors and the resistance factors used are to be such that the level of safety is equivalent to that of the fuel containment systems as described in sections 6.4.2.1 to 6.4.2.5. This may be carried out by calibrating the factors against known successful designs.

4.6 The material factor γ_m is to in general reflect the statistical distribution of the mechanical properties of the material, and needs to be interpreted in combination with the specified characteristic mechanical properties. For the materials defined in section 6, the material factor γ_m may be taken as:

1.1 : when the characteristic mechanical properties specified by IRS/Administration typically represents the lower 2.5% quantile in the statistical distribution of the mechanical properties; or

1.0 : when the characteristic mechanical properties specified by IRS/Administration represents a sufficiently small quantile such that the probability of lower mechanical properties than specified is extremely low and can be neglected.

4.7 The partial resistance factors γ_{si} are to in general be established based on the uncertainties in the capacity of the structure considering construction tolerances, quality of construction, the accuracy of the analysis method applied, etc.

4.7.1 For design against excessive plastic deformation using the limit state criteria given in paragraph 4.8 of this standard, the partial resistance factors γ_{si} is to be taken as follows:

$$\gamma_{s1} = 0.76\frac{B}{k_1}$$

$$\gamma_{s2} = 0.76\frac{D}{k_2}$$

$$k_1 = Min\left(\frac{R_m}{R_e}\frac{B}{A}\,;1\right)$$

$$k_2 = Min\left(\frac{R_m}{R_e}\frac{D}{C}\,;1\right)$$

Factors A, B, C and D are defined in 6.4.15.2.3.1. R_m and R_e are defined in 6.4.12.1.1.3.

The partial resistance factors given above are the results of calibration to conventional type B independent tanks.

4.8 Design against excessive plastic deformation

4.8.1 Stress acceptance criteria given below refer to elastic stress analyses.

4.8.2 Parts of fuel containment systems where loads are primarily carried by membrane response in the structure shall satisfy the following limit state criteria:

$\sigma_m \leq f$

$\sigma_L \leq 1.5\ f$

$\sigma_b \leq 1.5F$

$\sigma_L + \sigma_b \leq 1.5F$

$\sigma_m + \sigma_b \leq 1.5F$

$\sigma_m + \sigma_b + \sigma_g \leq 3.0F$

$\sigma_L + \sigma_b + \sigma_g \leq 3.0F$

where:

σ_m = equivalent primary general membrane stress

σ_L = equivalent primary local membrane stress

σ_b = equivalent primary bending stress

σ_g = equivalent secondary stress

$$f = \frac{R_e}{\gamma_{s1}\,\gamma_m\,\gamma_C}$$

$$F = \frac{R_e}{\gamma_{s2}\,\gamma_m\,\gamma_C}$$

Guidance Note:
The stress summation described above is to be carried out by summing up each stress component (σ_x, σ_y, σ_{xy}), and subsequently the equivalent stress is to be calculated based on the resulting stress components as shown in the example below.

$$\sigma_L + \sigma_b = \sqrt{(\sigma_{Lx} + \sigma_{bx})^2 - (\sigma_{Lx} + \sigma_{bx})(\sigma_{Ly} + \sigma_{by}) + (\sigma_{Ly} + \sigma_{by})^2 + 3(\tau_{Lxy} + \tau_{bxy})^2}$$

4.8.3 Parts of fuel containment systems where loads are primarily carried by bending of girders, stiffeners and plates, are to satisfy the following limit state criteria:

$\sigma_{ms} + \sigma_{bp} \leq 1.25F$ (see notes 1, 2)

$\sigma_{ms} + \sigma_{bp} + \sigma_{bs} \leq 1.25F$ (see note 2)

$\sigma_{ms} + \sigma_{bp} + \sigma_{bs} + \sigma_{bi} + \sigma_g \leq 3.0F$

Note 1: The sum of equivalent section membrane stress and equivalent membrane stress in primary structure ($\sigma_{ms} + \sigma_{bp}$) will normally be directly available from three-dimensional finite element analyses.

Note 2: The coefficient, 1.25, may be modified by IRS/Administration considering the design concept, configuration of the structure, and the methodology used for calculation of stresses.

where:

σ_{ms} = equivalent section membrane stress in primary structure

σ_{bp} = equivalent membrane stress in primary structure and stress in secondary and tertiary structure caused by bending of primary structure

σ_{bs} = section bending stress in secondary structure and stress in tertiary structure caused by bending of secondary structure

σ_{hi} = section bending stress in tertiary structure

σ_g = equivalent secondary stress

$$f = \frac{R_e}{\gamma_{s1}\,\gamma_m\,\gamma_C}$$

$$F = \frac{R_e}{\gamma_{s2}\,\gamma_m\,\gamma_C}$$

The stresses σ_{ms}, σ_{bp}, σ_{hs} and σ_{bi} are defined in 4.8.4.

Skin plates is to be designed in accordance with the requirements of the Administration. When membrane stress is significant, the effect of the membrane stress on the plate bending capacity is to be appropriately considered in addition.

Guidance Note:
The stress summation described above is to be carried out by summing up each stress component (σ_x, σ_y, σ_{xy}), and subsequently the equivalent stress is to be calculated based on the resulting stress components.

4.8.4 Section stress categories

4.8.4.1 Normal stress is the component of stress normal to the plane of reference.

4.8.4.2 Equivalent section membrane stress is the component of the normal stress that is uniformly distributed and equal to the average value of the stress across the cross section of the structure under consideration. If this is a simple shell section, the section membrane stress is identical to the membrane stress defined in paragraph 4.8.2 of this standard.

4.8.4.3 Section bending stress is the component of the normal stress that is linearly distributed over a structural section exposed to bending action, as illustrated in Fig.1.

4.9 The same factors γ_c, γ_m, γ_{si} are to be used for design against buckling unless otherwise stated in the applied recognized buckling standard. In any case the overall level of safety shall not be less than given by these factors.

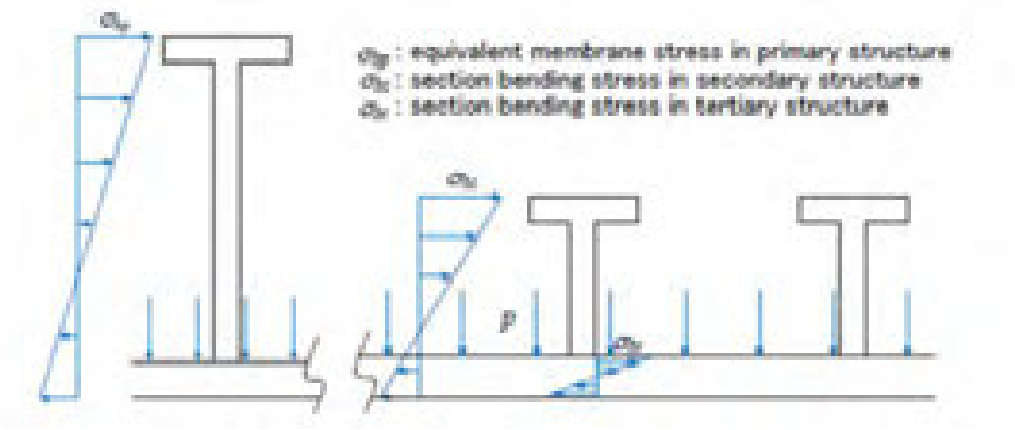

Fig.1 : Definition of the three categories of section stress (Stresses σ_{bp} and σ_{bs} are normal to the cross section shown.)

5 FATIGUE LIMIT STATES

5.1 Fatigue design condition as described in 6.4.12.2 is to be complied with as applicable depending on the fuel containment system concept. Fatigue analysis is required for the fuel containment system designed under 6.4.16 and this standard.

5.2 The load factors for FLS are to be taken as 1 for all load categories.

5.3 Consequence class factor and resistance factor is to be taken as 1.

5.4 Fatigue damage is to be calculated as described in 6.4.12.2.2 to 6.4.12.2.2.5. The calculated cumulative fatigue damage ratio for the fuel containment systems is to be less than or equal to the values given in Table 3.

Table 3 : Maximum allowable cumulative fatigue damage ratio consequence class

	Consequence class		
C_w	**Low**	**Medium**	**High**
	1.0	0.5	0.5*
Note*: Lower value is to be used in accordance with 5.4.12.2.7 to 5.4.12.2.9, depending on the detectability of defect or crack, etc.			

5.5 Lower values may be fixed by IRS/Administration.

5.6 Crack propagation analyses are required in accordance with 6.4.12.2.6 to 6.4.12.2.9. The analysis is to be carried out in accordance with methods laid down in a standard recognized by IRS/Administration.

6 ACCIDENT LIMIT STATES

6.1 Accident design condition as described in 5.4.12.3 is to be complied with as applicable, depending on the fuel containment system concept.

6.2 Load and resistance factors may be relaxed compared to the ultimate limit state considering that damages and deformations can be accepted as long as this does not escalate the accident scenario.

6.3 The load factors for ALS are to be taken as 1 for permanent loads, functional loads and environmental loads.

6.4 Loads mentioned in 6.4.9.3.3.8 and 6.4.9.5 need not be combined with each other or with environmental loads, as defined in 6.4.9.4.

6.5 Resistance factor in general is to be taken as 1.

6.6 Consequence class factors in general are to be taken as defined in paragraph 4.4 of this standard, but may be relaxed considering the nature of the accident scenario.

6.7 The characteristic resistance in general is to be taken as for the ultimate limit state, but may be relaxed considering the nature of the accident scenario.

6.8 Additional relevant accident scenarios are to be determined based on a risk analysis.

7 TESTING

7.1 Fuel containment systems designed according to this standard is to be tested to the same extent as described in 16.2, as applicable depending on the fuel containment system concept.

Appendix-II *Model Table of Contents for the Polar Water Operations Manual (PWOM)*

Introduction

IR 1.0 General

IR 1.1 These Rules have been prepared to ensure that vessels intended to operate in Polar regions built with a view to Classification with IRS will also comply with the relevant requirements of the IMO Polar Code (IMO Res. MSC 385(94)).

IR 1.2 The IMO Polar Code applies from 01 Jan 2017 to ships operating in polar waters. Ships constructed before 01 Jan 2017 are to meet the relevant requirements of the Polar Code by the first intermediate or renewal survey whichever occurs first after 01 Jan 2018 (according to SOLAS Chapter XIV).

IR 1.3 Responsibility for interpretation of the Polar Code requirements for the purpose of issuing a 'Polar Ship Certificate' under the SOLAS Convention and certificates under the MARPOL Convention lies with the Government of the State, whose flag the ship is entitled to fly.

IR 1.4 This Chapter incorporates the Introduction and the following Chapters of the Polar Code in full, which are relevant for Classification. The Rules also address the structural requirements for prevention of pollution by oil of the Polar Code (Chapter 1 of Part II-A) in Section 8.

Part I A : Safety Measures

Chapter 1 General

Chapter 2 Polar Water Operational Manual

Chapter 3 Ship Structure

Chapter 4 Subdivision and Stability

Chapter 5 Watertight and Weathertight Integrity

Chapter 6 Machinery installations

Chapter 7 Fire Safety / Protection

IR 1.5 The following Chapters of the Polar Code are not addressed in these Rules as they are purely statutory requirements not related to Classification.

Part I A : Safety Measures

Chapter 8 Life Saving Appliances and Arrangements

Chapter 9 Safety of Navigation

Chapter 10 Communication

Chapter 11 Voyage Planning

Chapter 12 Manning and Training

Part II A : Pollution Prevention Measures

Chapter 1 Prevention of Pollution by Oil (Operational Requirements)

Chapter 2 Control of Pollution by Noxious Liquid Substances in Bulk

Chapter 3 Prevention of Pollution by Harmful Substances carried by Sea in Packaged Form

Chapter 4 Prevention of Pollution by Sewage from Ships

Chapter 5 Prevention of Pollution by Garbage from Ships

IR 1.6 The additional guidance provided in the Polar Code (Parts I-B and II-B) for the Chapters covered in these Rules are given as Appendix I to this Chapter. Further, Appendix II of this Chapter gives the model table of contents for Polar Water Operational Manual (PWOM) as provided in the Polar Code.

IR 2.0 Class Notations

IR 2.1 Vessels complying with the requirements of this Chapter will be assigned Class Notation “POLAR”. It may be noted that the ice strength requirements for polar operations for Category A and Category B ships are covered in Pt.5, Ch.32 of the Rules and the appropriate notations (‘PC 1’ to ‘PC 7’) would also be assigned to such ships, based on compliance with the relevant ice class requirements of that Chapter.

Preamble (to the Polar Code)

1 The International Code for Ships Operating in Polar Waters has been developed to supplement existing IMO instruments in order to increase the safety of ships' operation and mitigate the impact on the people and environment in the remote, vulnerable and potentially harsh polar waters.

2 The Code acknowledges that polar water operation may impose additional demands on ships, their systems and operation beyond the existing requirements of the International Convention for the Safety of Life at Sea (SOLAS), 1974, the International Convention for the Prevention of Pollution from Ships, 1973, as modified by the Protocol of 1978 relating thereto as amended by the 1997 Protocol, and other relevant binding IMO instruments.

3 The Code acknowledges that the polar waters impose additional navigational demands beyond those normally encountered. In many areas, the chart coverage may not currently be adequate for coastal navigation. It is recognized even existing charts may be subject to un-surveyed and uncharted shoals.

4 The Code also acknowledges that coastal communities in the Arctic could be, and that polar ecosystems are, vulnerable to human activities, such as ship operation.

5 The relationship between the additional safety measures and the protection of the environment is acknowledged as any safety measure taken to reduce the probability of an accident, will largely benefit the environment.

6 While Arctic and Antarctic waters have similarities, there are also significant differences. Hence, although the Code is intended to apply as a whole to both Arctic and Antarctic, the legal and geographical differences between the two areas have been taken into account.

7 The key principles for developing the Polar Code have been to use a risk-based approach in determining scope and to adopt a holistic approach in reducing identified risks.

Introduction (to the Polar Code)

1. Goal

The goal of the Polar Code is to provide for safe ship operation and the protection of the polar environment by addressing risks present in polar waters and not adequately mitigated by other IMO instruments.

2. Definitions

For the purpose of the Polar Code and this Chapter, the terms used have the meanings defined in the following paragraphs. Terms used in Part I-A of the Code (and Section 1 to Section 7 of this Chapter), but not defined in this Introduction shall have the same meaning as defined in SOLAS. Terms used in Part II-A of the Code (See Section 8 of this Chapter), but not defined in this Introduction shall have the same meaning as defined in Article 2 of MARPOL and the relevant MARPOL Annexes.

2.1 **Category A** ship means a ship designed for operation in polar waters in at least medium first-year ice, which may include old ice inclusions.

2.2 **Category B** ship means a ship not included in category A, designed for operation in polar waters in at least thin first-year ice, which may include old ice inclusions.

2.3 **Category C** ship means a ship designed to operate in open water or in ice conditions less severe than those included in categories A and B.

2.4 **First-year ice** means sea ice of not more than one winter growth developing from young ice with thickness from 0.3 [m] to 2.0 [m].

2.5 **Ice free waters** means no ice present. If ice of any kind is present this term is not to be used.

2.6 **Ice of land origin** means ice formed on land or in an ice shelf, found floating in water.

2.7 **MARPOL** means the International Convention for the Prevention of Pollution from Ships, 1973, as modified by the Protocol of 1978 relating thereto as amended by the 1997 Protocol.

2.8 **Medium first-year ice** means first-year ice of 70 [cm] to 120 [cm] thickness.

2.9 **Old ice** means sea ice which has survived at least one summer's melt; typical thickness up to 3 [m] or more. It is subdivided into residual first-year ice, second-year ice and multi-year ice.

2.10 **Open water** means a large area of freely navigable water in which sea ice is present in concentrations less than 1/10. No ice of land origin is present.

2.11 **Organization** means the International Maritime Organization.

2.12 **Sea ice** means any form of ice found at sea which has originated from the freezing of sea water.

2.13 **SOLAS** means the International Convention for the Safety of Life at Sea, 1974, as amended.

2.14 **STCW Convention** means the International Convention on Standards of Training, Certification and Watchkeeping for Seafarers, 1978, as amended.

2.15 **Thin first-year ice** means first-year ice 30 [cm] to 70 [cm] thick.

3. Sources of Hazards

3.1 The Polar Code considers hazards which may lead to elevated levels of risk due to increased probability of occurrence, more severe consequences, or both:

.1 Ice, as it may affect hull structure, stability characteristics, machinery systems, navigation, the outdoor working environment, maintenance and emergency preparedness tasks and malfunction of safety equipment and systems;

.2 experiencing topside icing, with potential reduction of stability and equipment functionality;

.3 low temperature, as it affects the working environment and human performance, maintenance and emergency preparedness tasks, material properties and equipment efficiency, survival time and

performance of safety equipment and systems;

.4 extended periods of darkness or daylight as it may affect navigation and human performance;

.5 high latitude, as it affects navigation systems, communication systems and the quality of ice imagery information;

.6 remoteness and possible lack of accurate and complete hydrographic data and information, reduced availability of navigational aids and seamarks with increased potential for groundings compounded by remoteness, limited readily deployable SAR facilities, delays in emergency response and limited communications capability, with the potential to affect incident response;

.7 potential lack of ship crew experience in polar operations, with potential for human error;

.8 potential lack of suitable emergency response equipment, with the potential for limiting the effectiveness of mitigation measures;

.9 rapidly changing and severe weather conditions, with the potential for escalation of incidents; and

.10 the environment with respect to sensitivity to harmful substances and other environmental impacts and its need for longer restoration.

3.2 The risk level within polar waters may differ depending on the geographical location, time of the year with respect to daylight, ice-coverage, etc. Thus, the mitigating measures required to address the above specific hazards may vary within polar waters and may be different in Arctic and Antarctic waters.

4. Structure of the Polar Code

The Polar Code consists of Introduction, Parts I and II. The Introduction contains mandatory provisions applicable to both Parts I and II. Part I is subdivided into Part I-A, which contains mandatory provisions on safety measures, and Part I-B containing recommendations on safety. Part II is subdivided into Part II-A, which contains mandatory provisions on pollution prevention, and Part II-B containing recommendations on pollution prevention.

5. Figures 1 and 2 illustrate the Antarctic area and Arctic waters, as defined in SOLAS regulations XIV/1.2 and XIV/1.3, respectively, and MARPOL Annex I, regulations 1.11.7 and 46.2; Annex II, regulations 13.8.1 and 21.2; Annex IV, regulations 17.2 and 17.3; and Annex V, regulations 1.14.7 and 13.2.

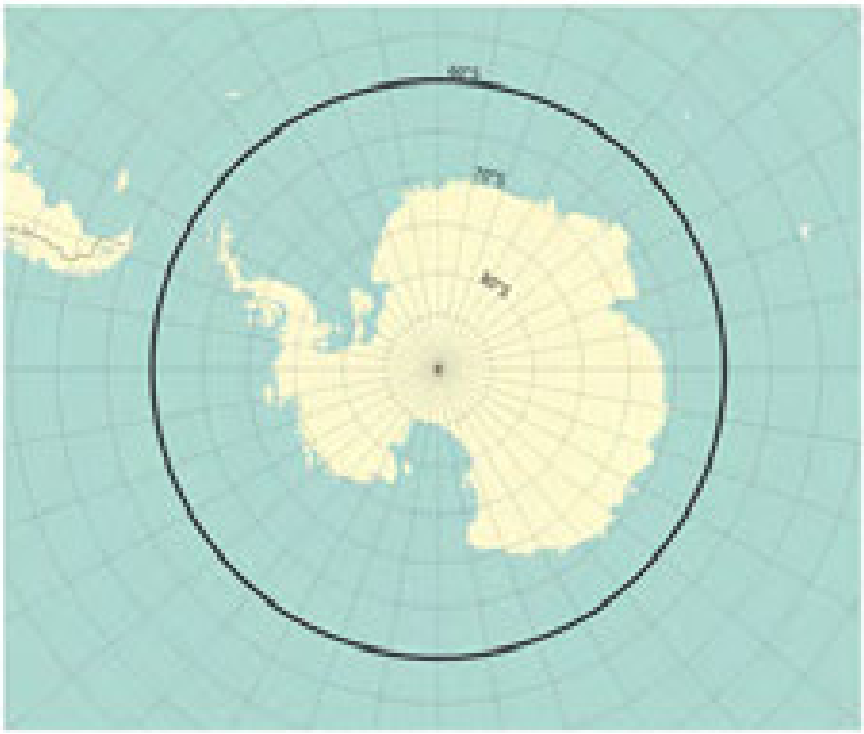

Fig. 1 : Maximum extent of Antarctic area application

Figure 2 : Maximum extent of Arctic waters application

Note : The above figures are for illustrative purposes only

Section 1

General

1.1 Structure

Each Section of this Chapter consists of the overall goal of the Section, functional requirements to fulfill the goal, and regulations. A ship is to be considered to meet a functional requirement set out in these Sections, when either:

.1 the ship's design and arrangements comply with all the rules associated with that functional requirement; or

.2 part(s) or all of the ship's relevant design and arrangements have been reviewed and approved in accordance with the alternative design and arrangement requirements of regulation 4 of SOLAS Chapter XIV, and any remaining parts of the ship comply with the relevant requirements.

1.2 Definitions

In addition to the definitions included in the relevant SOLAS chapters and the introduction of this Chapter, the following definitions are applicable to Sections 1 to 7.

1.2.1 *Bergy waters* mean an area of freely navigable water in which ice of land origin is present in concentrations less than 1/10. There may be *sea ice* present, although the total concentration of all ice shall not exceed 1/10.

1.2.2 *Escort* means any ship with superior ice capability in transit with another ship.

1.2.3 *Escorted operation* means any operation in which a ship's movement is facilitated through the intervention of an escort.

1.2.4 *Habitable environment* means a ventilated environment that will protect against hypothermia.

1.2.5 *Icebreaker* means any ship whose operational profile may include escort or ice management functions, whose powering and dimensions allow it to undertake aggressive operations in ice-covered waters.

1.2.6 *Ice Class* means the notation assigned to the ship by IRS that the ship has been designed for navigation in sea-ice conditions.

(Note: Refer Pt.5, Ch.21 of the Rules for applicable requirements of Ice Class Ships).

1.2.7 *Maximum expected time of rescue* means the time adopted for the design of equipment and system that provide survival support. It is never to be less than 5 days.

1.2.8 *Machinery Installations* means equipment and machinery and its associated piping and cabling, which is necessary for the safe operation of the ship.

1.2.9 *Mean Daily Low Temperature* (MDLT) means the mean value of the daily low temperature for each day of the year over a minimum 10 years period. A data set acceptable to the Administration may be used if 10 years of data is not available. (Refer Pt.3, Ch.2, Sec. 2 of the Rules for method of determining MDLT).

1.2.10 *Polar Class (PC)* means the ice class assigned to the ship by IRS.

(Note: ******* *Refer Pt.5, Ch.32 of the Rules for applicable requirements of Polar Class PC 1 to PC 7).*

1.2.11 *Polar Service Temperature (PST)* means a temperature specified for a ship which is intended to operate in low air temperature, which shall be set at least 10°C below the lowest MDLT for the intended area and season of operation in polar waters.

1.2.12 *Ship intended to operate in low air temperature* means a ship which is intended to undertake voyages to or through areas where the lowest Mean Daily Low Temperature (MDLT) is below -10ºC.

1.2.13 *Tankers* mean oil tankers as defined in SOLAS regulation II-1/2.22, chemical tankers as defined in SOLAS regulation II-1/3.19 and gas carriers as defined in SOLAS regulation VII/11.2.

1.2.14 *Upper ice waterline* means the waterline defined by the maximum draughts forward and aft for operation in ice.

1.3 Polar Ship Certificate and Survey

1.3.1 Every ship to which the Polar Code applies is to have on board a valid Polar Ship Certificate.

1.3.2 Except as provided for in 1.3.3, the Polar Ship Certificate is to be issued after an initial or renewal survey to a ship which complies with the relevant requirements of the Polar Code.

1.3.3 For category C cargo ships, if the result of the assessment in 1.5 is that no additional equipment or structural modification is required to comply with this Chapter, the Polar Ship Certificate may be issued based upon documented verification that the ship complies with all relevant requirements of the Polar Code. In this case, for continued validity of the certificate, an onboard survey is to be undertaken at the next scheduled survey.

1.3.4 The Polar Ship Certificate would be issued either by the Administration or by IRS when authorized. In every case, that Administration assumes full responsibility for the certificate.

1.3.5 The Polar Ship Certificate is to be drawn up in the form corresponding to the model given in Appendix 1 to the Polar Code If the language used is neither English, nor French nor Spanish, the text is to include a translation into one of these languages.

1.3.6 Polar Ship Certificate validity, survey dates and endorsements are to be harmonized with the relevant SOLAS certificates in accordance with the provisions of regulation I/14 of the SOLAS Convention. The certificate is to include a supplement recording equipment required by the Polar Code.

1.3.7 Where applicable, the certificate is to reference a methodology to assess operational capabilities and limitations in ice to the satisfaction of the Administration / IRS taking into account the guidelines developed by the Organization (Refer Appendix-I).

1.4 Performance Standards

1.4.1 Unless expressly provided otherwise, ship systems and equipment addressed in this Chapter are to satisfy at least the same performance standards referred to in SOLAS and the Rules.

1.4.2 For ships operating in low air temperature, a polar service temperature (PST) is to be specified and is to be at least 10°C below the lowest MDLT for the intended area and season of operation in polar waters. Systems and equipment required by this Chapter are to be fully functional at the polar service temperature.

1.4.3 For ships operating in low air temperature, survival systems and equipment are to be fully operational at the polar service temperature during the maximum expected rescue time.

1.5 Operational assessment

In order to establish procedures or operational limitations, an assessment of the ship and its equipment is to be carried out, taking into consideration the following:

.1 the anticipated range of operating and environmental conditions, such as:

.1 operation in low air temperature;
.2 operation in ice;
.3 operation in high latitude; and
.4 potential for abandonment onto ice or land;

.2 hazards, as listed in Para 3 of the Introduction, as applicable; and

.3 additional hazards, if identified.

(Note: Refer to MSC.1/Circ.1519 "Guidance On Methodologies For Assessing Operational Capabilities And Limitations In Ice").

Section 2

Polar Water Operational Manual (PWOM)

2.1 Goal

The goal of this Section is to provide the owner, operator, master and crew with sufficient information regarding the ship's operational capabilities and limitations in order to support their decision-making process.

2.2 Functional requirements

2.2.1 In order to achieve the goal set out in 2.1 above, the following functional requirements are embodied in the rules of this Section.

2.2.2 The Manual is to include information on the ship-specific capabilities and limitations in relation to the assessment required under 1.5.

2.2.3 The Manual is to include or refer to specific procedures to be followed in normal operations and in order to avoid encountering conditions that exceed the ship's capabilities.

2.2.4 The Manual is to include or refer to specific procedures to be followed in the event of incidents in polar waters.

2.2.5 The Manual is to include or refer to specific procedures to be followed in the event that conditions are encountered which exceed the ship's specific capabilities and limitations in 2.2.2.

2.2.6 The Manual is to include or refer to procedures to be followed when using icebreaker assistance, as applicable.

2.3 Rule Requirements

2.3.1 In order to comply with the functional requirements of 2.2.1 to 2.2.6, the Manual is to be carried on board.

2.3.2 In order to comply with the functional requirements of 2.2.2, the Manual is to contain, where applicable, the methodology used to determine capabilities and limitations in ice.

2.3.3 In order to comply with the functional requirements of 2.2.3, the Manual is to include risk-based procedures for the following:

.1 voyage planning to avoid ice and/or temperatures that exceed the ship's design capabilities or limitations;

.2 arrangements for receiving forecasts of the environmental conditions;

.3 means of addressing any limitations of the hydrographic, meteorological and navigational information available;

.4 operation of equipment required under other Sections of this Chapter; and

.5 implementation of special measures to maintain equipment and system functionality under low temperatures, topside icing and the presence of sea ice, as applicable.

2.3.4 In order to comply with the functional requirements of 2.2.4, the Manual is to include risk-based procedures to be followed for:

.1 contacting emergency response providers for salvage, search and rescue (SAR), spill response, etc., as applicable; and

.2 in the case of ships ice strengthened in accordance with Section 3, procedures for maintaining life support and ship integrity in the event of prolonged entrapment by ice.

2.3.5 In order to comply with the functional requirements of 2.2.5, the Manual is to include risk-based procedures to be followed for measures to be taken in the event of encountering ice and/or temperatures which exceed the ship's design capabilities or limitations.

2.3.6 In order to comply with the functional requirements of 2.2.6, the Manual is to include risk-based procedures or monitoring and maintaining safety during operations in ice, as applicable, including any requirements for escort operations or icebreaker assistance.

Different operational limitations may apply depending on whether the ship is operating independently or with icebreaker escort. Where appropriate, the PWOM is to specify both options
.

Section 3

Ship Structure

3.1 Goal

The goal of this Section is to provide that the material and scantlings of the structure retain their structural integrity based on global and local response due to environmental loads and conditions.

3.2 Functional requirements

In order to achieve the goal set out in 3.1 above, the following functional requirements are embodied in the rules of this Section:

.1 for ships intended to operate in low air temperature, materials used are to be suitable for operation at the ships polar service temperature; and

.2 in ice strengthened ships, the structure of the ship is to be designed to resist both global and local structural loads anticipated under the foreseen ice conditions.

3.3 Rule Requirements

3.3.1 In order to comply with the functional requirements of 3.2.1 above, materials of exposed structures in ships are to be approved by IRS, taking into account standards acceptable to the Organization* or other standards offering an equivalent level of safety based on the polar service temperature.

*(Note: ***** Refer Pt.2, Ch.3, Sec.5 and Pt.5, Ch.32, Sec.2 of the Rules for applicable requirements of steel for low temperature applications).*

3.3.2 In order to comply with the functional requirements of 3.2.2 above, the following apply:

.1 scantlings of category A ships are to be approved by IRS, taking into account standards acceptable to the Organization* or other standards offering an equivalent level of safety;

*(Note: ***** Refer Pt.5, Ch.32 of the Rules for applicable requirements of Polar Class PC 1 to PC 5).*

.2 scantlings of category B ships are to be approved by IRS, taking into account standards acceptable to the Organization* or other standards offering an equivalent level of safety;

*(Note: ***** Refer Pt.5, Ch.32 of the Rules for applicable requirements of Polar Class PC 6 to PC 7).*

.3 scantlings of ice strengthened category C ships are to be approved by IRS, taking into account acceptable standards adequate for the ice types and concentrations encountered in the area of operation; and

*(Note: ***** Refer Pt.5, Ch.21 of the Rules for applicable requirements of Ice Class Ships).*

.4 a category C ship need not be ice strengthened if, in the opinion of the Administration / IRS, the ship's structure is adequate for its intended operation.

Section 4

Subdivision and Stability

4.1 Goal

The goal of this Section is to ensure adequate subdivision and stability in both intact and damaged conditions.

4.2 Functional requirements

In order to achieve the goal set out in 4.1 above, the following functional requirements are embodied in the rules of this Section:

.1 ships are to have sufficient stability in intact conditions when subject to ice accretion; and

.2 ships of category A and B, constructed on or after 1 January 2017, are to have sufficient residual stability to sustain ice-related damages.

4.3 Rule Requirements

4.3.1 Stability in intact conditions

4.3.1.1 In order to comply with the functional requirement of 4.2.1, for ships operating in areas and during periods where ice accretion is likely to occur, the following icing allowance is to be made in the stability calculations:

.1 30 [kg/m^2] on exposed weather decks and gangways;

.2 7.5 [kg/m^2] for the projected lateral area of each side of the ship above the water plane; and

.3 the projected lateral area of discontinuous surfaces of rail, sundry booms, spars (except masts) and rigging of ships having no sails and the projected lateral area of other small objects is to be computed by increasing the total projected area of continuous surfaces by 5% and the static moments of this area by 10%.

4.3.1.2 Ships operating in areas and during periods where ice accretion is likely to occur are to be:

.1 designed to minimize the accretion of ice; and

.2 equipped with such means for removing ice as the Administration / IRS may require; for example, electrical and pneumatic devices, and/or special tools such as axes or wooden clubs for removing ice from bulwarks, rails and erections.

4.3.1.3 Information on the icing allowance included in the stability calculations is to be given in the PWOM.

4.3.1.4 Ice accretion is to be monitored and appropriate measures taken to ensure that the ice accretion does not exceed the values given in the PWOM.

4.3.2 Stability in damaged conditions

4.3.2.1 In order to comply with the functional requirements of 4.2.2, ships of categories A and B, constructed on or after 1 January 2017, are to be able to withstand flooding resulting from hull penetration due to ice impact. The residual stability following ice damage is to be such that the factor s_i, as defined in SOLAS regulations II-1/7-2.2 and II-1/7-2.3, is equal to one for all loading conditions used to calculate the attained subdivision index in SOLAS regulation II-1/7. However, for cargo ships that comply with subdivision and damage stability regulations in another instrument developed by the Organization, as provided by SOLAS regulation II-1/4.1, the residual stability criteria of that instrument is to be met for each loading condition.

4.3.2.2 The ice damage extents to be assumed when demonstrating compliance with 4.3.2.1 are to be such that:

.1 the longitudinal extent is 4.5% of the upper ice waterline length if centred forward of the maximum breadth on the upper ice waterline, and 1.5% of upper ice waterline length otherwise, and is to be assumed at any longitudinal position along the ship's length;

.2 the transverse penetration extent is 760 [mm], measured normal to the shell over the full extent of the damage; and

.3 the vertical extent is the lesser of 20% of the upper ice waterline draught or the longitudinal extent, and is to be assumed at any vertical position between the keel and 120% of the upper ice waterline draught.

IR4.3.2 In damaged stability calculations, ice accretion effects need not be considered (implied according to 4.2.1 and 4.3.2).

Section 5

Watertight and Weathertight Integrity

5.1 Goal

The goal of this Section is to provide measures to maintain watertight and weathertight integrity.

5.2 Functional requirements

In order to achieve the goal set out in 5.1 above, all closing appliances and doors relevant to watertight and weathertight integrity of the ship are to be operable.

5.3 Rule Requirements

In order to comply with the functional requirements of 5.2 above, the following apply:

.1 for ships operating in areas and during periods where ice accretion is likely to occur, means are to be provided to remove or prevent ice and snow accretion around hatches and doors; and

.2 in addition, for ships intended to operate in low air temperature the following apply:

.1 if the hatches or doors are hydraulically operated, means are to be provided to prevent freezing or excessive viscosity of liquids; and

.2 watertight and weathertight doors, hatches and closing devices which are not within an habitable environment and require access while at sea are to be designed to be operated by personnel wearing heavy winter clothing including thick mittens.

Section 6

Machinery Installations

6.1 Goal

The goal of this Section is to ensure that, machinery installations are capable of delivering the required functionality necessary for safe operation of ships.

6.2 Functional requirements

6.2.1 In order to achieve the goal set out in 6.1 above, the following functional requirements are embodied in the rules of this Section.

6.2.1.1 Machinery installations are to provide functionality under the anticipated environmental conditions, taking into account:

.1 ice accretion and/or snow accumulation;
.2 ice ingestion from seawater;
.3 freezing and increased viscosity of liquids;
.4 seawater intake temperature; and
.5 snow ingestion.

6.2.1.2 In addition, for ships intended to operate in low air temperatures:

.1 machinery installations are to provide functionality under the anticipated environmental conditions, also taking into account:

.1 cold and dense inlet air; and

.2 loss of performance of battery or other stored energy device; and

.2 materials used are to be suitable for operation at the ships polar service temperature.

6.2.1.3 In addition, for ships ice strengthened in accordance with Section 3, machinery installations are to provide functionality under the anticipated environmental conditions, taking into account loads imposed directly by ice interaction.

6.3 Rule Requirements

6.3.1 In order to comply with the functional requirement of 6.2.1.1 above, taking into account the anticipated environmental conditions, the following apply:

.1 machinery installations and associated equipment are to be protected against the effect of ice accretion and/or snow accumulation, ice ingestion from sea water, freezing and increased viscosity of liquids, seawater intake temperature and snow ingestion;

.2 working liquids are to be maintained in a viscosity range that ensures operation of the machinery; and

.3 seawater supplies for machinery systems are to be designed to prevent ingestion of ice* or otherwise arranged to ensure functionality.

*(Note: ***** MSC /Circ. 504, as amended, "Guidance on design and construction of sea inlets under slush ice conditions" may be used).*

6.3.2 In addition, for ships intended to operate in low air temperatures, the following apply:

.1 in order to comply with the functional requirement of 6.2.1.2 above, exposed machinery and electrical installation and appliances are to function at the polar service temperature;

.2 in order to comply with the functional requirement of 6.2.1.2.1 above, means are to be provided to ensure that combustion air for internal combustion engines driving essential machinery is maintained at a temperature in compliance with the criteria provided by the engine manufacturer; and

.3 in order to comply with the functional requirements of 6.2.1.2.2 above, materials of exposed machinery and foundations are to be approved by IRS, taking into account standards acceptable to the Organization* or other standards offering an equivalent level of safety based on the polar service temperature.

*(Note: ***** Refer Pt.5, Ch.32 of the Rules for applicable requirements of Polar Class PC 1 to PC 7).*

6.3.3 In addition, for ships ice strengthened in accordance with Section 3, in order to comply with the functional requirements of 6.2.1.3 above, the following apply:

.1 scantlings of propeller blades, propulsion line, steering equipment and other appendages of category A ships are to be approved by IRS, taking into account standards acceptable to the Organization* or other standards offering an equivalent level of safety;

*(Note: ***** Refer Pt.5, Ch.32 of the Rules for applicable requirements of Polar Class PC 1 to PC 5).*

.2 scantlings of propeller blades, propulsion line, steering equipment and other appendages of category B ships are to be approved by IRS, taking into account standards acceptable to the Organization* or other standards offering an equivalent level of safety; and

*(Note: ***** Refer Pt.5, Ch.32 of the Rules for applicable requirements of Polar Class PC 6 to PC 7).*

.3 scantlings of propeller blades, propulsion line, steering equipment and other appendages of ice-strengthened category C ships are to be approved by IRS, taking into account acceptable standards adequate with the ice types and concentration encountered in the area of operation.

Section 7

Fire Safety / Protection

7.1 Goal

The goal of this Section is to ensure that fire safety systems and appliances are effective and operable, and that means of escape remain available so that persons on board can safely and swiftly escape to the lifeboat and liferaft embarkation deck under the expected environmental conditions.

7.2 Functional requirements

7.2.1 In order to achieve the goal set out in 7.1 above, the following functional requirements are embodied in the rules of this Section:

.1 all components of fire safety systems and appliances if installed in exposed positions are to be protected from ice accretion and snow accumulation;

.2 local equipment and machinery controls are to be arranged so as to avoid freezing, snow accumulation and ice accretion and their location to remain accessible at all time;

.3 the design of fire safety systems and appliances are to take into consideration the need for persons to wear bulky and cumbersome cold weather gear, where appropriate;

.4 means are to be provided to remove or prevent ice and snow accretion from accesses; and

.5 extinguishing media are to be suitable for intended operation.

7.2.2 In addition, for ships intended to operate in low air temperature, the following apply:

.1 all components of fire safety systems and appliances are to be designed to ensure availability and effectiveness under the polar service temperature; and

.2 materials used in exposed fire safety systems are to be suitable for operation at the polar service temperature.

7.3 Rule Requirements

7.3.1 In order to comply with the requirement of 7.2.1.1, the following apply:

.1 isolating and pressure/vacuum valves in exposed locations are to be protected from ice accretion and remain accessible at all time; and

.2 all two-way portable radio communication equipment are to be operable at the polar service temperature.

7.3.2 In order to comply with the requirement of 7.2.1.2, the following apply:

.1 fire pumps including emergency fire pumps, water mist and water spray pumps are to be located in compartments maintained above freezing;

.2 the fire main is to be arranged so that exposed sections can be isolated and means of draining of exposed sections shall be provided. Fire hoses and nozzles need not be connected to the fire main at all times, and maybe stored in protected locations near the hydrants;

.3 firefighter's outfits are to be stored in warm locations on the ship; and

.4 where fixed water-based firefighting systems are located in a space separate from the main fire pumps and use their own independent sea suction, this sea suction is to be also capable of being cleared of ice accumulation.

7.3.3 In addition, for ships intended to operate in low air temperature, the following apply:

.1 In order to comply with the requirement of 7.2.2.1, portable and semi-portable extinguishers are to be located in positions protected from freezing temperatures, as far as practical. Locations subject to freezing are to be provided with extinguishers capable of operation under the polar service temperature.

.2 In order to comply with the functional requirements of 7.2.2.2 above, materials of exposed fire safety systems are to be approved by IRS, taking into account standards acceptable to the Organization* or other standards offering an equivalent level of safety based on the polar service temperature.

*(Note: ***** Refer Pt.2, Ch.3, Sec.5 and Pt.5, Ch.32, Sec.2 of the Rules for applicable requirements of steel for low temperature applications).*

Section 8

Prevention of Pollution by Oil (Structural Requirements)

8.1 Structural Requirements

8.1.1 For category A and B ships constructed on or after 1 January 2017 with an aggregate oil fuel capacity of less than 600 [m^3], all oil fuel tanks are to be separated from the outer shell by a distance of not less than 0.76 [m]. This provision does not apply to small oil fuel tanks with a maximum individual capacity not greater than 30 [m^3].

8.1.2 For category A and B ships other than oil tankers constructed on or after 1 January 2017, all cargo tanks constructed and utilized to carry oil are to be separated from the outer shell by a distance of not less than 0.76 [m].

8.1.3 For category A and B oil tankers of less than 5,000 tonnes deadweight constructed on or after 1 January 2017, the entire cargo tank length is to be protected with:

.1 double bottom tanks or spaces complying with the applicable requirements of regulation 19.6.1 of MARPOL Annex I; and

.2 wing tanks or spaces arranged in accordance with regulation 19.3.1 of MARPOL Annex I and complying with the applicable requirements for distance referred to in regulation 19.6.2 of MARPOL Annex I.

IR8.1.3 In general, provisions of Marpol Annex I, Regulation 19 are applicable to oil tankers of 5000 tonnes deadweight and above.

8.1.4 For category A and B ships constructed on or after 1 January 2017 all oil residue (sludge) tanks and oily bilge water holding tanks shall be separated from the outer shell by a distance of not less than 0.76 [m]. This provision does not apply to small tanks with a maximum individual capacity not greater than 30 [m^3].

Appendix-I

Additional Guidance regarding the Provisions of the Introduction and Part I-A of the Polar Code (Sections 1 to 7 of this Chapter)

1 Additional Guidance to (Definitions in the Introduction to the Polar Code, Para 2 of Introduction)

1.1 The Mean Daily Low Temperature may be determined in accordance with the requirements of Pt.3, Ch.2, Sec. 2, 2.3.

2. Additional Guidance to Chapter 1 of the Code (Section 1 of this Chapter)

2.1 **Limitations for operating in ice**

2.1.1 Limitations for operation in ice can be determined using systems, tools or analysis that evaluate the risks posed by the anticipated ice conditions to the ship, taking into account factors such as its ice class, seasonal changing of ice strength, icebreaker support, ice type, thickness and concentration. The ship's structural capacity to resist ice load and the ship's planned operations are to be considered. The limitations are to be incorporated into an ice operational decision support system.

2.1.2 Limitations for operating in ice are to be determined using an appropriate methodology, such methodologies exist, have been in use for a number of years and have been validated with service experience. Existing methodologies and other systems may be acceptable to the Administration / IRS.

2.1.3 Operation in ice are to take into account any operational limitations of the ship; extended information on the ice operational methodology contained in the PWOM; the condition of the ship and ship's systems, historical weather/ice data and weather/ice forecasts for the intended area of operation, current conditions including visual ice observations, sea state, visibility and the judgment of qualified personnel.

2.2 Operational assessment

2.2.1 This guidance is intended to support ship owners carrying out, and Administrations reviewing, the assessment required in Sec 1, 1.5, for operational limitations and procedures for the Polar Ship Certificate.

2.2.2 Steps for an operational assessment:

.1 identify relevant hazards, as listed in Para 3 of the Introduction and other hazards based on a review of the intended operations;

.2 develop a model***** to analyse risks considering:

.1 development of accident scenarios;
.2 probability of events in each accident scenario; and
.3 consequence of end states in each scenario;

*(Note: ***** Techniques in Appendix 3 of the Revised Guidelines for Formal Safety Assessment (FSA) for use in the IMO Rule Making Process (MSC-MEPC.2/Circ.12) and Standard IEC/ISO 31010 "Risk Management-Risk Assessment Techniques" may be used for development of models referred in 2.2.2.2)*

.3 assess risks and determine acceptability:

.1 estimate risk levels in accordance with the selected modeling approach; and
.2 assess whether risk levels are acceptable; and

.4 in the event that risk levels determined in steps 1 to 3 are considered to be too high, identify current or develop new risk control options that aim to achieve one or more of the following:

.1 reduce the frequency of failures through better design, procedures, training, etc;
.2 mitigate the effect of failures in order to prevent accidents;
.3 limit the circumstances in which failures may occur; or
.4 mitigate consequences of accidents; and

.5 incorporate risk control options for design, procedures, training and limitations, as applicable.

2.3 Performance standards

2.3.1 A system previously accepted based on manufacturer certifications, IRS certifications and/or satisfactory service of existing systems may be acceptable for installation on new and existing ships if no performance or testing standards are accepted by the Organization.

3 Additional Guidance to Chapter 2 of the Code (Section 2 of this Chapter)

3.1 Recommendation on the content of the Polar Water Operational Manual

.1 The Polar Water Operational Manual (PWOM) is intended to address all aspects of operations addressed by Chapter 2 of Part I-A of the Code (Section 2 of this Chapter). When appropriate information, procedures or plans exist elsewhere in a ship's documentation, the PWOM itself does not need to replicate this material, but may instead cross-reference the relevant reference document. A model Table of Contents is provided in Appendix-II to this Chapter.

.2 The model follows the general structure of Section 2. Not every item outlined below will be applicable to every polar ship. Many category C ships that undertake occasional or limit polar voyages will not need to have procedures for situations with a very low probability of occurrence. However, it may still be advisable to retain a common structure for the PWOM as a reminder that if assumptions change then the contents of the manual may also need to be updated. Noting an aspect as "not applicable" also indicates to the Administration that this aspect has been considered and not merely omitted.

3.2 Guidance on navigation with icebreaker assistance

.1 With respect to navigation with icebreaker assistance, the following is to be considered:

.1 while approaching the starting point of the ice convoy to follow an icebreaker / icebreakers or in the case of escorting by icebreaker of one ship to the point of meeting with the icebreaker, ships should establish radio communication on the VHF channel 16 and act in compliance with the icebreaker's instructions;

.2 the icebreaker rendering the icebreaker assistance of ship ice convoy is to command ships in the ice convoy;

.3 position of a ship in the ice convoy is to be determined by the icebreaker rendering the assistance;

.4 ship within the ice convoy, in accordance with the instructions of the icebreaker rendering the assistance, should establish communication with the icebreaker by VHF channel indicated by the icebreaker;

.5 the ship, while navigating in the ice convoy, is to ensure compliance with the instructions of the icebreaker;

.6 position in the ice convoy, speed and distance to a ship ahead is to be as instructed by the icebreaker;

.7 the ship is to immediately notify the icebreaker of any difficulties to maintain the position within the ice convoy, speed and/or distance to any other ship in the ice convoy; and

.8 the ship is to immediately report to the icebreaker of any damage.

3.3 Guidance on the development of contingency plans

.1 In developing the ship's contingency plans ships are to consider damage control measures arrangements for emergency transfer of liquids and access to tanks and spaces during salvage operations.

.2 Additional guidance for Safety of Navigation may also be referred in the Polar Code, whilst making the PWOM.

4 Additional Guidance to Chapter 3 of the Code (Section 3 of this Chapter)

4.1 The guidance presented below is intended to assist in determining equivalency with standards acceptable to the Organization, as referenced in Sections 3 and 6 of this Chapter. The methodology is consistent with guidance

developed by the Organization* while allowing for the use of a simplified approach.

*(Note: * MSC.1/Circ. 1455, as amended, "Guidelines for the approval of alternatives and equivalents as provided for in various IMO instruments" may be used).*

4.2 The basic approach for considering equivalency for categories A and B ships can be the same for both new and existing ships. It involves comparing other ice classes to the IACS Polar Classes (Refer Pt.5, Ch.32). For ice classes under category C, additional information on comparisons of strengthening levels is available for the guidance of owners and Administrations*. The responsibility for generating the equivalency request and supporting information required is to rest with the owner/operator. Review / approval of any equivalency request will be undertaken by the flag State Administration / IRS.

*(Note: * Annex to Helcomm Recommendations 25/7, Safety of Winter Navigation in the Baltic Sea Area may be used).*

4.3 The scope of a simplified equivalency assessment (referring to 4.6.1 to 4.6.3 below) is expected to be limited to materials selection, structural strength of the hull and propulsion machinery.

4.4 If there is not full and direct compliance, then an equivalent level of risk can be accepted in accordance with guidance provided by the Organization. An increase in the probability of an event can be balanced by a reduction in its consequences. Alternatively, a reduction in probability could potentially allow acceptance of more serious consequences. Using a hull area example, a local shortfall in strength level or material grade could be accepted if the internal compartment is a void space, for which local damage will not put the overall safety of the ship at risk or lead to any release of pollutants.

4.5 For existing ships, service experience can assist in risk assessment. As an example, for an existing ship with a record of polar ice operations a shortfall in the extent of the ice belt (hull areas) may be acceptable if there is no record of damage to the deficient area; i.e. a ship that would generally meet requirements of PC 5 Class Ships but in limited areas is only PC 7 could still be considered as a category A, PC 5 ship. In all such cases, the ship's documentation is to make clear the nature and scope of any deficiencies.

4.6 The process includes the following stages of assessment:

.1 select the target Polar Class for equivalency;

.2 compare materials used in the design with minimum requirements in Pt.5, Ch. 32; identify any shortfalls; and

.3 compare strength levels of hull and machinery components design with requirements in Pt.5, Ch.32; quantify levels of compliance.

4.7 Where gaps in compliance are identified in 4.6.1 to 4.6.3, additional steps are necessary to demonstrate equivalency, as outlined below:

.4 identify any risk mitigation measures incorporated in the design of the ship (over and above the requirements of the Polar Code and Pt.5, Ch.32);

.5 where applicable, provide documentation of service experience of existing ships, in conditions relevant to the target ice class for equivalency; and

.6 undertake an assessment, taking into account information from 4.6.1 to 4.6.5 as applicable, and on the principles outlined in 4.2 to 4.6 above.

4.8 Documentation provided with an application for equivalency are to identify each stage that has been undertaken, and sufficient supporting information to validate assessments.

4.9 Where a ship in categories A or B is provided with an equivalency for ice class by its flag State, this is to be noted in its Polar Ship Certificate.

Appendix-II

Model Table of Contents for the Polar Water Operations Manual (PWOM)
Safety Measures

Division 1 – Operational capabilities and limitations

Chapter 1 Operation in ice

1.1 Operator guidance for safe operation

Guidance: The PWOM is to establish the means by which decisions as to whether ice conditions exceed the ship's design limits should be made, taking into account the operational limitations on the Polar Ship Certificate. An appropriate decision support system, such as the Canada's Arctic Ice Regime Shipping System, and/or the Russian Ice Certificate as described in the Rules of Navigation on the water area of the Northern Sea Route, can be used. Bridge personnel are to be trained in the proper use of the system to be utilized. For ships that will operate only in ice-free waters, procedures to ensure that will keep the ship from encountering ice should be established.

1.2 Icebreaking capabilities

Guidance: The PWOM is to provide information on the ice conditions in which the ship can be expected to make continuous progress. This may be drawn, for example from numerical analysis, model test or from ice trials. Information on the influence of ice strength for new or decayed ice and of snow cover may be included.

1.3 Manoeuvring in ice

1.4 Special features

Guidance: Where applicable, the PWOM is to include the results of any equivalency analyses made to determine Polar Ship category/ice class. The manual is also to provide information on the use of any specialized systems fitted to assist in ice operations.

Chapter 2 Operation in low air temperatures

2.1 System design

Guidance: The PWOM is to list all ship systems susceptible to damage or loss of functionality by exposure to low temperatures, and the measures to be adopted to avoid malfunction.

Chapter 3 Communication and navigation capabilities in high latitudes

Guidance: The PWOM is to identify any restrictions to operational effectiveness of communications and navigational equipment that may result from operating in high latitudes.

Chapter 4 Voyage duration

Guidance: The PWOM is to provide information on any limitations on ship endurance such as fuel tankage, fresh water capacity, provision stores, etc. This will normally only be a significant consideration for smaller ships, or for ships planning to spend extended periods in ice.

Division 2 – Ship operations

Chapter 1 Strategic planning

Assumptions used in conducting the analyses referred to below are to be included in the Manual.

1.1 Avoidance of hazardous ice

Guidance: For ships operating frequently in polar waters, the PWOM is to provide information with respect to periods during which the ship should be able to operate for intended areas of operation. Areas that pose particular problems, e.g. chokepoints, ridging, as well as worst recorded ice conditions are to be noted. Where the available information is limited or of uncertain quality, this is to be recognized and noted as a risk for voyage planning.

1.2 Avoidance of hazardous temperatures

Guidance: For ships operating frequently in polar waters, the PWOM is to provide information with respect to, the daily mean daily low temperature as well as the minimum recorded temperature for each of the days during the intended operating period. Where the available information is limited or of uncertain quality, this is to be recognized as a risk for voyage planning.

1.3 Voyage duration and endurance

Guidance: Procedures to establish requirements for supplies are to be established, and appropriate safety levels for safety margins determined taking into account various scenarios, e.g. slower than expected steaming, course alterations, adverse ice conditions, places of refuge and access to provisions. Sources for and availability of fuel types are to be established, taking into account long lead times required for deliveries.

1.4 Human resources management

Guidance: The PWOM is to provide guidance for the human resources management, taking into account the anticipated ice conditions and requirements for ice navigation, increased levels of watch keeping, hours of rest, fatigue and a process that ensures that these requirements will be met.

Chapter 2 Arrangements for receiving forecasts of environmental conditions

Guidance: The PWOM is to set out the means and frequency for provision of ice and weather information. Where a ship is intended to operate in or in the presence of ice, the manual is to set out when weather and ice information is required and the format for the information.
When available, the information is to include both global and localized forecasts that will identify weather and ice patterns/regimes that could expose the ship to adverse conditions.
The frequency of updates is to provide enough advance notice that the ship can take refuge or use other methods of avoiding the hazard if the conditions are forecast to exceed its capabilities.
The PWOM may include use of a land-based support information provider an effective method of sorting through available information, thereby providing the ship only with information that is relevant, reducing demands on the ship's communications systems. The manual may also indicate instances in which additional images should be obtained and analysed, as well as where such additional information may be obtained.

2.1 Ice information

Guidance: The PWOM is to include or refer to guidance on how radar is to be used to identify ice floes, how to tune the radar to be most effective, instructions on how to interpret radar images, etc. If other technologies are to be used to provide ice information, their use is also to be described.

2.2 Meteorological information

Chapter 3 Verification of hydrographic, meteorological and navigational information

Guidance: The PWOM is to provide guidance on the use of hydrographic information. as further described in the additional guidance to chapter 10 of the Code.

Chapter 4 Operation of Special Equipment

4.1 Navigation systems

4.2 Communications systems

Chapter 5 Procedures to maintain equipment and system functionality

5.1 Icing prevention and de-icing

Guidance: The PWOM is to provide guidance on how to prevent or mitigate icing by operational means, how to monitor and assess ice accretion, how to conduct de-icing using equipment available on the ship, and how to maintain the safety of the ship and its crew during all of these aspects of the operation.

5.2 Operation of seawater systems

Guidance: The PWOM is to provide guidance on how to monitor, prevent or mitigate ice ingestion by seawater systems when operating in ice or in low water temperatures. This may include recirculation, use of low rather than high suctions, etc.

5.3 Procedures for low temperature operations

Guidance: The PWOM is to provide guidance on maintaining and monitoring any systems and equipment that are required to be kept active in order to ensure functionality; e.g. by trace heating or continuous working fluid circulation.

Division 3 – Risk management

Chapter 1 Risk mitigation in limiting environmental condition

1.1 Measures to be considered in adverse ice conditions

Guidance: The PWOM is to contain guidance for the use of low speeds in the presence of hazardous ice. Procedures are also to be set for enhanced watchkeeping and lookout manning in situations with high risks from ice, e.g. in proximity to icebergs, operation at night, and other situations of low visibility. When possibilities for contact with hazardous ice exist, procedures are to address regular monitoring, e.g. soundings/inspections of compartments and tanks below the waterline.

1.2 Measures to be considered in adverse temperature conditions

Guidance: The PWOM is to contain guidance on operational restrictions in the event that temperatures below the ships polar service temperature are encountered or forecast. These may include delaying the ship, postponing the conduct of certain types of operation, using temporary heating, and other risk mitigation measures.

Chapter 2 Emergency response

Guidance: In general, where the possibility of encountering low air temperatures, sea ice, and other hazards is present, the PWOM is to provide guidance on procedures that will increase the effectiveness of emergency response measures.

2.1 Damage control

Guidance: the PWOM is to consider damage control measures arrangements for emergency transfer of liquids and access to tanks and spaces during salvage operations.

2.2 Firefighting

2.3 Escape and evacuation

Guidance: Where supplementary or specialized lifesaving equipment is carried to address the possibilities of prolonged durations prior to rescue, abandonment onto ice or adjacent land, or other aspects specific to polar operations, the PWOM is to contain guidance on the use of the equipment and provision for appropriate training and drills.

Chapter 3 Coordination with emergency response services

3.1 Ship emergency response

Guidance: The PWOM is to include procedures to be followed in preparing for a voyage and in the event of an incident arising.

3.2 Salvage

Guidance: The PWOM is to include procedures to be followed in preparing for a voyage and in the event of an incident arising.

3.3 Search and rescue

Guidance: The PWOM is to contain information on identifying relevant Rescue Coordination Centres for any intended routes, and should require that contact information and procedures be verified and updated as required as part of any voyage plan.

Chapter 4 Procedures for maintaining life support and ship integrity in the event of prolonged entrapment by ice.

Guidance: Where any ship incorporates special features to mitigate safety or environmental risks due to prolonged entrapment by ice, the PWOM is to provide information on how these are to be set up and operated. This may include, for example, adding additional equipment to be run from emergency switchboards, draining systems at risk of damage through freezing, isolating parts of HVAC systems, etc.

4.1 System configuration

4.2 System operation

Division 4 – Joint operations

Chapter 1 Escorted operations

Guidance: The PWOM is to contain or reference information on the rules and procedures set out by coastal States who require or offer icebreaking escort services. The manual is also to emphasize the need for the master to take account of the ship's limitations in agreeing on the conduct of escort operations.

Chapter 2 Convoy operations

End of Chapter

Chapter 37

Ballast Water Management

Section	Contents
1	*General*
2	*Ballast Water Exchange*
3	*Ballast Water Treatment*

Section 1

General

1.1 Application

1.1.1 The requirements of this chapter are applicable to vessels that are undertaking ballast water management i.e. performing ballast water exchange or are fitted with ballast water treatment systems and are supplementary to the assignment of main characters of class.

1.1.2 The additional class notations for ballast water management are assigned for ships complying with the requirements of the International Convention for the Control and Management of Ships' Ballast Water and Sediments, 2004, the relevant IMO guidelines and requirements of this Chapter.

1.1.3 The definitions stated in the BWM Convention, its appendices and related IMO documents are applicable to these Rules.

1.1.4 In accordance with the BWM convention, a BWMS installed on board a vessel is to be an IMO Member State type-approved and certified system and the installation of this system must have their prior approval/acceptance of the vessel's flag Administration.

1.1.5 Attention is drawn to any relevant statutory requirements of the country in which the ship is to be registered. Several national Administrations have in place additional requirements pertaining to the management of ballast water for vessels operating in their territorial waters. These requirements may require additional vessel features, performance standards, equipment, reporting and record keeping, which are not included in this Chapter.

1.2 Notations

1.2.1 The additional class notation **BWE ( )** is assigned to ships complying with the International Convention for the Control and Management of Ships' Ballast Water and Sediments, 2004, the relevant IMO Guidelines, and performing ballast water exchange in accordance with the requirements of Section 2. The letter or letters separated by commas in brackets denotes the method/s for exchange that has been applied as follows:

s for sequential method

f for flow through method

d for dilution method

Examples: **BWE (s); BWE (s,f); BWE (s,f,d)**

- *Sequential Method*: A process by which a ballast tank is first emptied and then refilled with replacement ballast water
- *Flow-through Method*: A process by which replacement ballast water is pumped into a ballast tank, allowing water to flow through overflow or other arrangements. At least three times the tank volume is to be pumped through the tank
- *Dilution Method*: A method by which replacement ballast water is filled through the top of the ballast tank with simultaneous discharge from the bottom at the same flow rate and maintaining a

constant level in the tank throughout the ballast exchange operation. At least three times the tank volume is to be pumped through the tank

1.2.2 The additional class notation **BWT** is assigned to ships complying with the International Convention for the Control and Management of Ships' Ballast Water and Sediments, 2004, the relevant IMO Guidelines, and fitted with a ballast water treatment system approved by an IMO Member State, in accordance with the requirements of Section 3.

1.2.3 Vessels equipped with a BWMS where the installation was not conducted under IRS survey may obtain **BWT** notation, provided that the BWMS and the installation on board the vessel have been determined to comply with the design and installation criteria contained in this chapter. The operation of the BWMS is to be demonstrated by a shipboard function test, and documentation confirming that the BWMS has been type-approved in accordance with IMO G-8 Guidelines as satisfying the ballast water performance standard contained in Regulation D-2 of the Convention is to be submitted.

1.3 General Requirements

1.3.1 Ballast Water Discharge Standards

1.3.1.1 Ballast Water Exchange

1.3.1.1.1 The ballast water exchange standards required for issuance of the **BWE ( )** notation are specified in Reg. D-1 of the BWM Convention.

1.3.1.1.2 Ships performing Ballast Water exchange are to do so with an efficiency of at least 95 percent volumetric exchange of Ballast Water. For ships exchanging Ballast Water by the pumping-through method, pumping through three times the volume of each Ballast Water tank shall be considered to meet the standard described above. Pumping through less than three times the volume may be accepted provided the ship can demonstrate that at least 95 percent volumetric exchange is met.

1.3.1.2 Ballast Water Treatment

1.3.1.2.1 The ballast water discharge standards required for issuance of the **BWT** notation are as specified in the Reg. D-2, of the BWM Convention.

1.3.1.2.2 Ships conducting Ballast Water Management in accordance with Reg.D-2 are to discharge less than 10 viable organisms per cubic metre greater than or equal to 50 micrometres in minimum dimension and less than 10 viable organisms per millilitre less than 50 micrometres in minimum dimension and greater than or equal to 10 micrometres in minimum dimension; and discharge of the indicator microbes is not to exceed the specified concentrations described as below.

1.3.1.2.3 Indicator microbes, as a human health standard, are to include:

.1 Toxicogenic Vibrio cholerae (O1 and O139) with less than 1 colony forming unit (cfu) per 100 millilitres or less than 1 cfu per 1 gram (wet weight) zooplankton samples;

.2 Escherichia coli less than 250 cfu per 100 millilitres;

.3 Intestinal Enterococci less than 100 cfu per 100 milliliters.

1.3.2 System Certification

1.3.2.1 Systems using the following three main categories of treatment are considered acceptable.

(a) Mechanical Treatment (For e.g. Filtration, Cyclonic Separation, Electro-mechanical separation);

(b) Physical Treatment (For e.g. Ultra Violet Light, Cavitation/ Ultrasounds, De-oxygenation);

(c) Chemical Treatment (For e.g. Disinfecting Biocides, Electrolytic Chlorination)

1.3.2.2 The ballast water management system installed onboard those vessels receiving **BWT** notation is to be a type-approved and certified system in accordance with the testing, approval and certification processes outlined in the IMO's G8 Guidelines. For the BWMS employing an active substance(s), further requirements and additional approval procedures apply as per IMO G9 Guidelines.

1.3.2.3 For a system that makes use of active substances, documentation relating to the IMO Basic Approval and Final Approval are required to be submitted.

1.4 Definitions

1.4.1 **Ballast Water Management System** (hereinafter referred to as 'BWMS') means any system which processes ballast water such that it meets or exceeds the Ballast Water Performance Standard in Regulation D-2 of the BWM Convention. The BWMS includes ballast water equipment, all associated piping arrangements as specified by the manufacturer, control and monitoring equipment and sampling facilities. The categorization of BWMS technologies is given in Table 3.1. Applicability of the requirements for each BWMS technology is in accordance with Table 3.2.

1.4.2 Cargo area of tankers is defined in:

- for tankers to which Part 6, Ch.1, 1.5.1 applies, Part 6, Ch.1, 3.6 ;

- for chemical tankers, Part 5, Ch.3, 1.3.6;

- for gas carriers, Part 5, Ch.4, 1.2.7; and

- for offshore support vessels, Paragraph 1.3.1 of the IMO Resolution A.673(16) as amended by Resolution MSC.236(82) or Paragraph 1.2.7 of the IMO Resolution A.1122(30), as applicable.

1.4.2 **Dangerous gas** means any gas which may develop an atmosphere being hazardous to the crew and/or the ship due to flammability, explosivity, toxicity, asphyxiation, corrosivity or reactivity and for which due consideration of the hazards is required, e.g. hydrogen (H_2), hydrocarbon gas, oxygen (O_2), carbon dioxide (CO_2), carbon monoxide (CO) ozone (O_3), chlorine (Cl_2) and chlorine dioxide (ClO_2), etc.

1.4.3 **Hazardous area** is defined in IEC 60092-502:1999 and means an area in which an explosive gas atmosphere is or may be expected to be present, in quantities such as to require special precautions for the construction, installation and use of electrical apparatus. When a gas atmosphere is present, the following hazards may also be present: toxicity, asphyxiation, corrosivity and reactivity.

1.4.4 **Non-hazardous area** means an area which is not a hazardous area as defined in 1.4.3 above.

1.4.5 **Dangerous liquid** means any liquid that is identified as hazardous in the Material Safety Data Sheet or other documentation relating to this liquid.

1.5 Sediment Management

1.5.1 As per Regulation B-5 of the BWM Convention and IMO Guidelines, it is required that ships should, without compromising safety or operational efficiency, be designed and constructed with a view to minimize the uptake and undesirable entrapment of sediments, facilitate the removal of sediments, and provide safe access to allow for sediment removal and sampling.

1.5.2 Practical steps are to be taken during ballast water uptake to avoid the accumulation of sediments. Ballast water tanks and their internal structures should be designed to minimize accumulation of sediments and allow for easy cleaning and maintenance.

1.5.3 Details of the methods and operational procedures for the sediment management on board the ship, including the disposal of sediments and the associated safety considerations, etc., are to be documented in the ship's Ballast Water Management Plan.

1.5.4 In new ships or ships undergoing major modification in way of ballast tanks, the internal arrangement of ballast tanks (e.g. stiffener orientation) is to be such that there is:

(i) minimum accumulation of sediments e.g. adequate provision of scallops and drain holes
(ii) absence of stagnant pool or sediment traps;
(iii) minimal horizontal surfaces;
(iv) arrangement for effective flushing.

1.5.5. In ships, where ballast water treatment plants are being retrofitted, it may not be feasible to undertake major changes to the stiffener arrangement, etc. In such cases, measures to enable effective flushing of the sediments are to be provided, as practicable.

1.6 Ballast Water Management Plan (BWMP)

1.6.1 Each ship is to have on board and implement a Ballast Water Management plan. Such a plan is to be approved by/on behalf of the Administration, taking into account Guidelines (G-4) developed by IMO. The Ballast Water Management plan is to be specific to each ship and is to at least:

- detail safety procedures for the ship and the crew associated with Ballast Water Management as required by the Convention;

- provide a detailed description of the actions to be taken to implement the Ballast Water Management requirements and supplemental Ballast Water Management practices as set forth in the Convention;

- detail the procedures for the disposal of sediments:

  at sea; and

  to shore

- include the procedures for coordinating shipboard Ballast Water Management that involves discharge to the sea with the authorities of the State into whose waters such discharge will take place;

- designate the officer on board in charge of ensuring that the plan is properly implemented and list his duties;

- contain the reporting requirements for ships provided for under the Convention; and

- be written in the working language of the ship.

1.6.2 The Ballast Water Management Plan is to include training and education for ship's crew on ballast water management practices and the systems and procedures used on board the ship.

1.6.3 Regular review of the Plan is required to be conducted by the owner, operator, or master to ensure that the information contained is accurate and updated.

1.6.4 Changes to the provisions of the Plan will need re-approval of the BWMP.

1.7 Ballast Water Record Book (BWRB)

1.7.1 Each ship is to have a Ballast Water Record Book that may be in electronic form and which has to at least contain information specified in Appendix II to the Convention.

1.7.2 Ballast Water record book entries are to be maintained on board the ship for a minimum period of two years after the last entry has been made and thereafter in the Company's control for a minimum period of three years.

1.7.3 All discharges of Ballast Water pursuant to Reg. A-3, A-4 or B-3.6 of the Convention, and/ or including accidental or exceptional discharges, not otherwise exempted by the Convention, are to be recorded, without delay in the Ballast Water Record Book. The circumstances and the reason for the discharge are also to be indicated.

1.7.4 The Ballast Water Record Book is to be kept readily available for inspection at all times and, in the case of an unmanned ship under tow, may be kept on the towing ship.

Section 2

Ballast Water Exchange

2.1 Application

2.1.1 The requirements given in this Section are applicable to ships where ballast water exchange at sea is accepted as a process in lieu of treatment of ballast water.

2.2 Documentation

2.2.1 In addition to the information and plans required by Pt.3, Ch.1, Sec.3, the following are to be submitted as applicable for approval:

.1 Machinery plans showing piping details of the ballast system and

.2 ballast water management plan having detailed calculation showing compliance with strength and stability requirements.

2.3 General

2.3.1 Stability

2.3.1.1 All stability and trim requirements applicable to the ship are to be met during the ballast water management operations, including free surface effects.

2.3.2 Strength

2.3.2.1 All strength requirements, as applicable are to be met. Depending on the method of exchange, the following are to be specially considered during the ballast water management operations:

- Hull girder strength (bending, shear and torsion)
- Sloshing in tanks
- Bottom slamming
- Overpressure in tanks

2.4 Flow Through Method

2.4.1 The tank volumes, available pumps and estimated time for the flow-through of water, corresponding to a volume three times the tank volume are to be included in the Ballast Water Management Plan (BWMP). In cases the floating position changes due to using flow-through method for partially filled tanks, calculation showing compliance with stability and strength requirements during the exchange steps are to be presented in the BWMP as required by 2.6.1

2.4.2 The capability of the ballast water system for BWE by the flow-through method without risk of the tank being subject to a pressure greater than for what it has been designed is to be shown by calculations.

2.4.3 Provision is to be made to prevent overflow through the air pipe heads unless the air pipe heads are type approved for these operations.

2.5 Dilution Method

2.5.1 The tank volumes, available pumps and estimated time for the exchange of water, corresponding to a volume three times the tank volume are to be included in the Ballast Water Management Plan (BWMP).

2.5.2 A monitoring system to monitor the levels in tanks is to be provided where maintenance of constant level is essential to the safety of the ship during BWE.

2.6 Sequential Method

2.6.1 Calculations showing compliance with stability and strength requirements for each step in the ballast exchange sequence are to be submitted. The following are to be shown in the calculations:

- Ballast water volume for each tank
- Pumps involved
- Estimated time for exchange
- Stress values in relation to permissible values
- Stability effects under consideration of free-surface effects during filling or discharging
- Draught values at FP, AP and heeling

2.6.2 The following loading conditions are to be indicated if the sequential method is applicable:

- Standard ballast condition
- Heavy ballast and emergency ballast conditions, if applicable
- A critical loading condition for one of the stages, where the least safety margin(s) to the valid stability and/or strength limits occur.

Section 3

Ballast Water Treatment

3.1 Application

3.1.1 The requirements given in this Section are applicable to ships where treatment of ballast water is undertaken such that the discharge meets the IMO D-2 standard.

3.1.2 The categorization of ballast water management system technologies is given in Table 3.1. Applicability of the requirements for each BWMS technology is in accordance with Table 3.2.

3.2 Documentation

3.2.1 Following plans and documentation are to be submitted for approval:

.1 General arrangement drawings of the BWMS. Installation arrangement drawings on the ship including location and layout

.2 Ballast piping system drawings including layout, filling arrangement and construction details of piping system

.3 Location of ballast water sampling facilities

.4 Electrical circuit drawings and main power cable drawings

.5 Power calculation document including electrical load analysis

.6 Control, monitoring and safety system documentation especially where the controls and monitoring of the BWMS have been connected to or integrated with the ship's control and monitoring system(s)

.7 Local instrumentation arrangement plan

.8 Structural plans showing installation details of attachment, supports and foundations of principal components of the BWMS

.9 Hazardous area installations and hazardous area plans, as applicable

.10 Storage tanks and day tanks containing chemicals and preparations used to treat ballast water including complete piping details of filling, drain system, vents, drip trays, and safety precautions, etc.

.11 Leakage detection system and safety features associated with the generation of toxic or flammable gases. Safety features are to include sensors, alarms and shutdown settings, etc. Schematic plans detailing arrangement and location of sensors are to be provided.

.12 Risk assessment documentation, where applicable. For BWMS that employs active substances and preparations, arrangement, handling and safety plans of auxiliary systems for the treatment system, as applicable.

.13 Ballast Water Management Plan (BWMP). BWMP to be specific to the ship and in a standard format as per G4 Guidelines

.14 BWMS operations and technical manual specific to the actual installation onboard the ship

.15 Shipboard function test plan for sea or quay trial. Function test of the installed BWMS at the sea trial or quay trial in the presence of attending Surveyor; function test plan as per paragraph 5.1.9 of G8 Guidelines

3.2.2 Following plans and documentation are to be submitted for information:

.1 Arrangement and capacity of ballast tanks and pumps

.2 List of electrical equipment in hazardous area

.3 Safety documentation for hazardous chemicals in recognized industry format, such as MSDS, CHRIS Code

.4 Ballast water record book specific to the ship

3.2.3 A risk assessment may be conducted to ensure that risks, including but not limited to those arising from the use of dangerous gas affecting persons on board, the marine environment, the structural strength or integrity of the ship are identified.

Table 3.1 - Categorization of BWMS technologies

BWMS's Technology category (informative Annex II should be referred to) →		**1**	**2**	**3a**	**3b**	**3c**	**4**	**5**	**6**	**7a**	**7b**	**8**
Characteristics ↓		In-line UV or UV + Advanced Oxidation Technology (AOT) or UV + TiO_2 or UV + Plasma	In-line Flocculation	In-line membrane separation and de-oxygenation (injection of N_2 from a N_2 Generator)	In-line de-oxygenation (injection of Inert Gas from Inert Gas Generator)	In-tank de-oxygenation with Inert Gas Generator	In-line full flow electrolysis	In-line side stream electrolysis (2)	In-line (stored) chemical injection	In-line side-stream ozone injection without gas/liquid separation tank and without Discharge treatment tank	In-line side-stream ozone injection with gas/liquid separation tank and Discharge water treatment tank	In-tank pasteurization and de-oxygenation with N_2 generator
Dis-infection when ballasting	Making use of active substance		X			In-tank technology: No treatment when ballasting or de-ballasting	X	X	X	X	X	In-tank technology: No treatment when ballasting or de-ballasting
	Full flow of ballast water is passing through the BWMS	X	X	X	X		X				X	
	Only a small part of ballast water is passing through the BWMS to generate the active substance							X				
After-treatment de-when ballasting	Full flow of ballast water is passing through the BWMS	X									X	
	Injection of neutralizer						X	X	X	X	X	
	Not required by the Type Approval Certificate issued by the Administration		X	X								
Examples of dangerous gas as defined in 1.4.2			(1)	O_2 N_2	CO_2 CO		H_2 Cl_2	H_2 Cl_2	(1)	O_2 O_3 N_2		O_2 N_2

Note:
(1) To be investigated on a case by case basis based on the result of the IMO (GESAMP) MEPC report for Basic and Final approval in accordance with the G9 Guideline.
(2) In-line side stream electrolysis may also be applied in-tank in circulation mode (no treatment when ballasting or de-ballasting)

Taking into consideration future developments of BWMS technologies, some additional technologies may be considered in this Table 3.1 by identifying their characteristics in the same manner as for the above BWMS categories 1, 2, 3a, 3b, 3c, 4, 5, 6, 7a, 7b and 8.

Table 3.2 - Applicability of the requirements for each BWMS technology											
BWMS's Technology category (informative Annex II should be referred to)→	**1**	**2**	**3a**	**3b**	**3c**	**4**	**5**	**6**	**7a**	**7b**	**8**
Requirement ↓	In-line UV or UV + Advanced Oxidation Technology (AOT) or UV + TiO_2 or UV + Plasma	In-line Flocculation	In-line membrane separation and de-oxygenation (injection of N_2 from a N_2 Generator)	In-line de-oxygenation (injection of Inert Gas from Inert Gas Generator)	In-tank de-oxygenation with Inert Gas Generator	In-line full flow electrolysis	In-line side stream electrolysis	In-line (stored) chemical injection	In-line side-stream ozone injection without gas/liquid separation tank and without Discharge treatment tank	In-line side-stream ozone injection with gas/liquid separation tank and Discharge water treatment tank	In-tank pasteurization and de-oxygenation with N_2 generator
3.5.5			x	x	x						x
3.8.6	x	x	x	x	x	x	x	x	x	x	x
3.7.1.3			x	x	x						x
3.7.1.2				x						x	
3.7.2	x	x	x	x	x	x	x	x	x	x	x
3.9.1.1				x	x				x	x	
3.9.1.2						x	x	x			
3.9.2	x	x	x	x		x	x	x	x	x	
3.9.3	x	x	x	x	x	x	x	x	x	x	x
3.9.4	x	x	x	x		x	x	x	x	x	
3.10.1.1		x	x			x	x	x	x	x	x
3.10.1.2			x	x	x				x	x	x
3.10.1.3									x	x	
3.10.1.4						x	x	x	x	x	
3.10.1.5						x	x	x			
3.10.1.6			x	x	x				x	x	x
3.10.2.1 to 3.10.2.4		x	x	x	x	x	x	x	x	x	x
3.10.2.5			x			x	x	x	x	x	x
3.10.2.6			x						x	x	x
3.10.2.7			x			x	x	x	x	x	x
3.10.3		x				x	x	x	x	x	
3.10.4						x	x	x	x	x	

3.3 Ballast Treatment capacities

3.3.1 The BWMS is to be operated in accordance with the requirements specified in the Type Approval Certificate (TAC) issued by the Flag Administration. BWMS is to be operated within its Treatment Rated Capacity (TRC) as per the TAC. This may require limiting of ship's ballast pump flowrates. The arrangement of the bypasses or overrides of the BWMS is to be consistent with the approved Operation Maintenance and Safety Manual by the Flag Administration's Type Approval. In case the maximum capacity of the ballast pump(s) exceeds the maximum treatment rated Capacity (TRC) of the BWMS specified in the TAC issued by the Flag Administration, there is to be a limitation on the BWMP giving a maximum allowable flow rate for operating the ballast pump(s) that is not to exceed the maximum TRC of the BWMS.

3.4 General Requirements/ Layout

3.4.1 Supporting structure

3.4.1.1 A support structure for the foundation of the BWM system is to be provided, considering all operational conditions of the BWM system.

3.4.2 Where the BWMS is installed in an independent compartment, the compartment is to be:

.1 provided with fire integrity equivalent to "other machinery spaces";

.2 provided with fire detection, fire-fighting as per fire control plan;

.3 positioned outside of any combustible, corrosive, toxic, or hazardous areas unless otherwise specifically approved.

3.5 Piping

3.5.1 All valves, piping fittings and flanges are to comply with the relevant requirements of Pt. 4, Ch. 2 of the Rules. Where plastic pipes have been accepted for use, these are to meet the specification as in IMO Res. A.753(18) with regard to strength, fire endurance, flame spread etc.

3.5.2 Bulkhead/ deck penetrations or penetrations of the ballast system piping are to be to the relevant approved standards.

3.5.3 The BWMS is to be provided with by-pass or override arrangement to effectively isolate it from any essential ship system to which it is connected. For new installation or retrofit to existing ships, under normal operating conditions of ballasting and de-ballasting given in the Ballast Water Management Plan (BWMP) the adequacy of the generating plant capacity installed on the vessel is to be demonstrated by an electrical load analysis. For retrofit installation to exiting ships, a revised electrical load analysis with preferential trips of non-essential services can be accepted.

3.5.4 BWMS is to be subject to design review by IRS to verify the compliance of the BWMS's manufacturer package with the Rules. Manufacturers of the BWMS may apply for this design review at the type approval process. In general, monitoring functions of BWMS belongs to system category I under the application of the Pt.4, Ch.7, Sec.6 . However, in case a by-pass valve is integrated in the valve remote control system, the by-pass valve belongs to the system category II Ballast transfer remote control system. The BWMS's components are required to be inspected and certified by IRS at the manufacturer's works (Society Certificate (SC) as defined in IRS Classification Note *"Approval of IC Engines"*) including pressure vessels, piping class I or II, filters, switchboards, etc.

3.5.5 Where a vacuum or overpressure may occur in the ballast piping or in the ballast tanks due to the height difference or injection of inert gas or nitrogen(N_2), a suitable protection device is to be provided (i.e. P/V breakers, P/V breather valves or pressure safety relief valve or high/low pressure alarms). The pressure and vacuum settings of the protection device is not to exceed the design pressure of the ballast piping (BWMS categories 3a and 3b) or ballast tank (BWMS categories 3a, 3b and 3c), as relevant.

For BWMS categories 3a, 3b and 3c, the inert gas or nitrogen product enriched air from the inert gas system and from the protection devices installed on the ballast tanks (i.e. P/V valves, P/V breakers or P/V breather valves) are to be discharged to a safe location*(1) & (2) on the open deck.

When the concerned ballast tanks are hazardous areas, an extension of hazardous area is to be considered at the outlet of the protection devices: with reference to IEC 60092-502:1999 §4.2.2.9 the areas on open

deck, or semi-enclosed spaces on open deck, within 1.5 m of their outlets are to be categorized hazardous zone 1 and with reference to IEC 60092-502:1999 clause 4.2.3.1, an additional 1.5 m surrounding the 1.5 m hazardous zone 1 is to be categorized hazardous zone 2. Any source of ignition such as anchor windlass or opening into chain locker are to be located outside the hazardous areas.

Where products covered by IEC 60092-502:1999 are stored on-board or generated during operation of the BWMS, the requirements of this standard is to be followed in order to:

- Define hazardous areas and acceptable electrical equipment, and

- Design ventilation systems.

Notes :

Safe location needs to address the specific types of discharges separately.

Signboards or similar warnings at the discharge areas are to be provided.

Safe location*(1): inert gas or nitrogen product enriched air from:

- in-line (categories 3a and 3b) and in-tank (categories 3c and 8) de-oxygenation BWMS: the protection devices installed on the ballast tanks, nitrogen or inert gas generators, nitrogen buffer tank (if any); or

- in-line ozone injection BWMS (categories 7a and 7b): the oxygen generator;

safe locations on the open deck are:

- not within 3 [m] of areas traversed by personnel; and

- not within 6 [m] of air intakes for machinery (engines and boilers) and all ventilation inlets/outlets.

Safe location*(2): oxygen-enriched air from:

- in-line and in-tank de-oxygenation BWMS (categories 3a and 8): the nitrogen generator; or

- in-line ozone injection BWMS (categories 7a and 7b): the protection devices or vents from oxygen generator, compressed oxygen vessel, the ozone generator and ozone destructor devices;

safe locations on the open deck are:

- outside of hazardous area;

- not within 3 [m] of any source of ignition and from deck machinery, which may include anchor windlass and chain locker openings, and equipment which may constitute an ignition hazard;

- not within 3 [m] of areas traversed by personnel; and

- not within 6 [m] of air intakes for machinery (engines and boilers) and all ventilation inlets.

3.5.6 The length of pipe and the number of connections are to be minimized in piping systems containing dangerous gases/ liquids in high concentration.

3.5.7 Pipe joints are to be of welded type except for connections to shut off valves, double walled pipes or pipes in ducts equipped with mechanical exhaust ventilation. Alternatively, it is to be demonstrated that risk of leakage is minimized and the formation of toxic or flammable atmosphere is prevented.

3.5.8 Location of the piping system is to be away from heat sources and protected from mechanical damage.

3.6 Sampling points

3.6.1 The ballast water system is to be provided with sampling, arranged according to the provisions of the IMO G2 guidelines, as amended. Accordingly, the sampling point is to be arranged in the discharge pipe as close as possible at the shell.

3.7 System Specific Requirements

3.7.1 The plan/ documentation requirements would vary depending upon the technology used (for compliance to D-2 Standard) in the BWM system. Certain system specific requirements based on the type of technology currently used in the BWMS are as follows:

3.7.1.1 BWMS using mechanical separation systems

.1 Pressure loss across the BWMS should not reduce the ability of the ballast system to supply at an acceptable flow rate to a remote ballast tank;

.2 Arrangement for backwashing are to be provided in order to confirm that the wastes can be adequately removed from the system taking into account the

maximum static head when the ship is at maximum draft;

.3 Arrangements are to be provided (e.g. controls, procedures etc.) to allow separation system and associated piping to be backwashed and flushed clean upon completion of ballasting as well as de-ballasting operations.

3.7.1.2 BWMS using cavitation and ultrasound systems

3.7.1.2.1 When cavitation is the BWMS treatment process (for example by use of pressure vacuum reactor working in combination with a vertical ballast water drop line) or part of the BWMS treatment process (for example by use of “smart pipe” or “special pipe” in BWMS category 7b or by use of “venturi pipe” in BWMS technology 3b) or by use other means, the design and the wall thickness or grade of materials or inside coating or surface treatment of the part of the piping where the cavitation is taking place is to be specifically considered.

3.7.1.3 BWMS using Inert Gas De-oxygenation systems

3.7.1.3.1 Inert gas systems installed for de-oxygenation BWMS (categories 3a, 3b, 3c and 8) are to be designed in accordance with the following requirements:

.1 Part 6, Chapter 8, Section 15 requirements

- 15.2.1.2, 15.2.1.3

- 15.2.2.1.3, 15.2.2.1.4, 15.2.2.2.1,15. 2.2.2.2, 15.2.2.2.3, 15.2.2.2.6, 15.2.2.4.1, 15.2.2.4.2, 15.2.2.4.3, 15.2.2.4.4, 15.2.2.4.5 except 15.2.2.4.5.1.3 and 15.2.2.4.5.3

- 15.2.3.1.1.2, 15.2.3.1.2, 15.2.3.1.4.2, 15.2.3.1.5, 15.2.3.1.6, 15.2.3.2 except 15.2.3.2.2.1

- 15.2.4.1.3, 15.2.4.1.4 and 15.2.4.2

- For inert gas systems installed for in-tank de-oxygenation BWMS (category 8): 2.2.3.1, 2.2.3.2 except 2.2.3.2.6, 2.2.3.2.7 and 2.2.3.2.10

In general, when applying Part 6, Chapter 8, Section 15 requirements to inert-gas based BWMS, the following modifications are to be considered:

- The terms "cargo tank" and "cargo piping" are to be replaced by "ballast water tank" or "ballast water piping" as relevant.

- The term "cargo control room" is to be replaced by "BWMS control station" as relevant

- Requirements for slop tanks on combination carriers are to be disregarded

- When applying Part 6, Chapter 8 15.2.2.4.5.1.1, the acceptable oxygen content is to be specified by the manufacturer, 5% oxygen content need not necessarily be applied.

.2 Pt.6, Ch.8, Sec 15, IR15.2.2.1.1, IR 15.2.5.1, IR15.2.5.3, IR15.2.5.7, IR15.2.5.8, IR15.2.6.4, IR15.2.6.5, and IR15.2.6.6. In applying IR15.2.6.6, the terms “cargo tanks” and “cargo piping” are to be understood as “ballast tanks” and “ballast piping” respectively. For de-oxygenation BWMS (categories 3a, 3b, 3c and 8), the requirements in 3.7.1.3.1.1 prevail.

3.7.1.4 BWMS using Ultraviolet (UV) disinfection systems

.1 Arrangements are to be provided such that exposure to UV light is avoided during operation, maintenance or repairs of the system;

.2 High temperature alarm, provision for shut down, UV intensity meter and means to prevent operation of UV lamps without water in treatment chamber are to be provided.

3.7.1.5 BWMS using Ozone Injection systems

.1 Vents from safety valves of ozone system are to be led to open deck and arrangements are to be provided to automatically shut down the system when the ozone concentration exceeds limits;

.2 Warning plates are to be installed in all areas into which ozone can escape.

3.7.1.6 BWMS using Electro-chlorination systems

.1 Operation of the system is to be interlocked with the ventilation system for the compartment housing the electro-chlorination system;

.2 Exhaust vents from the system are to be led to a safe area in the open deck;

.3 Interlock arrangement is to be provided so that the system cannot be energized if the water level /flow is less;

.4 A fixed hydrogen gas detection system with automatic shut-down (as per recognized national/ international standards) is to be provided in the compartment housing the electro-chlorination system.

3.7.1.7 BWMS using In-Tank treatment systems

.1 Ballast tanks fitted with in-tank treatment systems and subject to over or under pressure are to be fitted with P-V valves and pressure measuring devices;

.2 Ballast tanks with in-tank treatment systems are to be provided with

(i) safety alarm system to indicate deviation from the normal working pressure and;
(ii) a system for shutting down the system when the pressure deviation is beyond specified limits.

3.7.1.8 BWMS using Active Substances

.1 Sufficient quantity of active substance(s) are to be provided on board;

.2 Dosage instruction for active substances or preparations are required to be available on board;

.3 Active substance(s) is to be stored at location taking into account the risks/hazards involved with the substance as provided in the safety data sheet;

.4 Materials used for the chemical storage tanks, piping and fittings are to be resistant to such chemicals;

.5 Separate pumping and piping system is to be used for chemicals;

.6 Chemical storage tanks are required to be of sufficient strength, provided with gauging system, protected against overflowing and constructed such that maintenance and inspection can be easily performed;

.7 Air pipes for the chemical storage tank are to be led to a safe area on open deck;

.8 Operation manual containing chemical injection procedures, alarm systems, measures in case of emergency, etc. is to be provided.

3.7.1.9 For BWMS using chemical substances, handling procedures are to be in accordance with the Material Safety Data Sheet and BWM.2/Circ.20, and the following measures are to be taken as appropriate:

.1 The materials used for the chemical storage tanks, piping and fittings are to be resistant to such chemicals.

.2 Chemical storage tanks are to have sufficient strength and be constructed such that maintenance and inspection can be easily performed.

.3 Air pipes of the chemical storage tank are to be led to a safe area on open deck.

.4 An operation manual containing chemical injection procedures, alarm systems, measures in case of emergency, etc is to be kept onboard.

3.7.2 When it is required to have an automatic shutdown of the BWMS for safety reasons, this must be initiated by a safety system independent of the BWM control system.

3.8 Electrical Installations

3.8.1 In general, electrical installations are to be designed and installed in accordance with Pt. 4, Ch. 8 of the Rules.

3.8.2 It should be confirmed that ship's generator/s are able to cater to the additional load for BWMS.

3.8.3 The electrical and control equipment for BWMS is to conform to the manufacturer's equipment specification and installation specifications.

3.8.4 Necessary protection as per specification is to be provided including earthing protection for equipment or components /bonding provision for control of static electricity.

3.8.5 Equipment that may be installed in exposed areas on the open deck are to be IP 56 type of IEC 529 publication or equivalent

3.8.6 Electric and electronic components are not to be installed in a hazardous area unless they are of certified safe type for use in the area. Cable penetrations of decks and bulkheads are to be sealed when a pressure difference between the areas is to be maintained.

3.8.7 In case of any by-pass or override operation of BWMS, an audible and visual alarm is to be given and these events are to be automatically recorded in control equipment. The valves in the by-pass line which trigger the by-pass operation are to be remote-controllable by control equipment or fitted with open/close indicator for automatic detection of the by-pass event.

3.9 Additional requirements for tankers carrying flammable cargo

3.9.1 Hazardous area classification is to be in accordance with IEC 60092-502. Where the prescriptive requirements within SOLAS and related Codes (IBC, IGC) and the standards published by the International Electrotechnical Commission, such as but not limited to IEC 60092-502, are not aligned; the prescriptive requirements in SOLAS and Codes take precedence and are to be applied.

.1 BWMS using ozone generators (categories 7a and 7b) and de-oxygenation BWMS using inert gas generator by treated flue gas from main or auxiliary boilers or gas from an oil or gas-fired gas generator (categories 3b and 3c) are to be located outside the cargo area in accordance with Pt.6, Ch.8, 15.2.3.1.1.2.

Note: this requirement does not apply to inert gas generators for which Pt.6, Ch.8, 15.2.4, IR15.2.5, and IR15.2.6 apply.

.2 In-line full flow electrolysis BWMS (category 4), in-line side-stream electrolysis BWMS (category 5) and in-line injection BWMS using chemical which is stored onboard (category 6) can be located inside the hazardous areas with due consideration of the requirement of 3.8.6 but is not to be located inside the cargo pump room unless it is demonstrated by the BWMS manufacturer that the additional hazards that could be expected from dangerous liquids and dangerous gases stored or evolved from the BWMS (for example H_2 generation):

- do not lead to an upgrade of the hazardous area categorization of the cargo pump room,

- are not reactive with the cargo vapours expected to be present in the cargo pump room,

- are not reactive with the fire-extinguishing medium provided inside the cargo pump room,

- are not impacting the performance of the existing fire-fighting systems provided inside the cargo pump room, and

- are not introducing additional hazards inside the cargo pump room such as toxicity hazards that would not have been prior addressed by suitable counter measures.

Notes:

1) In-line full flow electrolysis BWMS (category 4) could be accepted in cargo compressor rooms of liquefied gas carriers and inside cargo pump rooms of oil tankers or chemical tankers if that cargo pump room is located above the cargo tank deck.

2) For submerged cargo pumps, the room containing the hydraulic power unit or electric motors is not to be considered as the “cargo pump room”.

3) Ballast pump rooms and other pump rooms not containing the cargo pumps are not to be considered as the “cargo pump room”.

3.9.2 In general, two independent BWMS should be required i.e. one for ballast tanks located within the cargo area and the other one for ballast tanks located outside cargo area. Specific arrangements where only one single In-line BWMS (categories 1, 2, 3a, 3b, 4, 5, 6, 7a and 7b) could be accepted are given in Annex I.

Note 1: When the Fore Peak Tank is ballasted with the piping system serving the other ballast tanks within the cargo area in accordance with Pt.5, Ch.2, 6.2.7, the ballast water of the Fore

Peak tank is to be processed by the BWMS processing the ballast water of the other ballast tanks within the cargo area.

Note 2: The figures in Annex I and Annex II are given for better clarity in implementation of the requirements. These figures will be subject to revision to address new technologies as and when they are available.

3.9.3 Isolation between ballast piping serving the ballast tanks inside and outside of the cargo area is to be in accordance with the following requirements:

3.9.3.1 Interconnection in between the ballast piping serving the ballast tanks located within the cargo area and ballast piping serving the ballast tanks located outside cargo area may be accepted if appropriate isolation arrangement is provided in accordance with Annex I is applied.

Note 1: The means of appropriate isolation described in 3.9.3.1 is necessary for the interconnection specified in said Paragraph regardless of the diameter of the piping.

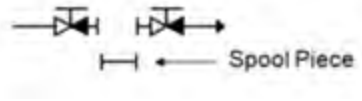
Note 2: As indicated in Annex I, the means of appropriate isolation described in 3.9.3.1 is necessary for the interconnection specified in said Paragraph in the case of the active substance piping such as N_2 gas piping, inert gas piping, neutralizer piping, fresh water piping for filter cleaning, compressed air piping for remaining water purge and sea water piping for adjusting the salinity etc. At the discretion of IRS and for active substance piping and neutralizer piping (both up to 2 inches) only, alternative isolation arrangements, provided preferably on the open deck, offering enhanced safety and gastightness may be considered for penetration of the bulkhead separating the non-hazardous machinery space from a hazardous area (such as the cargo pump room) at as high an elevation in the machinery space as possible, preferably, just below the main deck. The arrangements are to provide suitable protection measures in addressing the pollution hazards and safety concerns due to the potential migration of hydrocarbon or flammable or toxic liquids or vapours from the hazardous areas.

Note 3: The means of appropriate isolation described in 3.9.3.1 for the interconnection specified in said Paragraph need not be applied to the sampling lines described in 3.9.4.

The means of appropriate isolation is to be one of the following:

.1 Two non-return valves with positive means of closing in series with a spool piece(also mentioned “means of dis-connection” in Annex I), or

Note: As an alternative to positive means of closure, an additional valve having such means of closure may be provided between the non-return valve and the spool piece.



.2 Two non-return valves with positive means of closing in in series with a liquid seal at least 1.5 [m] in depth, or

Note 1: As an alternative to positive means of closure, an additional valve having such means of closure may be provided between the non-return valve and the liquid seal.

Note 2: For ships operating in cold weather conditions, freeze protection should be provided in the water seal. A portable heating system can be accepted for this purpose.

.3 Automatic double block and bleed valves and a non-return valve with positive means of closing

3.9.3.2 The above-mentioned means of appropriate isolation is to be provided on the open deck in the cargo area.

Note: When the Fore Peak Tank is ballasted with the piping system serving the other ballast tanks within the cargo area in accordance with Pt.5, Ch.2, 6.2.7, the means of appropriate isolation described in 3.9.3.1 and 3.9.3.1 is not required in between the Fore Peak Tank and the common ballast water piping serving the other ballast water tanks within the cargo area.

3.9.4 Sampling lines which are connected to the ballast water piping system serving the tanks in the cargo area and provided for the purpose of the following:

- for any BWMS: ballast water sampling required by the IMO G2 Guideline of the BWM Convention (2004), or

- for BWMS technologies categories 4, 5, 6, 7a and 7b: total residual oxidant (TRO) analysis in closed loop system;

are not to be led into a non-hazardous enclosed space outside the cargo area.

However, the sampling lines may lead into a non-hazardous enclosed space outside the cargo area provided the following requirements are fulfilled (Refer to Fig 3.9.4):

.1 The sampling facility (for BWMS monitoring/control) is to be located within a gas tight enclosure (hereinafter, referred to as a 'cabinet'), and the following i) through iv) are to be complied.

i) In the cabinet, a stop valve is to be installed on each sampling line.

ii) Gas detection equipment is to be installed in the cabinet and the valves specified in i) above are to be automatically closed upon activation of the gas detection equipment.

iii) Audible and visual alarm signals are to be activated both locally and at the BWMS control station when the concentration of explosive gases reaches a pre-set value, which should not be higher than 30% of the lower flammable limit (LFL). Upon an activation of the alarm, all electrical power to the cabinet is to be automatically disconnected.

Note: when the electrical equipment is of a certified safety type, the automatic disconnection of power supply is not required.

iv) The cabinet is to be vented to a safe location in non-hazardous area on open deck and the vent is to be fitted with a flame arrester.

.2 The standard internal diameter of sampling pipes is to be the minimum necessary in order to achieve the functional requirements of the sampling system.

.3 The cabinet is to be installed as close as possible to the bulkhead facing the cargo area, and the sampling lines located outside the cargo area are to be routed on their shortest ways.

.4 Stop valves are to be located in the non-hazardous enclosed space outside the cargo area, in both the suction and return lines close to the penetrations through the bulkhead facing the cargo area. A warning plate stating "Keep valve closed when not performing measurements" is to be posted near the valves. Furthermore, in order to prevent backflow, a water seal or equivalent arrangement is to be installed on the hazardous area side of the return pipe.

.5 A stop valve is to be installed on the cargo area for each sampling line (i.e. both the suction and return lines).

.6 The samples which are extracted from the ballast water piping system serving the tanks within the cargo area are not to be discharged to a tank located outside the cargo area and not to discharge to a piping line supplying the spaces located outside the cargo area.

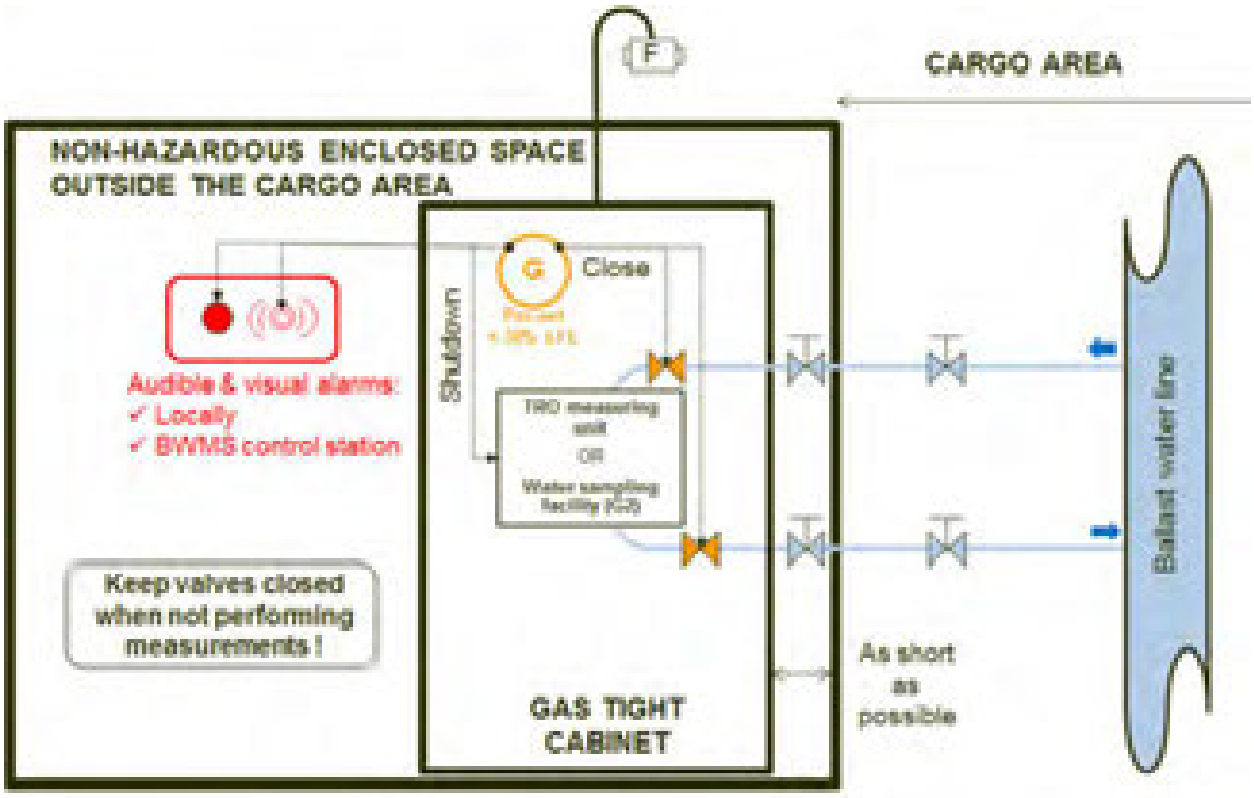


Fig. 3.9.4 : Arrangement of Sampling Lines

3.9.4 When a BWMS is installed in more than one compartment and where some of the components of the BWMS are installed in a separate compartment located in a hazardous area on the deck of a tanker in the interior of the compartment may be considered as non-hazardous, subject to the provisions of the following arrangements:

.1 Deck and bulkhead penetrations are to be sealed gas tight;

.2 No part of the ballast water piping is to be located in the compartment;

.3 No source of release of gas e.g. flange connection/valves are to be located in the compartment;

.4 Access to the compartment from hazardous area is to be through two gastight self-closing doors with air lock capable of maintaining a positive pressure. Audible and visual alarm at control station for loss of pressure in the air lock, and safety interlock for cutting out electrical supply due to loss of pressure, are to be provided.

Note: No air lock however will be required where a vertical separation of at least 2.4 [m] is maintained between the flooring of the compartment and main deck plating or a cofferdam is provided in between the compartment and main deck.

.5 Ventilation inlet and outlets are to be located outside hazardous area;

.6 Ventilation system for the compartment is to be capable of at least 20 air changes an hour or as required by manufacturer, whichever is greater.

3.10 Special requirements for BWMS categories 2, 3a, 3b, 3c, 4, 5, 6, 7a, 7b and 8 generating dangerous gas or dealing with dangerous liquids.

3.10.1 Where the operating principle of the BWMS involves the generation of a dangerous gas, the following requirements are to be satisfied:

3.10.1.1 Gas detection equipment is to be fitted in the spaces where dangerous gas could be present, and an audible and visual alarm is to be activated both locally and at the BWMS control station in the event of leakage.
The gas detectors are to be located as close as possible to the BWMS components where the dangerous gas may accumulate.
For flammable gases and explosive atmosphere including but not limited to H_2, the construction, testing and performance of the gas detection devices is to be in accordance with IEC 60079-29-1:2016, IEC 60079-29-2:2015, IEC 60079-29-3:2014 and/or IEC 60079-29-4:2009, as applicable.
Where other hazards are considered like toxicity, asphyxiation, corrosive and reactivity hazards, a recognized standard acceptable to IRS is to be selected with due consideration of the specific gases to be detected and due consideration of the performance of the detection device with regards to the specific atmosphere where it is used.

3.10.1.2 In spaces where inert gas generator systems are fitted (BWMS categories 3b and 3c) or nitrogen generators are fitted (BWMS categories 3a and 8), at least two oxygen sensors are to be positioned at appropriate locations (as required by Pt.6, Ch.8, 15.2.2.4.5.4 to alarm when the oxygen level falls below 19%. The alarms are to be both audible and visual and are to be activated:

- inside the space;

- at the entry into the space; and

- inside the BWMS control station.

For BWMS categories 7a and 7b, at least two oxygen sensors are to be positioned at appropriate locations in the following spaces:

- spaces where ozone generators are fitted, or

- spaces where ozone destructors are fitted, or

- spaces where ozone piping is routed;

to alarm when the oxygen level raises above 23 %. The alarms are to be both audible and visual and are to be activated at the following locations:

- inside the space; and

- at the entry into the space; and

- inside the BWMS control station.

Automatic shut-down of the BWMS is to be arranged when the oxygen level raises above 25%. Audible and visual alarms independent from those specified in the preceding paragraph are to be activated prior to this shut-down.

3.10.1.3 For BWMS categories 7a and 7b, at least one ozone sensor is to be provided at the vicinity of the discharge outlet to the open deck from the ozone destructors addressed in Footnote *(4) to alarm when the ozone concentration level raises above 0.1 ppm. The alarms are to be both audible and visual and are to be activated in the BWMS control room. In addition, at least two ozone sensors are to be positioned at appropriate location in the following spaces:

- spaces where ozone generators are fitted, or

- spaces where ozone destructors are fitted, or

- spaces where ozone piping is routed;

to alarm when the ozone concentration level raises above 0.1 ppm. The alarms are to be both audible and visual and are to be activated at the following locations:

- inside the space;

- at the entry into the space; and

- inside the BWMS control station.

Automatic shut-down of the BWMS is to be arranged when the ozone concentration measured from one of the two sensors inside the space raises above 0.2 ppm.

3.10.1.4 Inside double walled spaces or pipe ducts constructed for the purpose of 3.10.2.1 Note 1), sensors are to be provided for the detection of H_2 leakages (BWMS categories 4, 5 and 6 when relevant) or O_2 leakages (BWMS categories 7a and 7b) or O_3 leakages (BWMS categories 7a and 7b). The sensors are to activate an alarm at the high level settings and automatic shut-down of the BWMS at the high-high level settings described in above 3.10.1.1 to 3.10.1.3.

Note: As an alternative to the sensor for the gas detection, monitored under-pressurization inside the double walled spaces or pipe ducts could be provided with an automatic alarm and shut-down of the BWMS in case of loss of the under-pressurization. The monitoring can be achieved either by monitoring the pressure inside the double walled spaces or pipe ducts or by monitoring the exhaust fan.

3.10.1.5 For in-line full flow electrolysis BWMS (category 4), in-line side-stream electrolysis BWMS (category 5) and in-line injection BWMS using chemical which is stored onboard (category 6): the hydrogen de-gas arrangement (when provided) is to be provided with redundant ventilation fans and redundant monitoring of the ventilation system.
In addition the ventilation fan is to be certified explosion proof and have spark arrestor to avoid ignition sources to enter the ventilation systems whereas remaining H_2 gas may be present in dangerous concentrations.
Audible and visual alarms and automatic shut-down of the BWMS are to be arranged for respectively high and high-high levels of H_2 concentration. The open end of the hydrogen by-product enriched gas relieving device is to be led to a safe location*(3) on open deck.

3.10.1.6 The open end of inert gas or nitrogen gas enriched air (BWMS categories 3a, 3b, 3c and 8) or oxygen-enriched air (BWMS categories 3a, 7a, 7b and 8) are to be led to a safe location*(1) & (2) on open deck.

3.10.2 Where the piping is conveying active substances, by-products or neutralizers that are containing dangerous gas or dangerous liquids as defined respectively in 1.4.2 and 1.4.5 , the following requirements are to be satisfied:

Notes:

1) This requirement is applicable to the injection lines conveying the dangerous gas or dangerous liquids but not applicable to the ballast water lines where the dangerous gas or dangerous liquids are diluted.

2) The IMO reports issued during the basic and final approval procedures of the BWMS that make use of active substances (G9 Guideline) could be used for assessing the hazards that could be expected from the media conveyed by the BWMS piping.

3.10.2.1 Irrespective of design pressure and temperature, the piping is to be either of Class I (without special safeguard) or Class II (with special safeguard) as required by Pt.4, Ch.2, Table 1.2.1. The selected materials, the testing of the material, the welding, the non-destructive tests of the welding, the type of connections, the hydrostatic tests and the pressure tests after assembly on-board are to be as required in Pt.4, Ch.2. Mechanical joints, where allowed, are to be selected in accordance with Pt.4, Ch.2, Table 2.7.2.

Notes:

1) For piping class II with special safeguards conveying dangerous gas like hydrogen (H_2), oxygen (O_2) or ozone (O_3), the special safeguards are to be either double walled pipes or pipe duct.

2) For piping class II with special safeguards conveying dangerous liquids, other special safeguards could be considered like shielding, screening, etc.

3) Plastic pipes may be accepted after due assessment of the dangerous gas or dangerous liquids conveyed inside. When plastic pipes are accepted, the requirements of Pt.4, Ch.2, Sec 5 apply.

3.10.2.2 The length of pipe and the number of connections are to be minimised.

3.10.2.3 Inside double walled space or pipe ducts constructed as the special safeguard for the purpose of 3.10.2.1 Note 1) are to be equipped with mechanical exhaust ventilation leading to a safe location*(3) & (4) on open deck.

3.10.2.4 The routing of the piping system is to be kept away from any source of heating, ignition and any other source that could react hazardously with the dangerous gas or liquid conveyed inside. The pipes are to be suitably supported and protected from mechanical damage.

3.10.2.5 Pipes carrying acids are to be arranged so as to avoid any projection on crew in case of a leakage.

3.10.2.6 H_2 by-product enriched air vent pipes (BWMS categories 4, 5 and 6) or O_2 enriched air vent pipes (BWMS categories 3a, 7a, 7b and

8) or O_3 piping (BWMS categories 7a and 7b) are not to be routed through accommodation spaces, services spaces and control stations.

3.10.2.7 O_2 enriched air vent pipes (BWMS categories 3a, 7a, 7b and 8) are not to be routed through hazardous areas unless it is arranged inside double walled pipes or pipe ducts constructed as the special safeguard for the purpose of 3.10.2.1 Note 1) and provided with suitable gas detection as described in 3.10.1.4 and mechanical exhaust ventilation as described in 3.10.2.3.

3.10.2.8 The routing of H_2 by-product enriched air vent pipes (BWMS categories 4, 5 and 6) or O2 enriched air vent pipes (BWMS categories 3a, 7a, 7b and 8) is to be as short and as straight as possible. When necessary, horizontal portions may be arranged with a minimum slope in accordance with the manufacturer's recommendation.

3.10.3 For BWMS using chemical substances or dangerous gas which are stored on-board for either:

- storage or preparation of the active substances (BWMS categories 2 and 6), or

- storage or preparation of the neutralizers (BWMS categories 4, 5, 6, 7a and 7b), or

- recycling the wastes produced by the BWMS (BWMS category 2),

procedures are to be in accordance with the Material Safety Data Sheet and BWM.2/Circ.20 "*Guidance to ensure safe handling and storage of chemicals and preparations used to treat ballast water and the development of safety procedures for risks to the ship and crew resulting from the treatment process*", and the following measures are to be taken as appropriate:

3.10.3.1 The materials, inside coating used for the chemical storage tanks, piping and fittings are to be resistant to such chemicals substances.

3.10.3.2 Chemical substances (even if they are not defined as dangerous liquid in the sense of 2.4) and gas storage tanks are to be designed, constructed, tested, inspected, certified and maintained in accordance with:

- for independent tanks permanently fixed onboard containing dangerous liquids (eg. sulfuric acid H_2SO_4) or dangerous gas (eg. oxygen O_2): the Classification Rules as applicable to pressure vessels

- for independent tanks permanently fixed onboard not containing dangerous liquid (eg. sodium sulphite, sodium biosulphite or sodium thiosulfphate neutralizers) and not containing dangerous gas (eg. nitrogen N_2): the Rules or other industry standard recognized by IRS.

- for portable tanks: the IMDG Code or other industry standard recognized by IRS.

3.10.3.3 When the chemical substances are stored inside integral tanks, the ship's shell plating is not to form any boundary of the tank.

3.10.3.4 Dangerous liquids and dangerous gas storage tank air pipes are to be led to a safe location*(1) & (2) on open deck.

3.10.3.5 An operation manual containing chemical injection procedures, alarm systems, measures in case of emergency, etc. is to be kept onboard.

3.10.3.6 Dangerous liquid storage tanks and their associated components like pumps and filters, are to be provided with spill trays or secondary containment system of sufficient volume to contain potential leakages from tank openings, gauge glasses, pumps, filters and piping fittings.
Further to the safety and/or pollution assessment of the concerned chemical substances, consideration should be provided for segregation of the drains from such spill trays (or secondary containment system) or piping systems from engine room bilge system or from cargo pump room bilge system, as applicable. When necessary, arrangement should be provided within the spill trays (or within the secondary containment system) for the detection of dangerous liquid or dangerous gas as defined respectively in 1.4.2 and 1.4.5.

Note: The IMO reports issued during the basic and final approval procedures of the BWMS that make use of active substances (IMO G9 Guideline) could be used for this assessment.

3.10.4 A risk assessment is to be conducted in a generic manner during the design review mentioned in 3.5.4 and submitted to IRS for approval for the following BWMS categories:

- BWMS category 4: in all cases;

- BWMS category 5: in all cases;

- BWMS category 6: when one of the MSDS indicates that the chemical substance stored on-board is either flammable, toxic, corrosive or reactive;

- BWMS category 7a and 7b: in all cases.

Note: The IMO reports issued during the basic and final approval procedures of the BWMS that make use of active substances (G9 Guideline) could be used as a reference for this assessment.

3.10.4.1 The recommended risk assessment techniques for BWMS and other guidances are listed below but not limited to:

- FMEA, FMECA, HAZID, HAZOP, etc.

- ISO 31010 – Risk Assessment Techniques

- IACS Recommendation Rec. 146

- IRS Guidelines on Alternative and Risk Based Design Evaluation

3.10.4.2 The risk assessment is to ensure that the package supplied by the BWMS's manufacturer is intrinsically safe and/or provides mitigation measures to the hazards created by the BWMS which have been identified during the design review mentioned in 3.5.4 but that need to be implemented during the installation on-board.

3.11. Fire safety requirements

3.11.1 General

3.11.1.1 Application

.1 This subsection details fire safety measures, in addition to that required by Part 6, related to the installation of Ballast Water Management Systems onboard any ship.

.2 The requirements of this subsection apply for BWMS technologies as listed in Table 3.1. BWMS with alternative technologies are to be specially considered by the IRS.

3.11.1.2 Definitions

.1 Airlock - An airlock is a space enclosed by gastight steel bulkheads with two gastight doors spaced not more than 2.5 m apart. The doors are to be self-closing without any holding back arrangements. Air locks are to have mechanical ventilation and are not to be used for other purposes. An audible and visual alarm system to give a warning on both sides of the air lock are to be provided to indicate if more than one door is moved from the closed position. The air lock space is to be monitored for dangerous gas as defined in 1.4.2.

.2 Ballast Water Management Room (BWMR) - A Ballast Water Management Room is any space containing equipment belonging to the Ballast Water Management System. A space containing remote controls for the BWMS or a space dedicated to the storage of liquid or solid chemicals for BWMS need not be considered as a BWMR for the purposes of this subsection.

.3 BWMS storing, introducing or generating chemicals. - In general, BWMS storing, introducing or generating chemicals refer to:

- In-line flocculation (cat.2 as per Table 3.1),

- Chemical injection (cat.6 as per Table 3.1) and

- BWM technologies using neutralizers injection (cat.4, 5, 6 and 7 as per Table 3.1)

BWMS that do not store, introduce or generate toxic or flammable chemicals may be specially considered as detailed in Table 3.11.1 below.

Table 3.11.1: Requirements that may be reduced for BWMS storing, introducing or generating chemicals depending on the chemicals.	
Requirement	**Conditions to be met before reducing the requirement**
3.11.2.3.4	The stored chemicals are neither toxic nor flammable
3.11.3.1.1	The BWMS does not use any flammable or toxic chemical substances
3.11.3.3.1	No dangerous gas as defined in 1.4.2 will be generated by the BWMS
3.11.6.1.1	No toxic chemical is stored and no toxic gas will be generated by the BWMS
3.11.7.1.1 3.11.7.1.3 3.11.7.1.6	No toxic chemical is used or will be generated by the BWMS

The IMO reports issued during the basic and final approval procedures of the BWMS that make use of active substances (IMO G9 Guidelines) and ''safety hazard'' as listed in Pt.5, Ch.3. Sec 17 are to be considered for this purpose.

Note: Chemicals include additives for BWMS.

3.11.2 Fire categorization

3.11.2.1 General

BWMR is to be classified as follows for the purpose of applying the requirements of Part 6:

- BWMR containing oil-fired inert gas generators (i.e. BWMS cat.3b and 3c as per Table 3.1) are to be treated as machinery spaces of category A

- Other BWMR is to be considered as other machinery spaces and is to be categorized, depending on the ship type (10) or (11) according to Pt.6, Ch.3, 3.2.2.3, 3.2.3, and 3.2.4

3.11.2.2 BWMS located in the cargo area of tankers

Notwithstanding the above, where a BWMS is located in the cargo area of a tanker as allowed by previous subsection, the BWMR is to be categorized as (8), a cargo pump-room, according to Pt.6, Ch.3, 3.2.4.2.2 for determining the extent of fire protection to be provided.

Note: The cargo area of a tanker is defined in Section 1.

3.11.2.3 Storage of chemicals

.1 Spaces where the storage of liquid or solid chemicals for BWMS is intended are to be categorized as store-rooms for the purpose of applying the requirements of Part 6 i.e.:

- On passenger ships carrying more than 36 passengers:

  - "Other spaces in which flammable liquids are stowed" as defined in Pt.6, Ch.3, 3.2.2.3.2.2(14), if flammable products are stored

  - "Store-rooms, workshops, pantries, etc." as defined in Pt.6, Ch.3, 3.2.2.3.2.2(13) otherwise

- On other ships:

  - "Cargo pump-rooms" as defined in Pt.6, Ch.3, 3.2.4.2.2.2(8) if located in the cargo area of a tanker

  - "Service spaces (low risk)" as defined in Pt.6, Ch.3, 3.2.2.4.2.2(5), 3.2.3.3.2.2(5) or 3.2.4.2.2.2(5) if the surface area is less than $4m^2$ and if no flammable products are stored

  - "Service spaces (high risk)" as defined in Pt.6, Ch.3, 3.2.2.4.2.2(9), 3.2.3.3.2.2(9) or 3.2.4.2.2.2(9) otherwise

Note: It is understood that only chemical injection (cat.6 as per Table 3.1), in-line flocculation (cat.2 as per Table 3.1) and technologies using neutralizer injection (cat.4,

5, 6 and 7 as per Table 3.1) will require chemical or additive storage.

.2 Where the storage of chemicals is foreseen in the same room as the ballast water management machinery, this room is to be considered both as a store-room and as a machinery space in line with 3.11.2.1.

.3 When the chemical substances are stored inside integral tanks, the ship's shell plating is not to form any boundary of the tank.

.4 Tanks containing chemicals are to be segregated from accommodation, service spaces, control stations, machinery spaces not related to the BWMS and from drinking water and stores for human consumption by means of a cofferdam, void space, cargo pump-room, empty tank, oil fuel storage tank, BWMR or other similar space. On-deck stowage of permanently attached deck tanks or installation of independent tanks in otherwise empty hold spaces are to be considered as satisfying this provision.

3.11.3 BWMR location and boundaries

3.11.3.1 BWMS using chemical substances

.1 For BWMS storing, introducing or generating chemicals, the BWMR and chemical substance storage rooms are not to be located in the accommodation area. Any ventilation exhaust or other openings from these rooms are to be located not less than 3m from entrances, air inlets and openings to accommodation spaces. This requirement need not apply in case the BWMS is located in the engine room.

3.11.3.2 Ozone-based BWMS

.1 Ozone-based BWMS – i.e. cat.7a and 7b – are to be located in dedicated compartment, separated from any other space by gastight boundaries. Access to the BWMR from any other enclosed space is to be through airlock only, except if the only access to that space is from the open deck.

Access to the ozone based BWMR may be provided through the engine room only provided:

- Access from the engine room to the BWMR is through airlock and,
- An alarm repeater is provided in the BWMR, which will repeat any alarm activated in the engine room.

.2 A sign is to be affixed on the door providing personnel with a warning that ozone may be present and with the necessary instructions to be followed before entering the room

3.11.3.3 General

.1 BWMR containing equipment for BWMS of the following types is to be equipped with tested gastight and self-closing doors without any holding back arrangements:

- BWMS storing, introducing or generating chemical substances
- De-oxygenation based on inert gas generator
- Electrolysis
- Ozone injection

Doors leading to the open deck need however not to be self-closing.

3.11.4 Fire Fighting

3.11.4.1 Fixed fire-extinguishing system

3.11.4.1.1 Where fitted, fixed fire extinguishing systems are to comply with the relevant provisions of the Pt.6, Ch.8

3.11.4.1.2 Ozone-based BWMS

BWMR containing equipment related to ozone-based BWMS is to be provided with a fixed fire extinguishing system suitable for category A machinery spaces and capable of manual release.

3.11.4.1.3 Where a fixed fire-extinguishing system is provided in the BWMR, it is to be compatible with the BWMS and the chemical products that are used, produced or stored in the BWMR. Specific attention is to be paid to potential chemical reactions between the fire extinguishing medium and chemical products used for water treatment.

Especially, water-based fire-extinguishing systems should be avoided in case of sulfuric acid storage.

3.11.4.1.4 Foam fixed fire-extinguishing system

For all kinds of BWMS, in case a foam fire extinguishing system is installed in the BWMR, its efficiency is not to be impaired by chemicals used by the BWMS where relevant.

3.11.4.1.5 Where a fixed fire-extinguishing system is installed in the BWMR, automatic shutdown of the BWMS upon release of the fixed fire extinguishing system is to be arranged. Any need for cooldown necessary for safe shutdown to be considered in the shutdown sequence.

3.11.4.1.6 Where BWMS that includes air or O_2 storage is located in a room covered by a fixed gas fire-extinguishing system, air or O_2 storage is to be taken into account for the gas capacity calculation, unless the discharge pipe from safety valves for air or O_2 storage are led directly to outside the room.

3.11.4.2 Portable fire-fighting equipment

3.11.4.2.1 There is to be at least one portable fire extinguisher that complies with the provisions of the Pt.6, Ch.8 and suitable for electrical fires in the BWMR containing UV-type BWMS.

3.11.5 Fire prevention

3.11.5.1 Equipment protection

3.11.5.1.1 Overcurrent or overvoltage protection is to be installed to protect UV type BWMS.

3.11.5.1.2 Electrolysis reactors are to be provided with at least with two independent means of monitoring operation. The monitoring system is to initiate audible and visual alarms and automatic shutdown of the BWMS in the event that an anomaly is detected. Requirements for shutdown arrangement are clarified in 3.5.4.

Note: If a pressure relief valve is also provided, the vent of this valve is to be led to a safe location on the open deck, as clarified in 3.5. The valve should be positioned to optimally remove gas from the electrolysis reactor.

3.11.5.2 Fire detection

3.11.5.2.1 A fixed fire detection and fire alarm system complying with the provisions of Pt.6, Ch.8 is to be installed in spaces containing an inert gas generator or an ozone generator.

3.11.5.2.2 A section of fire detectors which covers a control station, a service space or an accommodation space is not to include a BWMR containing equipment related to ozone based BWMS.

3.11.6 Ventilation

3.11.6.1 Ventilation arrangement

3.11.6.1.1The ventilation systems for BWMR containing BWMS of the following types are to be independent of the ventilation systems serving any other spaces:

- BWMS storing, introducing or generating chemical substances.
- De-oxygenation, including pasteurization and de-oxygenation (cat.3 and cat.8)
- Electrolysis
- Ozone injection

3.11.6.1.2 The ventilation exhaust for BWMR containing a nitrogen generator is to be located in the lower part of the room in order to efficiently evacuate dangerous gases heavier than air.

3.11.6.1.3 The ventilation exhaust for BWMR containing electrolysis systems is to be located so as to be able to efficiently evacuate dangerous gases that could be generated during the electrolysis process. Due regard is to be paid to the expected quantity and density of such gases when designing the ventilation exhaust.

3.11.6.1.4 The following requirements apply to ventilation ducts serving BWMR for ozone-based BWMS:

- The part of the ducts located outside of the BWMR is to be made of steel having a thickness of at least 3 mm for ducts with a free cross-sectional area of less than 0.075 m^2, at least 4 mm for ducts with a free cross-sectional area of between 0.075 m^2 and 0.45 m^2, and at least 5 mm for ducts with a free cross-sectional area of over 0.45 m^2; and

- The ducts are to be suitably supported and stiffened

- The outside openings of the ducts are to be fitted with protective screens of not more than 13 mm square mesh.

3.11.6.1.5 The ventilation system for BWMR containing ozone-based BWMS or ventilation system for hydrogen de-gas arrangement as required by 3.10.1.5 is to be interlocked with the BWMS such that:

- In case of loss of ventilation (primary and secondary), a visual and audible alarm is to be triggered both inside and outside the BWMR and at a place where a responsible member of the crew is on duty. If the ventilation is not restored after a pre-set time, the BWMS is to then be automatically shut down. Any need for cooldown necessary for safe shutdown is to be considered in the shutdown sequence.

- It is not to be possible to start the BWMS without the ventilation running

For ventilation systems serving BWMR and containing or conveying a dangerous gas, relevant requirements in 3.10 are to be satisfied.

3.11.6.2 Ventilation rate

3.11.6.2.1 An adequate power ventilation system is to be provided in enclosed BWMR.

3.11.6.2.2 The ventilation capacity is to be at least 30 air changes per hour where explosive or toxic gases may be generated during operation of the BWMS. The IMO reports issued during the basic and final approval procedures of the BWMS that make use of active substances (IMO G9 Guidelines) and ''safety hazard'' as listed in Pt.5, Ch.3, Sec.17 are to be used as references for identifying those cases.

3.11.6.2.3 The ventilation capacity may be reduced as follows:

- Flocculation-type BWMS - 6 air changes per hour
- De-oxygenation, incl. pasteurization and de-oxygenation (cat.3 and cat.8 as per Table 3.1) - 6 air changes per hour
- Full flow electrolysis - 6 air changes per hour
- Side-stream electrolysis - 20 air changes per hour
- Ozone injection - 20 air changes per hour
- Chemical injection - 6 air changes per hour

Note: More stringent ventilation capacity requirements may arise from other regulations e.g. IBC Code requirements for spaces located in the cargo area.

3.11.7 Personal equipment

3.11.7.1.1 Suitable protection equipment is to be available onboard for the protection of the crew members who are engaged in the servicing, maintenance and repair of BWMS storing, introducing or generating chemicals, as recommended by the product manufacturers. The protection equipment is to consist of large aprons, special gloves with long sleeves, suitable footwear, coveralls of chemical-resistant materials, and tight fitting goggles or face shields or both. The protective clothing and equipment are to cover all skin so that no part of the body is unprotected. This protection equipment is to be provided separately without taking into account equipment required by other mandatory requirements.

3.11.7.1.2 Work clothes and protective equipment are to be kept in easily accessible places and in special lockers. Such equipment are not to be kept within accommodation spaces, with the exception of new, unused equipment and equipment which has not been used since undergoing a thorough cleaning process. Notwithstanding the above, storage rooms for such equipment within accommodation spaces if adequately segregated from living spaces such as cabins, passageways, dining rooms, bathrooms, etc.

3.11.7.1.3 When a BWMS storing, introducing or generating chemicals is installed on board, suitably marked decontamination showers and an eyewash are to be available in a convenient location in close proximately to the BWMS and the chemical store room(s).

3.11.7.1.4 An emergency escape breathing apparatus (EEBD) is to be provided in the BWMR. This emergency escape breathing apparatus may be one of the EEBDs provided in accordance with the requirements of SOLAS II-2/13.

An EEBD need not be required for BWMS of cat.1 as per Table 3.1.

3.11.7.1.5 A personal ozone detector, calibrated as per the manufacturer's specifications, is to be provided for each person engaged in the servicing, maintenance and repair of BWMS utilizing ozone.

3.11.7.1.6 A two-way portable radiotelephone apparatus dedicated for the BWMS service, maintenance and repair is to be provided, in addition to those required by SOLAS for fire-fighting purposes. This two-way radiotelephone apparatus is to be properly identified in order to avoid mix-up with the apparatus intended for fire-fighting operations. Where the BWMS may release explosive gases, this two-way radiotelephone apparatus is to be of a certified safe type suitable for use in zone 1 hazardous areas, as defined in IEC Publication 60079. Where the BWMS stores, utilizes or introduces chemicals, the apparatus is to undergo deep cleaning or de-contamination after use.

A two-way portable radiotelephone apparatus need not be required for BWMS of cat.1 as per Table 3.1.

Annex I

Installation of one single BWMS on Tankers

Note: This Annex does not cover In-tank technologies categories 3c and 8.

Table 1: In-line BWMS's technlogies categorization

		1	2	3a	3b	4	5	6	7a	7b
BWMS's Technology category → **Characteristics ↓**		In-line UV or UV + Advanced Oxidation Technology (AOT) or UV + TiO2 or UV + Plasma	In-line Flocculation	In-line membrane separation and de-oxygenation (injection of N2 from a N2 Generator)	In-line de-oxygenation (injection of Inert Gas from Inert Gas Generator)	In-line full flow electrolysis	In-line side stream electrolysis (3)	In-line (stored) chemical injection	In-line side-stream ozone injection without gas/liquid separation tank and without Discharge treatment tank	In-line side-stream ozone injection with gas/liquid separation tank and Discharge water treatment tank
Dis-infection when ballasting	Making use of active substance		X			X	X	X	X	X
	Full flow of ballast water is passing through the BWMS	X	X	X	X	X				X
	Only a small part of ballast water is passing through the BWMS to generate the active substance						X			
After-treatment de-ballasting	Full flow of ballast water is passing through the BWMS	X								X
	Injection of neutralizer					X	X	X	X	X
	Not required by the Type Approval Certificate issued by the Administration		X	X						
Examples of dangerous gas as defined in 1.4.2			(1)	O_2 N_2	CO_2, CO	H_2, Cl_2	H_2, Cl_2	(1)	O_2, O_3, N_2	
Arrangement of one single BWMS	BWMS is located in the outside the cargo area	Not Acceptable	Case 1.2 (2)	Case 1.3a (2)	Case 1.3b	Case 1.4 (2)	Case 1.5	Case 1.6	Case 1.7a	Case 1.7b (2)

Notes:

(1) To be investigated on a case by case basis based on the result of the IMO (GESAMP) MEPC report for Basic and Final approval in accordance with the IMO G9 Guideline.

(2) Only « Means of dis-connection » as described in 3.9.3.1 are to be applied.

(3) In-line side stream electrolysis may also be applied in-tank in circulation mode (no treatment when ballasting or deballasting)

6	*Survey , Testing and Trials*

Section 1

General

1.1 Application

1.1.1 The requirements of this Chapter apply to Liquefied Natural Gas (LNG) carriers fitted with regasification systems and meeting the applicable requirements of Pt.5, Ch.4 " Liquefied Gas Carriers" .

1.1.2 Attention is drawn to any relevant statutory requirements of the country in which the vessel is to be registered and/or requirements of local authority where the vessel is operating.

1.1.3 The requirements of this Chapter are applicable to both new construction and conversions.

1.2 Notations

1.2.1 Vessels that comply with the requirements of this chapter will be assigned following additional class notation:

RV (LNG)

1.3 Definitions

1.3.1 Definitions in Pt.5 Ch.4 "Liquefied Gas Carriers" are applicable.

1.3.2 **Blowdown** is defined as the depressurization of a system, part of a system and its equipment to allow the safe disposal of both vapor and liquid discharged from blowdown valves. Depressurization is used to mitigate the consequences of a pipeline or vessel leak by reducing the leakage rate and/or inventory within the pipe or vessel prior to a potential failure.

1.3.3 **Regasification System** is the complete gasification process plant from LNG cargo storage tanks to the gas export (send-out) shore connection including regasification unit, suction drum, associated pumping, piping and ancillary systems.

1.3.4 **Regasification Unit** is refers to vaporizers, heaters, LNG high pressure pump and associated piping intended for the gasification of LNG from the cargo storage tanks.

1.3.5 **Send-Out** is the discharge of the high pressure gas after the vaporization and heating process. Send-out may include additional processes, such as trim heating, calorific correction, odourisation, or dew point correction/ dehumidification.

1.4 Plans

1.4.1 In addition to those required by Pt.5, Ch.4, the following regasification plant plans, calculations and information, as applicable, are to be submitted :

1.4.1.1 For Approval:

a) Hazardous area arrangement

b) Booklet of installations in classified hazardous areas

c) Risk assessment

d) Scantlings and details of foundation drawing in way of regasification and power generation modules, where provided.

e) Strength analysis document in way of regasification and power generation modules.

f) Cargo containment and Pump Tower strength analysis (including sloshing analysis)

g) Escape routes

h) Project specification and overall process concept description

i) Machinery arrangement of regasification plant and power generation system

j) Ventilation system for compartment of cargo machinery space and turret, if applicable

k) Cryogenic spill containment

l) Failure Modes and Effects Analysis (FMEA)

m) Emergency shutdown (ESD) system, ESD Cause and effect diagram

n) Fire and gas detection and alarm systems

o) Fire extinguishing systems

p) Piping and Instrumentation Diagram (P&ID)

q) Piping material specification

r) Piping arrangement

s) Pipe stress analysis (high pressure and cryogenic)

t) Details of all cargo and vapor handling equipment including high pressure system

u) Details and installation of the safety valves/blow down valves and capacity calculations

v) Inert-gas system

w) Pressure relief and blowdown calculations

x) Mooring details and specification

y) Regasification plant testing procedures

1.4.1.2 For Information:

a) General arrangement of the regasification plant

b) Operational manual

c) Process Flow Diagram (PFD)

1.5 Risk Assessment

1.5.1 A Risk assessment report as per the requirements of Pt.5 Ch.4, Sec 1, 1.1.10 & 1.1.11 is to be submitted for review. Risk assessment is to be carried out to identify hazards and accident scenarios that may affect the vessel and is to consider the existing or potential risk control options.

1.5.2 The scope of the risk assessment may include but not be limited to:

a) normal operation, start-up, normal shutdown, non-use, and emergency shutdown of the system, including:

   i. pressurized gas discharge to shore;

   ii. high pressure gas venting;

   iii. storage and handling of flammable refrigerants (as applicable);

iv. continuous presence of liquid and vapour cargo outside the cargo containment system;

v. ship-to-ship transfer of liquid cargo.

b) physical equipment layout, machinery and equipment layout, arrangements and location, including extension of hazardous areas and evacuation arrangements;

c) fire and explosion, process upset conditions, over-pressure and under-pressure, mechanical and electrical failures and human error.

1.5.3 The risk assessment is to be undertaken by suitably qualified and experienced individuals in accordance with a recognized Standard (e.g. ISO/IEC 31010-2009: *Risk management – Risk assessment techniques*).

1.5.4 The risk assessment is to address at least the following aspects:

a) fire and explosions in areas or spaces containing piping, machinery, equipment and components;

b) fire and explosions adjacent to areas or spaces containing piping, machinery, equipment and components;

c) cryogenic leakage from piping, equipment and components associated with the regasification system;

d) corrosion/erosion in gas high pressure piping, components and tanks associated with the regasification system;

e) mechanical failure in regasification machinery, equipment or components;

f) control/electrical failure in regasification machinery, equipment or components;

g) manufacturing defects in equipment and machinery;

h) human error in operation, maintenance, inspection and testing of regasification machinery, equipment and components;

i) location of piping, machinery, equipment and components;

j) cargo tanks over-pressure and under-pressure situations associated with the regasification and ship-to-ship transfer operations;

k) analysis of risk associated with the LNG transfer in accordance with the following

i. ISO 28460:2010 " *Petroleum and natural gas industries – Installation and equipment for liquefied natural gas – Ship-to-shore interface and port operations"* and

ii. EN 1474 " *Installation and equipment for liquefied natural gas. Design and testing of marine transfer systems. Offshore transfer systems*" as applicable, and

iii. SIGTTO Publication *"Ship to Ship Transfer Guide for Petroleum, Chemicals and Liquefied Gases*" as applicable

l) process upsets associated with the land-based receiving systems;

m) risk of fire propagation from turret compartment and susceptibility of turret structure to explosions or uncontrolled gas release;

n) jet fires and blast.

1.6 Operations Manual

1.6.1 An operations manual is to be provided addressing the following:

a) Operational limitations for the transfer operation, if applicable.

b) Preparations prior to start up, i.e. readiness of safety equipment, connection of offloading system, means and procedures for communication.

c) Start-up procedures, i.e. gassing up and cool down of the system.

d) Filling and venting of suction drum.

e) Precautions to avoid excessive temperature differentials.

f) Normal shut down procedures and venting of the system.

g) Emergency procedures i.e. initiation of PSD, ESD and blow-down.

h) Inerting and gas freeing.

i) Isolation of the regasification units for inspection and maintenance

j) Operating restrictions, mitigating measures associated with sloshing loads (if any).

Section 2

Vessel Arrangements and Structure

2.1 Location and Arrangement of Regasification System

2.1.1 The layout of regasification system is to be designed giving due consideration to

a) safety of personnel,

b) prevention potential pollution,

c) environment impact and

d) protection of the vessel.

2.1.2 The installation is to be so arranged as to minimize the risk of occurrence of accident, risk of escalation, to protect manned spaces from consequences of accidents affecting other areas, ensure integrity of LNG storage and allow a safe evacuation when necessary. The locations of the system arrangements, including vaporizers, high pressure pumps, suction drums, heaters, liquid pumps and ancillary piping systems, are to be defined and evaluated in the risk assessment. The regasification unit is to be protected from external forces and impact such as green sea water forces and dropped objects as relevant according to outcome of risk analysis required in 1.5

2.1.3 Adequate provisions and arrangements are to be made to facilitate safe access to control, cleaning and inspection of various places on regular basis during normal operation of regasification plant. Arrangement is to be made such that there is safe access at all times to valves that may need to be handled in normal operation.

2.1.4 Arrangement is to be made for adequate lighting and ventilation when deemed necessary.

2.1.5 The regasification unit location is to be considered part of the cargo area as defined in Pt.5, Ch.4 “Liquefied Gas Carriers”. The regasification unit and all its associated equipment are to be located as far as is reasonably possible from the accommodation spaces

2.1.6 The regasification system machinery may be located on the open deck or in cargo pump and cargo compressor rooms. Arrangements of such spaces are to be in accordance with the requirements of Pt.5, Ch.4, Sec.3 “Ship Arrangements”.

2.2 Structure

2.2.1 The steel structure of regasification unit is to be designed and strengthened to support component weight and relevant forces including weather and sea dynamic motions.

2.2.2 The local strength of the structure is to be assessed according to methods, recognized codes or standards to the satisfaction of the IRS.

2.2.3 The suitability of the vessels hull structure, containment system, and other in tank components such as pump tower are to be reviewed for sloshing loads based on the site-specific condition where the vessel will operate in regasification mode. Any special considerations to environmental limitations, operating restrictions, and mitigating measures as associated with sloshing are to be included in the operations manual.

2.3 Protection from Cryogenic Releases

2.3.1 Hull structures under suction drums, pumps and vaporizers are to be protected against cryogenic spill. If drip trays are fitted, they are to be drained overboard.

2.3.2 Provisions are to be incorporated in the design to minimize the number of flanged connections. In order to protect personnel from cryogenic burns and prevent ship structure or other carbon steel structures on deck from being exposed to brittle fracture due to LNG pressure jet, consideration is to be given to the fitting of spray shield arrangements to any flanged connection of piping containing LNG at a pressure above 10 [bar].

2.4 Turret Compartment Arrangement

2.4.1 Turret compartments are to comply with the requirements of Pt.5, Ch.4, 3.11.4 and 3.3.1

2.4.2 The risk of fire propagation from turret compartments to adjacent spaces is to be evaluated by a risk analysis. Further preventive measures, such as the arrangement of a cofferdam around the turret compartment, are to be provided if needed.

2.4.3 Turret compartments are to be designed to retain their structural integrity in case of explosion or uncontrolled high-pressure gas release (overpressure and/or brittle fracture), the characteristics of which are to be substantiated on the basis of a risk analysis with due consideration of the capabilities of the pressure relieving devices. Blast relief panels may be provided.

2.5 Ventilation inlets

2.5.1 Ventilation inlets to accommodation are to be arranged for remote closing at navigation bridge and in the control room.

2.6 Escape

2.6.1 Passages for safe escape from areas of the regasification units, the export manifold and loading manifold are to be arranged. Shielding from fire and heat radiation is to be provided for as necessary.

2.6.2 Two escape routes from normally manned areas are to be arranged at least one of which is to be available following an accidental event.

Section 3

System Design

3.1 General

3.1.1 Materials, components and equipment to be used in the construction of regasification systems are to be suitable for the intended service conditions. Materials are to comply with the requirements of Pt.5, Ch.4, Sec 6 "*Materials of Construction and Quality Control*".

3.1.2 The design, arrangement and selection of equipment is to be such as to minimize the risk of fire and explosion from flammable products.

3.1.3 The regasification plant is to be designed so that a single accidental event is not to result in a critical situation.

3.2 Regasification System

3.2.1 General

3.2.1.1 Regasification system may include the following main components but not be limited to:

a) low pressure liquefied natural gas transfer pump

b) boil off gas compressor

c) boil off recondenser tank or suction drum

d) high pressure liquefied natural gas pump or send out pump

e) liquefied natural gas heat exchanger or vaporizer

f) gas metering and analyzer skid

g) associated liquefied natural gas and gas pipes and fittings including main send out gas manifold

h) gas off-loading system

i) associated automation systems

j) utilities, heating medium systems (water glycol, refrigerant, steam or sea water)

k) steel structure

3.2.1.2 The manufacture, installation and testing of vaporizers, including the intermediate heat transfer vessels and pumping systems, is to be undertaken in accordance with the requirements of the Pt.5, Ch.4.

3.2.2 Vaporizers

3.2.2.1 For Shell and Tube type heat exchangers and Open rack type heat exchangers, sea-water may be used as a primary heat source for vaporization. An intermediate heat transfer fluid may be proposed to reduce the chance of freezing and effects of corrosion.

3.2.2.2 Where sea-water is used as the source of heat to vaporize the LNG, the tubes are to be manufactured from a corrosion resistant material, taking into consideration the type and temperature of media conveyed.

3.2.2.3 Where potential risk of failure of a tube or passage could result in gas entering the sea-water side:

a) the sea-water side is to be designed to accept the full gas pressure of the gas side;

b) the sea-water side is to be protected with relief valves in readily visible positions; the discharge from these relief valves is to be taken to a suitable high-pressure venting arrangement and the number and position of valves is to be adequate to relieve the flow occurring due to failure of a single tube.

3.2.2.4 Adequate protection against corrosion is to be provided where aluminium alloy vertical tubes and horizontal headers are constantly covered with sea-water.

3.2.2.5 Commissioning and testing of vaporizers is to be undertaken by the manufacturer prior to units being installed on board.

3.2.2.6 Water supply pumps are to be fitted with suitable inlet filters. Removal and cleaning of filters is to be possible whilst the regasification system remains operational. Any regasification system-related sea-water inlet is to be fitted with gratings and provision made to allow cleaning by low pressure steam or compressed air.

3.2.2.7 A water treatment system is to be incorporated for use with submerged combustion vaporizers to eliminate degradation of the tubes.

3.2.3 High Pressure Pumps

3.2.3.1 All LNG high pressure pumps supplying vaporizers, which are capable of developing a pressure exceeding the design pressure of the system into which they are pumping, are to be provided with relief valves in closed circuit.

3.2.4 Heating System

3.2.4.1 Heating may be arranged as direct heating or indirect heating.

3.2.4.2 Means are to be provided to detect leakage of high pressure LNG/NG into the heating fluid and to prevent overpressure in the heating system.

3.2.4.3 If steam is used in a heat exchanger containing either propane or other gas, the condensate is not to be passed directly back to the engine room. The condensate is to be passed through a degassing tank located in a gas-dangerous area. The vent outlet from the degassing tank is to be routed to a safe location and be fitted with a flame screen. The degassing tank is to be covered by the gas detection and alarm system.

3.2.4.4 Vaporizers are to be protected against freezing of heating medium.

3.2.4.5 Hydrocarbon heating medium storage tanks are to be considered as a cargo tank in Pt.5, Ch.4.

3.3 Piping System Requirements

3.3.1 Regasification system piping is to meet the applicable requirements of Pt.5, Ch.4, Sec.5 *"Process Pressure Vessels and Liquid, Vapour and Pressure Piping Systems"*.

3.3.2 All piping, valves and fittings are to be suitable for the operating and environmental conditions.

3.3.3 All materials used in the piping systems are to be suitable for use with the intended medium, service and ambient conditions, and are to comply with the applicable requirements of Pt.5, Ch.4, Sec.6 *"Materials of Construction and Quality Control"*.

3.3.4 The spool piece, reducers, valves and other fittings to which the cargo system or the send-out system is directly connected are to be of approved material. They are to be of robust construction, adequately supported and suitable for the stated design conditions and manifold forces. For LNG transfer, attention is drawn to SIGTTO '*Manifold Recommendations for Liquefied Gas Carriers*'.

3.3.5 Means of purging, inerting and gas-freeing the pipe lines used for the regasification system are to be provided.

3.3.6 Means for mechanical separation are to be provided between the regasification piping system and the ship's inert gas and nitrogen systems.

3.3.7 All main isolating valves serving the regasification systems and equipment are to be located in a readily accessible location.

3.3.8 The fabrication and installation of the piping associated with the regasification system and its ancillary systems is to be in accordance with the relevant Sections of Pt.4 and Pt.5, Ch.4 to the satisfaction of the Surveyor.

3.3.9 Where applicable, all LNG pipework servicing the regasification system are to be suitably insulated and are to be covered with an efficient vapour barrier.

3.3.10 All low and high pressure LNG supply pipework serving the regasification systems is to be subject to a stress analysis, taking into account all the stresses due to weight of pipes, including acceleration loads if significant, internal pressure, thermal contraction and loads induced by hog and sag of the ship for each branch of the piping system.

3.4 Pressure Relief and Venting

3.4.1 If a suction drum is arranged to supply the high pressure booster pumps it is to be provided with a relief valve sized for relevant cases i.e. fire exposure with relief valve capacity according to Pt.5 Ch.4 Sec.8 for cargo tanks.

3.4.2 Pressure relief valves are to be sized according to requirements in Pt.5 Ch.4.

3.4.3 Pressure relief valves are to be fitted in sections of the piping system where liquid can be trapped, complying with the requirements in Pt.5 Ch.4 Sec.5, 5.5.7.

3.4.4 In case of relief to cargo tanks, the effect of routing high pressure LNG/NG to the cargo tank is to be documented.

3.4.5 Vent system is to be designed such that no liquid is vented. Part of the regasification plant will contain high pressure LNG and part will contain high pressure gas. Relief arrangements for both phases need to be considered.

3.4.6 A knock out drum is to be fitted between the blow down valves and the vent mast, unless it is documented that liquid release cannot occur. The knock out drum is to be fitted with high level alarm and a high-high level sensor which initiates a complete process shutdown. At the high-high activation level the knock out drum is to still have sufficient capacity to allow full process depressurisation.

3.5 Liquefied Natural Gas Loading

3.5.1 LNG may be transferred from LNG carrier using loading arms fitted on the FSRU or using cryogenic hoses.

3.5.2 Operational limitations for the transfer operation are to be set with respect to parameters such as:

a) sea conditions for safe approach, berthing and departure of the LNG carrier

b) operational envelopes (relative motion, accelerations)

c) loads in the mooring lines and fenders between the terminal and the carrier.

3.5.3 Piping between the LNG ship cargo system and the regasification system is to be equipped with a manually operated stop valve and a remotely controlled emergency shut-down valve. These valves are to be located as close to the tank as practicable. When the regasification unit is located in the forward section of the ship, such isolation is to be as near as possible to the boundary of the forward most cargo tank bulkhead and within the cargo area.

3.5.4 For ship to ship transfer, each transfer line is to be fitted with emergency release system (e.g using dry break quick-release connectors) to minimize the possible liquid spill and with insulating flange.

3.5.5 The regasification vessel is to have adequate capability for managing the boil-off gas generated by heat ingress through headers, manifolds and loading arms/hoses during ship-to-ship transfer operations.

3.5.6 The regasification system is to include provision to pre-cool the product transfer piping system prior to ship-to-ship transfer operations commencing.

3.6 Natural Gas Offloading (Send-out system)

3.6.1 Minimum requirements for offloading equipment are:

a) Offloading connections are to be fitted with ESD valves.

b) Offloading hoses (if arranged) are to be type approved.

3.6.2 Dry break quick-release connectors are to be provided for use in an emergency in send-out gas piping between a regasification vessel and receiving terminal.

3.6.3 A manually operated shut-off terminal valve is to be provided at the send-out manifold, in addition to any other automatic shut-off valves required by Pt.5, Ch.4.

Section 4

Safety Systems

4.1 Gas Detection System

4.1.1 In addition to the gas detection system fitted to allow compliance with Pt.5, Ch.4, a permanently installed system of gas detection with audible and visual alarms is to be fitted in the following locations:

a) all enclosed spaces containing gas piping, liquid piping or regasification equipment;
b) other enclosed or semi-enclosed spaces where gas vapours may accumulate;
c) air-locks;
d) secondary fluid expansion tanks;
e) the condensate degassing tank.
f) Export manifold
g) Metering unit
h) Ventilation inlet to accommodation and machinery spaces
i) Turret compartment (if applicable)

4.1.2 The gas detection system serving the regasification system may be either independent or combined with the gas detection system installed to allow compliance with Pt.5, Ch.4.

4.1.3 Gas detection equipment is to be designed, installed and tested in accordance with IEC 60079-29-1, and is to be suitable for the gases to be detected.

4.1.4 The gas detection is to be of the continuous monitoring type, capable of immediate response.

4.1.5 The number and the positions of detection heads or sampling heads is to be determined with due regard to the size and layout of the compartment, the air flow from compartment purging or ventilation and stagnant areas, and the manufacturer’s recommendations.

4.1.6 The gas detection system serving the regasification system is otherwise to comply with the construction and installation requirements of Pt.5, Ch.4.

4.2 Emergency Shutdown System

4.2.1 The ESD system is to be activated by the manual and automatic inputs as per Pt.5 Ch.4. Any additional inputs are only to be included in the ESD system if it can be shown that their inclusion does not reduce the integrity and reliability of the system overall.

4.2.2 The ESD system is to return the regasification system to a safe static condition, allowing remedial action to be taken. Due regard is to be given in the design of the ESD system to avoid the generation of surge pressures within the pipework.

4.2.3 The equipment to be shut down on ESD activation is to include manifold valves during loading or discharge, and pumps and compressors associated with transferring cargo in either liquid or gaseous state.

4.2.4 The number and location of additional shutdown positions is to be determined by the type, number, location and position of the regasification systems and equipment.

4.2.5 Other ESD system controls identified by Risk Assessment, as applicable, are to be provided.

4.2.6 A cause and effect diagram is to reflect:

a) Cause inputs that initiate the automatic shutdown effect output

b) Parameters (set points) that trigger the cause

c) Action item of the effects (e.g. valve closure, machinery shutdown)

4.3 Process Shutdown System

4.3.1 A process shutdown (PSD) system for the regasification system is to be arranged in accordance with the requirements indicated in Section 5.

4.3.2 A process shut-down system that covers the total regasification system is to be arranged. PSD is to result in the following actions:

a) stop of LNG supply to the regasification plant;

b) stop utility systems containing hydrocarbon serving regasification plant;

c) closing of suction drum outlet;

d) stop of high pressure pumps;

e) closing of isolation valves.

4.3.3 Individual regasification units may be shut down in situations where a total PSD is not required to maintain a satisfactory safety level and is related to that unit only and as given in Sec 5. Activation of the unit PSD is to result in the following actions:

a) stop of the relevant high pressure pumps

b) closing of isolation valves to the relevant unit.

4.3.4 PSD system is to be activated by manual push buttons also. Manual PSD points are to be arranged at the regasification system control station, export manifold and at locations as determined by the type, number, location and position of the regasification systems and equipment. The process shutdown points are to be clearly visible.

4.3.5 Process shutdown valves in liquid piping are to close fully under all service conditions within 30 seconds of actuation. Information about the closing time of the valves and their operating characteristics is to be available on board and the closing time is to be verifiable and reproducible. The closure time of 30 seconds for the shutdown valve is to be measured from the time of manual or automatic initiation to final closure. This is called the total shutdown time and is made up of a signal response time and a valve closure time. The valve closure time is to be such as to avoid surge pressure in pipelines. Valves are to close smoothly.

4.4 Depressurisation and Blow down System

4.4.1 A depressurisation and blowdown system is to be provided for depressurising the high pressure liquid and gas pumps, vessels and pipework.

4.4.2 Where a liquid depressurisation system is provided, adequate provision is to be made in the design and installation for the effects of back pressure in the system and vapour flash-off when the pressures of liquids in the blowdown system are reduced.

4.4.3 Manual and automatic activation of the depressurisation system is to be provided.

4.4.4 Manual activation is to be possible from the regasification control station, at the send-out manifold, and from other locations as determined by the type, number, location and position of the regasification systems and equipment.

4.4.5 Automatic activation of the blow down system is to be part of the emergency shutdown arrangements.

4.5 Fire Safety

4.5.1 Fire Mains

4.5.1.1 The fire water main is to be such that at least two jets of water can reach any part of the regasification plant and with a pressure of at least 0.5 [MPa] gauge. The water supply to the fire main serving the regasification units is to be a ring main supplied by the main fire pumps or a single main supplied by fire pumps positioned fore and aft of the cargo area, one of which is to be independently driven.

4.5.2 Water Spray System

4.5.2.1 A fixed water-spray system with an application rate of 10 [l/m^2/min] for the horizontally projected area and 4 [l/m^2/min] for the vertical surface of the regasification plant is to be arranged to protect:

a) the regasification units

b) suction drum

c) export manifold

d) internal surfaces of the turret compartment

e) storage tanks for propane or other flammable fluids, if fitted

f) equipment such as metering station, oderant tank and HIPPS, if fitted.

For structures having no clearly defined horizontal or vertical surfaces, the capacity of the water-spray system is not to be less than the projected horizontal surface multiplied by 10 [l/m^2/min].

4.5.2.2 The arrangements and capacities of the water spray system are to be such that with one pump out of operation the remaining pump(s) are to have capacity to supply the spray system.

4.5.2.3 If the fire water pumps and spray pumps are combined the capacity is to be sufficient to supply water spray to the largest fire section as well as two fire hoses.

4.5.2.4 Release of the water spray systems is to be possible both locally and remotely at the control station where the operating status of the systems is monitored.

4.5.3 Dry Chemical Powder Fire Extinguishing System

4.5.3.1 The fixed dry chemical powder fire extinguishing system is to cover the regasification plant.

a) The system is to be capable of delivering powder from at least two hand hose lines, or a combination of monitor/ hand hose lines to any part of the exposed regasification plant.

b) If loading arms are installed, the dry chemical powder is to cover the presentation flange of the loading arm.

The system is to comply with the requirements in Pt.5, Ch.4, Sec.11.

4.5.4 Fire detection

4.5.4.1 Flame detectors are to be fitted to cover the regasification units, suction drum and export manifold.

Section 5

Control, Alarm and Monitoring

5.1 General

5.1.1 The regasification system is to be provided with control, monitoring, alert and safety systems that will maintain the system throughout all normal and reasonably foreseeable abnormal conditions

5.1.2 The system is to be provided with automatic and/or remote controls to ensure the system operates within its design parameters.

5.1.3 A system for monitoring and indicating alerts is to be provided.

5.1.4 The system is to be provided with safeguards which will operate to prevent a hazard occurring or to reduce an existing hazard to persons, machinery or the ship or the environment.

5.1.5 Locations at which the regasification system is controlled are to be provided with a means of communication with the gas-receiving terminal.

5.1.6 The system is to be provided with the alarms and shutdowns as identified by the system manufacturer. In the absence of such guidance, the alarms and shutdowns indicated in these Rules may be used.

5.1.7 A control station for the regasification system and ship-to-ship operations is to be arranged within a non-hazardous area. Emergency procedures, concerning regasification and ship-to-ship transfer operations are to be capable of being performed from this station.

5.1.8 At least two means of communication are to be provided between the control station and the receiving terminal, one of these systems is to be independent of the main electrical supply.

5.1.9 Internal communication cables are to comply with the applicable requirements of Part 4.

5.1.10 The cable installation is to provide adequate protection against mechanical damage and electromagnetic interference.

5.1.11 Components are to be located with appropriate segregation such that the risk of mechanical damage or electromagnetic interference resulting in the loss of both active and stand-by components is minimized. Duplicated communication links and equipment are to be routed to give as much physical separation as is practicable.

5.2 Equipment and Systems

5.2.1 Suitable interlocks are to be provided to prevent start-up of the regasification system under conditions which could hazard the system or its equipment and components.

5.2.2 The manufacturer is to identify the required alarms, shutdowns and safeguards for regasification system. The minimum required shutdowns are indicated in Table 5.2.2.

Table 5.2.2 : Monitoring and Control of Regasification System		
Item/ Activity	**Monitoring**	**Control**
	Alarm Activation	**Total Process Shutdown(PSD) Activation**
Suction Drums		
Pressure	L, H	LL, HH
Level	L	LL
Vaporizers		
Inlet temperature of heating medium	L	LL (Note 1)
Inlet pressure of heating medium	L	LL (Note 1)
Outlet temperature of heating medium	L	LL (Note 1)
Outlet temperature of Natural Gas	L	LL (Note 1)
Outlet pressure of Natural Gas	L, H	LL, HH (Note 1)
Natural Gas Offloading to Shore		
Pressure	L, H	LL, HH
Temperature	L	LL
Heat Exchangers		
Steam condensate return temperature	L, H (Note 2)	LL, HH (Note 2)
Steam Supply Pressure	L (Note 2)	LL (Note 2)
Knock Out Drums		
Level	H	HH
Pressure in heating system using hydrocarbon heating medium (e.g propane)	H	
Gas detection in Regasification Area	X	
Fire Detection in Regasification Area	X	X (Note 3)
Activation of Emergency Shutdown System (Refer to Pt.5, Ch 4, Sec 18)	X	X
Activation of PSD including by means of manual push buttons	X	X
Activation of Blow down including by means of push buttons	X	X (Note 3)
Loss of signal to control station	X	X

X - Activated
L – Activated for Low Value
LL – Activated for Low Low Value
H – Activated for High Value
HH – Activated for High High Value

Note 1: Only unit PSD may be relevant if designed as per 4.3.3
Note 2 : Required only if steam is not direct heating medium
Note 3 : Also ESD activation

Section 6

Survey, Testing and Trials

6.1 Surveys during Construction

6.1.1 A survey is to be conducted before the regasification system is put into service, which will include a complete examination of its structure, equipment, fittings, arrangements and materials of the regasification system, to ensure compliance with the provisions of the Rules.

6.2 Testing

6.2.1 The following additional tests for the regasification system are to be carried out during construction or conversion of the vessel:

a) Pressure and leak test of LNG and gas piping.
b) Leak test of suction drum.
c) Checks of safety valves setting.
d) Function tests of

   i. fire safety systems,
   ii. emergency shutdown system,
   iii. process shutdown system,
   iv. gas detection system,
   v. depressurizing and blowdown system.
   vi. control, monitoring, alert and safety systems
   vii. regasification heating pumps.

e) Verification of the requirements resulting from the Risk Analysis.

6.2.2 The relevant requirements of Pt.5, Ch.4 are to be complied with, for testing and non-destructive examination of the regasification unit, LNG and gas piping systems.

6.2.3 All piping systems are to be subjected to a hydrostatic test to at least 1.5 times the design pressure. When piping systems or parts of systems are completely manufactured and equipped with all fittings, the hydrostatic test may be conducted prior to installation aboard ship. Joints welded on board are to be hydrostatically tested to at least 1.5 times the design pressure. Proposals for alternative testing fluids or means are to be submitted for special consideration by the Surveyor in cases where the piping cannot be dried prior putting into service or where the presence of water cannot be allowed.

6.2.4 After assembly on board, all cargo and process piping are to be subjected to a leak test using air, halides or other suitable medium to a pressure dependent on the leak detection method applied.

6.2.5 All piping systems including valves, fittings and associated equipment for handling cargo or vapors are to be tested under normal operating conditions. This testing is to be carried out, not later than at the first regasification operation.

6.3 Regasification Trials

6.3.1 The regasification trials program, including technical and operation information relevant to such testing, is to be prepared and submitted for approval.

6.3.2 Preliminary regasification trials are to consist of a running test of the regasification system with LNG low flow and are to be carried out after gas trials and before delivery.

6.3.3 The full capacity test of the regasification plant is to be carried out at an operational site.

6.3.4 The test and measurements are to be carried out according to the relevant regulations, manufacturer’s standards and industry's best practices.

6.3.5 A trial report is to be submitted on completion of the regasification trials. A copy of the trial report is to be retained on board.

End of Chapter

Chapter 39

Passenger and Crew Comfort

Contents

Section

1 *General*
2 *Noise and Vibration*
3 *Indoor Climate and Lighting*
4 *Measurements and Reports*

Section 1

General

1.1 General

1.1.1 This Chapter provides requirements for factors which affect human performance as well as habitability on-board, such as noise, vibration, indoor climate and lighting, on all types of ships.

The effect of the above mentioned aspects on structure, machinery or any other systems are outside the scope of this Chapter.

1.1.2 Compliance with the requirements of this Chapter is to be verified through measurements carried out in accordance with Section 4. A Ship would be assigned the following additional Class Notations, as applicable, on completion of satisfactory review of the results of such measurements:

1.1.2.1 **CMF(Px)**: This notation would be assigned to ships which have acceptable levels of noise and vibration in the passenger spaces, in accordance with the requirements of Section 2, 2.2; where '**x**', is the comfort rating (numerical values of 1, 2, 3) assigned to passenger spaces.

Ships which additionally comply with the requirements for indoor climate and lighting in Section 3, for passenger spaces will be assigned additional qualifiers '**c**' and/ or '**l**', respectively (e.g. **CMF(Px-c)**, **CMF(Px-l)**, **CMF**(**Px-c-l**)).

1.1.2.2 **CMF(Cy)**: This notation would be assigned to ships which have acceptable levels of noise and vibration in the crew spaces, in accordance with the requirements of Section 2, 2.3; where, '**y**' is the comfort rating (numerical values of 1, 2, 3) assigned to crew spaces.

Ships which additionally comply with the requirements for indoor climate and lighting in Section 3, for crew spaces will be assigned additional qualifiers '**c**' and/ or '**l**', respectively (e.g. **CMF(Cy-c)**, **CMF(Cy-l)**, **CMF(Cy-c-l**)).

1.1.2.3 **CMF(Px,Cy)**: This notation would be assigned to ships which have acceptable levels of noise and vibration in both passenger and crew spaces, in accordance with the requirements of Section 2; where, '**x**' and '**y**' denote the comfort rating (numerical values of 1, 2, 3) assigned to passenger spaces and crew spaces respectively.

Ships which additionally comply with the requirements for indoor climate and lighting in Section 3, for passenger and crew spaces will be assigned additional qualifiers '**c**' and/ or '**l**', respectively (e.g. **CMF(Px, Cy)**, **CMF(Px-c-l, Cy-c-l)**.

1.2 Definitions

1.2.1 *Crew spaces*: All spaces intended for use by the crew. Such spaces include crew accommodation, crew recreation areas, mess

rooms, offices and work areas (such as wheelhouse, engine control room, workshops etc.)

1.2.2 *Noise level*: A-weighted equivalent continuous sound pressure level, measured in accordance with recognized national/ international standards (e.g. IEC 61672-1).

1.2.3 *Passenger spaces*: All areas intended for passenger use. Such spaces include passenger accommodation spaces, as well as public spaces such as restaurants, hospitals, auditoriums, gymnasiums, recreation areas etc.

1.2.4 *Relative humidity range*: Acceptable range of relative humidity in indoor atmosphere.

1.2.5 *Thermal comfort*: A temperature range considered comfortable for most persons indoors.

1.2.6 *Vibration level*: The overall frequency weighted r.m.s value of vibration over the frequency range 1 to 80Hz measured in accordance with ISO 21984(2018).

1.3 Documentation

1.3.1 The following plans/ documents are to be submitted to IRS for approval for assignment of Comfort notations:
a) Plan(s) specifying the following:

- measurement locations for noise, vibration, indoor climate and lighting measurements;
- operating conditions for the vessel during the measurements;
- expected loading conditions during measurement;
- normal range of loading conditions;
- instrumentation used for measurement; and
- any other additional details which are required by specific sections of this Chapter or which IRS may deem appropriate for a specific type of vessel.

b) A report which includes the following:

- trial conditions
- results of noise, vibration, indoor climate and lighting measurements, as applicable;
- Any other additional details which are required by specific sections of this Chapter, or any other details which IRS may request for a specific type of vessel.

The report is to include a description of minor deviations, if any, from the required measurement procedures, or the approved measurement plan.

Section 2

Noise and Vibration

2.1 General

2.1.1 It is recommended that owners/ builders undertake predictions/ calculations of noise and vibration characteristics at the design stage of the ship, in order to avoid major modifications at a later stage for complying with the requirements.

2.1.2 The maximum allowable noise and vibration levels for each type of space, in order to obtain the relevant comfort rating, are indicated in this Section.

2.1.3 Rating '1' stands for the highest level of comfort, with regard to noise and vibration, whereas rating '3' denotes the minimum level of comfort acceptable for assignment of CMF notation.

2.1.4 When any machinery or equipment is intended for continuous operation for long periods during vessel operation, the noise and vibration requirements for all spaces are to be satisfied with that machinery or equipment in operating condition.

2.2 Passenger Spaces

2.2.1 The maximum allowable noise levels corresponding to the respective comfort ratings, for passenger spaces, are specified in Table 2.2.1.

2.2.2 The airborne sound insulation properties for bulkheads and decks within passenger spaces, are to comply with weighted sound reduction index (Rw), according to ISO 717-1:2013 (as amended), Part 1, as indicated in Table 2.2.2. The airborne sound insulation properties are to be determined by laboratory tests in accordance with ISO 10140-2:2010, as amended.

2.2.3 The maximum allowable vibration levels corresponding to the respective comfort ratings for passenger spaces are given in Table 2.2.3.

Table 2.2.1 : Maximum allowable noise levels in passenger spaces (in db(A))

Space	Comfort Rating		
	1	**2**	**3**
Passenger Cabins (Standard)	49	52	55
Passenger Cabins (Superior)	45	47	50
Passenger Public Spaces	55	58	62
Medical and First Aid Centres	50	55	60
Theatres/Auditoriums	50	55	60
Open deck recreational Areas	67	72	75

Note:

1. The noise levels may be exceeded by 5 dB(A) within 3 [m] of a ventilation inlet/outlet
2. The levels for open deck recreation areas refer to ship generated noise only.
3. Not more than 20 percent of the passenger cabins, 30 percent of the public spaces and 20 percent of the crew cabins should exceed the relevant noise criteria by more than 3 dB(A).

Table 2.2.2 : Minimum airborne sound insulation Indices, Rw

Space	Comfort Rating		
	1	**2**	**3**
Passenger Cabins (Standard) to cabin	40	38	37
Passenger Cabins (Superior) to cabin	45	42	40
Passenger Cabin (Standard) to corridor	38	36	34
Passenger cabin (Superior) to corridor	42	40	37
Passenger (Standard) Cabin to Stairwell	47	45	43
Passenger (Superior) Cabin to Stairwell	50	47	45
Passenger cabin (Standard) to passenger/crew public space	52	48	48
Passenger cabin (Superior) to passenger/crew public space	55	50	50
Passenger Cabins to machinery spaces	55	53	50

Note:
1. Not more than 20 percent of the interfaces tested should have airborne sound insulation indices, Rw, more than 3 dB(A) lower than the minimum specified values.

Table 2.2.3 : Maximum allowable vibration levels for passenger space (Units: frequency weighted (1-80 Hz) velocity mm/s rms)

Space	Comfort Rating		
	1	**2**	**3**
Passenger Cabins (Standard)	1.8	2.1	2.4
Passenger Cabins (Superior)	1.5	1.8	2.1
Passenger Public spaces	2.0	2.5	3.0
Open deck recreation areas	2.5	3.0	3.5

Note:
1. Not more than 20 percent of all passenger spaces and public spaces should exceed the relevant vibration criteria by more than 0.3 [mm/s].

2.3 Crew Spaces

2.3.1 The comfort ratings, and corresponding maximum allowable noise levels for crew spaces are specified in Table 2.3.1.

2.3.2 The bulkhead and deck air-borne sound insulation indices for crew spaces, Rw, calculated in accordance with ISO 717-1:2013 are to be in compliance with the values given in Table 2.3.2.

2.3.3 The maximum allowable vibration levels corresponding to the respective comfort ratings for crew spaces are given in Table 2.3.3.

Table 2.3.1 : Maximum allowable noise levels in crew spaces (in db(A))

Space	Comfort Rating			
	1	**2**	**3 (Ships<10000 GT)**	**3 (Ships≥10000 GT)**
Crew Cabins and hospitals	50	53	60	55
Conference rooms, offices, mess rooms, indoor crew recreation rooms	55	58	65	60
Open deck recreational areas	67	72	75	75
Changing rooms, laundries, bathrooms	70	75	75	75
Galleys and pantries	75			
Machinery Spaces	110[2]			
Machinery Control Rooms	75			
Wheelhouse, radar room, chart room	65			
Radio Room	60			
Workshops and other work spaces	85			
Normally unoccupied spaces (e.g. holds, decks)	90			

Note:

1. Personnel entering spaces with nominal noise greater than 85 db(A) are required to wear hearing protectors while in those spaces.
2. The limit of 110 db(A) indicated assumes that hearing protectors giving protection meeting the requirements for hearing protectors in Chapter 7 of MSC Res. 337(91) are worn. The limits specified are to be regarded as maximum levels and not as desirable levels. It is desirable for the noise level to be lower than the maximum levels specified.

Table 2.3.2 : Minimum airborne sound insulation Indices

Space	**Comfort Rating**		
	1	**2**	**3**
Crew Cabin to cabin	40	38	35
Crew cabin to corridors, stairways, passageways	35	32	30
Crew cabin and hospitals, to public spaces/recreation rooms/mess rooms	45		
Crew Cabins to machinery spaces and engine casings	50		

Note:
1. Not more than 20 percent of the interfaces tested should have airborne sound insulation indices, Rw, more than 3 dB(A) lower than the minimum specified values.

Table 2.3.3 : Maximum allowable vibration levels for crew spaces (Units: frequency weighted (1-80 Hz) velocity mm/s rms)

Space	**Comfort Rating**		
	1	**2**	**3**
Crew Cabins	2.8	3.0	3.2
Navigation spaces	3.0	3.5	4.0
Crew dining and recreational areas	3.0	3.5	4.0
Medical and First Aid Centres	2.8	3.0	3.2
Offices	3.0	3.5	4.0
Workshops and Engine Control Room	5		

Note:
1. Not more than 20 percent of all crew spaces should exceed the relevant vibration criteria by more than 0.3 [mm/s].

Section 3

Indoor Climate and Lighting

3.1 General

3.1.1 This Section provides requirements related to thermal and visual comfort of passengers and crew on board ships. Ships which comply with the requirements in this section will be assigned additional qualifiers '**c**' and '**l**', for indoor climate and lighting, respectively. For example, **CMF (P1-c, C1-l)** indicates that the ship complies with the requirements of this Section for indoor climate in passenger spaces, and for lighting in crew spaces.

3.2 Indoor climate

3.2.1 General

3.2.1.1 The thermal control or Heating, Ventilation and Air-conditioning (HVAC) systems on a vessel are to be designed to effectively control the indoor thermal environment parameters to within acceptable limits, thus ensuring thermal comfort for passengers and crew on board.

3.2.1.2 Thermal environment parameters to be considered are air temperature, supply of fresh air (number of air changes), air velocity and relative humidity.

3.2.2 Definitions

3.2.2.1 *Air velocity*: The rate of displacement of ambient air in a specific direction in meters-per-second

3.2.2.2 *HVAC Zone*: A group of spaces, which are monitored and controlled for thermal comfort, independently of monitoring and control systems of other groups of spaces.

3.2.2.3 *Relative Humidity*: The amount of water vapour present in air expressed as a percentage of the amount needed for saturation at the same temperature.

3.2.2.4 *Vertical Gradient*: The vertical air temperature difference within an enclosed space.

3.2.3 Passenger Spaces

3.2.3.1 Air temperature

.1 HVAC systems are to be designed to provide an adjustable range of air temperatures between 18^0 C to 27^0 C.

.2 In any space, the difference in temperature between 100 [mm] above deck and 1700 [mm] above deck is to be maintained within 3^0 C

.3 In passenger cabin areas, the difference between inside bulkhead surface temperature adjacent to passenger berths and the average air temperature within the space should be less than 10^0 C.

3.2.3.2 Relative Humidity

.1 HVAC systems are to be designed to provide and maintain relative humidity within a range of 40 to 60 percent in passenger spaces.

3.2.3.3 Air velocity

.1 Air velocities are not to exceed 0.5 [m/s] at the measurement position in any space.

3.2.3.4 Air exchange rate

.1 The rate of air exchange for all passenger accommodation and public spaces is to be at least six complete changes per hour

3.2.4 Crew Spaces

3.2.4.1 Air temperature

.1 HVAC systems are to be designed to provide an adjustable range of air temperatures between 18^0 C to 27^0 C.

.2 In any space, the difference in temperature between 100 [mm] above deck and 1700 [mm] above deck is to be maintained within 3^0 C.

.3 In crew cabins, the difference between inside bulkhead surface temperature adjacent to crew berths and the average air temperature within the space is to be less than 10^0 C.

3.2.4.2 Relative Humidity

.1 HVAC systems are to be designed to provide and maintain relative humidity within a range of 30 percent to 70 percent in crew spaces.

3.2.4.3 Air velocity

.1 Air velocities are not to exceed 0.5 [m/s] at the measurement position in any space

3.2.4.4 Air exchange rate

.1 The rate of air exchange for enclosed crew spaces is to be at least six complete changes per hour.

3.3 Lighting

3.3.1 General

3.3.1.1 Lighting in passenger and crew spaces is to be provided in a manner which facilitates visual comfort, supports activities envisaged to be undertaken in that space and aids in the creation of an appropriate visual environment.

3.3.1.2 The required illuminance levels in Lux which support task, performance, safety and visual comfort within a particular space, is provided in this sub-section. These values are to be used by designers when deciding the mode of illumination, as well as the ergonomic design of spaces. The measured values of illumination may fall within an acceptable range, which is 10 lux above or below the required values provided in the Tables.

3.3.2 Lighting in Passenger Spaces

3.3.2.1 The requirements for lighting in passenger spaces are indicated in Table 3.3.2.1.

3.3.2.2 Emergency lighting is not covered by the requirements of this sub-section, and the same is to be provided in accordance with the relevant statutory requirements.

3.3.3 Lighting in Crew Spaces

3.3.3.1 The requirements for lighting in crew accommodation and service spaces are indicated in Table 3.3.3.1.

3.3.3.2 The requirements for lighting in machinery operation and maintenance areas are indicated in Table 3.3.3.2.

Table 3.3.2.1 : Lighting in passenger spaces

Space	Illuminance level in Lux
Interior walkways and stairways	100
Passenger Cabins	200 (general), <30 (during sleeping periods)
Dining Spaces	300 (mess rooms/cafeteria) , 100 (restaurants/fine dining)
Recreation spaces	200
Sanitary spaces	200
Medical and First Aid Centres	500, 200(waiting areas)
Surgical dressing rooms	800
Operation theatres -General Lighting -Operating Table	500 1000

Table 3.3.3.1 : Lighting in crew accommodation and service spaces	
Space	**Illuminance level in Lux**
Interior walkways and stairways	100
Crew Cabins	150 (general), <30 (during sleeping periods)
Mess room and cafeteria	300
Recreation spaces	200
Sanitary spaces	200
Medical and First Aid Centres	500
Wheelhouse, Pilot house and Bridge	300
Chart Room -General Lighting -Chart table	 150 500
Control Stations -General Lighting -Switchboards	 300 500
Other control rooms (e.g. cargo Transfer)	300
Galleys and other food preparation spaces	500
Storerooms -non refrigerated -refrigerated	 200 100
Muster/Embarkation area	200

Table 3.3.3.2 : Lighting in machinery operation and maintenance areas	
Space	**Illuminance level in Lux**
Machinery spaces (General), pump rooms, battery rooms	200
Main propulsion machinery space	300
Shaft Alley	100
Crane Cabin	400
Switchboard, Transformer room	500
Cargo handling (weather decks)	200
Workshops	500

Section 4

Measurements and Reports

4.1 General

4.1.1 The methods and procedures for measurements to be undertaken in order to verify compliance with the requirements of Sections 1 to 3 are indicated in this Section.

4.1.2 The measurements of parameters may be undertaken either by IRS or an organization recognized by IRS as competent to carry out such work. In the latter case, the measurements are to be witnessed by IRS Surveyor (s).

4.1.3 A measurement/ test plan is to be submitted to IRS for approval prior to undertaking measurements.

4.1.4 Measurements are to be undertaken as per the approved measurement plan. However, the attending surveyor may allow for minor deviations provided that he is satisfied that the same will not affect the accuracy of results. Any deviations from the measurement conditions specified in this section are to be clearly stated in the measurement report.

4.1.5 Tests and trials are to be conducted when the ship is fully outfitted and all systems contributing to the noise, vibration and indoor climate are operational. The operational systems also include those that would run simultaneously, whilst the ship is in normal service.

4.1.6 Measurements are to be taken at normal service speed of the vessel, and unless otherwise addressed in the provisions below, propulsion machinery run at no less than 80% MCR or higher.

All machinery and equipment which will be operational during a normal voyage are to be in operational condition and operating during the test.

4.1.7 The measurements are to be taken at a loading condition which is representative of, or as close as possible, to the normal operating condition of the Ship.

4.2 Noise and Vibration

4.2.1 Measurement conditions and procedures are generally to be in accordance with MSC Res. 337(91) for noise, and ISO 21984 and ISO 20283-5, as applicable, for vibration.

4.2.2 Measurements are to be carried out using duly calibrated instrumentation (such as sound level meters, octave filter sets) conforming to recognized National/ International Standards (for examples of such standards, refer Ch.2 of MSC Res 337(91).

4.2.3 Noise and vibration measurement locations are to be chosen such that the measurement provides a representative indication of noise and vibration levels in that space.

4.2.4 Higher density of measuring positions would be required near major noise sources such as propellers, stabilizers, thrusters and main/ auxiliary machinery.

4.2.5 Potential worst case locations are to be identified based on their proximity to noise emitting sources, such as propulsion or other rotating machinery, or where noise is likely to be transmitted to passenger accommodation areas, public, or recreation space, via the vessel’s structure. Measurements are to be taken in all identified worst case locations (e.g. spaces adjacent to a machinery space).

4.2.6 For ships equipped with thrusters, additional measurements are to be made at 40% thruster power and the ship's speed is to be appropriate for thruster operation. Measurements locations are to include positions around such machinery when in operation and in adjacent accommodation spaces and duty stations.

4.2.7 For ships equipped with stabilizers, the measurements are to be taken with the stabilizers engaged and active. If such equipment (thrusters/ stabilizers) is intended for continuous operation, measurements are to be made for ensuring compliance with Chapter 4 of MSC Res. 337(91) (*Code on Noise Levels on-board Ships*). If such systems are intended for short temporary use only, for instance during port manoeuvres, measurements are only

relevant for ensuring compliance with Chapter 5 of MSC Res. 337(91) on noise exposure.

4.2.8 For ships equipped with dynamic positioning systems, which are intended for use in normal working condition, additional noise measurements at DP mode are to be made at control stations, duty stations, and accommodation spaces to ensure that the maximum noise level limits in these spaces are not exceeded. The system is to be operating on at least 40 percent power, during these measurements.

4.2.9 In large public spaces where there may be considerable variation of noise levels within the space, measurements are to be taken at locations not greater than 7 [m] apart.

4.2.10 In addition, for passenger ships, and ships which are designed to spend a considerable period of time in harbour, the noise and vibration are to be also measured for this condition, with the auxiliary machinery and HVAC systems running at their normal rated capacity.

4.2.11 In addition to the noise measurement locations for crew spaces as specified in MSC Res. 337(91), the following measurement locations are to be included for passenger ships:

- all public spaces
- 50 percent of the cabins in the aft one third of the ship.
- 25 percent of the cabins, elsewhere.

4.2.12 If the specified criterion is exceeded or annoying low frequency noise or tonal components are observed, then 1/3 octave band analysis of the noise is to be performed.

4.2.13 Vibration levels are to be generally measured in the centre of the floor area of the space over a period of not less than one minute. In large public spaces more than one measurement locations may be required.

4.2.14 At all locations, vibrations in the vertical direction are to be assessed. Sufficient measurements are to be taken in the fore and aft, athwartships direction to define the global deck vibrations.

4.2.15 In general, the testing conditions are to replicate, as far as practicable, conditions which will exist during course of the ship's normal service. For ships which are normally operated in deep waters, the tests are to be carried out in water depth not less than five times the design draft of the ship. For ships which would be continuously operating in shallow waters, the test is to be conducted at the relevant water depth.

4.2.16 Trials are to be conducted in sea conditions not greater than Sea State 3 on the WMO sea state code. Noise measurements are not to be taken when the wind force exceeds 4 on the Beaufort scale.

4.2.17 Rudder angles during measurements are to be restricted to within 2 degrees port or starboard, and rudder movements are to be kept to a minimum throughout the measurement periods.

4.2.18 The noise and vibration measurement reports will be reviewed by IRS for assignment of the Comfort rating, as applicable.

4.3 Indoor Climate

4.3.1 Certification towards indoor climate and thermal comfort on board will include measurements taken on board, and additionally for passenger ships, a design review of the HVAC system, to assess its performance at the typical ambient climatic conditions to which the ship will be subjected to during its intended use.

4.3.2 Climate parameters are to be verified through design evaluation and/or measurements include air temperature, supply of fresh air (number of air changes), air velocity and relative humidity.

4.3.3 Documentation/ data pertaining to the following need to be submitted to IRS for review:

- General arrangement of the vessel
- Appropriate vessel and HVAC system design specifications
- Schematics/ layout of the HVAC system

4.3.4 The measurement plan for indoor climate is to include conditions under which the tests are performed, measurement locations, as well as details regarding software and instrumentation used for testing and data analysis. The measurement locations are to be selected such that they give a representative description of the climate in the space.

4.3.5 All measurement instrumentation is to conform to recognized National/ International Standards.

4.3.6 The following quantities are to be measured in each of the spaces or zones identified in the measurement plan, and shown to not exceed the requirements of this Chapter:-

- Air temperature characteristics
- Relative humidity
- Air velocity
- Vertical gradient

4.3.7 Air temperature and humidity measurements are to be made at intervals of at least five minutes for a period of one hour. The minimum, maximum and average values are to be reported for each space.

4.3.8 Air velocity is to be measured at the geometric centre of the room. However, the Surveyor may recommend this measurement to be taken at the most commonly occupied position in that particular space. Air velocity measurements are to be taken over a period of three minutes.

4.3.9 Where a single instance of a particular space exists within the vessel (for example, Navigation Bridge), the space is to be selected for measurement. Where multiple instances of a space with similar purpose as well as arrangement exist (for example, laundries), a representative sample of at least twenty-five percent of each type of space are to be selected for measurement.

4.3.10 For crew/ passenger cabins, measurements are to be carried out in at least 30 percent of the total number of cabins on each deck, which are as far as practicable, evenly distributed over the length and breadth of the ship. In case of ships with less than 10 cabins on a particular deck, measurements are to be undertaken in at least 3 cabins.

4.3.11 In large public spaces where there may be considerable variation of thermal parameters within the space, more than one measurement location may need to be identified such that the maximum spacing between two such locations is not greater than 15 [m].

4.3.12 All doors and windows of the space, are to be closed during the evaluation period, except for routine entry and exit.

4.3.13 When thermal conditions have a high sensitivity to ambient weather conditions, the measurements are to be made such that the high and low extremes of the thermal parameters are accurately determined.

4.3.14 The indoor climate test report and results will be reviewed by IRS for assignment of the '**c**' qualifier for Comfort notation.

4.4 Lighting

4.4.1 For certification towards lighting and visual comfort on board, test plan preparation, test measurement procedures and test reporting are to be in accordance with ISO 8995-1:2002.

4.4.2 Light meters used for measurements are to conform to the requirements specified in ISO 8995-1:2002.

4.4.3 In spaces with windows or portholes, measurement of lighting levels is to be undertaken after dark, or during the day with all natural lighting blocked out.

4.4.4 All stray lighting is to be masked out during measurements. In cases where this is not possible, a control measurement is to be made which may be deducted from measured values, to obtain the actual lighting level within the space.

4.4.5 During lighting measurements, only the personnel needed for the normal operation of the equipment in that space, as well as those carrying out measurements, are to be present in that space.

4.4.6 In general, measurement locations within spaces are to be selected such that they give a representative value of the lighting within the space. In large public spaces, more than one measurement location may need to be selected for measurement. As a general principle, one measurement location for each 40 square meters of floor space may be considered acceptable.

4.4.7 For crew/ passenger cabins, measurements are to be carried out in at least 30 percent of the total number of cabins on each deck, which are as far as practicable, evenly distributed over the length and breadth of the ship. In case of ships with less than 10 cabins on a particular deck, measurements are to be undertaken in at least 3 cabins.

4.4.8 In addition to the results obtained during measurement, the test report is to include details of the ambient conditions such as time of the day, external lighting conditions etc. Details of measurement equipment (accuracy, resolution, calibration details etc.), as well as actual measurement locations are to be included as part of the measurement report.

4.4.9 The lighting test report and results will be reviewed by IRS for assignment of the '**I**' qualifier for Comfort notation.

3	*Stability and Strength*
4	*Systems serving Livestock Spaces*
5	*Fire-fighting arrangements in Livestock Spaces*
6	*Electrical Equipment*

Section 1

General

1.1 Application

1.1.1 Ships complying with the requirements in this Chapter may be assigned with class notation **LIVESTOCK CARRIER**.

1.1.2 In addition to the general list of plans in the following documents/ plans are to be submitted for information:

- Livestock arrangement (including loading - unloading arrangement and distribution of livestock pens at various decks/ platforms)
- Distribution of fodder and consumable liquids on various decks and platforms

1.1.3 The following documents/ plans are to be submitted for approval:

- Stowage/ securing arrangement of livestock in pens
- Access and escape from livestock pens/ decks/ spaces
- Ventilation system
- Storage and distribution system for fodder and water including piping systems
- Sewage drainage and discharge system
- Load schedule of main and emergency power
- Electrical equipment, panels switchboard plans,
- Main and emergency lighting system
- Firefighting arrangements in livestock spaces and arrangement of firefighting appliances

1.1.4 The following documents/ plans are to be submitted for review:

- Type approval of water level detection system including sensors, wiring and control panel
- General arrangement of sensors and cables
- power supply electrical diagram
- detailed installation drawing of sensors

Section 2

Livestock Arrangements

2.1 Livestock arrangements

2.1.1 The livestock are to be kept in pens. The dimensions of the pens are to be suitable for the type of livestock carried.

2.1.2 The livestock are not to be carried on hatch covers, unless the hatch covers are effectively protected.

2.1.3 The livestock are not to be carried in more than one tier in a deck.

2.1.4 If dangerous goods are carried on a vessel, livestock must not be held:

(a) within 6 [m] horizontally of the dangerous goods; or
(b) in the same underdeck compartment as the dangerous goods; or
(c) in any position where they could be affected by spillage or leakage of the goods.

2.2 Arrangement of livestock spaces

2.2.1 The requirements of this sub-section are applicable to the arrangement of spaces dedicated to the carriage of livestock. The spaces may need to be adapted or suitably modified depending on the particular species of animals being carried.

2.2.2 Suitable arrangements are to be provided for protecting the livestock from injury, avoidable suffering and exposure to weather, sea or hot parts.

2.2.3 Livestock may not be carried or loaded for carriage, in any part of the ship where the livestock, livestock fittings, livestock equipment or carrying arrangements may:

- obstruct access to any accommodation space or working space necessary for the safe running of the ship, or the means of egress from any hold or underdeck space
- interfere with life-saving or fire-fighting appliances interfere with the tank sounding equipment or bilge pumping
- interfere with the operation of closing appliances
- interfere with the operation of freeing ports
- interfere with the lighting or ventilation of other parts of the ship
- interfere with the proper navigation of the ship.

2.2.4 A pen floor or stall floor is to have a surface that provides a satisfactory non-slip foothold for livestock.

2.3 Means of access and escape for livestock

2.3.1 A ramp or other suitable means of access, appropriate to the species being carried, is to be provided for the loading or unloading of livestock. It is to be so erected as to prevent any gap occurring between it and the ship and is to be set at a gradient (not exceeding 1 in 2) suitable for the species to be loaded or unloaded.

2.3.2 The means of access is to be fitted with:

- side panels free of protrusions and of sufficient strength and height to prevent escape of livestock
- a walking surface of battens suitable for the species
- a closing arrangement

2.3.3 If the means of access is part of the ship's equipment, it is to be designed to support a uniformly distributed load over the walking surface not less than the values indicated in Table 2.3.3

Table 2.3.3

Species	Load [N/m^2]
Cattle and Horses	4700
Sheep, goats and pigs	2400

2.3.4 The permissible tensile strength for material used in the means of access is indicated in Table 2.3.4

Table 2.3.4

Material	Permissible tensile stress
Steel	0.5 σ_y
Aluminium	0.5 $\sigma_{p0.2}$
Other	Specially considered

Where,

σ_y = Minimum yield stress [N/mm2]

$\sigma_{p0.2}$ = 0.2 percent proof stress

2.3.5 Livestock pens and means of access for livestock are to be provided in accordance with the requirements of Tables 2.3.5 (a), 2.3.5 (b) and 2.3.5 (c) for pigs and sheep, cattle and horses respectively. Details of pens dedicated for carriage of other livestock are to be submitted to IRS for special consideration. The rails in the pens are to be provided taking into account the size of particular species of livestock.

Table 2.3.5(a) : Limiting dimensions of pens and passageways for pigs, sheep and goats

Maximum distance between rails aligned fore and aft (breadth)	4.5 [m]
Minimum distance between rails aligned fore and aft (breadth)	2.0 [m]
Maximum distance between rails aligned athwartships (length)	Not more than twice the breadth
Minimum length	Not less than the breadth
Maximum clear floor area within pen	40.5 [m^2]
Minimum clear height within pen	1.1 [m]
Maximum clear vertical distance between rails	0.3 [m]
Maximum clear vertical distance below bottom edge of lowest rail of pen installed at deck level	0.2 [m]
Maximum clear vertical distance below bottom edge of lowest rail of pen not installed at deck level	0.05 [m]
Minimum height of top edge of uppermost rail above pen floor	0.9 [m]
Minimum width of adjacent passageway clear of receptacles and any other obstructions	0.9 [m]

Table 2.3.5(b) : Limiting dimensions of pens and passageways for cattle

Maximum distance between rails aligned fore and aft (breadth)	4.5 [m]
Minimum distance between rails aligned fore and aft (breadth)	2.1 [m]
Minimum distance between rails aligned athwartships	2.3 [m]
Maximum clear floor area within pen	21 [m^2]
Maximum height of top edge of lowest rail above pen floor between pen	0.6 [m]
Minimum clear height within pen	2.0 [m].
Minimum clear height within deck outside pens	1.8 [m]
Minimum width of adjacent passageway, measured clear between rails, when pens are on both sides of the passageway and cattle are loaded and discharged through the pens	0.9 [m]
Minimum width of adjacent passageway, measured clear of any fixed structure, fittings, receptacles or obstruction (e.g. pillars, feed chutes, fixed fodder or water troughs), when pens are on both sides of the passageway and cattle are loaded and discharged through the pens	0.75 [m]
Minimum width of adjacent passageway, measured clear of any fixed obstructions, when pens are on both sides of the passageway and cattle are loaded and discharged through the passageway	0.9 [m]
Minimum width of adjacent passageway clear from rails, when pens are on only one side of the passageway and livestock are not loaded through that passageway	0.75 [m]

Table 2.3.5(c) : Limiting dimensions of stalls, pens and passageways for horses		
Maximum clear length within stall		2.5 [m]
Minimum clear length within stall		2.3 [m]
Minimum clear passage	(i) between 2 rows of stalls and bounded by the front rails	1.7 [m]
	(ii) between 2 rows of stalls and bounded by the front and back rails	1.2 [m]
	(iii) in any other case	1.0 [m]
Minimum clear breadth within stall	(i) if the stall is aligned athwartships	0.7 [m]
	(ii)if the stall is aligned fore and aft	0.9 [m]
Height of uppermost front, back and side rail from floor to top edge		1.15 [m]
Height of lowest front, back and side rail from floor to top edge		0.75 [m]

2.3.6 Additional requirements for goats

2.3.6.1 There must be pen rails:

(i) to a height of at least 1.5 [m] above the pen floor; or
(ii) to a height where the clear height above the uppermost rail is less than 300 [mm]

2.3.7 Livestock pens are to be provided based on the loads determined by the application of the following:

$$F = \propto * B(0.574 + 0.0252 * Z)$$

Where,

F = Load per metre length of boundary, [N/m]

B= Maximum breadth of pen, [m]

Z = the vertical distance from a point 0.75[m] above the pen floor to the vessels' waterline corresponding to the lightest displacement, [m]

$\propto$ is a constant, taken as 1668 for sheep, goats or pigs and 3336 for cattle or horses.

Load bearing areas are:

For sheep, goats and pigs – uniformly distributed upto the rail, the centre of which is at a height of not more than 0.9 [m] above the floor of the pen.

For cattle and horses - uniformly distributed upto the rail, the centre of which is at a height of not more than 1.4 [m] above the floor of the pen.

2.3.8 Livestock pen floors or platforms are to be provided based on the loads determined by the application of the following:

$$P = \beta * \left[1 + \frac{1}{d}((0.094 - 0.00035L)y + (7.4 - 0.016L))\right]$$

Where,

P = Floor load per square metre, [N/m^2]

d = Minimum draught of the ship, [m]

y = Longitudinal distance from the midpoint of the pen to amidships, [m]

L = Length between perpendiculars of the ship, [m]

β is a constant taken as 2500 for sheep, goats or pigs and 5000 for cattle or horses.

2.3.9 The permissible stresses for materials used for livestock pens and floors is indicated in Table 2.3.9

Table 2.3.9		
Material	**Permissible tensile stress**	**Permissible shear stress**
Steel	0.75 σ_y	0.375 σ_y
Aluminium	0.75 $\sigma_{p0.2}$	0.375 σ_y
Other	Specially considered	

Where,
σ_y = Minimum yield stress [N/mm$_2$]

$\sigma_{p0.2}$ = 0.2 percent proof stress [N/mm$_2$

2.4 Means of access and escape for persons

2.4.1 Each space in which livestock is carried is to be provided with at least two means of escape, widely separated and giving access to an open deck. Such means of egress are to be clearly marked.

2.4.2 Access to livestock space for persons is to be safe. Where it is combined with a ramp used for moving livestock between decks, it is to be separated from the livestock ramp by protective fencing.

2.4.3 Pens, stalls and similar fittings are to be provided with a means of access for persons with secure closing arrangements, having structural strength at least equivalent to the strength of that part of the pen, stall or fitting.

2.4.4 The passageways in spaces for the carriage of livestock are to have a minimum clear height of 2.0 [m].

2.4.5 If, for the safe and proper operation of the vessel, access is required between the side of the vessel and a pen, stall or similar structure, there is to be a passageway that is at least 750 [mm] wide between the vessel's rail or bulwark and the rails of the pen, stall or structure.

However, the passageway width may be reduced to less than 750 [mm], but no less than 550 [mm], by obstructions outside the pen rails such as receptacles, pipework or other objects for the provision of livestock services.

2.4.6 Where it is necessary for persons to be on a means of access during the movement of livestock, a passage of at least 550 [mm] width is to be provided in accordance with the following:

- it is to be fenced to a height of at least 1 [m] and with an intermediate horizontal rail approximately 550 [mm] above the walking surface; and
- Fitted with treads at suitable stepping distances.

Section 3

Stability and Strength

3.1 Stability

3.1.1 General

3.1.1.1 Livestock carriers are required to comply with the stability requirements for cargo ships in the International Code on Intact Stability 2008, as amended.

3.1.1.2 In addition, requirements of the national/ statutory authorities, where the ship is registered or in areas where the ship trades are also to be complied with.

3.1.2 Additional Requirements

3.1.2.1 The stability requirements of a vessel lo be met throughout a voyage, taking into account the effects of shift of livestock and feed and, if the vessel has a pen structure on or above the uppermost continuous deck, the effect of wind; are to be as follows:

(a) the area under the righting lever curve shall be not less than 0.055 [m-rad] up to 30 [deg] angle of heel and not less than 0.09 [m-rad] up to 40 [deg] angle of heel, or the angle of flooding if this angle is less than 40 [deg],

(b) the area under the righting lever curve between the angles of heel of 30 [deg] and 40 [deg], or between 30 [deg] and the angle of flooding if this angle is less than 40 [deg], is not to be less than 0.03 [m-rad],

(c) the righting lever is not to be less than 0.20 [m] at an angle of heel equal to, or greater than 30 [deg],

(d) the maximum righting lever is to occur at an angle of heel not less than 25 [deg],

(e) the initial metacentric height is not to be less than 0.15 [m],

(f) the area under the righting lever curve up to 40 [deg] or the angle of

flooding, whichever is less, in excess of the area under the heeling lever curve to the same limiting angle, is to be not less than 0.018 [m-rad] plus 20 per cent of the area of the righting lever curve to the same limiting angle, and

(g) the angle of heel due to wind is to be not more than 10 [deg].

3.1.2.2 The residual Area 'A' is to comply with the following requirements, taking into account the effects of the shift of livestock and fodder in pellet form and the effect of wind, as illustrated in Fig. 3.1.2.2 below:

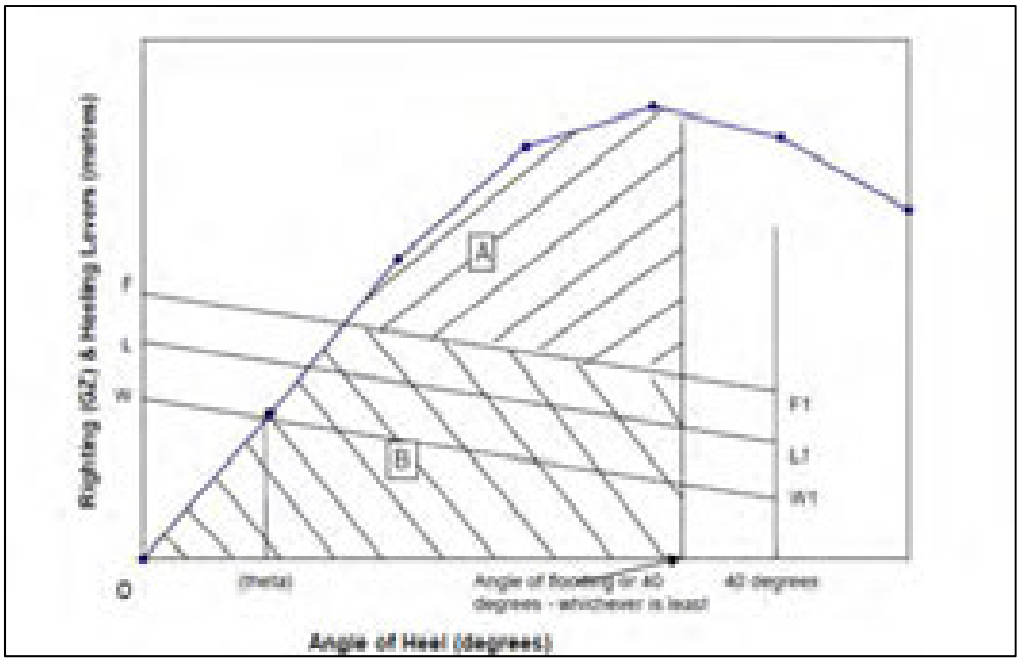

Fig. 3.1.2.2 Illustration of Stability Requirements

$A \geq 0.018 mrad + 0.2\, A_{(A+B)}$

Where,

$A_{(A+B)}$ is the sum of area A and area B under the righting lever curve, as illustrated in Fig. 3.1.2.2.

OW – the heeling lever at 0 [deg] due to wind;

WW1 – the heeling curve due to wind;

WL – the heeling curve at 0[deg] due to the shift of livestock;

LL1 – the heeling lever curve due to the combined effects of wind and shift of livestock.

LF – the heeling lever at 0 [deg] due to the effect of shift of fodder;

FF1 – the heeling lever curve due to the combined effects of wind and the shift of livestock and fodder;

θ – Angle of heel due to wind.

Note: If the fodder is not pellet feed carried in bulk, the heeling lever due to shift of fodder will be zero.

3.1.2.3 The heeling lever due to the effect of wind is to be determined according to the following:

(a) The heeling lever due to the effect of wind at 0 [deg] is to be calculated as follows:

$$OW = \frac{PAH}{\Delta}$$

Where; Δ - Displacement [tonnes];

P – Wind pressure, 504 [Pa];

A – Lateral area of the vessel above the waterline [sq.m];

H - vertical distance between the centroid of the lateral area of the vessel above the waterline and the centroid of the vessel's underwater lateral area. For most vessels the vertical position of the centroid of the underwater lateral area may be taken as half the draft to the underside of the keel at amidships

(b) The heeling lever due to the effect of wind at 40 [deg] is to be given by 0.8 (heeling lever due to the effect of wind at 0 [deg]).

(c) The heeling lever curve is to be taken as a straight line joining the heeling lever at 0 [deg] and the heeling lever at 40 [deg].

3.1.2.4 The heeling lever due to the shift of livestock is to be determined according to the following:

(a) The heeling lever due to the shift of livestock at 0 [deg] is to be calculated as follows:

$$WL = \frac{m * C}{f * \Delta}$$

Where; m – average mass of livestock being carried on the intended voyage [tonnes];

f – floor area required per head of average mass of the livestock being carried on the intended voyage [sq.m]

C – livestock shift constant;

$C = \frac{1}{6}\sum l\, b^2$, where

l – length of the pen[m],

b – breadth of the pen [m]

(i)For vessels with uniform breadth of pens, the ‘C’ is: 1/6 (breadth of the pen * total floor area of pens);

(ii)For vessels with varying breadth of pens, the largest breadth may be used and the ‘C’ is: 1/6 (maximum breadth of pen * total floor area of pens)

(b) The heeling lever due to the shift of livestock at 40 [deg] is to be given by 0.8 (heeling lever due to the shift of livestock at 0 [deg]).

(c) The heeling lever curve is to be taken as a straight line joining the heeling lever at 0 [deg] and the heeling lever at 40 [deg].

3.1.2.5 The heeling lever due to the shift of fodder is to be determined according to the following:

(a) The heeling lever due to the shift of fodder at 0 [deg] is to be calculated as follows:

$$LF = \frac{M_f}{s * \Delta}$$

Where; M_f – the sum of the shift moment of each compartment, the shift moment of each compartment is to be given by 0.04 l b ^{3,} where;

l – max. length of compartment [m];

b – max. breadth of compartment [m]

The use of volumetric shift moments for the fodder, where the surface is assumed to take up an angle of slope of 15 [deg] to the horizontal for full compartments and 25 [deg] to the horizontal for partly filled compartments is an acceptable alternative method to obtain the total shift moment of the fodder.

s – stowage factor (the volume of fodder in pellet form per unit weight)

(b) The heeling lever due to the shift of fodder in pellet form carried in bulk at 40 [deg] is to be given by 0.8 (heeling lever due to the shift of fodder at 0 [deg]).

(c) The heeling lever curve is to be taken as a straight line joining the heeling lever at 0 [deg] and the heeling lever at 40 [deg].

3.1.2.6 It is recommended that the following information be included in the stability information provided onboard the vessel:

(a) Livestock shift constant (as determined for all conditions of pen utilization that may arise in practice, unless the maximum value is used for all calculations)

(b) Heeling moment for fodder (the heeling moment for each compartment is to be determined separately, unless the greatest heeling moment for all compartments added together is provided: i.e. the total heeling moment for the worst condition of stability

(c) Wind effect (the heeling lever due to wind to be provided in tabular or graphical form)

3.2 Water level detectors

3.2.1 Water level detectors are to be provided on livestock carriers in accordance with the requirements in Pt.4, Ch. 3, Sec. 3.6 of the Rules.

3.3 Hull Girder Strength

3.3.1 In addition to compliance with the applicable requirements of Part 3 of the Rules, the following are to be taken cognizance of:

.1 In general, the decks and platform decks above the strength deck used for the carriage of livestock need not be taken into account for the calculation of the section modulus.

.2 In general, the movable or collapsible structural elements above the strength deck used for the stocking and the distribution of livestock on decks or platform decks are not a part of Classification.

3.4 Protection of cargo sides by battens

3.4.1 These requirements are applicable to sides in cargos spaces of livestock carriers.

3.4.2 In the case of transversely framed sides, longitudinal battens formed by spaced planks are to be fitted to the frames by means of clips.

3.4.3 Where sides are longitudinally framed, battens are to be fitted vertically.

3.4.4 Battens are to extend from the bottom of the cargo space to at least the underside of the beam knees.

3.4.5 Cargo battens are to be not less than 50 [mm] in thickness and 150 [mm] in width. The space between the battens is not to exceed 300 [mm].

Section 4

Systems serving Livestock Spaces

4.1 General

4.1.1: A vessel that is permanently equipped for the carriage of livestock is to be fitted with systems and equipment that ensure the maintenance of livestock services at a level necessary for the welfare of the livestock. These would include facilities and systems intended for:

- the supply of food, water and fresh air to livestock;
- cleaning of livestock spaces;
- draining and outside discharging of the sewage effluents produced by livestock

4.1.2 In addition to the provisions of this Section, piping systems are to comply with the requirements in Pt. 4, Ch. 2 and Ch. 3 of the Rules.

4.2 Ventilation System

4.2.1 Each enclosed space for the carriage of livestock is to have a mechanical ventilation system which provides efficient air circulation in all parts of that space and which is of sufficient capacity to change the entire volume of air in that space, as follows:

- where the minimum clear height in the space is 2 [m] or less, at a rate of not less than 40 times per hour;
- where the minimum clear height in the space is 3.20 [m] or more, at a rate of not less than 26 times per hour, and

- where the minimum clear height in the space is between 2 [m] and 3.20 [m] at a rate proportional to those specified above. This may be obtained by linear interpolation.

The total volume of the enclosed space is to include all the space contained between the vessel's side plating, bulkheads, tank top or decks enclosing the space, less the volume of any tank or trunk that is airtight within the space and no deduction is to be made in respect of the space occupied by livestock, pens or other livestock fittings.

4.2.2 A space for the carriage of livestock that is unenclosed, is to be provided with a mechanical ventilation system if

(i) the minimum clear height in the space is 2 [m] or less, or

(ii) because of a partial enclosure of the space, the natural ventilation is restricted.

The system is to be of sufficient capacity to change the entire volume of air in that space at a rate of 75 percent of the rates specified in 4.2.1.

4.2.3 A mechanical ventilation system must distribute air so that the whole of any livestock space is efficiently ventilated. The mechanical ventilation system is to be capable of providing a minimum air velocity across any part of a pen from a source of supply of not less than 0.5 [m/ sec].

4.2.4 Air intakes are to be so sited that air supplied to the livestock spaces is as clean and fresh as practicable and are to be effectively protected against blockage. Air exhaust outlets are to be sited as high as practicable and clear of accommodation structures.

4.2.5 Ventilators serving livestock spaces are to remain open in all weather conditions while livestock are on board. The height of ventilator coamings is to be in accordance with the requirements of Part 3 Chapter 13 Section 2.3, as these ventilators would be kept open in all weather conditions.

4.2.6 Ventilation circuits are to be supplied by at least two independent fans of such a capacity as to maintain the ventilation of all the spaces as required by 4.2.1 and 4.2.2 with one fan out of action.

4.2.7 Notwithstanding the above provisions, if a mechanical ventilation system is provided with adequate spare parts, the provision of only one fan is acceptable. Adequate spare parts are to be interpreted as including for each type of fan: one set of bearings; one rotor or impeller; and one complete motor.

4.2.8 Electrical supplies from both main and secondary sources of power are to be supplied to each group starter panel, with both supplies being as widely separated as practicable and neither passing through any space containing any part of the other source of power. Interlocks at each group starter are to prevent simultaneous supply by both sources of power.

4.2.9 The livestock services switchboard and ventilation fan group starters are to be electrically subdivided where practicable, in separate compartments, to provide redundancy and limited supply of ventilation and/or services to each livestock deck in the event of switchboard failure.

4.3 Fodder Arrangements

4.3.1 Spaces intended for livestock (including pens, stalls or similar fittings) are to be provided with receptacles for feeding and watering the animals concerned.

4.3.2 The receptacles are to be capable of containing at least 33 per cent of the daily allowance of fodder and water for the number of animals contained in the space (pen, stall or similar fitting).

4.3.3 A receptacle provided in accordance with 4.3.1 and 4.3.2 is to be:

- suitable for the species of livestock;
- readily accessible to the livestock;
- capable of being serviced from outside the pen, stall or other fitting;
- so installed as to not impede ventilation; and
- so constructed and positioned, that fodder dust is not disturbed by the flow of ventilation.

4.3.4 If the fodder distribution system is dependent on electric power, the system is to be capable of being powered by both the main and secondary sources of supply. It should also be able to operate if a fire or other emergency occurs in the space containing the main source of power.

4.4 Fresh Water Systems

4.4.1 All livestock spaces are to be provided with fresh water service.

4.4.2 The fresh water system is to include one main supply pump and one standby pump, of a capacity sufficient to continuously supply fresh water to the livestock.

When the water supply system is not automatic, the standby pump may be replaced by a portable pump ready to be connected to at least one fresh water tank.

4.4.3 If the fresh water system is dependent on electric power, it is to be powered by both the main and secondary sources of power and is to be able to continue to operate despite a fire or other casualty in the space containing the main source of power. One pump may be located in the space occupied by the main source of power and supplied by that source of power. The other is to be able to maintain supply despite a fire or other casualty affecting the space occupied by the main source of power.

4.4.4 When the water supply is automatic, water receptacles are to be fitted with means of automatic water level control and devices to avoid the return of water from the receptacle to the fresh water tank.

4.4.5 The fresh water system serving the livestock spaces is to be totally independent from the fresh water system serving the spaces intended for the crew.

4.5 Water washing system

4.5.1 A water washing system is to be provided with appropriate connections to wash the livestock spaces.

4.6 Drainage and discharge of sewage

4.6.1 Each space intended for the livestock is to be fitted with a pipe or gutter of sufficient size to drain the sewage and the washing effluents.

4.6.2 Drainage arrangements are to be such that fluids drained from a pen are, as far as practicable, kept clear of other pens and associated working and access spaces.

Where necessary, drainage gutters and upper parts of the draining pipes are to be covered by a strainer plate. In addition, drainage pipelines are to be so arranged that the drainage system can still be used with the ship's trim by bow or stern.

4.6.3 The drainage system serving the livestock spaces is to be independent from any piping system serving the other spaces of the ship, and in particular from the bilge system.

4.6.4 The pipes and other components of the draining system are to be made of a material resistant to the corrosion due to the effluents.

4.6.5 Essential drainage tanks, wells and the top of drainage pipes in a vessel are to be accessible from outside livestock pens for the purpose of inspection and cleaning.

4.6.6 Pumps and ejectors serving the drainage tanks or wells are to be capable of conveying semi-solid matter.

4.6.7 All electrical equipment fitted to meet the requirements of 4.6 are to be capable of being operated by both the primary and the secondary sources of power.

Section 5

Fire-fighting Arrangements in Livestock Spaces

5.1 Fire hydrants and fire hoses

5.1.1 The number and position of the hydrants are to be such that at least two jets of water not emanating from the same hydrant may reach any part of the spaces intended for the livestock. At least one of these jets is to be from a single length of hose without the necessity for hoses to pass over or through pens.

5.1.2 The fire hydrants referred to in 5.1.1 are to be connected to the fire main provided on the vessel.

5.1.3 A fire hose is to be provided in an enclosed space for each hydrant and in any other space or on a deck for each 50 [m] length, or part thereof, of space or deck.

5.1.4 Each fire hose is to be provided with the necessary connections and a nozzle capable of directing water in the form of a spray and a jet.

5.1.5 Each hose is to be capable of being connected to any hydrant and to any other hose (other than hydrants and hoses within the engine room or accommodation spaces).

5.1.6 Fire hoses are to be located in conspicuous locations, near the hydrants and close to the entrances or access to the spaces.

5.2 Additional fire-fighting means

5.2.1 Livestock structures, including livestock decks and containment structures but excluding livestock services such as water pipes and feed troughs, are to be constructed of non-combustible materials.

5.2.2 If hay or straw is carried or used in a livestock space, one of the following fire-fighting means is to be provided:

a. a fixed water fire-fighting system, or

b. portable water extinguishers spaced not more than 18 [m] apart, one of which is positioned at the entrance of the space concerned.

5.2.3 Where electrical equipment other than that referred to in Section 6 is located in an enclosed livestock space, suitable fire-fighting means are to be provided.

5.2.4 Where hay, straw, other foodstuff or bedding of a flammable nature is used or carried, notices shall be prominently posted prohibiting smoking or the use of naked lights in a space in which any such substance is located.

Section 6

Electrical Equipment

6.1 General

6.1.1 In addition to the applicable requirements of Pt. 4, Ch. 8 of the Rules, electrical equipment of livestock carriers is to comply with the provisions of this Section.

6.2 Sources of Electrical Power

6.2.1 The main source of power as specified in Pt. 4, Ch. 8 is to be provided and all electrical auxiliary services (including livestock services) necessary for maintaining the vessel in normal operational and habitable conditions are to be ensured without recourse to the emergency source of electrical power.

6.2.2 The secondary source of power is to meet the following requirements:

.1 The secondary source of power is to be located in a space that is not contiguous with any space containing the main source of power or part thereof, and be independent of any services provided from or through any such space. In case of a fire or other casualty in any space containing the

main source of power or any part thereof, the secondary source of power must be capable of supplying power to livestock services for a period of 72 hours.

.2 The prime mover of secondary source of power is to be capable of supplying power to the system within 15 [min] in the failure of main source of power. The prime mover may be started by an effective arrangement powered by an independent source of energy or the emergency source of power complying with the requirements of Pt. 4, Ch. 8, C1. 2.8.1, 2.8.4 and 2.8.9.1

.3 Instructions are to be provided for the changeover between main and secondary sources of power and vice-versa. A copy of such instructions is to be displayed in the space containing the livestock source of power, and is to be readable under the emergency lighting required by Pt. 4, Ch. 8, Cl. 2.8.9.1 b). The instructions are to detail, among other things, starting method, switchboard changeover and electrical supply changeover to livestock services.

.4 Cables of secondary source of power are to be kept away from cables of main source of power, as far as practicable and they are not to pass through the same space, in general.

6.3 Lighting

6.3.1 Adequate lighting (at least 20 [lux]) is to be provided in livestock spaces, passageways between pens and access routes between or to those livestock spaces.

6.3.2 Fixed or portable lamps providing adequate illumination (at least 110 [lux]), powered by the vessel's electrical system are to be provided in any pen in which livestock are carried, to facilitate the close inspection of livestock.

6.3.3 An emergency lighting system, that is automatically activated on the failure of the main electrical installation, is to be provided in all parts of the vessel where livestock is carried, passageways between pens and access routes between or from those parts.

The emergency lighting is to be capable of giving a level of illumination of at least 8 [lux], in all passageways and access routes for a continuous period of not less than 15 [min]. The lamp casings on light fittings for the emergency lighting system are to be painted red for ease of identification.

6.3.4 If fixed lighting is provided in a part of a vessel above the uppermost continuous deck then that lighting is to be capable of being controlled from the navigating bridge.

6.3.5 Light fittings are to be

- waterproof and
- either;
  - of sufficient strength and fitted with protective sheathing outside to resist damage by livestock, or
  - placed beyond possible contact by livestock.

6.4 Equipment for use in dust laden atmosphere

6.4.1 Electrical equipment and cables installed in areas where flammable dusts may be present (such as spaces used for the storage or handling of bulk fodder) are to comply with the requirements of Pt.4, Ch. 8, Section 11.

6.4.2 Lighting or power points for portable lighting, in a space used for carriage of fodder in bulk, are to be controlled by switches situated on the navigating bridge or at the fodder-handling machinery control station and indicator lights are to be provided to show when power is supplied to the lighting or power point.

Chapter 1 : General

Section 1 : General

1.1 Scope

1.2 Documentation

1.3 Requirements applicable to existing ships

1.4 Applicable requirements depending on ship type

1.5 Application of requirements for tankers

Section 2 : Fire Safety Objectives and Functional Requirements

2.1 Fire safety objectives

2.2 Functional requirements

2.3 Achievement of the fire safety objectives

Section 3 : Definitions

Chapter 2 : Prevention of Fire and Explosion

Section 1 : Probability of Ignition

1.1 Purpose

1.2 Arrangements for oil fuel, lubrication oil and other flammable oils

1.2.1 Limitations in the use of oils as fuel

1.2.2 Arrangements for oil fuel

1.2.3 Arrangements for lubricating oil

1.2.4 Arrangements for other flammable oils

1.2.5 Arrangements for oil fuel in periodically unattended machinery spaces

1.3 Arrangements for gaseous fuel for domestic purpose

1.4 Miscellaneous items of ignition sources and ignitability

1.4.1 Electric radiators

1.4.2 Waste receptacles

1.4.3 Insulation surfaces protected against oil penetration

1.4.4 Primary deck coverings

1.4.5 Films

1.5 Cargo areas of tankers

1.5.1 Separation of cargo oil tanks

1.5.2 Restriction on boundary openings

1.5.3 Cargo tank venting

1.5.4 Ventilation

1.5.5 Inert gas systems

1.5.6 Inerting, purging and gas-freeing

1.5.7 Gas measurement and detection

1.5.8 Air supply to double hull and double bottom spaces

1.5.9 Protection of cargo area

1.5.10 Protection of cargo pump rooms

Section 2 : Fire Growth Potential

2.1 Purpose

2.2 Control of air supply and flammable liquid to the space

2.2.1 Closing appliances and stopping devices of ventilation

2.2.2 Means of control in machinery spaces

2.2.3 Additional requirements for means of control in periodically unattended machinery spaces

2.3 Fire protection materials

2.3.1 Use of non-combustible materials

2.3.2 Use of combustible materials

2.3.3 Furniture in stairway enclosures of passenger ships

2.3.4 Furniture and furnishings on cabin balconies of passenger ships

3.7.5 Exhaust ducts from galley ranges

3.7.6 Ventilation rooms securing machinery spaces of category A containing internal combustion machinery

3.7.7 Ventilation systems for laundries in passenger ships carrying more than 36 passengers

Section 4 : Fire Fighting

4.1 Purpose

4.2 Water supply systems

4.2.1 Fire mains and hydrants

4.2.2 Fire pumps

4.2.3 Fire hoses and nozzles

4.3 Portable fire extinguishers

4.3.1 Type and design

4.3.2 Arrangement of fire extinguishers

4.3.3 Spare charges

4.4 Fixed fire extinguishing systems

4.4.1 Types of fixed fire extinguishing systems

4.4.2 Closing appliances for fixed gas fire-extinguishing systems

4.4.3 Storage rooms of fire-extinguishing medium

4.4.4 Water pumps for other fire-extinguishing systems

4.5 Fire extinguishing arrangements in machinery spaces

4.5.1 Machinery spaces containing oil-fired boilers or oil fuel units

4.5.2 Machinery spaces of Category A containing internal combustion machinery

4.5.3 Machinery spaces containing steam turbines or enclosed steam engines

4.5.4 Other machinery spaces

4.5.5 Additional requirements for passenger ships

4.5.6 Fixed local application fire-fighting systems

4.6 Fire extinguishing arrangements in control stations, accommodation and service spaces

4.6.1 Sprinkler and water spray systems in passenger ships

4.6.2 Sprinkler systems for cargo ships

4.6.3 Spaces containing flammable liquid

4.6.4 Deep-fat cooking equipment

4.7 Fire extinguishing arrangements in cargo spaces

4.7.1 Fixed gas fire-extinguishing systems for general cargo

4.7.2 Fixed gas fire-extinguishing systems for dangerous goods

4.7.3 Firefighting for ships constructed on or after 1 January 2016 designed to carry containers on or above the weather deck

4.8 Cargo tank protection

4.8.1 Fixed deck foam systems

4.9 Protection of cargo pump rooms in tankers

4.9.1 Fixed fire-extinguishing systems

4.9.2 Quantity of fire-extinguishing medium

4.10 Fire fighter's outfits

4.10.1 Types of fire-fighter’s outfits

4.10.2 Number of fire-fighter’s outfits

4.10.3 Storage of fire-fighter’s outfits

4.10.4 Fire-fighter’s communication

IR4.11 Ships not fitted with propelling machinery

Section 5 : Structural Integrity

5.1 Purpose

5.2 Material of hull, superstructures, structural bulkheads, decks and deckhouses

5.3 Structure of aluminium alloy

5.4 Machinery spaces of category A

5.4.1 Crowns and casings

5.4.2 Floor plating

5.5 Materials of overboard fittings

5.6 Protection of cargo tank structure against pressure or vacuum in tankers

5.6.1 General

5.6.2 Openings for small flow by thermal variations

5.6.3 Safety measures in cargo tanks

5.6.4 Size of vent outlets

Chapter 4 : Escape

Section 1 : Notification of Crew and Passengers

1.1 Purpose

1.2 General emergency alarm system

1.3 Public address systems in passenger ships

Section 2 : Means of Escape

2.1 Purpose

2.2 General requirements

2.3 Means of escape from control stations, accommodation and service spaces

2.3.1 General requirements

2.3.2 Means of escape in passenger ships

2.3.3 Means of escape in cargo ships

2.3.4 Emergency escape breathing devices

2.4 Means of escape from machinery spaces

2.4.1 Means of escape on passenger ships

2.4.2 Means of escape on cargo ships

2.4.3 Emergency escape breathing devices

2.5 Means of escape on passenger ships from special category and open ro-ro spaces to which any passengers carried can have access

2.6 Means of escape from ro-ro spaces

2.7 Additional requirements for ro-ro passenger ships

2.7.1 General

2.7.2 Instruction for safe escape

2.7.3 Strength of handrails and corridors

Chapter 5 : Operational Requirements

Section 1 : Operational Readiness and Maintenance

1.1 Purpose

1.2 General requirements

1.3 Additional requirements for passenger ships

1.4 Additional requirements for tankers

Section 2 : Instructions, Onboard Training and Drills

2.1 Purpose

2.2 General requirements

2.2.1 Instructions, duties and organization

2.2.2 Onboard training and drills

2.2.3 Training manuals

2.2.4 Fire control plans

2.3 Additional requirements for passenger ships

2.3.1 Fire drills

2.3.2 Fire control plans

Section 3 : Operations

3.1 Purpose

3.2 Fire safety operational booklets

3.3 Additional requirements for tankers

3.3.1 General

3.3.2 Procedures for cargo tank purging and/or gas-freeing

3.3.3 Operation of inert gas system

Chapter 6 : Alternative Design and Arrangements

Section 1 : Alternative Design and Arrangements

1.1 Purpose

1.2 General

1.3 Engineering analysis

1.4 Evaluation of the alternative design and arrangements

1.5 Exchange of information

1.6 Re-evaluation due to change of conditions

Chapter 7 : Special Requirements

Section 1 : Helicopter Facilities

1.1 Purpose

1.2 Application

1.3 Structure

1.3.1 Construction of steel or other equivalent material

1.3.2 Construction of aluminium or other low melting point metals

1.4 Means of escape

1.5 Fire fighting appliances

1.6 Drainage facilities

1.7 Helicopter refuelling and hangar facilities

1.8 Operations manual and fire-fighting service

Section 2 : Carriage of Dangerous Goods

2.1 Purpose

2.2 General requirements

2.3 Special requirements

2.3.1 Water supplies

2.3.2 Sources of ignition

2.3.3 Detection system

2.3.4 Ventilation arrangement

2.3.5 Bilge pumping

2.3.6 Personnel protection

2.3.7 Portable fire extinguishers

2.3.8 Insulation of machinery space boundaries

2.3.9 Water spray system

2.3.10 Separation of ro-ro spaces

2.4 Document of compliance

Section 3 : Protection of Vehicle, Special Category and Ro-ro Spaces

3.1 Purpose

3.2 General requirements

3.2.1 Application

3.2.2 Basic principles for passenger ships

3.3 Precaution against ignition of flammable vapours in closed vehicle spaces, closed ro-ro spaces and special category spaces

3.3.1 Ventilation systems

3.3.2 Electrical equipment and wiring

3.3.3 Electrical equipment and wiring in exhaust ventilation ducts

3.3.4 Other ignition sources

3.3.5 Scuppers and discharges

3.4 Detection and alarm

3.4.1 Fixed fire detection and fire alarm systems

3.4.2 Sample extraction smoke detection systems

3.4.3 Special category spaces

3.5 Structural protection

3.6 Fire extinction

3.6.1 Fixed fire-extinguishing systems

3.6.2 Portable fire extinguishers

Section 4 : Requirements for vehicle carriers carrying as cargo motor vehicles with compressed hydrogen or natural gas in their tanks for their own propulsion

4.1 Purpose

4.2 Application

4.3 Requirements for spaces intended for carriage of motor vehicles with compressed

natural gas in their tanks for their own propulsion as cargo

4.4 Requirements for spaces intended for carriage of motor vehicles with compressed hydrogen in their tanks for their own propulsion as cargo

4.5 Detection

Section 5 : Casualty Threshold, Safe Return to Port and Safe Areas

5.1 Application

5.2 Purpose

5.3 Casualty threshold

5.4 Safe return to port

IR5.4.1 Qualitative failure analysis for propulsion and steering on passenger ships

5.5 Safe area(s)

Section 6 : Design Criteria for Systems to Remain Operational after a Fire Casualty

6.1 Application

6.2 Purpose

6.3 Systems

Section 7 : Safety Centre on Passenger Ships

7.1 Application

7.2 Purpose

7.3 Location and arrangement

7.4 Layout and ergonomic design

7.5 Communications

7.6 Control and monitoring of safety systems

Chapter 8 : Fire Safety Systems Code

Preamble

Section 1 : General

1.1 Application

1.2 Definitions

1.3 Use of equivalents and modern technology

1.4 Use of toxic extinguishing media

Section 2 : International Shore Connections

2.1 Application

2.2 Engineering specifications

Section 3 : Personnel Protection

3.1 Application

3.2 Engineering specifications

3.2.1 Fire-fighter's outfit

3.2.2 Emergency escape breathing devices (EEBD)

Section 4 : Fire Extinguishers

4.1 Application

4.2 Engineering specifications

4.2.1 Fire extinguisher

4.2.2 Portable foam applicators

Section 1

General

1.1 Scope

1.1.1 The requirements of this part generally apply to ships of the following categories to be classed for unrestricted service :

- passenger ships
- cargo ships of 500 gross tons and over.

In case of Special Trade Passenger Vessels, consideration will be given to any exemptions granted by the National Statutory Authorities. (In such cases full compliances with the IMO Rules annexed to the Special Trade Passenger Ships, 1971 and the Protocol on Space Requirements for Special Trade Passenger Ships, 1973; is normally required).

Consideration will also be given to any exemptions granted by the National Statutory Authorities where the sheltered nature and conditions of normal operation are such as to render the application of any specific requirements of this part unreasonable or unnecessary.

Requirements for Cargo Ships below 500 GT will be specially considered, however, as a minimum, these are not to be less than that required by the National Statutory Authorities.

1.1.2 Alternative fire safety design and arrangements which may be proposed in lieu of prescriptive requirements given in Ch.2, 3, 4, 5 or 7 are to comply with the requirements in Ch.6.

1.1.3 Whilst the requirements of this part are considered to meet the Regulations of the International Convention for the Safety of Life at Sea (SOLAS), 1974, and applicable amendments, attention is, however, be given to any relevant requirements of the National Statutory Authority.

1.1.4 Consideration will be given to acceptance of the following as an alternative to the requirements of this part:

a) Requirements of the National Statutory Authority.
b) Fire insulating materials, fire fighting appliances and equipment approved by the National Statutory Authority.

1.1.5 A list of IMO MSC Circulars and Assembly Resolutions referred to in this part is given at the end of this chapter (Table 1).

1.2 Documentation

1.2.1 The plans and particulars detailed in 1.2.2 to 1.2.4 where applicable, are to be submitted for approval, together with all additional relevant information such as gross tonnage and number of passengers, date of build (in case of existing ships), arrangement of helicopter deck etc.

1.2.2 For fire protection, the following plans and information are to be submitted :

a) A statement of the method of structural fire protection adopted indicating compliance with the regulations;

b) A general arrangement plan showing the main fire zones, escape stairways and the structural fire protection bulkheads and decks within the main fire zones, including the engine and boiler rooms, the galleys, paint stores, navigating bridge, radio room, fire fighting control room, emergency generator rooms and battery locker;

c) A plan showing the details of construction of the fire protection bulkheads and decks and the particulars of any surface laminates employed;

d) A plan showing the construction of the fire doors;

e) A ventilation plan showing the ducts and any dampers in them, and the position of the controls for stopping the system;

f) A plan showing the sprinkler system and/or detection system, as applicable;

g) A plan showing the remote control for the fire doors, if applicable;

h) A plan showing the location and arrangement of the emergency stop for the oil fuel unit pumps and for closing the valves on the pipes from oil fuel tanks;

i) A plan of the fire alarm system;

j) Copies of the certificates of approval by National Authorities in respect of all 'A' and 'B' Class fire divisions, non-combustible materials and materials having low flame-spread characteristics, etc., which are to be used but have not been approved by IRS.

1.2.3 For fire extinguishing, the following plans are to be submitted:

a) A general arrangement plan showing the disposition of all the fire fighting equipment including the fire main, the fixed fire extinguishing systems in the cargo holds, on deck and in the machinery spaces; the disposition of the portable and non-portable extinguishers and the types used; and the position and details of the firemen's outfits;

b) A plan showing the layout and construction of the fire main, including the main and emergency fire pumps, isolating valves, pipe sizes and materials; the international shore connections and the cross connections to any other system;

c) A plan showing details of each fixed fire fighting system, including calculations for the quantities of the media used and the proposed rates of application.

1.2.4 For fire control, plans as required by Ch.5, 2.2.4.

1.3 Requirements applicable to existing ships

1.3.1 Unless expressly provided otherwise, for ships constructed before 1 July 2012 the requirements which are applicable under Chapter II-2 of the International Convention for the Safety of Life at Sea, 1974, as amended by resolutions MSC.1(XLV), MSC.6(48), MSC.13(57), MSC.22(59), MSC.24(60), MSC.27(61), MSC.31(63) MSC.57(67), MSC.99(73), MSC.134(76), MSC.194(80), MSC.201(81), MSC.216(82), MSC.256(84), MSC.269(85) and MSC.291(87) are to be complied with.

1.3.2 Ships constructed before 1 July 2002 are also to comply with:

.1 paragraphs 1.5.5 and 1.5.7 as appropriate; (regarding gas freeing of combination carriers and hydro-carbon gas detection systems in tankers);

.2 Ch.4, 2.3.4.2 to 2.3.4.5, 2.4.3 and Ch.5, (except 3.3.2.2 and 3.3.2.3) as appropriate, not later than the date of the first survey after 1 July 2002; (regarding emergency escape breathing devices and operational requirements for fire safety);

.3 Ch.3, 4.4.1.3 and 4.6.4 for new installations only; (regarding prohibition of Halon and safety of deep fat cooking equipment);

.4 Ch.3, 4.5.6 not later than 1 October 2005 for passenger ships of 2,000 gross tonnage and above. (regarding fixed local application fire fighting systems in machinery spaces);

.5 Ch.2, 2.3.1.3.2 (regarding linings, ceilings, partial bulkheads / decks for separating adjacent cabin balconies) and 2.3.4 (regarding furniture and furnishings on cabin balconies) to passenger ships not later than the date of the first survey after 1 July 2008; and

.6 Part 5, Ch 2, 8.2.6 (regarding portable instruments for gas measurement).

1.3.3 Ships constructed on or after 1 July 2002 and before 1 July 2010 are to comply with paragraphs 7.1.1, 7.4.4.2, 7.4.4.3 and 7.5.2.1.2 of SOLAS Regulation II-2/9, as adopted by Resolution MSC.99(73).

(Corresponding clauses 3.7.1.1, 3.7.4.4.2, 3.7.4.4.3 and 3.7.5.2.1.2 of Part 6, Chapter 3 of the previous versions (2002 to 2009) of these rules).

1.3.4 The following ships, with cargo spaces intended for the carriage of packaged dangerous goods, are to comply with Ch.7, Cl.2.3, except when carrying dangerous goods specified as classes 6.2 and 7 and dangerous goods in limited quantities* and excepted quantities** in accordance with Table 2.1 and 2.3 of Ch.7, Section 2, not later than the date of the first renewal survey on or after 1 January 2011:

* Refer to Chapter 3.4 of the IMDG Code.
** Refer to Chapter 3.5 of the IMDG Code.

a) cargo ships of 500 gross tonnage and upwards and passenger ships constructed on or after 1 September 1984 but before 1 January 2011; and

b) cargo ships of less than 500 gross tonnage constructed on or after 1 February 1992 but before 1 January 2011;

and not withstanding the above provisions:

c) cargo ships of 500 gross tonnage and upwards and passenger ships constructed on or after 1 September 1984 but before 1 July 1986 need not comply with Ch.7, Cl.2.3.3 provided that they comply with SOLAS Ch.II-2 regulation 54.2.3 as adopted by resolution MSC.1(XLV) (SOLAS 1981 amendments);

d) cargo ships of 500 gross tonnage and upwards and passenger ships constructed on or after 1 July 1986 but before 1 February 1992 need not comply with Ch.7, Cl.2.3.3 provided that they comply with SOLAS Ch.II-2 regulation 54.2.3 as adopted by resolution MSC.6(48) (SOLAS 1983 amendments);

e) cargo ships of 500 gross tonnage and upwards and passenger ships constructed on or after 1 September 1984 but before 1 July 1998 need not comply with Ch.7, Cl. 2.3.10.1 and Cl. 2.3.10.2; and

f) cargo ships of less than 500 gross tonnage constructed on or after 1 February 1992 but before 1 July 1998 need not comply with Ch.7, Cl.2.3.10.1 and 2.3.10.2.

g) cargo ships of 500 gross tonnage and upwards and passenger ships constructed on or after 1 February 1992 but before 1 July 2002 need not comply with Ch 7, 2.3.3 provided that they comply with SOLAS Ch.II-2 regulation 54.2.3 as adopted by resolution MSC.13(57)

h) cargo ships of 500 gross tonnage and upwards and passenger ships constructed on or after 1 September 1984 but before 1 July 2002 need not comply with Ch 7, 2.3.1, 2.3.5, 2.3.6, 2.3.9, provided that they comply with SOLAS Ch.II-2 regulations 54.2.1, 54.2.5, 54.2.6, 54.2.9 as adopted by resolution MSC.1(XLV).

1.3.5 Ships constructed before 01 July 2012 are to also comply with requirements of Chapter 3, 4.10.1.2.

1.3.6 Vehicle carriers constructed before 1 January 2016, including those constructed before 1 July 2012, are to comply with Pt 6, Ch 7, 4.2.2.

1.3.7 Tankers constructed before 1 January 2016, including those constructed before 1 July 2012, are to comply with Pt 6, Ch 5, 3.3.3 except 3.3.3.3.

1.3.8 Pt 6, Ch 2, 1.5.5.1.1 and 1.5.5.1.3 apply to ships constructed on or after 1 January 2002 but before 1 January 2016, and regulation 1.5.5.2.1 applies to all ships constructed before 1 January 2016

1.3.9 Pt.6, Ch.3, 4.5.1.2.2 applies to ships constructed before 1 January 2020, including those constructed before 1 July 2012.

1.4 Applicable requirements depending on ship type

Unless expressly provided otherwise:

.1 requirements not referring to a specific ship type apply to ships of all types; and

.2 requirements referring to "tankers" apply to tankers (see 3.48 for definition), however these are also subject to the requirements specified in paragraph 1.5 below.

1.5 Application of requirements for tankers

1.5.1 Requirements for tankers in this part are to apply to tankers carrying

a) crude oil or

b) petroleum products having a flashpoint not exceeding 60°C (closed cup test), as determined by an approved flashpoint apparatus and a Reid vapour pressure which is below the atmospheric pressure or

c) other liquid products having a similar fire hazard.

(Also see 3.48 for definition of 'tanker').

1.5.2 Where liquid cargoes other than those referred to in paragraph 1.5.1 or liquefied gases which introduce additional fire hazards are intended to be carried, additional safety measures are to be provided in accordance with the requirements of Pt.5, Ch.3 and Ch.4.

1.5.2.1 A liquid cargo with a flashpoint of not exceeding 60°C for which a regular foam firefighting system complying with the Fire Safety Systems Code is not effective, is considered to be a cargo introducing additional fire hazards in this context. The following additional measures are required:

.1 the foam is to be of alcohol resistant type;

.2 the type of foam concentrates for use in chemical tankers is to be approved by the National Statutory Authority (Refer to the Guidelines for performance and testing criteria and surveys of expansion foam concentrates for fire extinguishing systems for chemical tankers (MSC/Circ.799)); and

.3 the capacity and application rates of the foam extinguishing system is to comply with Pt.5, Ch.3, Sec.11, except that lower application rates may be accepted based on performance tests. For tankers fitted with inert gas systems, a quantity of foam concentrate sufficient for 20 min of foam generation may be accepted. (Refer to the Information on flashpoint and recommended fire-fighting media for chemicals to which neither the IBC nor BCH Codes apply (MSC/Circ. 553)).

1.5.2.2 For the purpose of this Section a liquid cargo with a vapour pressure greater than 1.013 bar absolute at 37.8°C is considered to be a cargo introducing additional fire hazards and ships carrying such substances are to comply with paragraph 15.14 of Pt.5, Ch.3. When such ships operate in restricted areas and at restricted times, the requirements for refrigeration systems may be waived in accordance with paragraph 15.14.3 of Pt.5, Ch.3.

1.5.3 Liquid cargoes with a flashpoint exceeding 60°C, other than oil products or liquid cargoes subject to the requirements of Pt.5, Ch.3, are considered to constitute a low fire risk, not requiring the protection of a fixed foam extinguishing system.

1.5.4 Tankers carrying petroleum products with a flashpoint exceeding 60°C are to comply with the requirements provided in Ch.3, 4.2.1.4.4 and 4.10.2.3 and the requirements for cargo ships other than tankers, except that, in lieu of the fixed fire extinguishing system required in Ch.3, 4.7 they are to be fitted with a fixed deck foam system which is to comply with the provisions of the Fire Safety Systems Code.

1.5.5 Combination carriers are not to carry cargoes other than oil unless all cargo tanks are empty of oil and gas freed or unless the arrangements in each case are approved in accordance with the Guidelines for inert gas systems (MSC/Circ.353), as amended by (MSC/Circ.387).

1.5.6 Chemical tankers and gas carriers are to comply with the requirements for tankers, except where alternative and supplementary arrangements are provided in accordance with Pt.5, Ch.3 and Ch.4 as appropriate.

1.5.7 The requirements of Pt.5, Ch.2, 6.4.2 and 6.4.5 and a system for continuous monitoring of the concentration of hydrocarbon gases are to be fitted on all tankers constructed before 1 July 2002 by the date of

the first scheduled dry-docking after 1 July 2002, but not later than 1 July 2005. Sampling points or detector heads are to be located in suitable positions in order that potentially dangerous leakages are to readily detected. When the hydrocarbon gas concentration reaches a pre-set level which is not to be higher than 10% of the lower flammable limit, a continuous audible and visual alarm signal is to be automatically effected in the pump-room and cargo control room to alert personnel to the potential hazard. However, existing monitoring systems already fitted having a pre-set level not greater than 30% of the lower flammable limit may be accepted.

Section 2

Fire Safety Objectives and Functional Requirements

2.1 Fire safety objectives

2.1.1 The fire safety objectives of this part are to:

.1 prevent the occurrence of fire and explosion;
.2 reduce the risk to life caused by fire;
.3 reduce the risk of damage caused by fire to the ship, its cargo and the environment;
.4 contain, control and suppress fire and explosion in the compartment of origin; and
.5 provide adequate and readily accessible means of escape for passengers and crew.

2.2 Functional requirements

2.2.1 In order to achieve the fire safety objectives set out in paragraph 2.1 above, the following functional requirements are embodied in the regulations of this chapter as appropriate:

.1 division of the ship into main vertical and horizontal zones by thermal and structural boundaries;

.2 separation of accommodation spaces from the remainder of the ship by thermal and structural boundaries;

.3 restricted use of combustible materials;

.4 detection of any fire in the zone of origin;

.5 containment and extinction of any fire in the space of origin;

.6 identification and protection of means of escape;

.7 access for fire-fighting;

.8 ready availability of fire-extinguishing appliances; and

.9 minimization of possibility of ignition of flammable cargo vapour.

2.3 Achievement of the fire safety objectives

2.3.1 The fire safety objectives set out in paragraph 2.1 above are to be achieved by ensuring compliance with the prescriptive requirements specified in chapters 2, 3, 4, 5 and 7, or by alternative design and arrangements which comply with chapter 6. A ship will be considered to meet the functional requirements set out in paragraph 2.2 and to achieve the fire safety objectives set out in paragraph 2.1 when either:

.1 the ship's designs and arrangements, as a whole complies with the relevant prescriptive requirements in chapters, 2, 3, 4, 5 and 7;

.2 the ship's designs and arrangements, as a whole, have been reviewed and approved in accordance with chapter 6;

.3 part(s) of the ship's design and arrangements have been reviewed and approved in accordance with chapter 6 and the remaining parts of the ship comply with the relevant prescriptive requirements in chapters 2, 3, 4, 5 and 7.

Section 3

Definitions

3. For the purpose of this chapter, unless expressly provided otherwise, the following definitions are to apply:

3.1 **Accommodation spaces** are those spaces used for public spaces, corridors, lavatories, cabins, offices, hospitals, cinemas, games and hobbies rooms, barber shops, pantries containing no cooking appliances and similar spaces.

3.2 **'A' class divisions** are those divisions formed by bulkheads and decks which comply with the following criteria:

1. they are constructed of steel or other equivalent material;

2. they are suitably stiffened;

3. they are so constructed as to be capable of preventing the passage of smoke and flame to the end of the one-hour standard fire test;

4. they are insulated with approved non-combustible materials such that the average temperature of the unexposed side will not rise more than 140°C above the original temperature, nor will the temperature, at any one point, including any joint, rise more than 180°C above the original temperature within the time listed below:

Class 'A-60'	60 minutes
Class 'A-30'	30 minutes
Class 'A-15'	15 minutes
Class 'A-0'	0 minutes

IR4. Insulated “A” class bulkheads and decks used on board ships, including the means of affixing the insulation to the "A” class structural members, are to be consistent with the materials, details and arrangements used during the tests and documented in the test reports issued for the approval for that insulating material.

5. a test of prototype bulkhead or deck will be required to ensure that it meets the above requirements for integrity and temperature rise.

3.3 **Atriums** are public spaces within a single main vertical zone spanning three or more open decks.

3.4 **'B' class divisions** are those divisions formed by bulkheads, decks, ceilings or linings which comply with the following criteria:

a) they are so constructed as to be capable of preventing the passage of flame to the end of the first half hour of the standard fire test;

b) they have an insulation value such that the average temperature of the unexposed side will not rise more than 140°C above the original temperature nor will the temperature at any point, including any joint, rise more than 225°C above the original temperature, within the time listed below:

Class 'B-15'	15 minutes
Class 'B-0'	0 minutes

c) they are constructed of approved non-combustible materials and all materials entering into the construction and erection of 'B' class divisions are to be non-combustible. A division consisting of a non-combustible core and combustible veneers may be accepted as a B class division, provided that the non combustible core and veneers are tested in accordance with relevant parts of Fire Test Procedure Code described in 3.23 of this section;

d) a test of a prototype division will be required to ensure that it meets the above requirements for integrity and temperature rise.

3.5 **Bulkhead deck** is the uppermost deck upto which the transverse watertight bulkheads are carried.

3.6 **Cargo area** is that part of the ship that contains cargo holds, cargo tanks, slop tanks and cargo pump-rooms including pump-rooms, cofferdams, ballast and void spaces adjacent to cargo tanks and slop tanks and also deck areas throughout the length and breadth of the

part of the ship over the above mentioned spaces. (Also see Ch.2, IR1.5.1.1.2).

3.7 **A cargo ship** is any ship which is not a passenger ship.

3.8 **Cargo spaces** are spaces used for cargo, cargo oil tanks, tanks for other liquid cargo and trunks to such spaces.

3.9 **Central Control station** is a control station in which the following control and indicator functions are centralized:

a) fixed fire detection and alarm systems;

b) automatic sprinklers, fire detection and alarm systems;

c) fire door indicator panels;

d) fire door closures;

e) watertight door indicator panels;

f) watertight door closures;

g) ventilation fans;

h) general/fire alarms;

i) communication systems including telephones; and

j) microphones to public address system.

3.10 **'C' class divisions** are divisions constructed of approved non- combustible materials. They need meet neither requirements relative to the passage of smoke and flame nor limitations relative to the temperature rise. A division consisting of a non-combustible core and combustible veneers may be accepted as a C class division, provided that the non-combustible core and veneers are tested in accordance with relevant parts of Fire Test Procedure Code.

3.11 **Chemical tanker** is a cargo ship constructed or adapted and used for the carriage in bulk of any liquid product of a flammable nature listed in Pt.5, Ch.3 of the Rules.

3.12 **Closed ro/ro spaces** are Ro/Ro spaces which are neither open Ro/Ro spaces nor weather decks.

3.13 **Closed vehicle spaces** are vehicle spaces which are neither open vehicle spaces or weather decks.

3.14 **A combination carrier** is a cargo ship designed to carry both oil and solid cargoes in bulk.

3.15 C**ombustible material** is any material other than a non-combustible material.

3.16 **Continuous 'B' class ceilings or linings** are those 'B' class ceilings or linings which terminate only at an 'A' or 'B' class division.

3.17 **Continuously manned central control station** is a central control station which is continuously manned by a responsible member of the crew.

3.18 **Control-stations** are those spaces in which the ship's radio or main navigating equipment or the emergency source of power is located or where the fire recording or fire control equipment is centralized. Spaces where the fire recording or fire control equipment is centralized are also considered to be a **Fire Control Station**.
If the CO_2 system discharge pipes are used for the sample extraction smoke detection system, the control panel can be located in the CO_2 room provided that an indicating unit is located on the navigation bridge. Such arrangements are considered to satisfy the requirements of Pt.6 Ch 8, 10.2.4.1.2.

Notes :

1) Indicating unit has the same meaning as repeater panel and observation of smoke should be made either by electrical means or by visual on repeater panel.

2) Main navigational equipment includes, in particular, the steering stand and the compass, radar and direction-finding equipment.

3) Steering gear rooms containing an emergency steering position are not considered to be control stations.

4) Where, in the Rules in Pt.6, relevant to fixed fire extinguishing systems, there are no specific requirements for the centralization within a control station of major components of the system, such major components may be placed in

spaces which are not considered to be a control station.

5) Spaces containing, for instance, the following battery sources are to be regarded as control stations regardless of battery capacity:

.1 emergency batteries in separate battery room for power supply from black-out till start of emergency generator.

.2 emergency batteries in separate battery room as reserve source of energy to radiotelegraph installation.

.3 batteries for start of emergency generator and

.4 in general, all emergency batteries required in accordance with Pt.4, Ch.8, 2.8.

3.19 **Crude oil** is any oil occurring naturally in the earth whether or not treated to render it suitable for transportation and includes :

a) crude oil from which certain distillate fractions may have been removed; and

b) crude oil to which certain distillate fractions may have been added.

3.20 **Dangerous goods** are those goods referred to in SOLAS Regulation VII/2.

3.21 **Deadweight** is the difference in tonnes between the displacement of a ship in water of a specific gravity of 1.025 at the load water-line corresponding to the assigned summer freeboard and the lightweight of the ship.

3.22 **Fire safety systems code** means the International Code for Fire Safety Systems as adopted by the Maritime Safety Committee of the IMO by resolution MSC.98(73) and as may be amended by IMO (Section 21 to 35). Refer Ch.8.

3.23 **Fire test procedures code** means the International Code for Application of Fire Test Procedures, 2010 (2010 FTP Code) as adopted by the Maritime Safety Committee of IMO by resolution MSC.307(88), and as may be amended by IMO.

3.24 **Flashpoint** is the temperature in degrees Celsius (closed cup test) at which a product will give off enough flammable vapour to be ignited, as determined by an approved flashpoint apparatus.

3.25 **Gas carrier** is a cargo ship constructed or adapted and used for the carriage in bulk of any liquefied gas or other products of a flammable nature listed in Pt.5, Ch.4.

3.26 **Helideck** is a purpose-built helicopter landing area located on a ship including all structure, fire-fighting appliances and other equipment necessary for the safe operation of helicopters.

3.27 **Helicopter facility** is a helideck including any refuelling and hangar facilities.

3.28 **Lightweight** is the displacement of a ship in tonnes without cargo, fuel, lubricating oil, ballast water, fresh water and feed water in tanks, consumable stores, and passengers and crew and their effects.

IR3.28 The weight of mediums on board for the fixed fire-fighting systems (e.g. freshwater, CO_2, dry chemical powder, foam concentrate, etc.) are to be included in the lightweight and lightship condition.

3.29 **Low flame spread** means that the surface thus described will adequately restrict the spread of flame, this being determined in accordance with Fire Test Procedures Code.

3.30 **Machinery spaces** are all machinery spaces of category 'A' and all other spaces containing propulsion machinery, boilers, oil fuel units, steam and internal combustion engines, generators and major electrical machinery, oil filling stations, refrigerating, stabilizing, ventilation and air conditioning machinery, and similar spaces, and trunks to such spaces.

IR3.30 In cases where urea or sodium hydroxide solution tanks for selective catalytic reduction (SCR) systems, exhaust gas recirculation (EGR) systems or exhaust gas cleaning systems (EGCS) are installed in a space separated from engine room, in determining fire integrity of divisions, the solution tank space should be considered as "*similar spaces*" in the definition of "Machinery spaces" above.

3.31 **Machinery spaces of category 'A'** are those spaces and trunks to such spaces which contain:

a) internal combustion machinery used for main propulsion; or

b) internal combustion machinery used for purposes other than main propulsion where such machinery has in the aggregate a total power output of not less than 375 [kW]; or

c) any oil-fired boiler or oil fuel unit, or any oil-fired equipment other than boilers, such as inert gas generators, incinerators, etc.

3.32 **Main vertical zones** are those sections into which the hull, superstructure, and deckhouses are divided by 'A' class divisions, the mean length of which on any deck does not in general exceed 40 [m].

3.33 **Non-combustible material** is a material which neither burns nor gives off flammable vapours in sufficient quantity for self-ignition when heated to approximately 750°C, this being determined in accordance with the Fire Test Procedures Code.

3.34 **Oil fuel unit** is the equipment used for the preparation of oil fuel heated or not, for delivery to an oil fired boiler (including inert gas generators, incinerator, waste disposal unit, etc.) or to an internal combustion engine (including gas turbines) and includes any oil pressure pumps, filters and heaters dealing with oil at a pressure of more than 0.18 [N/mm^2]. Oil fuel transfer pumps are not considered as oil fuel units.

3.35 **Open ro/ro spaces** are those ro/ro spaces that are either open at both ends or have an opening at one end and are provided with adequate natural ventilation effective over their entire length through permanent openings distributed in the side plating or deckhead or from above, having a total area of at least 10% of the total area of the spaces sides.

3.36 **Open vehicle spaces** are those vehicle spaces either open at both ends, or have an opening at one end and are provided with adequate natural ventilation effective over their entire length through permanent openings distributed in the side plating or deckhead or from above, having a total area of at least 10% of the total area of the space sides.

3.37 **A passenger ship** is a ship which carries more than twelve passengers, a passenger being every person other than :

- the master and members of the crew or other persons employed or engaged in any capacity on board a ship on the business of the ship; and

- a child under one year of age.

3.38 **Prescriptive requirements** means the construction characteristics, limiting dimensions or fire safety systems specified in chapters, 2, 3, 4, 5 or 7.

3.39 **Public spaces** are those portions of the accommodation which are used for halls, dining rooms, lounges and similar permanently enclosed spaces.

3.40 **Rooms containing furniture and furnishings of restricted fire risk** are those rooms containing furniture and furnishing of restricted fire risk (whether cabins, public spaces, offices or other types of accommodation) in which :

a) case furniture such as desks, wardrobes, dressing tables, bureaux, dressers, are constructed entirely of approved non-combustible materials, except that a combustible veneer not exceeding 2 [mm] may be used on the working surface of such articles;

b) free-standing furniture such as chairs, sofas, tables, is constructed with frames of non-combustible materials;

c) draperies, curtains and other suspended textile materials have qualities of resistance to the propagation of flame not inferior to those of wool of mass 0.8 [kg/m^2], this being determined in accordance with the Fire Test Procedures Code;

d) floor coverings have low flame spread characteristics;

e) exposed surfaces of bulkheads, linings and ceilings have low flame- spread characteristics;

f) upholstered furniture has qualities of resistance to the ignition and propagation of flame, this being determined in accordance with the Fire Test Procedures Code; and

g) bedding components have qualities of resistance to the ignition and propagation of flame, this being determined in accordance with the Fire Test Procedures Code.

3.41 **Ro/ro spaces** are spaces not normally subdivided in any way and normally extending to either a substantial length or the entire length of the ship in which motor vehicles with fuel in their tanks for their own propulsion and/or goods (packaged or in bulk, in or on rail or road cars, vehicles (including road or rail tankers), trailers, containers, pallets, demountable tanks or in or on similar stowage units or other receptacles) can be loaded and unloaded normally in horizontal direction.

3.42 **A Ro-ro passenger ship** means a passenger ship with ro-ro cargo spaces or special category spaces.

3.43 **Steel or other equivalent material**. Where the words **steel or other equivalent material** occur, 'equivalent material' means any non- combustible material which, by itself or due to insulation provided, has structural and integrity properties equivalent to steel at the end of the applicable fire exposure to the standard fire test (e.g. aluminium alloy with appropriate insulation).

3.44 **Sauna** is a hot room with temperatures normally varying between 80°C - 120°C where the heat is provided by a hot surface (e.g. by an electrically-heated oven). The hot room may also include the space where the oven is located and adjacent bathrooms.

3.45 **Service spaces** are those spaces used for galleys, pantries containing cooking appliances, lockers, mail and specie rooms, store rooms, workshops other than those forming part of machinery spaces, and similar spaces and trunks to such spaces.

3.46 **Special category spaces** are those enclosed vehicle spaces above and below the bulkhead deck, into and from which vehicles can be driven and to which passengers have access. Special category spaces may be accommodated on more than one deck provided that the total overall clear height for vehicles does not exceed 10 [m].

3.47 **A standard fire test** is one in which specimens of the relevant bulkheads or decks are exposed in a test furnace to temperatures corresponding approximately to the standard time temperature curve. The test method is to be in accordance with the Fire Test Procedures Code.

3.48 **A tanker** is a cargo ship constructed or adapted for the carriage in bulk of liquid cargoes of a flammable nature.

3.49 **Vehicle spaces** are cargo spaces intended for carriage of motor vehicles with fuel in their tanks for their own propulsion.

3.50 **Weather deck** is a deck which is completely exposed to the weather from above and from at least two sides.

3.51 **Cabin balcony** is an open deck space which is provided for the exclusive use of the occupants of a single cabin and has direct access from such a cabin.

3.52 **Safe area** in the context of a casualty and from the perspective of habitability is any area(s) which is not flooded or which is outside the main vertical zone(s) in which a fire has occurred such that it can safely accommodate all persons onboard to protect them from hazards to life or health and provide them with basic services.

3.53 **Safety centre** is a control station dedicated to the management of emergency situations. Safety systems' operation, control and/or monitoring are an integral part of the safety centre.

3.54 **Fire damper** is, for the purpose of implementing Pt 6, Ch 3, 3.7, a device installed in a ventilation duct, which under normal conditions remains open allowing flow in the duct, and is closed during a fire, preventing the flow in the duct to restrict the passage of fire. In using the above definition the following terms may be associated:

.1 automatic fire damper is a fire damper that closes independently in response to exposure to fire products;

.2 manual fire damper is a fire damper that is intended to be opened or closed by the crew by hand at the damper itself; and

.3 remotely operated fire damper is a fire damper that is closed by the crew through a control located at a distance away from the controlled damper.

3.55 **Smoke damper** is, for the purpose of implementing Pt 6, Ch 3, 3.7, a device installed in a ventilation duct, which under

normal conditions remains open allowing flow in the duct, and is closed during a fire, preventing the flow in the duct to restrict the passage of smoke and hot gases. A smoke damper is not expected to contribute to the integrity of a fire rated division penetrated by a ventilation duct. In using the above definition the following terms may be associated:

.1 automatic smoke damper is a smoke damper that closes independently in response to exposure to smoke or hot gases;

.2 manual smoke damper is a smoke damper intended to be opened or closed by the crew by hand at the damper itself; and

.3 remotely operated smoke damper is a smoke damper that is closed by the crew through a control located at a distance away from the controlled damper.

3.56 **Vehicle carrier** means a cargo ship which only carries cargo in ro-ro spaces or vehicle spaces, and which is designed for the carriage of unoccupied motor vehicles without cargo.

3.57 **Helicopter landing area** is an area on a ship designated for occasional or emergency landing of helicopters but not designed for routine helicopter operations.

3.58 **Winching area** is a pick-up area provided for the transfer by helicopter of personnel or stores to or from the ship, while the helicopter hovers above the deck.

Table 1 : List of IMO MSC Circulars and Assembly Resolutions referred to in this part

MSC Circ./Assembly Resolution No.	***Description***
MSC/Circ.353	*Guidelines for inert gas systems*
MSC/Circ.387	*Revised guidelines for inert gas systems (MSC/Circ.353), as amended by MSC/Circ.387*
MSC/Circ.450/Rev.1	*Revised factors to be taking into consideration when designing cargo tank venting and gas-freeing arrangements*
MSC/Circ.451	*Guidance concerning the location of fire control plans for assistance of shoreside fire-fighting personnel*
MSC/Circ.485	*Clarification of inert gas system requirements under the Convention*
MSC/Circ. 553	*Information on flashpoint and recommended fire-fighting media for chemicals to which neither the IBC nor BCH Codes apply*
MSC.1/Circ.1312 as corrected by MSC.1/Circ.1312 Corr.1	*Revised guidelines for the performance and testing criteria and surveys of foam concentrates for fixed fire-extinguishing systems*
MSC/Circ.608/Rev.1	*Interim guidelines for open-top containerships*
MSC/Circ.670	*Guidelines for performance and testing criteria and surveys of high expansion foam concentrates for fire-extinguishing systems*
MSC.1/Circ.1395/Rev.6	*List of solid bulk cargoes for which for which a fixed gas fire-extinguishing system may be exempted or for which a fixed gas fire-extinguishing system is ineffective*
MSC/Circ.777	*Indication of the "assembly stations" in passenger ships*
MSC/Circ.798	*Guidelines for the performance and testing criteria, and surveys of medium expansion foam concentrates for fixed fire-extinguishing systems*
MSC/Circ.848 amended by MSC.1/Circ.1267	*Revised guidelines for the approval of equivalent fixed gas fire-extinguishing systems, as referred to in SOLAS 74, for machinery spaces and cargo pump rooms*
MSC/Circ.849	*Guidelines for the performance, location, use and care of emergency escape breathing devices*
MSC.1/Circ.1432 amended by MSC.1/Circ.1516	*Revised guidelines for the maintenance and inspection of fire protection systems and appliances*
MSC.1/Circ.1533	*Revised guidelines on evacuation analysis for new and existing passenger ships*
MSC/Circ.913 *MSC.1/Circ.1387 and MSC.1/Circ.1387/Corr.1*	*Guidelines for the approval of fixed water-based local application fire-fighting systems for use in category A machinery spaces* *Revised guidelines for the approval of fixed water-based local application fire-fighting systems for use in category A machinery spaces. (MSC.1/Circ.1387 and MSC.1/Circ.1387/Corr.1 Supersedes MSC/Circ.913, except that fire and component tests previously conducted in accordance with MSC/Circ.913 remain valid for the approval of new systems. Existing fixed water-based local application fire-fighting systems approved and installed based on MSC/Circ.913 should be permitted to remain in service as long as they are serviceable.)*
MSC/Circ.917 as corrected by MSC/Circ.917/Corr.1	*"Guidelines on fire safety construction in accommodation areas"*

MSC Circ./Assembly Resolution No.	***Description***
MSC/Circ.1002 as corrected by MSC/Circ.1002/Corr.1 to Corr.3 and as amended by MSC.1/Circ.1552	*Guidelines on alternative design and arrangements for fire safety*
MSC/Circ.1165 Amended MSC.1/Circ.1237 and MSC.1/Circ.1269	*Revised guidelines for the approval of fixed water based fire extinguishing systems for machinery spaces and cargo pump rooms*
MSC.1/Circ.1242	*Guidelines for the approval of fixed fire detection and fire alarm systems for cabin balconies*
MSC.1/Circ.1266	*Document of compliance with the special requirements for ships carrying dangerous goods under the provisions of regulation II-2/19 SOLAS 74, as amended*
MSC.1/Circ.1268	*Guidelines for the approval of fixed pressure water spraying and water based fire extinguishing systems for cabin balconies*
MSC.1/Circ.1430/Rev.3	*Revised Guidelines for the design and approval of fixed water-based fire-fighting systems for Ro-Ro spaces and special category spaces*
MSC.1/Circ/1275 as corrected by MSC.1/Circ.1275/Corr.1	*Unified interpretations of SOLAS Chapter II-2 on the number and arrangement of portable fire extinguishers on board ships*
MSC.1/Circ.1276/Rev.1	*Unified interpretations of SOLAS Ch.II-2*
MSC.1/Circ.1320	*Guidelines for the drainage of fire-fighting water from closed vehicle and ro-ro spaces and special category spaces of passenger and cargo ships*
A.123(V)	*Recommendation on fixed fire-extinguishing systems for special cargo spaces*
A.434(XI)	*Code of safe practice of solid bulk cargoes (BC Code)*
A.565(14)	*Recommended procedures to prevent the illegal or accidental use of low flashpoint cargo oil as fuel*
A.567(14)	*Regulation for inert gas systems on chemical tankers*
A.654(16)	*Graphical symbols for fire control plans (Refer to A.952(23) for ships constructed on or after 01 January 2004)*
A.752(18)	*Guidelines for the evaluation, testing and application of low-location lighting on passenger ships*
A.756(18)	*Guidelines on the information to be provided with fire control plans and booklets*
A.760(18) as amended by MSC.82(70)	*Symbols related to life-saving appliances and arrangements*
A.800(19) as amended by MSC.265(84) and MSC.284(86)	*Guidelines for approval of sprinkler systems*
A.1021(26)	*Code on Alerts and Indicators, 2009*
A.951(23)	*Improved guidelines for marine portable fire extinguishers*

End of Chapter

Chapter 2

Prevention of Fire and Explosion

Contents

Section

1 *Probability of Ignition*
2 *Fire Growth Potential*
3 *Smoke Generation Potential and Toxicity*

Section 1

Probability of Ignition

1.1 Purpose

The purpose of this section is to prevent the ignition of combustible materials or flammable liquids. For this purpose the following functional requirements are to be met:

.1 means are to be provided to control leaks of flammable liquids;

.2 means are to be provided to limit the accumulation of flammable vapours;

.3 the ignitability of combustible materials is to be restricted;

.4 ignition sources are to be restricted;

.5 ignition sources are to be separated from combustible materials and flammable liquids; and

.6 the atmosphere in cargo tanks is to be maintained out of the explosive range.

1.2 Arrangements for oil fuel, lubrication oil and other flammable oils

1.2.1 Limitations in the use of oils as fuel

The following limitations are to apply to the use of oil as fuel:

.1 except as otherwise permitted by this paragraph, no oil fuel with a flashpoint of less than 60°C is to be used; (Refer to IMO Resolution A.565(14));

.2 in emergency generators oil fuel with a flashpoint of not less than 43°C may be used;

.3 the use of oil fuel having a flashpoint of less than 60°C but not less than 43°C may be permitted (e.g. for feeding the emergency fire pump's engines and the auxiliary machines which are not located in the machinery spaces of category A) subject to the following:

.3.1 fuel oil tanks except those arranged in double bottom compartments are to be located outside the machinery spaces of category A;

.3.2 provisions for the measurement of oil temperature are provided on the suction pipe of the oil fuel pump;

.3.3 stop valves and/or cocks are provided on the inlet side and outlet side of the oil fuel strainers; and

.3.4 pipe joints of welded construction or of circular cone type or spherical type union joint are applied as much as possible;

.4 in cargo ships, to which SOLAS, Chapter II-1, Part G is not applicable, the use of oil fuel having a lower flashpoint than otherwise specified in 1.2.1.1, for example crude oil, may be permitted provided that such fuel is not stored in any machinery space and subject to

the approval by the Administration/IRS of the complete installation; and

.5 in ships, to which SOLAS, Chapter II-1, Part G is applicable, the use of oil fuel having a lower flashpoint than otherwise specified in 1.2.1.1 is allowed.

1.2.2 Arrangements for oil fuel

In a ship in which oil fuel is used, the arrangements for the storage, distribution and utilization of the oil fuel are to be such as to ensure the safety of the ship and persons on board and are to at least comply with the following provisions.

1.2.2.1 Location of oil fuel systems

As far as practicable, parts of the oil fuel system containing heated oil under pressure exceeding 0.18 [N/mm^2] are not to be placed in a concealed position such that defects and leakage cannot readily be observed. The machinery spaces in way of such parts of the oil fuel system are to be adequately illuminated.

1.2.2.2 Ventilation of machinery spaces

The ventilation of machinery spaces is to be sufficient under normal conditions to prevent accumulation of oil vapour. Also refer Pt.4, Ch.1, Sec.2.4.

1.2.2.3 Oil fuel tanks

.1 Fuel oil, lubrication oil and other flammable oils are not be carried in forepeak tanks, Also refer Pt.3, Ch.10, Cl.2.7.1.

.2 As far as practicable, oil fuel tanks are to be part of the ship's structure and are to be located outside machinery spaces of category A. Where oil fuel tanks, other than double bottom tanks, are necessarily located adjacent to or within machinery spaces of category A, at least one of their vertical sides is to be contiguous to the machinery space boundaries and they are preferably to have a common boundary with the double bottom tanks and the area of the tank boundary common with the machinery spaces are to be kept to a minimum. Where such tanks are situated within the boundaries of machinery spaces of category A they are not to contain oil fuel having a flashpoint of less than 60°C. In general, the use of free-standing oil fuel tanks is to be avoided. When such tanks are employed their use is to be prohibited in category A machinery spaces on passenger ships. Where permitted, they are to be placed in an oil-tight spill tray of ample size having a suitable drain pipe leading to a suitably sized spill oil tank.

.3 No oil fuel tank is to be situated where spillage or leakage therefrom can constitute a fire or explosion hazard by falling on heated surfaces.

.4 For pipes connected to tanks, refer Pt.4, Ch.3, Cl.4.4.4, 4.4.5, 4.4.6.

.5 Safe and efficient means of ascertaining the amount of oil fuel contained in any oil fuel tank are to be provided. For details, refer Pt.4, Ch.3, Sec.3.4.

.5.1 Where sounding pipes are used, they are not to terminate in any space where the risk of ignition of spillage from the sounding pipe might arise. In particular, they are not to terminate in passenger or crew spaces. As a general rule, they are not to terminate in machinery spaces. However, where IRS considers that these latter requirements are impracticable, sounding pipes may terminate in machinery spaces subject to following requirements being met:

a) an oil-level gauge is provided meeting the requirements of .5.2 below;

b) the sounding pipes terminate in locations remote from ignition hazards unless precautions are taken, such as the fitting of effective screens, to prevent the oil fuel in the case of spillage through the terminations of the sounding pipes from coming into contact with a source of ignition; and

c) the termination of sounding pipes are fitted with self-closing blanking devices and with a small-diameter self-closing control cock located below the blanking device for the purpose of ascertaining before the blanking device is opened that oil fuel is not present. Provisions are to be made so as to ensure that any spillage of oil fuel through the control cock involves no ignition hazard.

(Also refer Pt.4, Ch.3, 3.4.3 and 3.4.4).

IR.5.1.1 Oil level gauge referred at .5.1a) above need not be provided for tanks (other than double bottom tanks) having overflow system.

IR.5.1.2 The short sounding pipes are to be arranged in such a way that overflow or oil spray will not reach the vicinity of any of the machinery components like boilers, preheaters, heated surfaces, electric generators or motors with commutator or collector rings or electric appliances.

IR.5.1.3 The self-closing blanking devices are to be cocks having cylindrical plugs with weight loaded levers permanently attached and with approved arrangements for opening.

.5.2 Other oil-level gauges may be used in place of sounding pipes as per details given in Pt.4, Ch.3, Cl.3.4.2.

.5.3 The means prescribed in paragraph .5.2 above are to be maintained in the proper condition to ensure their continued accurate functioning in service.

1.2.2.4 Prevention of overpressure

Provisions are to be made to prevent overpressure in any oil tank or in any part of the oil fuel system, including the filling pipes served by pumps on board. Air and overflow pipes and relief valves are to discharge to a position where there is no risk of fire or explosion from the emergence of oils and vapour and are not to lead into crew spaces, passenger spaces nor into special category spaces, closed ro-ro cargo spaces, machinery spaces or similar spaces. Also refer Pt.4, Ch.3, Sections 3 and 4.

1.2.2.5 Oil fuel piping

.1 Oil fuel pipes and their valves and fittings are to be of steel or other approved material, except that restricted use of flexible pipes are permissible in positions where IRS is satisfied that they are necessary. Such flexible pipes and end attachments are to be of approved fire-resisting materials of adequate strength and are to be constructed to the satisfaction of IRS. For valves, fitted to oil fuel tanks and which are under static pressure, steel or spheroidal-graphite cast iron may be accepted. However, ordinary cast iron valves may be used in piping systems where the design pressure is lower than 7 bar and the design temperature is below 60°C.

IR.1 Materials other than steel may be assessed in relation to the risk of fire associated with the component and its installation. The use of materials other than steel is considered acceptable for the following applications:

1. internal pipes which cannot cause any release of flammable fluid onto the machinery or into the machinery space in case of failure, or

2. components that are only subject to liquid spray on the inside when the machinery is running, such as machinery covers, rocker box covers, camshaft end covers, inspection plates and sump tanks. It is a condition that the pressure inside these components and all the elements contained therein is less than 0.18 [N/mm^2] and that wet sumps have a volume not exceeding 100 [litres], or

3. components attached to machinery which satisfy fire test criteria according to standard ISO 19921:2005/19922:2005 or other standards acceptable to the Administration, and which retain mechanical properties adequate for the intended installation.

.2 For jacketing of external high-pressure fuel delivery lines between the high-pressure fuel pumps and fuel injectors, refer Pt.4, Ch.4, Sec.4.8.5.

.3 Oil fuel lines are not to be located immediately above or near units of high temperature including boilers, steam pipelines, exhaust manifolds, silencers or other equipment required to be insulated by 1.2.2.6. As far as practicable, oil fuel lines are to be arranged far away from hot surfaces, electrical installations or other sources of ignition and are to be screened or otherwise suitably protected to avoid oil spray or oil leakage onto the sources of ignition. The number of joints in such piping systems are to be kept to a minimum.

.4 For requirements for components of diesel engine fuel system refer Pt.4, Ch.4, 4.5.8.2.

.5 For multi-engine installations which are supplied from the same fuel source, refer to Pt.4, Ch.3, 4.10.2.4.

.6 For piping through accommodation and service spaces, refer Pt.4, Ch.3, 4.3.10.

1.2.2.6 Protection of high temperature surfaces

Refer Pt.4, Ch.1, Sec.2.3.

1.2.3 Arrangements for lubricating oil

1.2.3.1 The arrangements for the storage, distribution and utilization of oil used in pressure lubrication systems are to be such as to ensure the safety of the ship and persons onboard. The arrangements made in machinery spaces of category A and whenever practicable in other machinery spaces are at least to comply with the provisions of paragraphs 1.2.2.1, 1.2.2.3.3, 1.2.2.3.4, 1.2.2.3.5, 1.2.2.4, 1.2.2.5.1, 1.2.2.5.3 and 1.2.2.6, except that:

a) this does not preclude the use of sight-flow glasses in lubricating systems provided that they are shown by testing to have a suitable degree of fire resistance; and

b) sounding pipes may terminate in machinery spaces; however, the requirements of 1.2.2.3.5.1a) and 1.2.2.3.5.1.c) need not be applied on condition that the sounding pipes are fitted with appropriate means of closure.

1.2.3.2 For valves on lubricating oil tanks, refer to Pt.4, Ch.3, 8.6.1.

1.2.4 Arrangements for other flammable oils

1.2.4.1 The arrangements for the storage, distribution and utilization of other flammable oils employed under pressure in power transmission systems, control and activating systems and heating systems are to be such as to ensure the safety of the ship and persons onboard. Suitable oil collecting arrangements for leaks are to be fitted below hydraulic valves and comply with the provisions of 1.2.2.3.3, 1.2.2.3.5, 1.2.2.5.3 and 1.2.2.6 and with the provisions of 1.2.2.4 and 1.2.2.5.1 in respect of strength and construction.

1.2.5 Arrangements for oil fuel in periodically unattended machinery spaces

In addition to the requirements of 1.2.1 to 1.2.4, the oil fuel and lubricating oil systems in a periodically unattended machinery space are to comply with the following:

a) where daily service oil fuel tanks are filled automatically, or by remote control, means are to be provided to prevent overflow spillages. Other equipment which treat flammable liquids automatically (e.g. oil fuel purifiers) which, whenever practicable, are to be installed in a special space reserved for purifiers and their heaters are to have arrangements to prevent overflow spillages;

and

b) where daily service oil fuel tanks or settling tanks are fitted with heating arrangements, a high temperature alarm is to be provided if the flashpoint of the oil fuel can be exceeded.

1.3 Arrangements for gaseous fuel for domestic purpose

1.3.1 Gaseous fuel systems used for domestic purposes are to be approved by IRS. Storage of gas bottles are to be located on the open deck or in a well-ventilated space which opens only to the open deck.

IR1.3.1 A portion of open deck, recessed into a deck structure, machinery casing, deck house, etc., utilized for the exclusive storage of gas bottles is considered acceptable for the purpose of 1.3.1 provided that:

.1 such a recess has an unobstructed opening, except for small appurtenant structures, such as opening corner radii, small sills, pillars, etc. The opening may be provided with grating walls and door;

.2 the depth of such a recess is not greater than 1 m.

A portion of open deck meeting the above is to be considered as open deck in applying tables 3.1 to 3.8 of Ch.3.

1.4 Miscellaneous items of ignition sources and ignitability

1.4.1 Electric radiators

1.4.1.1 Electric radiators, if used are to be fixed in position and so constructed as to reduce fire risks to a minimum. No such radiators are to be fitted with an element so exposed that clothing, curtains, or other similar materials can be scorched or set on fire by heat from the element.

1.4.2 Waste receptacles

1.4.2.1 Waste receptacles are to be constructed of non-combustible materials with no openings in the sides or bottom.

IR1.4.2.1 Waste receptacles of combustible materials may however be used in galleys, pantries, bars, garbage handling or storage spaces and incinerator rooms provided they are intended purely for the carriage of wet waste, glass bottles and metal cans and are suitably marked.

1.4.3 Insulation surfaces protected against oil penetration

1.4.3.1 In spaces where penetration of oil products is possible, the surface of insulation is to be impervious to oil or oil vapours. Also refer Pt.4, Ch.1, Cl. 2.3.1.

1.4.4 Primary deck coverings

1.4.4.1 Primary deck coverings, if applied, within accommodation and service spaces and control stations or if applied on cabin balconies of passenger ships constructed on or after 1 July 2008 are to be of an approved material which will not readily ignite, or give rise to toxic or explosive hazards at elevated temperatures, this being determined in accordance with the Fire Test Procedures Code.

1.4.5 Films

1.4.5.1 Cellulose-nitrate based films are not to be used for cinematograph installations.

1.5 Cargo areas of tankers

1.5.1 Separation of cargo oil tanks

1.5.1.1 Cargo pump-rooms, cargo tanks, slop tanks and cofferdams (see Note below) are to be positioned forward of machinery spaces. However, oil fuel bunker tanks need not be forward of machinery spaces. Cargo tanks and slop tanks are to be isolated from machinery spaces by cofferdams, cargo pump-rooms, oil bunker tanks or ballast tanks. Pump-rooms containing pumps and their accessories for ballasting those spaces situated adjacent to cargo tanks and slop tanks and pumps for oil fuel transfer are to be considered as equivalent to a cargo pump-room within the context of these requirements provided that such pump-rooms have the same safety standard as that required for cargo pump-rooms. Pump-rooms intended solely for ballast or oil fuel transfer, however, need not comply with the requirements of Ch.3, Sec.4.9. The lower portion of the pump-room may be recessed into machinery spaces of category A to accommodate pumps, provided that the deck head of the recess is in general not more than one third of the moulded depth above the keel, except that in the case of ships of not more than 25,000 tonnes deadweight, where it can be demonstrated that for reasons of access and satisfactory piping arrangements this is impracticable a recess in excess of such height, but not exceeding one half of the moulded depth above the keel may be permitted.

IR1.5.1.1.1 Pump rooms intended solely for ballast transfer or fuel oil transfer are also not required to comply with the requirement of 1.5.10. The requirements of 1.5.10 are only applicable to the pump-rooms, regardless of their location, where pumps for cargo, such as cargo pumps, stripping pumps, pumps for slop tanks, pumps for COW or similar pumps are provided.
“Similar pumps” includes pumps intended for transfer of fuel oil having a flashpoint of less than 60ºC. Pump rooms intended for transfer of fuel oil having a flashpoint of not less than 60ºC need not comply with the requirements of 1.5.10.

1.5.1.2 Main cargo control stations, control stations, accommodation and service spaces (excluding isolated cargo handling gear lockers) are to be positioned aft of cargo tanks, slop tanks and spaces which isolate cargo or slop tanks from machinery spaces, but not necessarily aft of the oil fuel bunker tanks and ballast tanks and are to be arranged in such a way that a single failure of a deck or bulkhead will not permit the entry of gas or fumes from the cargo tanks into an accommodation space, main cargo control stations, control station, or service spaces. A recess provided in accordance with 1.5.1.1 need not be taken into account when the position of these spaces is being determined.

IR1.5.1.1.2 Void space or ballast water tank protecting fuel oil tank as shown in Fig. 1.1 need not be considered as ‘cargo area’ defined in Ch.1, 3.6 even though they have a cruciform contact with the cargo oil tank or slop tank.

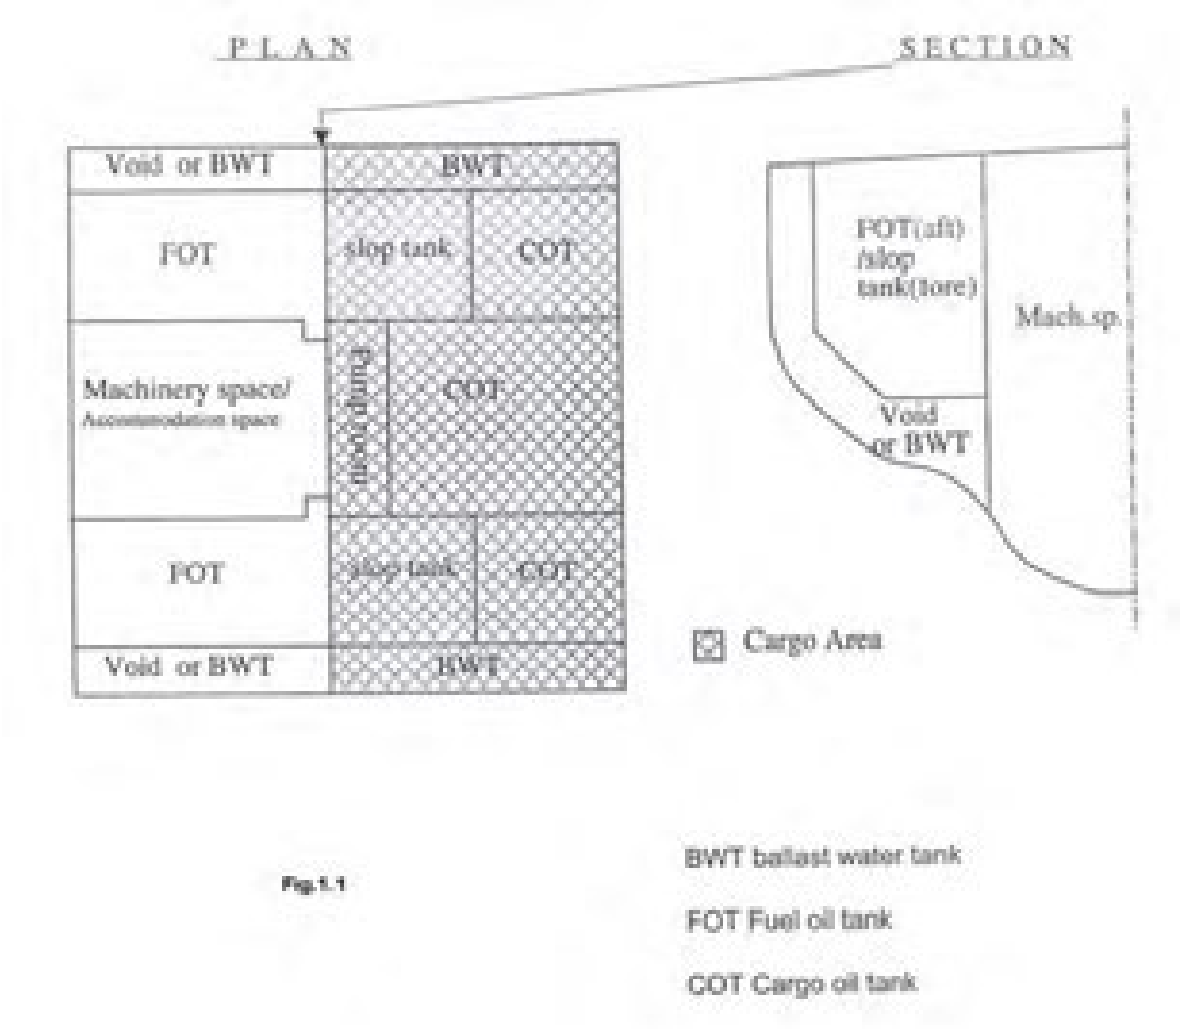

Fig.1.1

1.5.1.3 However, where deemed necessary, IRS may permit main cargo control stations, control stations, accommodation and service spaces forward of the cargo tanks, slop tanks and spaces which isolate cargo and slop tanks from machinery spaces, but not necessarily forward of oil fuel bunker tanks or ballast tanks. Machinery spaces, other than those of category A, may be permitted forward of the cargo tanks and slop tanks provided they are isolated from the cargo tanks and slop tanks by cofferdams, (see Note below) cargo pump-rooms, oil fuel bunker tanks or ballast tanks and have at least one portable fire extinguisher. In cases where they contain internal combustion machinery, one approved foam-type extinguisher of at least 45 l capacity or equivalent is to be arranged in addition to portable fire extinguishers. If operation of a semi-portable fire extinguisher is impracticable, this fire extinguisher may be replaced by two additional portable fire extinguishers. Accommodation spaces, main cargo control spaces, control stations and service spaces are to be arranged in such a way that a single failure of a deck or bulkhead will not permit the entry of gas or fumes from the cargo tanks into such spaces. In addition, where deemed necessary for the safety or navigation of the ship, IRS may permit machinery spaces containing internal combustion machinery not being main propulsion machinery having an output greater than 375 kW to be located forward of the cargo area provided the arrangements are in accordance with the provisions of this clause.

IR1.5.1.3 Paint lockers, regardless of their use are not to be located above the cargo tanks, slop tanks and spaces which isolate cargo or slop tanks from machinery spaces for oil tankers (refer 1.5.1.2) and the cargo area for chemical tankers and liquefied gas carriers.

IR1.5.1.1.3 The void space protecting fuel oil tank is not considered as cofferdam specified in 1.5.1.1 and the void space as shown in Fig.

1.1 is considered acceptable although it has cruciform contact with the slop tank.

1.5.1.4 In combination carriers only: Refer to Pt.5, Ch.2, 12.4.2 to 12.4.5.

1.5.1.5 Where the fitting of a navigation position above the cargo area is shown to be necessary, it is to be for navigation purposes only and it is to be separated from the cargo tank deck by means of an open space with a height of at least 2 m. The fire protection for such a navigation position is to be that required for control stations, as specified in Ch.3, 3.2.4.2 and other provisions for tankers, as applicable.

1.5.1.6 Means are to be provided to keep deck spills away from the accommodation and service areas. This may be accomplished by provision of a permanent continuous coaming of a height of at least 300 [mm], extending from side to side. Special consideration will be given to the arrangements associated with stern loading.

Note: For the purpose of clause 1.5.1 the expression ‘cofferdam’ means an isolating space between two adjacent steel bulkheads or decks. The minimum distance between the two bulkheads or decks is to be sufficient for safe access and inspection. In order to meet the single failure principle, in particular case when a corner-to-corner situation occurs, this principle may be met by welding a diagonal plate across the corner. No cargo, wastes or other goods are to be contained in cofferdams.

1.5.2 Restriction on boundary openings

1.5.2.1 Except as permitted by 1.5.2.2, access doors, air inlets and openings to accommodation spaces, service spaces, control stations and machinery spaces are not to face the cargo area. They are to be located on the transverse bulkhead not facing the cargo area or on the outboard side of the superstructure or deckhouse at a distance of at least 4% of the length of the ship but not less than 3 [m] from the end of the superstructure or deckhouse facing the cargo area. This distance need not exceed 5 [m].

1.5.2.2 IRS may permit access doors in boundary bulkheads facing the cargo area or within the 5 [m] limits specified in 1.5.2.1, to main cargo control stations and to such service spaces used as provision rooms, store-rooms and lockers, provided they do not give access directly or indirectly to any other space containing or providing for accommodation, control stations or service spaces such as galleys, pantries or workshops, or similar spaces containing sources of vapour ignition. The boundary of such a space is to be insulated to "A-60" standard, with the exception of the boundary facing the cargo area. Bolted plates for the removal of machinery may be fitted within the limits specified in 1.5.2.1. Wheelhouse doors and windows may be located within the limits specified in 1.5.2.1 so long as they are designed to ensure that the wheelhouse can be made rapidly and efficiently gas and vapour tight.

IR1.5.2.2

.1 An access to a deck foam system room (including the foam tank and the control station) can be located within the limits mentioned in clause 1.5.2.1, provided that the conditions listed in clause 1.5.2.2 are satisfied and that the door is located flush with the bulkhead.

.2 The navigation bridge external doors and windows which are located within the limits of clause 1.5.2.1 are to be tested for gas-tightness. If a water hose test is applied, the following may be taken as a guide:

- nozzle diameter: minimum 12 [mm];
- water pressure just before the nozzle: not less than 0.2 [N/mm^2]; and
- distance between the nozzles and the doors or windows: max. 1.5 [m].

.3 Access to forecastle spaces containing sources of ignition may be permitted through doors facing cargo area provided the doors are located outside hazardous areas as defined in IEC Publication 60092-502:1999.

1.5.2.3 Windows and side scuttles facing the cargo area and on the sides of the superstructures and deckhouses within the limits specified in 1.5.2.1 are to be of a fixed (non-opening) type. Such windows and side scuttles, except wheelhouse windows are to be constructed to "A-60" class standard except that “A-0” class standard is acceptable for windows and side scuttles outside the limit specified in Ch.3, 3.2.4.2.5.

1.5.2.4 Where there is permanent access from a pipe tunnel to the main pump-room, a watertight door is to be fitted complying with

the requirements of Pt.3, Ch.10, Cl.2.5.2 and in addition, with the following:

.1 in addition to the bridge operation, the watertight door is to be capable of being manually closed from outside the main pump-room entrance; and

.2 the watertight door is to be kept closed during normal operations of the ship except when access to the pipe tunnel is required.

1.5.2.5 Permanent approved gas tight lighting enclosures for illuminating cargo pump rooms may be permitted in bulkheads and decks separating cargo pump rooms and other spaces provided they are of adequate strength and integrity and gastightness of the bulkhead or deck is maintained.

1.5.2.6 The arrangement of ventilation inlets and outlets and other deckhouse and superstructure boundary space openings are to be such as to complement the provisions of 1.5.3 and Ch.3, 5.6. Such vents, especially for machinery spaces are to be situated as far aft as practicable. Due consideration in this regard is to be given when the ship is equipped to load or discharge at the stern. Sources of ignition such as electrical equipment are to be so arranged as to avoid an explosion hazard.

1.5.3 Cargo tank venting

1.5.3.1 General requirements

Refer to Pt.5, Ch.2, 8.1.1.

1.5.3.2 Venting arrangements

Refer to Pt.5, Ch.2, 8.1.6, 8.1.7 and 8.1.11.

1.5.3.3 Safety devices in venting systems

Refer to Pt.5, Ch.2, 8.1.12.

1.5.3.4 Vent outlets for cargo handling and ballasting

1.5.3.4.1 For vent outlets for cargo loading, discharging and ballasting required by Ch.3, 5.6.1.2, refer to Pt.5, Ch.2, 8.1.15 and 8.1.16.

1.5.3.5 Slop tanks in combination carriers

Refer to Pt.5, Ch.2, 12.4.4.

1.5.4 Ventilation

1.5.4.1 Ventilation systems in cargo pump-rooms

Cargo pump-rooms are to be mechanically ventilated and discharges from the exhaust fans are to be led to a safe place on the open deck. The ventilation of these rooms is to have sufficient capacity to minimize the possibility of accumulation of flammable vapours. The number of air changes is to be at least 20 per hour, based upon the gross volume of the space. The air ducts are to be arranged so that all of the space is effectively ventilated. The ventilation is to be of the suction type using fans of the non-sparking type. (Also refer Pt.5, Ch.2, Cl.6.1).

1.5.4.2 Ventilation systems in combination carriers

In combination carriers, cargo spaces and any enclosed spaces adjacent to cargo spaces are to be capable of being mechanically ventilated. The mechanical ventilation may be provided by portable fans. An approved fixed gas warning system capable of monitoring flammable vapours is to be provided in cargo pump-rooms, pipe ducts and cofferdams, as referred to in 1.5.1.4, adjacent to slop tanks. Suitable arrangements are to be made to facilitate measurement of flammable vapours in all other spaces within the cargo area. Such measurements are to be made possible from the open deck or easily accessible positions.

1.5.5 Inert gas systems

1.5.5.1 Application

1.5.5.1.1 For tankers of 20,000 tonnes deadweight and upwards constructed on or after 1 July 2002 but before 1 January 2016, the protection of the cargo tanks is to be achieved by a fixed inert gas system in accordance with the requirements of the Fire Safety Systems Code, as adopted by resolution MSC.98(73), except that the Administration may accept other equivalent systems or arrangements, as described in paragraph 1.5.5.4.

1.5.5.1.2 For tankers of 8,000 tonnes deadweight and upwards constructed on or after 1 January 2016 when carrying cargoes described in Pt 6, Ch 1, 1.5.1 or 1.5.2, the protection of the cargo tanks is to be achieved by a fixed inert gas system in accordance with the requirements of Pt 6, Ch 8, except that the Administration may accept other equivalent

systems or arrangements, as described in paragraph 1.5.5.4.

1.5.5.1.3 Tankers operating with a cargo tank cleaning procedure using crude oil washing are to be fitted with an inert gas system complying with Pt 6, Ch 8 and with fixed tank washing machines. However, inert gas systems fitted on tankers constructed on or after 1 July 2002 but before 1 January 2016 are to comply with the Fire Safety Systems Code, as adopted by resolution MSC.98(73).

1.5.5.1.4 Tankers required to be fitted with inert gas systems are to comply with the following provisions:

.1 double-hull spaces are to be fitted with suitable connections for the supply of inert gas;

IR.1 Double-hull spaces required to be fitted with suitable connections for the supply of inert gas as above, are all ballast tanks and void spaces of double-hull and double-bottom spaces adjacent to the cargo tanks, including the forepeak tank and any other tanks and spaces under the bulkhead deck adjacent to cargo tanks, except cargo pump-rooms and ballast pump-rooms.

.2 where hull spaces are connected to a permanently fitted inert gas distribution system, means are to be provided to prevent hydrocarbon gases from the cargo tanks entering the double hull spaces through the system; and

.3 where such spaces are not permanently connected to an inert gas distribution system, appropriate means are to be provided to allow connection to the inert gas main.

1.5.5.2 Inert gas systems of chemical tankers and gas carriers

1.5.5.2.1 The requirements for inert gas systems contained in the Pt.5, Ch.2, Sec.11, Pt.6 Ch.8 and FSS Code need not be applied to chemical tankers constructed before 1 January 2016, including those constructed before 1 July 2012, and all gas carriers:

.1 when carrying cargoes described in Ch.1, 1.6.1, provided that they comply with the requirements for inert gas systems on chemical tankers approved by the National Statutory Authority (refer to the regulations for inert gas systems on chemical tankers adopted by IMO Resolution A.567(14) Corr.1)

or

.2 when carrying flammable cargoes other than crude oil or petroleum products such as cargoes listed in Sections 17 and 18 of Pt.5, Ch.3, provided that the capacity of tanks used for their carriage does not exceed 3,000 [m^3] and the individual nozzle capacities of tank washing machines do not exceed 17.5 [m^3/h] and the total combined throughput from the number of machines in use in a cargo tank at any one time does not exceed 110 [m^3/h].

1.5.5.3 General requirements for inert gas systems

.1 The inert gas system is to be capable of inerting, purging and gas-freeing empty tanks and maintaining the atmosphere in cargo tanks with the required oxygen content.

.2 Tankers fitted with a fixed inert gas system are to be provided with a closed ullage system.

1.5.5.4 Requirements for equivalent systems

1.5.5.4.1 For tankers of 8,000 tonnes deadweight and upwards but less than 20,000 tonnes deadweight, in lieu of fixed installations, IRS may accept other equivalent arrangements or means of protection in accordance with paragraph 1.5.5.4.2.

1.5.5.4.2 Equivalent systems or arrangements are to :

.1 be capable of preventing dangerous accumulations of explosive mixtures in intact cargo tanks during normal service throughout the ballast voyage and necessary in-tank operations; and

.2 be so designed as to minimize the risk of ignition from the generation of static electricity by the system itself.

1.5.6 Inerting, purging and gas-freeing (Also refer Pt.5, Ch.2, 8.2)

.1 Arrangements for purging and/or gas-freeing are to be such as to minimize the hazards due to dispersal of flammable vapours in the atmosphere and to flammable mixtures in a cargo tank.

.2 The procedure for cargo tank purging and/or gas-freeing are to be carried out in accordance with Ch.5, 3.3.2.

.3 Also refer to Pt.5, Ch.2, 8.2.3.

1.5.7 Gas measurement and detection

1.5.7.1 Portable instrument

1.5.7.1.1 Tankers are to be equipped with at least one portable instrument for measuring oxygen and one for measuring flammable vapour concentrations, together with a sufficient set of spares. Suitable means are to be provided for the calibration of such instruments**.**

IR 1.5.7.1.1 Compliance with the provision "suitable means are to be provided for the calibration of such instruments" may be achieved by portable atmosphere testing instruments being calibrated on board or ashore in accordance with the manufacturer's instructions. For the avoidance of any doubt, the above consideration refers to the calibration of portable instruments for measuring oxygen or flammable vapour concentrations, as required by 1.5.7.1.1 and not to any pre-operational accuracy tests as recommended by the manufacturer.

1.5.7.2 Arrangements for gas measurement in double hull and double bottom spaces

Refer to Pt.5, Ch.2, 8.3.3, 8.3.4 and 8.3.5.

1.5.8 Air supply to double hull and double bottom spaces

Double hull and double bottom spaces are to be fitted with suitable connections for the supply of air.

1.5.9 Protection of cargo area

Drip pans of suitable material for collecting cargo residues in cargo lines and hoses are to be provided in the area of pipe and hose connections under the manifold area. Cargo hoses and tank washing hoses are to have electrical continuity over their entire lengths including couplings and flanges (except shore connections) and are to be earthed for removal of electrostatic charges.

1.5.10 Protection of cargo pump rooms

1.5.10.1 For details of protection in tankers; Refer Pt.5, Ch.2, 6.4.2 to 6.4.5 and IR6.4.5.

Section 2

Fire Growth Potential

2.1 Purpose

2.1.1 The purpose of this regulation is to limit the fire growth potential in every space of the ship. For this purpose, the following functional requirements are to be met:

a) means of control for the air supply to the space are to be provided;
b) means of control for flammable liquids in the space are to be provided; and
c) the use of combustible materials is to be restricted.

2.2 Control of air supply and flammable liquid to the space

2.2.1 Closing appliances and stopping devices of ventilation

2.2.1.1 The main inlets and outlets of all ventilation system are to be capable of being closed from outside the spaces being ventilated. The means of closing are to be easily accessible as well as prominently and permanently marked and are to indicate whether the shut-off is open or closed.

IR2.2.1.1 Battery room ventilators are to be fitted with a means of closing under the following conditions:

i) The battery room does not open directly onto an exposed deck; or

ii) The ventilation opening for the battery room is required to be fitted with a closing device according to the Pt.3, Ch.13, Cl.2.3.1 (i.e. the height of the opening does not extend to more than 4.5 [m] (14.8 feet) above the deck for

position 1 or to more than 2.3 [m] (7.5 feet) above the deck in position 2; or

iii) The battery room is fitted with a fixed gas fire extinguishing system.

Where a battery room ventilator is fitted with a closing device, a warning notice stating, for example “This closing device is to be kept open and closed only in the event of fire or other emergency – Explosive gas”, is to be provided at the closing device to mitigate the possibility of inadvertent closing.

Also refer Pt.4, Ch.8, Cl.7.1.5.

2.2.1.2 Power ventilation of accommodation spaces, service spaces, cargo spaces, control stations and machinery spaces are to be capable of being stopped from an easily accessible position outside the space being served. This position is not to be readily cut off in the event of a fire in the spaces served.

2.2.1.3 In passenger ships carrying more than 36 passengers, power ventilation, except machinery space and cargo space ventilation and any alternative system which may be required by Ch.3, 2.2 is to be fitted with controls so grouped that all fans may be stopped from either of two separate positions which are to be situated as far apart as practicable. Fans serving power ventilation systems to cargo spaces are to be capable of being stopped from a safe position outside such spaces.

IR2.2.1.3 The fan in a HVAC temperature control unit, or a circulation fan inside a cabinet/switchboard, is not considered to be a ventilation fan as addressed in 2.2.1.2, 2.2.1.3 and Ch 3, 1.9.3, if it is not capable of supplying outside air to the space when the power ventilation is shut down (e.g., small units intended for re-circulation of air within a cabin). Therefore, such fans need not be capable of being stopped from an easily accessible position (or a safe position) outside the space being served when applying 2.2.1.2 or 2.2.1.3, and need not be capable of being controlled from a continuously manned central control station for passenger ships carrying more than 36 passengers when applying Ch 3, 1.9.3.

2.2.2 Means of control in machinery spaces

2.2.2.1 Means of control are to be provided for opening and closure of skylights, closure of openings in funnels which normally allow exhaust ventilation and closure of ventilator dampers.

IR2.2.2.1 Ventilation inlets and outlets located at outside boundaries are to be fitted with closing appliances as required by 2.2.2.1 but need not comply with Ch.3, 3.7.3.1.

2.2.2.2 Means of control are to be provided for stopping ventilating fans. Controls provided for the power ventilation serving machinery spaces are to be grouped so as to be operable from two positions, one of which is to be outside such spaces. The means provided for stopping the power ventilation of the machinery spaces are to be entirely separate from the means provided for stopping ventilation of other spaces.

2.2.2.3 Means of control are to be provided for stopping forced and induced draught fans, oil fuel transfer pumps, oil fuel unit pumps, lubricating oil service pumps, thermal oil circulating pumps and oil separators (purifiers). However, 2.2.2.4 and 2.2.2.5 need not apply to oily water separators.

2.2.2.4 The controls required in 2.2.2.1 to 2.2.2.3 and in 1.2.2.3.4 are to located outside the space concerned so they will not be cut off in the event of fire in the space they serve.

2.2.2.5 In passenger ships, the controls required in 2.2.2.1 to 2.2.2.4 and in Ch.3, 2.3.3 and Ch.3, 3.5.2.3 and the controls for any required fire-extinguishing system are to be situated at one control position or grouped in as few positions as possible to the satisfaction of IRS. Such positions are to have a safe access from the open deck.

2.2.3 Additional requirements for means of control in periodically unattended machinery spaces

2.2.3.1 For periodically unattended machinery spaces, special consideration will be given to maintaining the fire integrity of the machinery spaces, the location and centralization of the fire-extinguishing system controls, the required shutdown arrangements (e.g. ventilation, fuel pumps, etc.) and that additional fire-extinguishing appliances and other fire-fighting equipment and breathing apparatus may be required.

2.2.3.2 In passenger ships, these requirements are be at least equivalent to those of machinery spaces normally attended.

2.3 Fire protection materials

2.3.1 Use of non-combustible materials

2.3.1.1 Insulating materials

Insulating materials are to be non-combustible, except in cargo spaces, mail rooms, baggage rooms and refrigerated compartments of service spaces. Vapour barriers and adhesives used in conjunction with insulation, as well as the insulation of pipe fittings for cold service systems, need not be of non-combustible materials, but they are to be kept to the minimum quantity practicable and their exposed surfaces are to have low flame-spread characteristics.

IR2.3.1.1 Cold service in 2.3.1.1 is understood to mean refrigeration systems and chilled water piping for air-conditioning systems.

2.3.1.2 Ceilings and linings

.1 In passenger ships, all linings, grounds, draught stops and ceilings are to be of non-combustible material in the following spaces except in mailrooms, baggage rooms and saunas and refrigerated compartments of service spaces:

a) accommodation spaces, service spaces and control stations
b) stairways, open deck spaces
c) machinery spaces.

.2 In cargo ships, all linings, ceilings, draught stops and their associated grounds are to be of non-combustible materials in the following spaces:

a) in accommodation and service spaces and control stations for ships where Method IC is specified as referred to in Ch.3, 3.2.3.1; and
b) in corridors and stairway enclosures serving accommodation and service spaces and control stations for ships where Method IIC and IIIC are specified as referred to in Ch.3, 3.2.3.1.

2.3.1.3 Partial bulkheads and decks on passenger ships

.1 Partial bulkheads or decks used to subdivide a space for utility or artistic treatment are to be of non-combustible material.

.2 Linings, ceilings or partial bulkheads or decks used to screen or to separate adjacent cabin balconies are to be of non-combustible materials. Cabin balconies on passenger ships constructed before 1 July 2008 are to comply with the requirements of this clause by the first survey after 1 July 2008.

2.3.2 Use of combustible materials

2.3.2.1 General

.1 In passenger ships, "A", "B" or "C" class divisions in accommodation and services spaces and cabin balconies which are faced with combustible materials, facings, mouldings, decorations and veneers are to comply with the provisions of 2.3.2.2 to 2.3.2.4 and section 3. However, traditional wooden benches and wooden linings on bulkheads and ceilings are permitted in saunas and such materials need not be subject to the calculations prescribed in 2.3.2.2 and 2.3.2.3. However, the provisions of 2.3.2.3 need not be applied to cabin balconies.

.2 In cargo ships, non-combustible bulkheads, ceilings and linings fitted in accommodation and service spaces may be faced with combustible materials, facings, mouldings, decorations and veneers provided such spaces are bounded by non-combustible bulkheads, ceilings and linings in accordance with the provisions of 2.3.2.2 to 2.3.2.4 and Section 3.

2.3.2.2 Maximum calorific value of combustible materials

Combustible materials used on the surfaces and linings specified in 2.3.2.1 are to have a calorific value not exceeding 45 [MJ/m^2] of the area for the thickness used. The requirements of this paragraph are not applicable to the surfaces of furniture fixed to linings or bulkheads. (Refer ISO 1716 on Determination of Calorific value).

2.3.2.3 Total volume of combustible materials

Where combustible materials are used in accordance with 2.3.2.1, they are to comply with the following requirements:

a) The total volume of combustible facings mouldings, decorations and veneers in accommodation and service spaces are not to exceed a volume equivalent to 2.5 [mm] veneer on the combined area of the walls and ceiling linings. Furniture fixed to

linings, bulkheads or decks need not be included in the calculation of the total volume of combustible materials; and

b) In the case of ships fitted with an automatic sprinkler system complying with the provisions of the Fire Safety Systems Code (Chapter 8), the above volume may include some combustible material used for erection of "C" class divisions.

2.3.2.4 Low flame-spread characteristics of exposed surfaces

The following surfaces are to have low flame-spread characteristics in accordance with the Fire Test Procedures Code:

.1 In passenger ships:

a) exposed surfaces in corridors and stairway enclosures and of bulkhead and ceiling linings in accommodation and service spaces (except saunas) and control stations; and
b) surfaces and grounds in concealed or inaccessible spaces in accommodation and service spaces and control stations.
c) Exposed surfaces of cabin balconies, except for natural hard wood decking systems.

.2 In cargo ships:

a) exposed surfaces in corridors and stairway enclosures and of ceilings in accommodation and service spaces (except saunas) and control stations; and
b) surfaces and grounds in concealed or inaccessible spaces in accommodation and service spaces and control stations.

2.3.3 Furniture in stairway enclosures of passenger ships

Furniture in stairway enclosures are to be limited to seating. It is to be fixed, limited to six seats on each deck in each stairway enclosure, be of restricted fire risk determined in accordance with the Fire Test Procedure Code, and is not to restrict the passenger escape route. Additional seating may be permitted in the main reception area within a stairway enclosure if it is fixed, non-combustible and does not restrict the passenger escape route. Furniture is not to be fixed in passenger and crew corridors forming escape routes in cabin areas. In addition to the above, lockers of non-combustible material, providing storage for non-hazardous safety equipment required by these rules, may be permitted. Drinking water dispensers and ice cube machines may be fixed in corridors provided they are fixed and do not restrict the width of the escape routes. This applies as well to decorative flower or plant arrangements, statues or other objects of art such as paintings and tapestries in corridors and stairways.

2.3.4 Furniture and furnishings on cabin balconies of passenger ships

On passenger ships, furniture and furnishings on cabin balconies are to comply with requirements of Ch.1, 3.40 a), b), c), f) and g) unless such balconies are protected by a fixed pressure water-spraying and fixed fire detection and fire alarm systems complying with Ch.3, 1.10 and Ch.3, 4.6.1.3. passenger ships constructed before 1 July 2008 are to comply with the requirements of this clause by the first survey after 1 July 2008.

Section 3

Smoke Generation Potential and Toxicity

3.1 Purpose

3.1.1 The purpose of this section is to reduce the hazard to life from smoke and toxic products generated during a fire in spaces where persons normally work or live. For this purpose, the quantity of smoke and toxic products released from combustible materials, including surface finishes, during fire is to be limited.

3.2 Paints, varnishes and other finishes

The following requirements apply to accommodation spaces, service spaces and control stations as well as stairway enclosures.

3.2.1 Paints, varnishes and other finishes used on exposed interior surfaces are not be capable of producing excessive quantities of smoke and toxic products, this being determined in accordance with the Fire Test Procedures Code.

3.2.2 On passenger ships constructed on or after 1 July 2008, paints, varnishes and other finishes used on exposed surfaces of cabin balconies, excluding natural hard wood decking systems, are not to be capable of producing excessive quantities of smoke and toxic products, this being determined in accordance with the Fire Test Procedures Code.

3.3 Primary deck coverings

3.3.1 Primary deck coverings, if applied within accommodation and service spaces and control stations are to be of approved material which will not give rise to smoke or toxic or explosive hazards at elevated temperatures, this being determined in accordance with the Fire Test Procedures Code.

3.3.2 On passenger ships constructed on or after 1 July 2008, primary deck coverings on cabin balconies are not to give rise to smoke, toxic or explosive hazards at elevated temperatures, this being determined in accordance with the Fire Test Procedures Code.

3.4 Asbestos

3.4.1 For all ships, new installations of materials which contain asbestos are prohibited.

5 *Structural Integrity*

Section 1

Detection and Alarm

1.1 Purpose

1.1.1 The purpose of this section is to detect a fire in the space of origin and to provide for alarm for safe escape and fire-fighting activity. For this purpose, the following functional requirements are to be met:

a) fixed fire detection and fire alarm system installations are to be suitable for the nature of the space, fire growth potential and potential generation of smoke and gases;

b) manually operated call points are to be placed effectively to ensure a readily accessible means of notification; and

c) fire patrols are to provide an effective means of detecting and locating fires and alerting the navigation bridge and fire teams.

1.2 General requirements

1.2.1 A fixed fire detection and fire alarm system is to be provided in accordance with the provisions of this section.

1.2.2 A fixed fire detection and fire alarm system and a sample extraction smoke detection system required in this section and other sections in this chapter are to be of an approved type and comply with the Fire Safety Systems Code (Chapter 8).

1.2.3 Where a fixed fire detection and fire alarm system is required for the protection of spaces other than those specified in 1.5.1, at least one detector complying with the Fire Safety Systems Code (Chapter 8) is to be installed in each such space.

1.2.4 A fixed fire detection and fire alarm system for passenger ships is to be capable of remotely and individually identifying each detector and manually operated call point.

1.3 Initial and periodical tests

1.3.1 The function of fixed fire detection and fire alarm systems required by the relevant sections of this part are to be tested under varying conditions of ventilation after installation.

1.3.2 The function of fixed fire detection and fire alarm systems is to be periodically tested to the satisfaction of IRS by means of equipment producing hot air at the appropriate temperature, or smoke or aerosol particles having the appropriate range of density or particle size, or other charateristics associated with incipient fires to which the detector is designed to respond.

1.4 Protection of machinery spaces

IR1.4 This requirement is applicable to machinery spaces of category 'A'.

1.4.1 Installation

A fixed fire detection and fire alarm system is to be installed in:

.1 periodically unattended machinery spaces;

.2 machinery spaces where:

a) the installation of automatic and remote control systems and equipment has been approved in lieu of continuous manning of the space; and

b) the main propulsion and associated machinery including sources of the main sources of electrical power are provided with various degrees of automatic or remote control and are under continuous manned supervision from a control room and:

c) enclosed spaces containing incinerators.

1.4.2 Design

1.4.2.1 This fire detection system is to be so designed and the detectors so positioned as to detect rapidly the onset of fire in any part of those spaces and under any normal conditions of operation of the machinery and variations of ventilation as required by the possible range of ambient temperatures. Consideration is to be given to avoid false alarms. The arrangement and the number of Sections and the location of detector heads is to be approved in each case. Except in spaces of restricted height and where their use is specially appropriate, detection systems using only thermal detectors will not be permitted. The detection system is to initiate audible and visual alarms distinct in both respects from the alarms of any other system not indicating fire, in sufficient places to ensure that the alarms are heard and observed on the navigating bridge and by a responsible engineer officer. When the navigating bridge is unmanned the alarm is to sound in a place where a responsible member of the crew is on duty. (Also refer Pt.5, Ch.22, 2.13 for other requirements).

1.5 Protection of accommodation and service spaces and control stations

1.5.1 Smoke detectors in accommodation spaces

Smoke detectors are to be installed in all stairways, corridors and escape routes within accommodation spaces as provided in 1.5.2, 1.5.3 and 1.5.4 Consideration will be given to the installation of special purpose smoke detectors within ventilation ducting.

1.5.2 Requirements for passenger ships carrying more than 36 passengers

.1 A fixed fire detection and fire alarm system is to be installed and arranged as to provide smoke detection in service spaces, control stations and accommodation spaces, including corridors, stairways and escape routes within accommodation spaces. Smoke detectors need not be fitted in private bathrooms and galleys. Spaces having little or no fire risk such as voids, public toilets, carbon dioxide rooms and similar spaces need not be fitted with a fixed fire detection and alarm system. Detectors fitted in cabins, when activated are also to be capable of generating or activating an audible alarm within the space where they are located.

IR.2 Heat detectors are acceptable in refrigerated chambers and in other spaces such as saunas and laundries where steam and fumes are emanated.

1.5.3 Requirements for passenger ships carrying not more than 36 passengers

There is to be installed throughout each separate zone, whether vertical or horizontal, in all accommodation and service spaces and where it is considered necessary by IRS, in control stations, except spaces which afford no substantial fire risk such as void spaces, sanitary spaces, etc., either:

.1 a fixed fire detection and fire alarm system so installed and arranged as to detect the presence of fire in such spaces and providing smoke detection in corridors, stairways and escape routes within accommodation spaces. Detectors fitted in cabins, when activated are also to be capable of generating or activating an audible alarm within the space where they are located; or

.2 an automatic sprinkler, fire detection and fire alarm system of an approved type complying with the relevant requirements of

the Fire Safety Systems Code (Chapter 8) and so installed and arranged as to protect such spaces and, in addition, a fixed fire detection and fire alarm system and so installed and arranged as to provide smoke detection in corridors, stairways and escape routes within accommodation spaces.

1.5.4 Protection of atriums in passenger ships

The entire main vertical zone containing the atrium is to be protected throughout with a smoke detection system.

1.5.5 Cargo ships

Accommodation and service spaces and control stations of cargo ships are to be protected by a fixed fire detection and fire alarm system and/or an automatic sprinkler, fire detection and fire alarm system as follows depending on a protection method adopted in accordance with Ch.3, 3.2.3.1.

1.5.5.1 Method IC

A fixed fire detection and fire alarm system is to be so installed and arranged as to provide smoke detection in all corridors, stairways and escape routes within accommodation spaces.

1.5.5.2 Method IIC

An automatic sprinkler, fire detection and fire alarm system of an approved type complying with the relevant requirements of the Fire Safety Systems Code (Chapter 8) are to be so installed and arranged as to protect accommodation spaces, galleys and other service spaces, except spaces which afford no substantial fire risk such as void spaces, sanitary spaces, etc. In addition, a fixed fire detection and fire alarm system of an approved type complying with the requirements of Ch.8, Sec.9 is to be so installed and arranged to provide smoke detection in all corridors, stairways and escape routes within accommodation spaces.

1.5.5.3 Method IIIC

A fixed fire detection and fire alarm system is to be so installed and arranged as to detect the presence of fire in all accommodation spaces and service spaces providing smoke detection in corridors, stairways and escape routes within accommodation spaces, except spaces which afford no substantial fire risk such as void spaces, sanitary spaces, etc.

IR1.5.5.3 The above requirement applies to accommodation block. Service spaces built away from accommodation block need not be fitted with a fixed fire detection and fire-alarm system complying with FSS Code (Chapter 8).

1.6 Protection of cargo spaces in passenger ships

A fixed fire detection and fire alarm system or a sample extraction smoke detection system is to be provided in any cargo space which is not accessible, except where it is shown to the satisfaction of IRS that the ship is engaged on voyages of such short duration that it would be unreasonable to apply this requirement.

1.7 Manually operated call points

1.7.1 Manual call points are to be installed throughout the accommodation spaces, service spaces and control stations. One manual call point is to be located at each exit. Manual call points are to be readily accessible in the corridors of each deck such that no part of the corridor is more than 20 [m] from a manual call point.

IR1.7.1 The phrase ‘Manually operated call points complying with the Fire Safety Systems Code are to be installed throughout the accommodation spaces, service spaces and control stations in 1.7.1 above does not require the fitting of a manually operated call point in an individual space within the accommodation spaces, service spaces and control stations. However, a manually operated call point is to be located at each exit (inside or outside) to the open deck from the corridor such that no part of the corridor is more than 20 [m] from a manually operated call point. Service spaces and control stations which have only one access, leading directly to the open deck are to have a manually operated call point not more than 20 [m] (measured along the access route using the deck, stairs and/or corridors) from the exit. A manually operated call point is not required to be installed for spaces having little or no fire risk, such as voids and carbon dioxide rooms, nor at each exit from the navigation bridge, in cases where the control panel (for fixed fire detection and fire alarm system) is located in the navigation bridge.

1.8 Fire patrols in passenger ships

1.8.1 Fire patrols

For ships carrying more than 36 passengers an efficient patrol system is to be maintained so that an outbreak of fire may be promptly detected. Each member of the fire patrol is to be trained to be familiar with the arrangements of the ship as well as the location and operation of any equipment he may be called upon to use.

1.8.2 Inspection hatches

The construction of ceiling and bulkheads is to be such that it will be possible, without impairing the efficiency of the fire protection, for the fire patrols to detect any smoke originating in concealed and inaccessible places, except where there is no risk of fire originating in such places.

1.8.3 Two-way portable radiotelephone apparatus

Each member of the fire patrol is to be provided with a two-way portable radiotelephone apparatus.

1.9 Fire alarm signalling systems in passenger ships (IMO Res.A.830(19) may be referred for Code of Alarms)

1.9.1 Passenger ships are at all times when at sea, or in port (except when out of service), to be so manned or equipped as to ensure that any initial fire alarm is immediately received by a responsible member of the crew.

1.9.2 The control panel of fixed fire detection and fire alarm systems is to be designed on the fail-safe principle (e.g. an open detector circuit is to cause an alarm condition).

1.9.3 Passenger ships carrying more than 36 passengers are to have the fire detection alarms for the systems required by 1.5.2 centralized in a continuously manned central control station. In addition, controls for remote closing of the fire doors and shutting down the ventilation fans are to be centralized in the same location. The ventilation fans are to be capable of reactivation by the crew at the continuously manned control station. The control panels in the central control station are to be capable of indicating open or closed positions of fire doors and closed or off status of the detectors, alarms and fans. The control panels are to be continuously powered and are to have an automatic change-over to standby power supply in case of loss of normal power supply. The control panels are to be powered from the main source of electrical power and the emergency source of electrical power unless other arrangements are permitted by applicable requirements. (Also refer to Ch 2, IR 2.2.1.3)

1.9.4 A special alarm, operated from the navigation bridge or fire control station, is to be fitted to summon the crew. This alarm may be part of the ship's general alarm system and is to be capable of being sounded independently of the alarm to the passenger spaces.

1.10 Protection of cabin balconies on passenger ships

A fixed fire detection and fire alarm system complying with the provisions of Ch.8 is to be installed on cabin balconies of ships to which requirement of Ch.2, 2.3.4 applies, when furniture and furnishings on such balconies are not as defined in Ch.1, 3.40 a), b), c), f) and g).

Section 2

Control of Smoke Spread

2.1 Purpose

The purpose of this regulation is to control the spread of smoke in order to minimize the hazards from smoke. For this purpose, means for controlling smoke in atriums, control stations, machinery spaces and concealed spaces are to be provided.

2.2 Protection of control stations outside machinery spaces

Such measures as practicable are to be taken in respect of control stations outside machinery spaces in order to ensure that ventilation, visibility and freedom from smoke are maintained, so that in the event of fire the machinery and equipment contained therein may be supervised and continue to function effectively. Alternative and separate means of air supply are to be provided; air inlets of the two sources of supply are to be so disposed that the risk of both inlets drawing in smoke simultaneously is minimized. Such requirements need not apply to control station situated on, and opening on to, an open deck, or where local closing arrangements would be equally effective. The ventilation system serving safety centers may be derived from the ventilation system serving the navigation bridge, unless located in an adjacent main vertical zone.

IR2.2 The expression ‘local closing arrange-ments would be equally effective’ in 2.2 means that in case of ventilators, the ventilators are fitted with fire dampers or smoke dampers which could be closed easily from within the control station in order to maintain the absence of smoke in the event of fire.

2.3 Release of smoke from machinery spaces

2.3.1 The following requirements are applicable to machinery spaces of category A and, where IRS considers desirable, to other machinery spaces.

2.3.2 Suitable arrangements are to be made to permit the release of smoke, in the event of fire, from the space to be protected, subject to the provisions of 3.5.2.1. The normal ventilation systems may be acceptable for this purpose.

2.3.3 Means of control are to be provided for permitting the release of smoke and such controls are to be located outside the space concerned so that, in the event of fire, they will not be cut off from the space they serve.

2.3.4 In passenger ships, the controls required by 2.3.3 are to be situated at one control position or grouped in as few positions as possible to the satisfaction of IRS. Such positions are to have a safe access from the open deck.

2.4 Draught stops

Air spaces enclosed behind ceilings, panelling or linings are to be divided by close-fitting draught stops spaced not more than 14 [m] apart. In the vertical direction, such enclosed air spaces, including those behind linings of stairways, trunks, etc., are to be closed at each deck.

2.5 Smoke extraction systems in atriums of passenger ships

Atriums are to be equipped with a smoke extraction system. The smoke extraction system is to be activated by the required smoke detection system and be capable of manual control. The fans are to be sized such that the entire volume within space can be exhausted in 10 min or less.

Section 3

Containment of Fire

3.1 Purpose

The purpose of this section is to contain a fire in the space of origin. For this purpose, the following functional requirements are to be met:

.1 the ship is to be subdivided by thermal and structural boundaries;

.2 thermal insulation of boundaries are to have due regard to the fire risk of the space and adjacent spaces; and

.3 the fire integrity of the divisions is to be maintained at openings and penetrations.

3.2 Thermal and structural boundaries

3.2.1 Thermal and structural subdivision

Ships of all types are to be subdivided into spaces by thermal and structural divisions having regard to the fire risks of the space.

3.2.2 Passenger ships

3.2.2.1 *Main vertical zones and horizontal zones*

3.2.2.1.1a) In ships carrying more than 36 passengers, the hull, superstructure and deckhouses are to be subdivided into main vertical zones by 'A-60' class divisions. Steps and recesses are to be kept to a minimum, but where they are necessary, they are also to be 'A-60' class divisions. These standard may be reduced to 'A-0' where one side of the division belong to any of the following categories or where fuel oil tanks are on both sides of the division:

- open deck spaces as per 3.2.2.3.2.2(5)
- sanitary and similar spaces as per 3.2.2.3.2.2(9)
- tanks, voids and auxiliary machinery space having little or no fire risk as per 3.2.2.3.2.2(10).

3.2.2.1.1b) In ships carrying not more than 36 passengers, the hull, superstructure and deckhouses in way of accommodation and service spaces are to be subdivided into main vertical zones by "A" class divisions. These divisions are to have insulation values in accordance with tables in 3.2.2.4.

3.2.2.1.2 As far as practicable the bulkheads forming the boundaries of the main vertical zones above the bulkhead deck are to be in line with watertight subdivision bulkheads situated immediately below the bulkhead deck. The length and width of main vertical zones may be extended to a maximum of 48 [m] in order to bring the ends of main vertical zones to coincide with watertight subdivision bulkheads or in order to accommodate a large public space extending for the whole length of the main vertical zone. The total area of the main vertical zone however, is not to be greater than 1600 [m^2] on any deck. The length and width of a main vertical zone is to be taken as the maximum distance between the furthermost points of the bulkheads bounding it.

IR3.2.2.1.2 If a stairway serves two main vertical zones, the maximum length of one main vertical zone is to be measured from the far side of the main vertical zone stairway enclosure. In this case, all boundaries of the stairway enclosure are to be insulated as main vertical zone bulkheads and access doors leading into the stairway are to be provided from the zones. (See Fig.3.2.2.1 to Fig.3.2.2.4). However, the stairway is not to be included in calculating the size of the main vertical zone if it is treated as its own main vertical zone.

The number of main vertical zones of 48 m length is not limited as long as they comply with all the requirements.

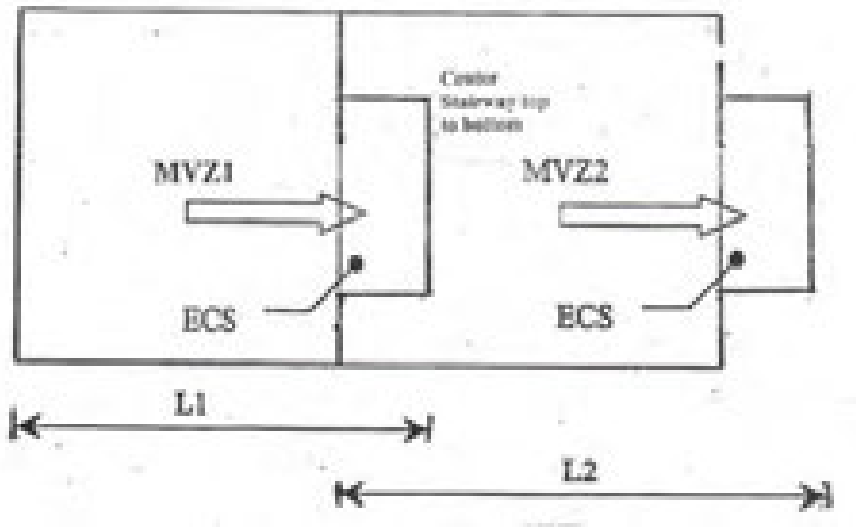

Fig.3.2.2.1 : ECS serves one MVZ

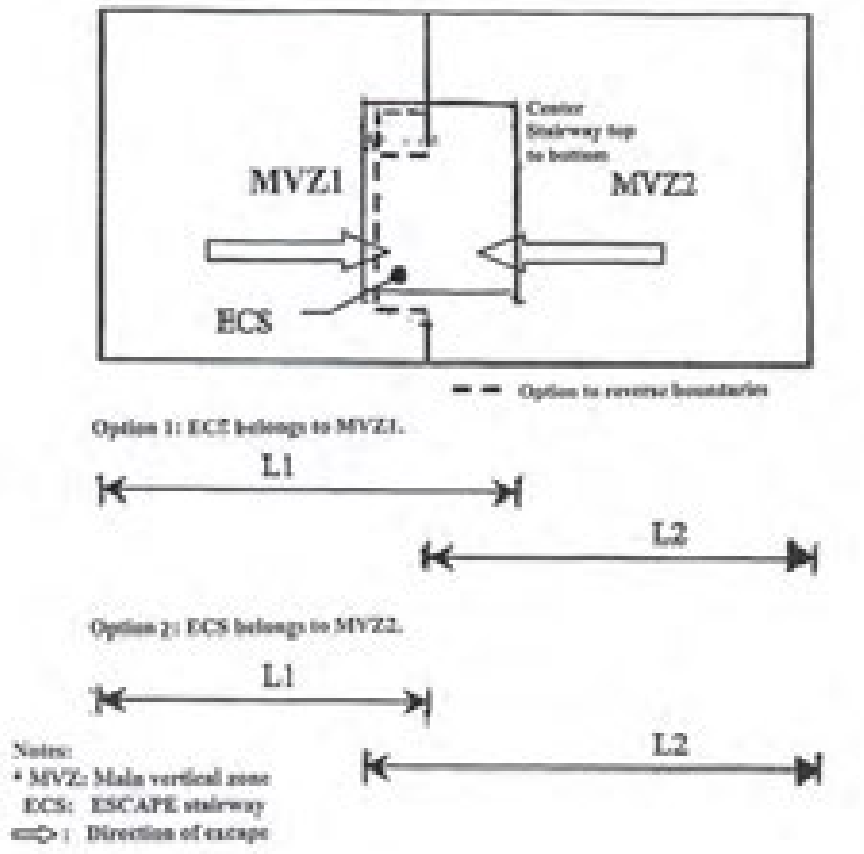

Fig.3.2.2.2 : ECS serves two MVZ's

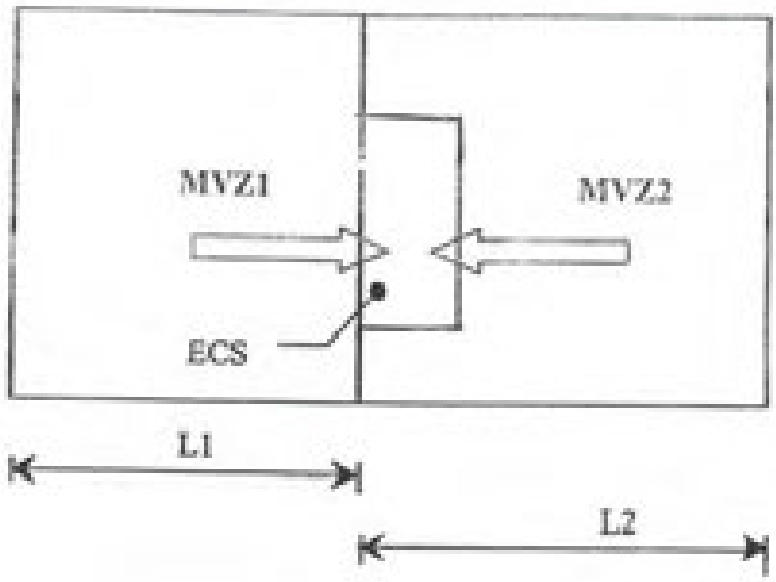

Fig.3.2.2.3 : ECS serves two MVZ's (ECS belongs to MVZ2)

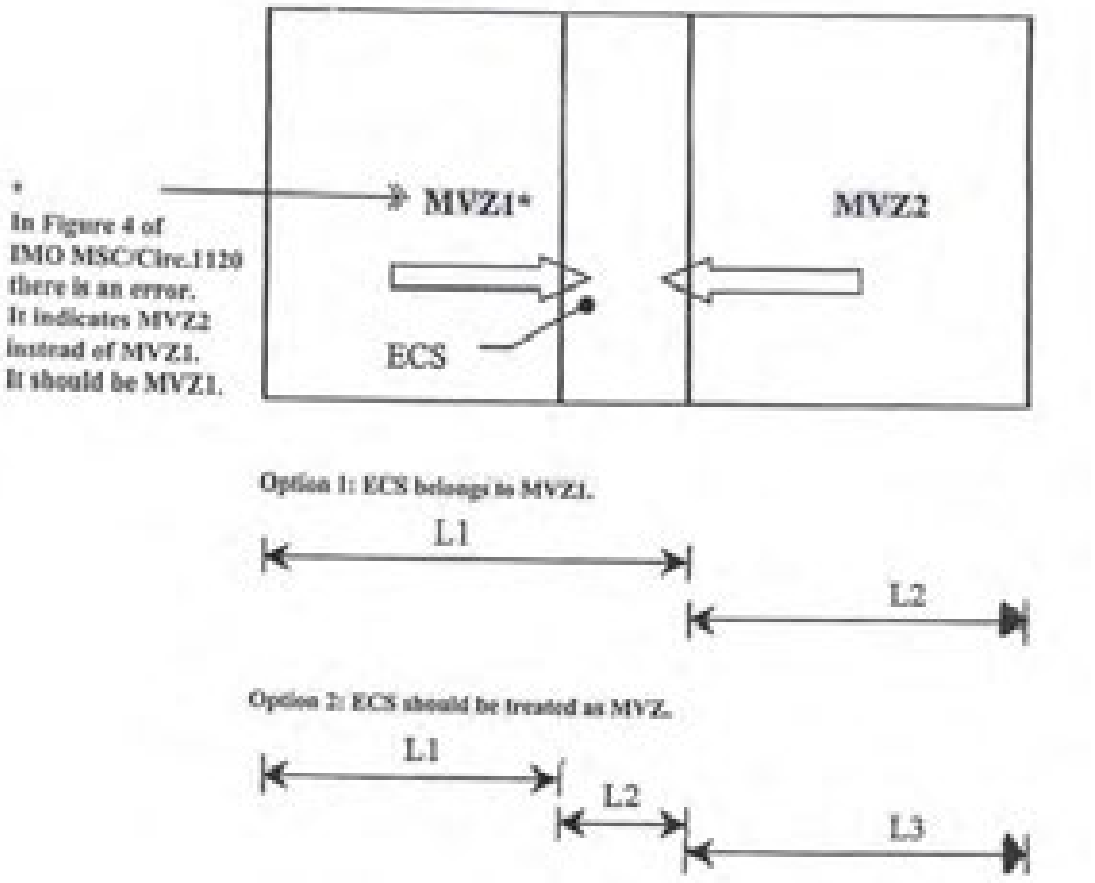

Fig.3.2.2.4 : ECS serves two MVZ's

3.2.2.1.3 Such bulkheads are to extend from deck to deck and to the shell or other boundaries.

3.2.2.1.4 Where a main vertical zone is subdivided by horizontal "A" class divisions into horizontal zones for the purpose of providing an appropriate barrier between a zone with sprinklers and a zone without sprinklers, the divisions are to extend between adjacent main vertical zone bulkheads and to the shell or exterior boundaries of the ship and are to be insulated in accordance with the fire insulation and integrity values given in Table 3.4.

3.2.2.1.5a) On ships designed for special purposes, such as automobile or railroad car ferries, where the provision of main vertical zone bulkheads would defeat the purpose for which the ship is intended, equivalent means for controlling and limiting a fire will be specially considered. Service spaces and ship stores are not to be located on ro-ro decks unless protected in accordance with the applicable requirements.

3.2.2.1.5b) However, in a ship with special category spaces, such spaces are to comply with the applicable provisions of Ch.7, Sec.3 and where such compliance would be inconsistent with other requirements for passenger ships specified in this part, the requirements of Ch.7, Sec.3 would apply.

3.2.2.2 *Bulkheads within a main vertical zone*

3.2.2.2.1 For ships carrying more than 36 passengers, bulkheads which are not required to be "A" class divisions are to be at least "B" class or "C" class divisions as prescribed in the tables in 3.2.2.3.

3.2.2.2.2 For ships carrying not more than 36 passengers, bulkheads within accommodation and service spaces which are not required to be "A" class divisions are to be at least "B" class or "C" class divisions as prescribed in the tables in 3.2.2.4. In addition, corridor bulkheads, where not required to be "A" class are to be "B" class divisions which are to extend from deck to deck except:

.1 when continuous "B" class ceilings or linings are fitted on both sides of the bulkhead, the portion of the bulkhead behind the continuous ceiling or lining is to be of material which, in thickness and composition, is acceptable in the construction of "B" class divisions, but which will be required to meet "B" class integrity standards only in so far as is reasonable and practicable; and

.2 in the case of a ship protected by an automatic sprinkler system complying with the provisions of the Fire Safety Systems Code (Chapter 8), the corridor bulkheads may terminate at a ceiling in the corridor provided such bulkheads and ceilings are of “B” class standard in compliance with 3.2.2.4. All doors and frames in such bulkheads are to be of non-combustible materials and are to have the same fire integrity as the bulkhead in which they are fitted.

3.2.2.2.3 Bulkheads required to be "B" class divisions, except corridor bulkheads as prescribed in 3.2.2.2.2, are to extend from deck to deck and to the shell or other boundaries. However, where a continuous "B" class ceiling or lining is fitted on both sides of a bulkhead which is at least of the same fire resistance as the adjoining bulkhead, the bulkhead may terminate at the continuous ceiling or lining.

IR3.2.2.2.3 If an air gap between cabins results in an opening in the continuous B-15 ceiling, the bulkheads on the both sides of the air gap are to be of class B-15. MSC Circ.917 "Guidelines on fire safety construction in accommodation areas" as corrected by MSC/Circ.917/Corr.1 may be referred for details of construction.

3.2.2.3 *Fire integrity of bulkheads and decks in ships carrying more than 36 passengers*

3.2.2.3.1 In addition to complying with the specific provisions for fire integrity of bulkheads and decks of passenger ships, the minimum fire integrity of all bulkheads and decks is to be as prescribed in Table 3.1 and Table 3.2. Where, due to any particular structural arrangements in the ship, difficulty is experienced in determining from the tables the minimum fire integrity value of any divisions, such values are to be determined to the satisfaction of IRS.

3.2.2.3.2 The following requirements are to govern application of the tables:

.1 Table 3.1 is to apply to bulkheads not bounding either main vertical zones or horizontal zones. Table 3.2 is to apply to

decks not forming steps in main vertical zones nor bounding horizontal zones;

.2 For determining the appropriate fire integrity standards to be applied to boundaries between adjacent spaces, such spaces are classified according to their fire risk as shown in categories (1) to (14) below. Where the contents and use of a space are such that there is a doubt as to its classification for the purpose of this regulation, or where it is possible to assign two or more classifications to a space, it is to be treated as a space within the relevant category having the most stringent boundary require-ments. Smaller, enclosed rooms within a space that have less than 30% communicating openings to that space are considered separate spaces. The fire integrity of the boundary bulkheads and decks of such smaller rooms is to be as prescribed in Table 3.1 and Table 3.2. The title of each category is intended to be typical rather than restrictive. The number in parentheses preceding each category refers to the applicable column or row in the tables.

(1) *Control stations*

- Spaces containing emergency sources of power and lighting.
- Wheelhouse and chartroom.
- Spaces containing the ship's radio equipment.
- Fire control stations.
- Control room for propulsion machinery when located outside the propulsion machinery space.
- Spaces containing centralized fire alarm equipment.
- Spaces containing centralized emer-gency public address system stations and equipment.

(2) *Stairways*

- Interior stairways, lifts, totally enclosed emergency escape trunks, and escalators (other than those wholly contained within the machinery spaces) for passengers and crew and enclosures thereto.
- In this connection a stairway which is enclosed at only one level is to be regarded as part of the space from which it is not separated by a fire door.

(3) *Corridors*

- Passenger and crew corridors and lobbies.

(4) *Evacuation stations and external escape routes*

- Survival craft stowage area.
- Open deck spaces and enclosed promenades forming lifeboat and liferaft embarkation and lowering stations.
- Assembly stations, internal and external.
- External stairs and open decks used for escape routes.
- The ship's side to the waterline in the lightest seagoing condition, superstructure and deckhouse sides situated below and adjacent to the liferaft and evacuation slide embarkation areas.

(5) *Open deck spaces*

- Open deck spaces and enclosed promenades clear of lifeboat and liferaft embarkation and lowering stations. To be considered in this category, enclosed promenades are to have no significant fire risk, meaning that furnishings are to be restricted to deck furniture. In addition, such spaces are to be naturally ventilated by permanent openings.
- Air spaces (the space outside superstructures and deckhouses).

(6) *Accommodation spaces of minor fire risk*

- Cabins containing furniture and furnishings of restricted fire risk.
- Offices and dispensaries containing furniture and furnishings of restricted fire risk.
- Public spaces containing furniture and furnishings of restricted fire risk and having a deck area of less than 50 [m^2].

(7) *Accommodation spaces of moderate fire risk*

- Spaces as in category (6) above but containing furniture and furnishings of other than restricted fire risk.
- Public spaces containing furniture and furnishings of restricted fire risk and having a deck area of 50 [m^2] or more.
- Isolated lockers and small store-rooms in accommodation spaces having areas less than 4 [m^2] (in which flammable liquids are not stowed)

- Motion picture projection and film stowage rooms. Diet kitchens (containing no open flame).
- Cleaning gear lockers (in which flammable liquids are not stowed).
- Laboratories (in which flammable liquids are not stowed).
- Pharmacies.
- Small drying rooms (having a deck area of 4 [m^2] or less).
- Specie rooms.
- Operating rooms.

(8) *Accommodation spaces of greater fire risk*

- Public spaces containing furniture and furnishings of other than restricted fire risk and having a deck area of 50 [m^2] or more.
- Barber shops and beauty parlours.
- Saunas.

(9) *Sanitary and similar spaces*

- Communal sanitary facilities, showers, baths, water closets, etc.
- Small laundry rooms.
- Indoor swimming pool area.
- Isolated pantries containing no cooking appliances in accommodation spaces.
- Private sanitary facilities are to be considered a portion of the space in which they are located.

IR.(9) “Isolated pantries containing no cooking appliances in accommodation spaces” are pantries enclosed in an accommodation space and are only accessible from accommodation spaces and/ or open deck. For the purpose of this categorization, “accommodation space” is as defined in Ch.1, Section 3.1. These pantries should not have communicating openings with main galley (category 12 space) and other enclosed spaces which are not accommodation spaces. (See Fig. 3.2.2.3.2).

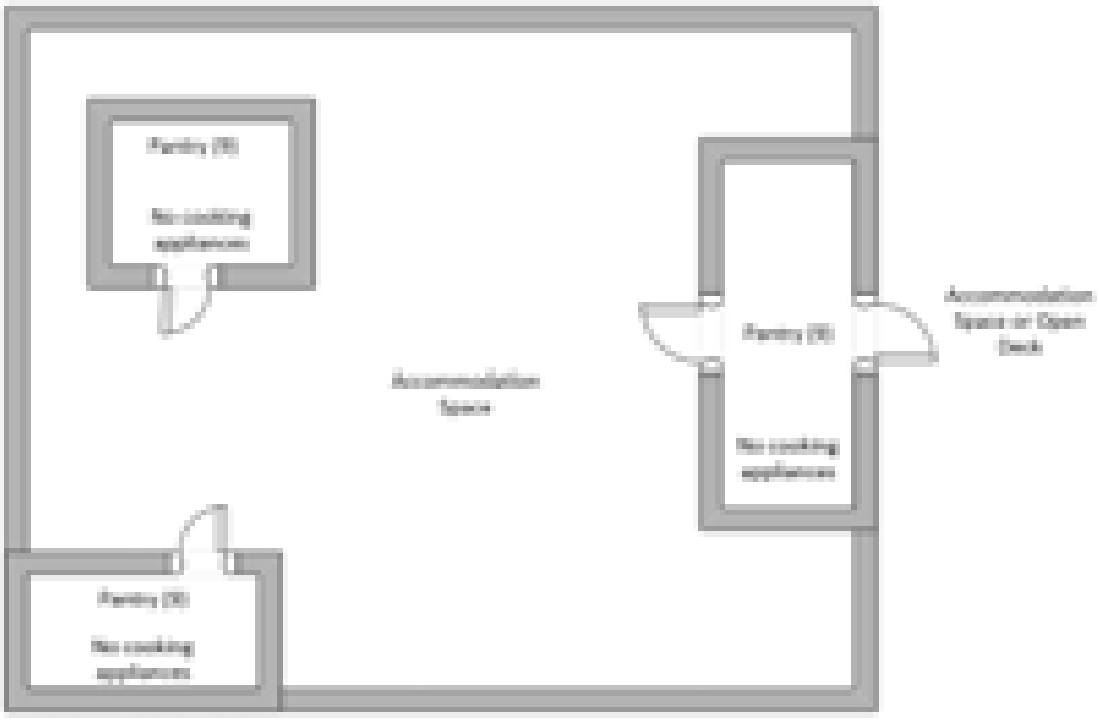

Fig. 3.2.2.3.2: Examples of Category 9 “Isolated pantry containing no cooking appliances in an accommodation space”.

(10) *Tanks, voids and auxiliary machinery spaces having little or no fire risk*

- Water tanks forming part of the ship's structure.
- Voids and cofferdams.
- Auxiliary machinery spaces which do not contain machinery having a pressure lubrication system and where storage of combustibles is prohibited, such as:
  - ventilation and air-conditioning rooms;
  - windlass room;
  - steering gear room;
  - stabilizer equipment room;
  - electrical propulsion motor room;
  - rooms containing section switchboards and purely electrical equipment other than oil-filled electrical transformers (above 10 kVA);
  - shaft alleys and pipe tunnels;
  - spaces for pumps and refrigeration machinery (not handling or using flammable liquids).
- Closed trunks serving the spaces listed above.
- Other closed trunks such as pipe and cable trunks.

IR.(10) In cases where urea or sodium hydroxide solution tanks for selective catalytic reduction (SCR) systems, exhaust gas recirculation (EGR) systems or exhaust gas cleaning systems (EGCS) are installed in a space separated from engine room, the solution tank space is to be considered in this category. The division between the engine room and the solution tank space should have a fire integrity of at least "A-0" class.

(11) *Auxiliary machinery spaces, cargo spaces, cargo and other oil tanks and other similar spaces of moderate fire risk*

- Cargo oil tanks.
- Cargo holds, trunkways and hatchways.
- Refrigerated chambers.
- Oil fuel tanks (where installed in a separate space with no machinery).
- Shaft alleys and pipe tunnels allowing storage of combustibles.
- Auxiliary machinery spaces as in category (10) which contain machinery having a pressure lubrication system or where storage of combustibles is permitted.
- Oil fuel filling stations.
- Spaces containing oil-filled electrical transformers (above 10 kVA).
- Spaces containing turbine and reciprocating steam engine driven auxiliary generators and small internal combustion engines of power output up to 110 kW driving generators, sprinkler, drencher or fire pumps, bilge pumps, etc.
- Closed trunks serving the spaces listed above.

(12) *Machinery spaces and main galleys*

- Main propulsion machinery rooms (other than electric propulsion motor rooms) and boiler rooms.
- Auxiliary machinery spaces other than those in categories (10) and (11) which contain internal combustion machinery or other oil-burning, heating or pumping units.
- Main galleys and annexes.
- Trunks and casings to the spaces listed above.

(13) *Store-rooms, workshops, pantries, etc*.

- Main pantries not annexed to galleys.
- Main laundry.
- Large drying rooms (having a deck area of more than 4 [m^2]).
- Miscellaneous stores.
- Mail and baggage rooms.
- Garbage rooms.
- Workshops (not part of machinery spaces, galleys, etc.).
- Lockers and store-rooms having areas greater than 4 [m^2], other than those spaces that have provisions for the storage of flammable liquids.

(14) *Other spaces in which flammable liquids are stowed*

- Paint lockers.
- Store-rooms containing flammable liquids (including dyes, medicines, etc.).
- Laboratories (in which flammable liquids are stowed);

.3 Where a single value is shown for the fire integrity of a boundary between two spaces, that value will apply in all cases;

.4 Notwithstanding the provision of a 3.2.2.2 there are no special requirements for material or integrity of boundaries where only a dash appears in the tables; and

.5 In respect of category (5) spaces the insulation values in Table 3.1 apply to ends of deckhouses and superstructures, and the insulation values in Table 3.2 apply to weather decks. In no case will the requirements of category (5) of Table 3.1 or Table 3.2 necessitate enclosure of spaces which need not be enclosed.

IR.6 Distribution boards may be located behind panels/linings within accommodation spaces including stairway enclosures, without the need to categorize the space. However, this space is not to be used for any other storage purpose.

If distribution boards are located in an identifiable space having a deck area of less than 4 [m^2], this space may be categorized as (7).

(Note : Category (7) applies to 'Accommodation spaces of moderate fire risk').

3.2.2.3.3 Continuous "B" class ceilings or linings, in association with the relevant decks or bulkheads, may be accepted as contributing wholly or in part, to the required insulation and integrity of a division.

3.2.2.3.4 *Construction and arrangement of saunas*

.1 The perimeter of the sauna is to be of "A" class boundaries and may include changing rooms, showers and toilets. The sauna is to be insulated to A-60 standard against other spaces except those inside of the perimeter and spaces of categories (5), (9) and (10).

.2 Bathrooms with direct access to saunas may be considered as part of them. In such cases, the door between sauna and the bathroom need not comply with fire safety requirements.

.3 The traditional wooden lining on the bulkheads and ceiling are permitted in the sauna. The ceiling above the oven is to be lined with a non-combustible plate with an air gap of at least 30 [mm]. The distance from the hot surfaces to combustible materials is to be atleast 500 [mm] or the combustible materials are to be protected (e.g. non-combustible plate with an air gap of at least 30 [mm]).

.4 The traditional wooden benches are permitted to be used in the sauna.

.5 The sauna door is to open outwards by pushing.

.6 Electrically heated ovens are to be provided with a timer.

3.2.2.4 *Fire integrity of bulkheads and decks in ships carrying not more than 36 passengers*

3.2.2.4.1 In addition to complying with the specific provisions for fire integrity of bulkheads and decks of passenger ships, the minimum fire integrity of bulkheads and decks are to be as prescribed in Table 3.3 and Table 3.4.

3.2.2.4.2 The following requirements govern application of the tables:

.1 Table 3.3 and Table 3.4 are to apply respectively to the bulkheads and decks separating adjacent spaces;
.2 For determining the appropriate fire integrity standards to be applied to divisions between adjacent spaces, such spaces are classified according to their fire risk as shown in categories (1) to (11) below. Where the contents and use of a space are such that there is a doubt as to its classification for the purpose of this regulation, or where it is possible to assign two or more classifications to a space, it is to be treated as a space within the relevant category having the most stringent boundary requirements. Smaller, enclosed rooms within a space that have less than 30 % communicating openings to that space are considered separate spaces. The fire integrity of the boundary bulkheads and decks of such smaller rooms are to be as prescribed in Table 3.3 and Table 3.4. The title of each category is intended to be typical rather than restrictive. The number in parentheses preceding each category refers to the applicable column or row in the tables.

Table 3.1 : Bulkheads not bounding either main vertical zones or horizontal zones (Ships with > 36 passengers)

Spaces		(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)	(11)	(12)	(13)	(14)
Control stations	(1)	B-0[a]	A-0	A-0	A-0	A-0	A-60	A-60	A-60	A-0	A-0	A-60	A-60	A-60	A-60

Other spaces in which flammable liquids are stowed	(14)	A-60	A-60	A-60	A-60	A-0	A-30	A-60	A-60	A-0	A-0	A-0	A-0	A-0	A-0

Note: To be applied to Table 3.1 and Table 3.2.

a Where adjacent spaces are in the same numerical category and superscript "a" appears a bulkhead or deck between such spaces need not be fitted if deemed unnecessary by IRS. For example, in category (12) a bulkhead will not be required between a galley and its annexed pantries provided the pantry bulkhead and decks maintain the integrity of the galley boundaries. A bulkhead is, however, required between a galley and machinery space even though both spaces are in category (12).

b The ship's side, to the waterline in the lightest seagoing condition, superstructure and deckhouse sides situated below and adjacent to liferafts and evacuation slides may be reduced to "A-30".

c Where public toilets are installed completely within the stairway enclosure, the public toilet bulkhead within the stairway enclosure can be of "B" class integrity.

d Where spaces of categories (6), (7), (8) and (9) are located completely within the outer perimeter of the assembly station, the bulkheads of these spaces are allowed to be of "B-0" class integrity. Control positions for audio, video and light installations may be considered as part of the assembly station.

(1) *Control stations*

- Spaces containing emergency sources of power and lighting.
- Wheelhouse and chartroom.
- Spaces containing the ship's radio equipment.
- Fire control stations.
- Control room for propulsion machinery when located outside the machinery space.
- Spaces containing centralized fire alarm equipment.

(2) *Corridors*

- Passenger and crew corridors and lobbies.

(3) *Accommodation spaces*

- Spaces as defined in Ch.1, 3.1 but excluding corridors.

(4) *Stairways*

- Interior stairways, lifts, totally enclosed emergency escape trunks, and escalators (other than those wholly contained within the machinery spaces) and enclosures thereto.
- In this connection, a stairway which is enclosed only at one level is to be regarded as part of the space from which it is not separated by a fire door.

(5) *Service spaces (low risk)*

- Lockers and store-rooms not having provisions for the storage of flammable liquids and having areas less than 4 [m^2] and drying rooms and laundries.

(6) *Machinery spaces of category A*

- Spaces as defined in Ch.1, 3.31.

(7) *Other machinery spaces*

- Electrical equipment rooms (auto-telephone exchange, air-conditioning duct spaces).
- Spaces as defined in Chapter 1, 3.30 excluding machinery spaces of category A.

IR.(7) In cases where urea or sodium hydroxide solution tanks for selective catalytic reduction (SCR) systems, exhaust gas recirculation (EGR) systems or exhaust gas cleaning systems (EGCS) are installed in a space separated from engine room, the solution tank space is to be considered in this category. The division between the engine room and the solution tank space should have a fire integrity of at least "A-0" class.

(8) *Cargo spaces*

- All spaces used for cargo (including cargo oil tanks) and trunkways and hatchways to such spaces, other than special category spaces.

(9) *Service spaces (high risk)*

- Galleys, pantries containing cooking appliances, paint and lamp rooms, lockers and store-rooms having areas of 4 [m^2] or more, spaces for the storage of flammable liquids, saunas and workshops other than those forming part of the machinery spaces.

(10) *Open decks*

- Open deck spaces and enclosed promenades having little or no fire risk. Enclosed promenades are to have no significant fire risk, meaning that furnishing are to be restricted to deck furniture. In addition, such spaces are to be naturally ventilated by permanent openings. Air spaces (the space outside superstructures and deckhouses).

(11) *Special category and ro-ro spaces*

- Spaces as defined in Ch.1, 3.41 and 3.46.

IR.2 For location of distribution boards in accommodation spaces, refer to IR.6, 3.2.2.3.2 of this chapter.

.3 In determining the applicable fire integrity standard of a boundary between two spaces within a main vertical zone or horizontal zone which is not protected by an automatic sprinkler system complying with the provisions of the Fire Safety Systems Code (Chapter 8) or between such zones neither of which is so protected, the higher of the two values given in the tables are to apply; and

.4 In determining the applicable fire integrity standard of a boundary between two spaces within a main vertical zone or horizontal zone which is protected by an automatic sprinkler system complying with the provisions of the Fire Safety Systems Code (Chapter 8) or between such zones both of which are so protected, the lesser of the two values given in the tables is to apply. Where a zone with sprinklers and a zone without sprinklers meet within accommodation and service spaces, the higher of the two values given in the tables is to apply to the division between the zones.

3.2.2.4.3 Continuous "B" class ceilings or linings, in association with the relevant decks or bulkheads, may be accepted as contributing, wholly or in part, to the required insulation and integrity of a division.

3.2.2.4.4 External boundaries which are required in 5.2 to be of steel or other equivalent material may be pierced for the fitting of windows and sidescuttles provided that there is no requirement for such boundaries of passenger ships to have "A" class integrity. Similarly, in such boundaries which are not required to have "A" class integrity, doors may be constructed of materials which are to the satisfaction of IRS.

3.2.2.4.5 Saunas are to comply with 3.2.2.3.4.

3.2.2.5 *Protection of stairways and lifts in accommodation area*

3.2.2.5.1 Stairways are to be within enclosures formed of "A" class divisions, with positive means of closure at all openings, except that:

.1 a stairway connecting only two decks need not be enclosed, provided the integrity of the deck is maintained by proper bulkheads or self-closing doors in one 'tween-deck space. When a stairway is closed in one 'tween-deck space, the stairway enclosure is to be protected in accordance with the tables for decks in 3.2.2.3 or 3.2.2.4; and

.2 stairways may be fitted in the open in a public space, provided they lie wholly within the public space.

3.2.2.5.2 Lift trunks are to be so fitted as to prevent the passage of smoke and flame from one ‘tween-deck to another and are to be provided with means of closing so as to permit the control of draught and smoke. Machinery for lifts located within stairway enclosures are to be arranged in a separate room, surrounded by steel boundaries, except that small passages for lift cables are permitted. Lifts which open into spaces other than corridors, public spaces, special category spaces, stairways and external areas are not to open into stairways included in the means of escape.

3.2.2.6 *Arrangement of cabin balconies*

On passenger ships constructed on or after 1 July 2008, non-load bearing partial bulkheads which separate adjacent cabin balconies are to be capable of being opened by the crew from each side for the purpose of fighting fires.

3.2.2.7 Protection of atriums

3.2.2.7.1 Atriums are to be within enclosures formed of "A" class divisions having a fire rating determined in accordance with Tables 3.2 and 3.4, as applicable.

3.2.2.7.2 Decks separating spaces within atriums are to have a fire rating determined in accordance with Tables 3.2 and 3.4, as applicable.

Table 3.3 : Fire integrity of bulkheads separating adjacent spaces (Ships with ≤ 36 passengers)

Spaces		(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)	(11)

Open decks	(10)	*	*	*	*	*	*	*	*	*	-	A-0
Special category and ro-ro spaces [g]	(11)	A-60	A-30[g]	A-30 A-0[d]	A-30[g]	A-0	A-60[g]	A-0	A-0	A-30	A-0	A-30[g]

Notes: To be applied to both Table 3.3 and Table 3.4 as appropriate.

a For clarification as to which applies, see 3.2.2.2 and 3.2.2.5.

b Where spaces are of the same numerical category and superscript b appears, a bulkhead or deck of the rating shown in the tables is only required when the adjacent spaces are for a different purpose, (e.g. in category (9)). A galley next to a galley does not require a bulkhead but a galley next to a paint room requires an "A-0" bulkhead.

c Bulkhead separating the wheelhouse and chartroom from each other may have a "B-0" rating. No fire rating is required for those partitions separating the navigation bridge and the safety centre when the latter is within the navigation bridge

IRc A navigation locker that can be accessed from the wheelhouse is to be considered as a control station with respect to the requirements in Table 3.3 and the bulkhead separating the wheelhouse and such a locker is to have fire integrity of at least “B-0” class

d See 3.2.2.4.2.3 and 3.2.2.4.2.4.

e For the application of 3.2.2.1.1b), "B-0" and "C", where appearing in Table 3.3, is to be read as "A-0".

f Fire insulation need not be fitted if the machinery space in category (7), in the opinion of IRS, has little or no fire risk.

g Ships constructed before 01 July 2014 are to comply, as a minimum, with the previous requirements applicable at the time the ship was constructed, as specified in Chapter 1, 1.3.

---

* Where an asterisk appears in the tables, the division is required to be of steel or other equivalent material, but is not required to be of "A" class standard. However, where a deck, except in a category (10) space, is penetrated for the passage of electric cables, pipes and vent ducts, such penetrations are to be made tight to prevent the passage of flame and smoke. Divisions between control stations (emergency generators) and open decks may have air intake openings without means for closure, unless a fixed gas fire-fighting system is fitted.

For the application of 3.2.2.1.1b), an asterisk, where appearing in Table 3.4, except for categories (8) and (10), is to be read as “A-0”.

3.2.3 Cargo ships except tankers

3.2.3.1 *Methods of protection in accommodation area*

3.2.3.1.1 One of the following methods of protection is to be adopted in accommodation and service spaces and control stations:

.1 **Method IC**

The construction of internal divisional bulkheads of non-combustible "B" or "C" class divisions generally without the installation of an automatic sprinkler, fire detection and fire alarm system in the accommodation and service spaces, except as required by 1.5.5.1; or

.2 **Method IIC**

The fitting of an automatic sprinkler, fire detection and fire alarm system as required by 1.5.5.2 for the detection and extinction of fire in all spaces in which fire might be expected to originate, generally with no restriction on the type of internal divisional bulkheads; or

.3 **Method IIIC**

The fitting of a fixed fire detection and fire alarm system as required by 1.5.5.3, in spaces in which a fire might be expected to originate, generally with no restriction on the type of internal divisional bulkheads, except that in no case must the area of any accommodation space or spaces bounded by an "A" or "B" class division exceed 50 [m^2]. However, increasing this area for public spaces will be specially considered.

IR3.2.3.1 For fire protection materials refer Fig.3.1 and Table 3.5b and Table 3.5c.

(1) Vapour barriers used on pipes for cold services (cold service means refrigeration system with temperatures below ambient air and sea water) may be of combustible materials provided that their surface has low flame spread characteristics. (Ch.2, Cl.2.3.1.1).

(2) Where the material is fitted on non-combustible bulkheads, ceiling and lining in accommodation and service spaces. (Ch.2, Cl.2.3.2.2).

(3) To be applied to those accommodation and service spaces bounded by non-combustible bulkhead, ceiling and linings. (Ch.2, Cl.2.3.2.3.a).

(4) Only in corridors and stairway enclosures serving accommodation and service spaces and control stations. (Ch.2, Cl.2.3.1.2.2).

(5) Applicable to paints, varnishes and other finishes. (Ch.2, Cl. 3.2.1).

(6) Only in corridors and stairway enclosures.

(7) Only in accommodation and service spaces and control stations (Ch.2, Cl.3.3.1)

- As far as window boxes construction is concerned, reference is also to be made to MSC/Circ.917 and MSC/Circ. 917 Corr.1

3.2.3.1.2 The requirements for the use of non-combustible materials in the construction and insulation of boundary bulkheads of machinery spaces, control stations, service spaces, etc., and the protection of the above stairway enclosures and corridors will be common to all three methods outlined in 3.2.3.1.1.

3.2.3.2 *Bulkheads within accommodation area*

3.2.3.2.1 All bulkheads required to be 'B' class divisions are to extend from deck to deck and to the shell or other boundaries, unless continuous 'B' class ceilings and linings are fitted on both sides of the bulkhead in which case the bulkhead may terminate at the continuous ceiling or lining. MSC Circ.917 "Guidelines on fire safety construction in accommodation areas" may be referred for details of construction.

IR3.2.3.2.1 MSC/Circ.917 "Guidelines on fire safety construction in accommodation areas" as corrected by MSC/Circ.917/Corr.1 may be referred for details of construction.

3.2.3.2.2 Method IC

Bulkheads not required by this or other regulations for cargo ships to be "A" or "B" class divisions, are to be of at least "C" class construction.

3.2.3.2.3 Method IIC

There are no restriction on the construction of bulkheads not required by this or other regulations for cargo ships to be "A" or "B" class divisions except in individual cases where "C" class bulkheads are required in accordance with Table 3.5a.

3.2.3.2.4 Method IIIC

There are no restriction on the construction of bulkheads not required for cargo ships to be "A" or "B" class divisions except that the area of any accommodation space or spaces bounded by a continuous "A" or "B" class division must in no case exceed 50 [m^2], except in individual cases where "C" class bulkheads are required in accordance with Table 3.5a. Consideration may be given to increasing this area for public spaces.

3.2.3.3 *Fire integrity of bulkheads and decks*

3.2.3.3.1 In addition to complying with the specific provisions for fire integrity of bulkheads and decks of cargo ships, the minimum fire integrity of bulkheads and decks are to be as prescribed in Table 3.5a and Table 3.6.

3.2.3.3.2 The following requirements are to govern application of the tables:

.1 Table 3.5a and Table 3.6 apply respectively to the bulkheads and decks separating adjacent spaces;

.2 For determining the appropriate fire integrity standards to be applied to divisions between adjacent spaces, such spaces are classified according to their fire risk as shown in categories (1) to (11) below. Where the contents and use of a space are such that there is a doubt as to its classification for the purpose of this section, or where it is possible to assign two or more classifications to a space, it is to be treated as a space within the relevant category having the most stringent boundary requirements. Smaller, enclosed rooms within a space that have less than 30% communicating openings to that space are considered separate spaces. The fire integrity of the boundary bulkheads and decks of such smaller rooms are to be as prescribed in Table 3.5a and Table 3.6. The title of each category is intended to be typical rather than restrictive. The number in parentheses preceding each category refers to the applicable column or row in the tables;

(1) *Control stations*

- Spaces containing emergency sources of power and lighting.
- Wheelhouse and chartroom.
- Spaces containing the ship's radio equipment.
- Fire control stations.
- Control room for propulsion machinery when located outside the machinery space.
- Spaces containing centralized fire alarm equipment.

(2) *Corridors*

- Corridors and lobbies.

(3) *Accommodation spaces*

- Spaces as defined in Ch.1, 3.1, excluding corridors.

(4) *Stairways*

- Interior stairway, lifts, totally enclosed emergency escape trunks, and escalators (other than those wholly contained within the machinery spaces) and enclosures thereto.

- In this connection, a stairway which is enclosed only at one level is to be regarded as part of the space from which it is not separated by a fire door.

(5) *Service spaces (low risk)*

- Lockers and store-rooms not having provisions for the storage of flammable liquids and having areas less than 4 [m^2] and drying rooms and laundries.

(6) *Machinery spaces of category A*

- Spaces as defined in Ch.1, 3.31.

(7) *Other machinery spaces*

- Electrical equipment rooms (auto-telephone exchange, air-conditioning duct spaces).
- Spaces as defined in Ch.1, 3.30 excluding machinery spaces of category A.

IR.(7) In cases where urea or sodium hydroxide solution tanks for selective catalytic reduction (SCR) systems, exhaust gas recirculation (EGR) systems or exhaust gas cleaning systems (EGCS) are installed in a space separated from engine room, the solution tank space is to be considered in this category. The division between the engine room and the solution tank space should have a fire integrity of at least "A-0" class.

(8) *Cargo spaces*

- All spaces used for cargo (including cargo oil tanks) and trunkways and hatchways to such spaces.

(9) *Service spaces (high risk)*

- Galleys, pantries containing cooking appliances, saunas, paint lockers and store-rooms having areas of 4 [m^2] or more, spaces for the storage of flammable liquids, and workshops other than those forming part of the machinery spaces.

(10) *Open decks*

- Open deck spaces and enclosed promenades having little or no fire risk. To be considered in this category, enclosed promenades are to have no significant fire risk, meaning that furnishings are to be restricted to deck furniture. In addition, such spaces are to be naturally ventilated by permanent openings.

- Air spaces (the space outside superstructures and deckhouses).

(11) *Ro-ro and vehicle spaces*

- Ro-ro spaces as defined in Ch.1, 3.41.
- Vehicle spaces as defined in Ch.1, 3.49.

IR.2 For location of distribution boards in accommodation spaces, refer to IR.6, 3.2.2.3.2 of this chapter.

IR 3.2.3.3.2 Navigation equipment room (radar transmitter) and battery rooms are considered as category (1) Control stations for the purpose of this Rule.

Note 1 – Provision chambers are to be treated as store rooms.

2 – Refrigerated provision chambers are to be considered as category (9) service spaces if thermally insulated with combustible materials or category (5) service spaces if thermally insulated with non-combustible materials.

3.2.3.3.3 Continuous "B" class ceilings or linings, in association with the relevant decks or bulkheads, may be accepted as contributing, wholly or in part, to the required insulation and integrity of a division.

3.2.3.3.4 External boundaries which are required in Ch.3, 5.2 to be of steel or other equivalent material may be pierced for the fitting of windows and sidescuttles provided that there is no requirement for such boundaries to have "A" class integrity. Similarly, in such boundaries which are not required to have "A" class integrity, doors may be constructed of materials which are to the satisfaction of IRS.

3.2.3.3.5 Saunas are to comply with 3.2.2.3.4.

3.2.3.4 *Protection of stairways and lift trunks in accommodation spaces, service spaces and control stations*

3.2.3.4.1 Stairways, which penetrate only a single deck are to be protected, at least at one level, by 'B-0' class division and self closing doors. Lifts penetrating a single deck only, are to be surrounded by 'A-0' class division with steel doors at both levels. Stairways and lift trunks penetrating more than a single deck are to be surrounded by at least 'A-0' class division and be protected by self closing doors at all levels.

IR 3.2.3.4.1 Dumb-waiters (food lifts) are to be regarded as lifts.

3.2.3.4.2 On ships having accommodation for 12 persons or less, where stairways penetrate more than a single deck and where there are at least two escape routes direct to the open deck at every accommodation level, the "A-0" requirements of 3.2.3.4.1 may be reduced to "B-0".

Note: To be applied to Table 3.5a and Table 3.6 as appropriate.

a No special requirements are imposed upon bulkheads in methods IIC and IIIC fire protection.

b In case of method IIIC "B" class bulkheads of "B-0" rating are to be provided between spaces or groups of spaces of 50 [m^2] and over in area.

c For clarification as to which applies, see 3.2.3.2 and 3.2.3.4.

d Where spaces are of the same numerical category and superscript d appear, a bulkhead or deck of the rating shown in the tables is only required when the adjacent spaces are for a different purpose, e.g. in category (9), a galley next to a galley does not require a bulkhead but a galley next to a paint room requires an "A-0" bulkhead.

e Bulkheads separating the wheelhouse, chartroom and radio room from each other may have a "B-0" rating.

IRe A navigation locker that can be accessed from the wheelhouse is to be considered as a control station with respect to the requirements in Table 3.5a and the bulkhead separating the wheelhouse and such a locker is to have fire integrity of at least “B-0” class

f An "A-0" rating may be used if no dangerous goods are intended to be carried or if such goods are stowed not less than 3 [m] horizontally from such a bulkhead.

g For cargo spaces in which dangerous goods are intended to be carried, Ch.7, 2.3.8 applies.

h Deleted.

i Fire insulation need not be fitted if the machinery in category (7) if, it has little or no fire risk.

j Ships constructed before 01 July 2014 are to comply, as a minimum, with the previous requirements applicable at the time the ship was constructed, as specified in Chapter 1, 1.3.

* Where an asterisk appears in the tables, the division is required to be of steel or other equivalent material but is not required to be of "A" class standard. However, where a deck, except an open deck, is penetrated for the passage of electric cables, pipes and vent ducts, such penetrations are to be made tight to prevent the passage of flame and smoke. Divisions between control stations (emergency generators) and open decks may have air intake openings without means for closure, unless a fixed gas fire-fighting system is fitted.

3.2.4 Tankers

3.2.4.1 *Application*

For tankers, only method IC as defined in 3.2.3.1.1 is to be used.

3.2.4.2 *Fire integrity of bulkheads and decks*

3.2.4.2.1 In lieu of 3.2.3 and in addition to complying with the specific provisions for fire integrity of bulkheads and decks of tankers, the minimum fire integrity of bulkheads and decks is to be as prescribed in Table 3.7 and Table 3.8.

3.2.4.2.2 The following requirements govern application of the tables:

.1 Table 3.7 and Table 3.8 apply respectively to the bulkhead and decks separating adjacent spaces;

.2 For determining the appropriate fire integrity standards to be applied to divisions between adjacent spaces, such spaces are classified according to their fire risk as shown in categories (1) to (10) below. Where the contents and use of a space are such that there is a doubt as to its classification for the purpose of this regulation, or where it is possible to assign two or more classifications

to a space, it is to be treated as a space within the relevant category having the most stringent boundary requirements. Smaller, enclosed areas within a space that have less than 30% communicating openings to that space are considered separate areas. The fire integrity of the boundary bulkheads and decks of such smaller spaces is to be as prescribed in Table 3.7 and Table 3.8. The title of each category is intended to be typical rather than restrictive. The number in parentheses preceding each category refers to the applicable column or row in the tables;

(1) *Control stations*

- Spaces containing emergency sources of power and lighting.
- Wheelhouse and chartroom.
- Spaces containing the ship's radio equipment.
- Fire control stations.
- Control room for propulsion machinery when located outside the machinery space.
- Spaces containing centralized fire alarm equipment.

(2) *Corridors*

- Corridors and lobbies.

(3) *Accommodation spaces*

- Spaces as defined in Ch.1, 3.1, excluding corridors.

(4) *Stairways*

- Interior stairways, lifts, totally enclosed emergency escape trunks, and escalators (other than those wholly contained within the machinery spaces) and enclosures thereto.
- In this connection, a stairway which is enclosed only at one level is to be regarded as part of the space from which it is not separated by a fire door.

(5) *Service spaces (low risk)*

- Lockers and store-rooms not having provisions for the storage of flammable liquids and having areas less than 4 [m^2] and drying rooms and laundries.

(6) *Machinery spaces of category A*

- Spaces as defined in Ch.1, 3.31.

(7) *Other machinery spaces*

- Electrical equipment rooms (auto-telephone exchange and air-conditioning duct spaces).\
- Spaces as defined in Ch.1, 3.30 excluding machinery spaces of category A.

IR.(7) In cases where urea or sodium hydroxide solution tanks for selective catalytic reduction (SCR) systems, exhaust gas recirculation (EGR) systems or exhaust gas cleaning systems (EGCS) are installed in a space separated from engine room, the solution tank space is to be considered in this category. The division between the engine room and the solution tank space should have a fire integrity of at least "A-0" class.

(8) *Cargo pump-rooms*

- Spaces containing cargo pumps and entrances and trunks to such spaces.

(9) *Service spaces (high risk)*

- Galleys, pantries containing cooking appliances, saunas, paint lockers and store-rooms having areas of 4 [m^2] or more, spaces for the storage of flammable liquids and workshops other than those forming part of the machinery spaces.

(10) *Open decks*

- Open deck spaces and enclosed promenades having little or no fire risk. To be considered in this category, enclosed promenades are to have no significant fire risk, meaning that furnishings are to be restricted to deck furniture. In addition, such spaces are to be naturally ventilated by permanent openings.
- Air spaces (the space outside superstructures and deckhouses).

IR.2 For location of distribution boards in accommodation spaces, refer to IR.6, 3.2.2.3.2 of this chapter.

IR 3.2.4.2.2 Navigation equipment room (radar transmitter) and battery rooms are considered as category (1) Control stations for the purpose of this Rule.

Note 1 – Provision chambers are to be treated as store rooms.

2 – Refrigerated provision chambers are to be considered as category (9) service spaces if thermally insulated with combustible materials or category (5) service spaces if thermally insulated with non-combustible materials.

3.2.4.2.3 Continuous "B" class ceilings or linings, in association with the relevant decks or bulkheads, may be accepted as contributing, wholly or in part, to the required insulation and integrity of a division.

3.2.4.2.4 External boundaries which are required in Ch.3, 5.2 to be of steel or other equivalent material may be pierced for the fitting of windows and side scuttles provided that there is no requirement for such boundaries of tankers to have "A" class integrity. Similarly, in such boundaries which are not required to have "A" class integrity, doors may be constructed of materials which are to the satisfaction of IRS.

3.2.4.2.5 Exterior boundaries of superstructures and deckhouses enclosing accommodation and including any overhanging decks which support such accommodation, are to be constructed of steel and insulated to "A-60" standard for the whole of the portions which face the cargo area and on the outward sides for a distance of 3 [m] from the end boundary facing the cargo area. The distance of 3 [m] is to be measured horizontally and parallel to the middle line of the ship from the boundary which faces the cargo area at each deck level. In the case of the sides of those superstructures and deckhouses, such insulation is to be carried up to the underside of the deck of the navigation bridge. (also see IR3.2.4.2.5).

IR3.2.4.2.5 “A-60” standard insulation is to be provided for the portions which face the cargo area upto the underside of the navigation bridge deck.

3.2.4.2.6 Skylights to cargo pump-rooms are to be of steel and are not to contain any glass. These are to be capable of being closed from outside the pump-room.

3.2.4.2.7 Construction and arrangement of saunas are to comply with 3.2.2.3.4.

Table 3.7 : Fire integrity of bulkheads separating adjacent spaces (tankers)

Notes: To be applied to Table 3.7 and Table 3.8 as appropriate.

a For clarification as to which applies, see 3.2.3.2 and 3.2.3.4.

b Where spaces are of the same numerical category and superscript b appears, a bulkhead or deck of the rating shown in the tables is only required when the adjacent spaces are for a different purpose (e.g. in category (9)). A galley next to a galley does not require a bulkhead but a galley next to a paint room requires an "A-0" bulkhead.

c Bulkheads separating the wheelhouse, chartroom and radio room from each other may have a "B-0" rating.

IRc A navigation locker that can be accessed from the wheelhouse is to be considered as a control station with respect to the requirements in Table 3.7 and the bulkhead separating the wheelhouse and such a locker is to have fire integrity of at least “B-0” class

d Bulkheads and decks between cargo pump-rooms and machinery spaces of category A may be penetrated by cargo pump shaft glands and similar gland penetrations, provided that gas tight seals with efficient lubrication or other means of ensuring the permanence of the gas seal are fitted in way of the bulkheads or deck.

e Where subscript 'e' appears in the Tables, fire insulation need not be fitted if the machinery space in Category (7) has little or no fire risk.

* Where an asterisk appears in the table, the division is required to be of steel or other equivalent material, but is not required to be of "A" class standard. However, where a deck, except an open deck, is penetrated for the passage of electric cables, pipes and vent ducts, such penetrations are to

be made tight to prevent the passage of flame and smoke. Divisions between control stations (emergency generators) and open decks may have air intake openings without means for closure, unless a fixed gas fire-fighting system is fitted.

3.3 Penetration in fire-resisting divisions and prevention of heat transmission

3.3.1 Where "A" class divisions are penetrated, such penetrations are to be tested in accordance with the Fire Test Procedures Code, subject to the provisions of 3.4.1.1.5. In the case of ventilation ducts, 3.7.1.2 and 3.7.3.1 apply. However, where a pipe penetration is made of steel or equivalent material having a thickness of 3 [mm] or greater and a length of not less than 900 [mm] (preferably 450 [mm] on each side of the division), and no openings, testing is not required. Such penetrations are to be suitably insulated by extension of the insulation at the same degree of fire integrity of the division.

3.3.2 Where "B" class divisions are penetrated for the passage of electric cables, pipes, trunks, ducts, etc., or for the fitting of ventilation terminals, lighting fixtures and similar devices, arrangements are to be made to ensure that the fire resistance is not impaired, subject to the provisions of 3.7.3.2. Pipes other than steel or copper that penetrate "B" class divisions are to be protected by either:

.1 a fire tested penetration device, suitable for the fire resistance of the division pierced and the type of pipe used; or

.2 a steel sleeve, having a thickness of not less than 1.8 [mm] and a length of not less than 900 [mm] for pipe diameters of 150 [mm] or more and not less than 600 [mm] for pipe diameters of less than 150 [mm] (preferably equally divided to each side of the division). The pipe is to be connected to the ends of the sleeve by flanges or couplings; or the clearance between the sleeve and the pipe is not to exceed 2.5 [mm]; or any clearance between pipe and sleeve is to be made tight by means of non-combustible or other suitable material.

3.3.3 Uninsulated metallic pipes penetrating "A" or "B" class divisions are to be of materials having a melting temperature which exceeds 950ºC for “A-0” and 850ºC for “B-0” class divisions.

3.3.4 In designing structural fire protection details, the risk of heat transmission at intersections and terminal points of required thermal barriers is to be considered. The insulation of a deck or bulkhead is to be carried past the penetration, intersection or terminal point for a distance of at least 450 [mm] in the case of steel and aluminium structures. If a space is divided with a deck or a bulkhead of "A" class standard having insulation of different values, the insulation with the higher value is to continue on the deck or bulkhead with the insulation of the lesser value for a distance of at least 450 [mm].

3.4 Protection of openings in fire resisting divisions

3.4.1 Openings in bulkheads and decks in passenger ships

3.4.1.1 *Openings in "A" class divisions*

3.4.1.1.1 Except for hatches between cargo, special category, store and baggage spaces, and between such spaces and weather decks, all openings are to be provided with permanently attached means of closing which are to be at least as effective for resisting fires as the divisions in which they are fitted.

3.4.1.1.2 The construction of doors and door frames in "A" class divisions, with the means of securing them when closed, is to provide resistance to fire as well as to the passage of smoke and flame equivalent to that of the bulkheads in which the doors are situated, this being determined in accordance with the Fire Test Procedures Code. Such doors and door frames are to be constructed of steel or other equivalent material. Doors approved without the sill being part of the frame, which are installed on or after 1 July 2010 are to be installed such that the gap under the door does not exceed 12 [mm]. A non-combustible sill is to be installed under the door such that floor coverings do not extend beneath the closed door.

3.4.1.1.3 Watertight doors need not be insulated.

3.4.1.1.4 It is to be possible for each door to be opened and closed from each side of the bulkhead by one person only.

3.4.1.1.5 Fire doors in main vertical zone bulkheads, galley boundaries and stairway enclosures other than power-operated watertight doors and those which are normally locked, are to satisfy the following requirements:

.1 the doors are to be self-closing and be capable of closing against an angle of inclination of up to 3.5° opposing closure;

.2 the approximate time of closure for hinged fire doors is to be not more than 40 seconds and no less than 10 seconds from the beginning of their movement with the ship in upright position. The approximate uniform rate of closure for sliding fire doors is to be of not more than 0.2 [m/s] and not less than 0.1 [m/s] with the ship in the upright position;

.3 the doors, except those for emergency escape trunks, are to be capable of remote release from the continuously manned central control station, either simultaneously or in groups and are to be capable of release also individually from a position at both sides of the door. Release switches are to have an on-off function to prevent automatic resetting of the system;

.4 use of hold-back hooks not subject to central control station release is prohibited;

.5 a door closed remotely from the central control station is to be capable of being re-opened at both sides of the door by local control. After such local opening the door is to close automatically again;

.6 indication is to be provided at the fire door indicator panel in the continuously manned central control station whether each of the remote-released doors are closed;

.7 the release mechanism is to be so designed that the door will automatically close in the event of disruption of the control system or central power supply;

.8 local power accumulators for power-operated doors are to be provided in the immediate vicinity of the doors to enable the doors to be operated after disruption of the control system or central power supply at least ten times (fully opened and closed) using the local controls;

.9 disruption of the control system or central power supply at one door is not to impair the safe functioning of the other doors;

.10 remote-released sliding or power-operated doors are to be equipped with an alarm that sounds for at least 5 seconds but no more than 10 seconds after the door is released from the central control station and before the door begins to move and continue sounding until the door is completely closed;

.11 a door designed to re-open upon contacting an object in its path is to re-open not more than 1 [m] from the point of contact;

.12 double-leaf doors equipped with a latch necessary for their fire integrity are to have a latch that is automatically activated by the operation of the doors when released by the control system;

.13 doors giving direct access to special category spaces which are power-operated and automatically closed need not be equipped with the alarms and remote- release mechanisms required in .3 and .10;

.14 the components of the local control system are to be accessible for maintenance and adjusting; and

.15 power-operated doors are to be provided with a control system of an approved type which is to be able to operate in case of fire, this being determined in accordance with the Fire Test Procedures Code. This system is to satisfy the following requirements:

i) the control system is to be able to operate the door at the temperature of at least 200°C for at least 60 minutes, served by the power supply;

ii) the power supply for all other doors not subject to fire is not to be impaired; and

iii) at temperatures exceeding 200°C the control system is to be automatically isolated from the power supply and is to be capable of keeping the door closed up to at least 945°C.

IR.16 indication signals for lift doors provided in accordance with .13 above are to meet the following:

i) the signal showing that "A" class lift doors are in the closed position is to be activated only when the order to close the main fire doors has been given by the continuously manned central control station;

ii) when there are several lifts giving access to the same stairway, the lift door indicators located in the continuously manned central control station are to be capable of indicating that all the lift doors giving access to the same landing are properly closed. This indication is to be shown on the panel; and

iii) when an order to close the main fire doors is given, the same order is also to stop the lifts from operating by sending them to pre-specified deck, to be determined on a case-by-case basis according to the ship's design. In addition, those inside the lift are to be able to order the lift doors open while those outside the lift are not to be able to do so.

3.4.1.1.6 In ships carrying not more than 36 passengers, where a space is protected by an automatic sprinkler fire detection and alarm system complying with the provisions the Fire Safety Systems Code or fitted with a continuous "B" class ceiling, openings in decks not forming steps in main vertical zones nor bounding horizontal zones are to be closed reasonably tight and such decks are to meet the "A" class integrity requirements in so far as is reasonable and practicable in the opinion of IRS.

3.4.1.1.7 The requirements for "A" class integrity of the outer boundaries of a ship do not apply to glass partitions, windows and sidescuttles, provided that there is no requirement for such boundaries to have "A" class integrity in 3.4.1.3.3. The requirements for "A" class integrity of the outer boundaries of the ship do not apply to exterior doors, except for those in superstructures and deckhouses facing lifesaving appliances, embarkation and external assembly station areas, external stairs and open decks used for escape routes. Stairway enclosure doors need not meet this requirement.

3.4.1.1.8 Except for watertight doors, weathertight doors (semi-watertight doors), doors leading to the open deck and doors which need to be reasonably gastight, all "A" class doors located in stairways, public spaces and main vertical zone bulkheads in escape routes are to be equipped with a self-closing hose port of material, construction and fire resistance which is equivalent to the door into which it is fitted, and is to be a 150 [mm] square clear opening with the door closed and is to be inset into the lower edge of the door, opposite the door hinges or, in the case of sliding doors, nearest the opening.

3.4.1.1.9 Where it is necessary that a ventilation duct passes through a main vertical zone division, a fail-safe automatic closing fire damper is to be fitted adjacent to the division. The damper is also to be capable of being manually closed from each side of the division. The operating position is to be readily accessible and be marked in red light-reflecting colour. The duct between the division and the damper is to be of steel or other equivalent material and, if necessary, insulated to comply with the requirements of 3.3.1. The damper is to be fitted on at least one side of the division with a visible indicator showing whether the damper is in the open position.

3.4.1.2 *Openings in "B" class divisions*

3.4.1.2.1 Doors and door frames in "B" class divisions and means of securing them is to provide a method of closure which will have resistance to fire equivalent to that of the divisions, this being determined in accordance with the Fire Test Procedure Code except that ventilation openings may be permitted in the lower portion of such doors. Where such opening is in or under a door the total net area of opening is not to exceed 0.05 [m^2]. Alternatively, a non-combustible air balance duct routed between the cabin and the corridor, and located below the sanitary unit is permitted where the cross-sectional area of the duct does not exceed 0.05 [m^2]. All ventilation openings are to be fitted with a grill made of non-combustible material. Doors are to be non-combustible. Doors approved without the sill being part of the frame, which are installed on or after 1 July 2010 are to be installed such that the gap under the door does not exceed 25 [mm].

IR3.4.1.2.1 Balancing openings or ducts between two enclosed spaces are prohibited except for openings as permitted by 3.4.1.2.1.

3.4.1.2.2 Cabin doors in "B" class divisions are to be of a self-closing type. Hold-back hooks are not permitted.

3.4.1.2.3 The requirements for 'B' class integrity of the outer boundaries of a ship are not to apply to glass partitions, windows and side scuttles. Similarly, the requirements for 'B' class integrity are not to apply to exterior doors in superstructures and deckhouses. For ships carrying not more than 36 passengers, the use of combustible materials in doors separating cabins from the individual interior sanitary spaces, such as showers, may be permitted.

3.4.1.2.4 In ships carrying not more than 36 passengers, where an automatic sprinkler system complying with the provisions of the Fire Safety Systems Code (Chapter 8) is fitted:

.1 openings in decks not forming steps in main vertical zones nor bounding horizontal zones are to be closed reasonably tight and such decks are to meet the "B" class integrity requirements in so far as is reasonable and practicable in the opinion of IRS; and
.2 openings in corridor bulkheads of "B" class materials are to be protected in accordance with the provisions of 3.2.2.2.

3.4.1.3 *Windows and sidescuttles*

3.4.1.3.1 Windows and sidescuttles in bulkheads within accommodation and service spaces and control stations other than those to which the provisions of 3.4.1.1.6 and of 3.4.1.2.3 apply, are to be so constructed as to preserve the integrity requirements of the type of bulkheads in which they are fitted, this being determined in accordance with the Fire Test Procedures Code.

3.4.1.3.2 Notwithstanding the requirements of Table 3.1 to Table 3.4, windows and sidescuttles in bulkheads separating accommodation and service spaces and control stations from weather are to be constructed with frames of steel or other suitable material. The glass is to be retained by a metal glazing bead or angle.

3.4.1.3.3 Windows facing life-saving appliances, embarkation and assembly stations, external stairs and open decks used for escape routes, and windows situated below liferaft and escape slide embarkation areas are to have fire integrity as required in Table 3.1. Where automatic dedicated sprinkler heads are provided for windows, "A-0" windows may be accepted as equivalent. To be considered under this paragraph, the sprinkler heads are either to be:

.1 dedicated heads located above the windows, and installed in addition to the conventional ceiling sprinklers; or

.2 conventional ceiling sprinkler heads arranged such that the window is protected by an average application rate of at least 5 l/m^2 and the additional window area is included in the calculation of the area of coverage; or

.3 water-mist nozzles that have been tested and approved based on the guidelines developed by IMO. [Refer to the revised guidelines for approval of sprinkler systems equivalent to that referred to in SOLAS regulation II-2/12 (Resolution A 800(19))].

Windows located in the ship’s side below the lifeboat embarkation area are to have fire integrity at least equal to "A-0" class.

Also refer MSC/Circ.917 "Guidelines on fire safety construction in accommodation" as corrected by MSC/Circ.917/Corr.1.

3.4.1.3.4 Notwithstanding the requirement in paragraph 3.4.1.3.3, the requirements in paragraphs 3.4.1.3.5 and 3.4.1.3.6 apply to ships constructed on or after 1 January 2020.

3.4.1.3.5 For ships carrying more than 36 passengers, windows facing survival craft, embarkation and assembly stations, external stairs and open decks used for escape routes, and windows situated below liferaft and escape slide embarkation areas are to have fire integrity as required in table 3.1. Where automatic dedicated sprinkler heads are provided for windows, "A-0" windows may be accepted as equivalent. To be considered under this paragraph, the sprinkler heads must either be:

.1 dedicated heads located above the windows, and installed in addition to the conventional ceiling sprinklers; or

.2 conventional ceiling sprinkler heads arranged such that the window is protected by an average application rate of at least 5 [l/min per square metre] and the additional window area is included in the calculation of the area of coverage; or

.3 water-mist nozzles that have been tested and approved in accordance with the *Revised guidelines for approval of sprinkler systems*

equivalent to that referred to in SOLAS regulation II-2/12 (resolution A.800(19), as amended);

and windows located in the ship's side below the lifeboat embarkation area are to have fire integrity at least equal to "A-0" class.

3.4.1.3.6 For ships carrying not more than 36 passengers, windows facing survival craft and escape slide, embarkation areas and windows situated below such areas are to have fire integrity at least equal to "A-0" class.

3.4.2 Doors in fire-resisting divisions in cargo ships

3.4.2.1 The fire resistance of doors is to be equivalent to that of the division in which they are fitted, this being determined in accordance with the Fire Test Procedures Code. Doors approved as “A” class without the sill being part of the frame, which are installed on or after 1 July 2010 are to be installed such that the gap under the door does not exceed 12 [mm] and a non-combustible sill is to be installed under the door such that floor coverings do not extend beneath the closed door. Doors approved as “B” class without the sill being part of the frame, which are installed on or after 1 July 2010 are to be installed such that the gap under the door does not exceed 25 [mm]. Doors and door frames in "A" class divisions are to be constructed of steel. Doors in "B" class divisions are to be non-combustible. Doors fitted in boundary bulkheads of machinery spaces of category A are to be reasonably gastight and self-closing. Where method IC is adopted the use of combustible materials in doors separating cabins from individual interior sanitary accommodation such as showers may be permitted.

3.4.2.2 Doors required to be self closing are not to be fitted with hold back hooks. However, hold back arrangements fitted with remote release devices of the fail safe type may be utilized.

3.4.2.3 In corridor bulkheads ventilation openings may be permitted in and under the doors of cabins and public spaces. Ventilation openings are also permitted in "B" class doors leading to lavatories, offices, pantries, lockers and store rooms. Except as permitted below, the openings are to be provided only in the lower half of a door. Such opening in or under a door is not to have the total net area exceeding 0.05 [m^2]. Alternatively, a non-combustible air balance duct routed between the cabin and the corridor, and located below the sanitary unit is permitted where the cross-sectional area of the duct does not exceed 0.05 [m^2]. Ventilation openings, except those under the door, are to be fitted with a grille made of non-combustible material.

IR3.4.2.3 Balancing openings or ducts between two enclosed spaces are prohibited except for openings as permitted by 3.4.2.3.

3.4.2.4 Watertight doors need not be insulated.

3.5 Protection of openings in machinery spaces boundaries

3.5.1 Application

3.5.1.1 The provision of 3.5 is to apply to machinery spaces of category A and, where IRS considers it desirable, to other machinery spaces.

3.5.2 Protection of openings in machinery space boundaries

3.5.2.1 The number of skylights, doors, ventilators, openings in funnels to permit exhaust ventilation and other openings to machinery spaces are to be reduced to a minimum consistent with the needs of ventilation and the proper and safe working of the ship.

3.5.2.2 Skylights are to be of steel and are not to contain glass panels.

3.5.2.3 Means of control are to be provided for closing power-operated doors or actuating release mechanisms on doors other than power-operated watertight doors. The control is to be located outside the space concerned, where they will not be cut off in the event of fire in the space it serves.

3.5.2.4 In passenger ships, the means of control required in 3.5.2.3 are to be situated at one control position or grouped in as few positions as possible to the satisfaction of IRS. Such positions are to have safe access from the open deck.

3.5.2.5 In passenger ships, doors, other than power-operated watertight doors are to be so arranged that positive closure is assured in case of fire in the space by power-operated closing arrangements or by the provision of self-closing doors capable of closing against

an inclination of 3.5° opposing closure, and having a fail-safe hook-back facilities provided with a remotely operated release device. Doors for emergency escape trunks need not be fitted with a fail-safe hold-back facility and a remotely operated release device.

3.5.2.6 Windows are not to be fitted in machinery space boundaries. Glass may be used in control rooms within the machinery spaces.

IR3.5.2.7 When access to any machinery space of category A is provided at a low level from an adjacent shaft tunnel, there must be provided in the shaft tunnel, near the watertight door, a light steel fire-screen door operable from both sides.

3.6 Protection of cargo space boundaries

3.6.1 In passenger ships carrying more than 36 passengers, the boundary bulkheads and decks of special category and ro-ro spaces are to be insulated to "A-60" class standard. However, where a category (5), (9) and (10) space, as defined in 3.2.2.3, is on one side of the division the standard may be reduced to "A-0". Where fuel oil tanks are below a special category space, the integrity of the deck between such spaces may be reduced to "A-0" standard.

3.6.2 In passenger ships, indicators are to be provided on the navigating bridge which will indicate when any fire door leading to or from the special category spaces is closed.

3.6.3 In tankers for the protection of cargo tanks carrying crude oil and petroleum products having a flash point not exceeding 60°C, materials readily rendered ineffective by heat are not to be used for valves, fittings, tank opening covers, cargo vent piping, and cargo piping so as to prevent the spread of fire to the cargo.

3.7 Ventilation systems

3.7.1 General

3.7.1.1 Ventilation ducts, including single and double wall ducts, are to be of steel or equivalent material except flexible bellows of short length not exceeding 600 [mm] used for connecting fans to the ducting in air-conditioning rooms. Unless expressly provided otherwise in paragraph 3.7.1.6, any other material used in the construction of ducts, including insulation, are also to be non-combustible. However, short ducts, not generally exceeding 2 [m] in length and with a free cross-sectional area* not exceeding 0.02 [m^2], need not be of steel or equivalent material, subject to the following conditions:

(* The term *free cross-sectional area* means, even in the case of a pre-insulated duct, the area calculated on the basis of the inner dimensions of the duct itself and not the insulation.)

.1 the ducts are to be made of non-combustible material, which may be faced internally and externally with membranes having low flame-spread characteristics and, in each case, a calorific value** not exceeding 45 [MJ/m^2] of their surface area for the thickness used;

(**Refer to the recommendations published by the International Organization for Standardization, in particular publication ISO 1716:2002, Reaction to the fire tests for building products – Determination of the heat of combustion.)

.2 the ducts are only used at the end of the ventilation device; and

.3 the ducts are not situated less than 600 [mm], measured along the duct, from an opening in an "A" or "B" class division, including continuous "B" class ceiling.

IR 3.7.1.1 With respect only to 3.7.1.1 above, a ventilation duct made of material other than steel may be considered equivalent to a ventilation duct made of steel, provided the material is non-combustible and has passed a standard fire test in accordance with Annex 1: Part 3 of the FTP code as non-load bearing structure for 30 minutes following the requirements for testing “B” class divisions.

3.7.1.2 The following arrangements are to be tested in accordance with the Fire Test Procedures Code:

.1 fire dampers, including their relevant means of operation, however, the testing is not required for dampers located at the lower end of the duct in exhaust ducts for galley ranges, which

must be of steel and capable of stopping the draught in the duct; and

.2 duct penetrations through "A" class divisions. However, the test is not required where steel sleeves are directly joined to ventilation ducts by means of riveted or screwed connections or by welding.

3.7.1.3 Fire dampers are to be easily accessible. Where they are placed behind ceilings or linings, these ceilings or linings are to be provided with an inspection hatch on which the identification number of the fire damper is marked. The fire damper identification number is also to be marked on any remote controls provided.

3.7.1.4 Ventilation ducts are to be provided with hatches for inspection and cleaning. The hatches are to be located near the fire dampers.

3.7.1.5 The main inlets and outlets of ventilation systems are to be capable of being closed from outside the spaces being ventilated. The means of closing is to be easily accessible as well as prominently and permanently marked and is to indicate the operating position of the closing device.

3.7.1.6 Combustible gaskets in flanged ventilation duct connections are not permitted within 600 [mm] of openings in "A" or "B" class divisions and in ducts required to be of "A" class construction.

3.7.1.7 Ventilation openings or air balance ducts between two enclosed spaces are not to be provided except as permitted by paragraphs 3.4.1.2.1 and 3.4.2.3.

3.7.2 Arrangement of ducts

3.7.2.1 The ventilation systems for machinery spaces of category A, vehicle spaces, ro-ro spaces, galleys, special category spaces and cargo spaces shall, in general, be separated from each other and from the ventilation systems serving other spaces. However, the galley ventilation systems on cargo ships of less than 4,000 gross tonnage and in passenger ships carrying not more than 36 passengers need not be completely separated from other ventilation systems, but may be served by separate ducts from a ventilation unit serving other spaces. In such a case, an automatic fire damper is to be fitted in the galley ventilation duct near the ventilation unit.

3.7.2.2 Ducts provided for the ventilation of machinery spaces of category A, galleys, vehicle spaces, ro-ro spaces or special category spaces are not to pass through accommodation spaces, service spaces, or control stations unless they comply with paragraph 3.7.2.4.

3.7.2.3 Ducts provided for the ventilation of accommodation spaces, service spaces or control stations are not to pass through machinery spaces of category A, galleys, vehicle spaces, ro-ro spaces or special category spaces unless they comply with paragraph 3.7.2.4.

3.7.2.4 As permitted by paragraphs 3.7.2.2 and 3.7.2.3 ducts are to be either:

.1.1 constructed of steel having a thickness of at least;

a) 3 [mm] for ducts with a free cross-sectional area of less than 0.075 [m^2],

b) 4 [mm] for ducts with a free cross-sectional area of between 0.075 [m^2] and 0.45 [m^2], and

c) at least 5 [mm] for ducts with a free cross-sectional area of over 0.45 [m^2];

.1.2 suitably supported and stiffened;

.1.3 fitted with automatic fire dampers close to the boundaries penetrated; and

IR .1.3 Fire dampers are to be preferably fitted in the space having low fire risk

.1.4 insulated to "A-60" class standard from the boundaries of the spaces they serve to a point at least 5 [m] beyond each fire damper;

or

.2.1 constructed of steel in accordance with paragraphs 3.7.2.4.1.1 and 3.7.2.4.1.2; and

.2.2 insulated to "A-60" class standard throughout the spaces they pass through, except for ducts that pass

through spaces of category (9) or (10) as defined in paragraph 3.2.2.3.2.2.

3.7.2.5 For the purposes of paragraphs 3.7.2.4.1.4 and 3.7.2.4.2.2, ducts are to be insulated over their entire cross-sectional external surface. Ducts that are outside but adjacent to the specified space, and share one or more surfaces with it, are to be considered to pass through the specified space, and are to be insulated over the surface they share with the space for a distance of 450 [mm] past the duct.

IR3.7.2.5 For determining the extent of insulation when the duct passes through an enclosed space, See Fig. 3.7.2.5.

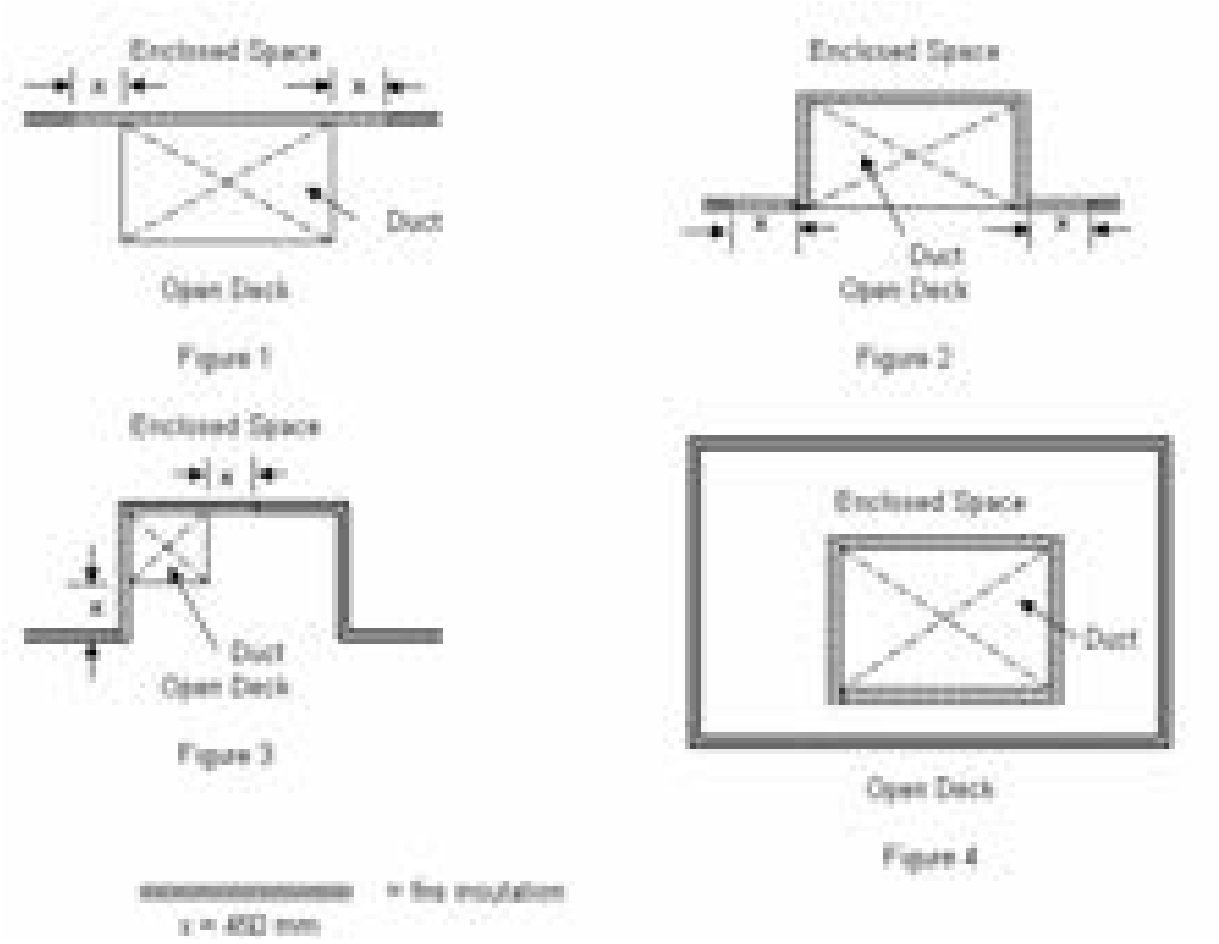

Fig.3.7.2.5 : Examples of galley ducts contiguous to enclosed spaces

3.7.2.6 Where it is necessary that a ventilation duct passes through a main vertical zone division, an automatic fire damper is to be fitted adjacent to the division. The damper is also to be capable of being manually closed from each side of the division. The control location is to be readily accessible and be clearly and prominently marked. The duct between the division and the damper is to be constructed of steel in accordance with paragraphs 3.7.2.4.1.1 and 3.7.2.4.1.2 and insulated to at least the same fire integrity as the division penetrated. The damper is to be fitted on at least one side of the division with a visible indicator showing the operating position of the damper.

IR3.7.2.6 When the galley is served by a duct from a common ventilation unit and not from an independent unit, automatic fire damper is to be provided outside the galley, irrespective of the size of the duct.

3.7.3 Details of fire dampers and duct penetrations

3.7.3.1 Ducts passing through "A" class divisions are to meet the following requirements:

.1 where a thin plated duct with a free cross sectional area equal to, or less than, 0.02 [m^2] passes through "A" class divisions, the opening is to be fitted with a steel sheet sleeve having a thickness of at least 3 [mm] and a length of at least 200 [mm], divided preferably into 100 [mm] on each side of a bulkhead or, in the case of a deck, wholly laid on the lower side of the decks penetrated;

.2 where ventilation ducts with a free cross-sectional area exceeding 0.02 [m^2], but not more than 0.075 [m^2], pass through "A" class divisions, the openings are to be lined with steel sheet sleeves. The ducts and sleeves are to have a thickness of at least 3 [mm] and a length of at least 900 [mm]. When passing through bulkheads, this length is to be divided preferably into 450 [mm] on each side of the bulkhead. These ducts, or sleeves lining such ducts, are to be provided with fire insulation. The insulation is to have at least the same fire integrity as the division through which the duct passes; and

.IR2 The fire insulation required by .2 above is to be provided only to the part of the duct and/or sleeve that is on the same side of the division being fire insulated, and be extended for a minimum of 450 mm along the duct and/or sleeve.

.3 automatic fire dampers are to be fitted in all ducts with a free cross-sectional area exceeding 0.075 [m^2] that pass through "A" class divisions. Each damper is to be fitted close to the division penetrated and the duct between the damper and the division penetrated is to be constructed of steel in accordance with paragraphs 3.7.2.4.1.1 and 3.7.2.4.1.2. The fire damper is to operate automatically, but is also to be capable of being closed manually from both sides of the division. The damper is to be fitted with a visible indicator which shows the operating position of the damper. Fire dampers are not required, however, where ducts pass through spaces surrounded by "A" class divisions, without serving those spaces, provided those ducts have the same fire integrity as the divisions which they penetrate. A duct of cross-sectional area exceeding 0.075 [m^2] is not to be divided into smaller ducts at the penetration of an "A" class division and then recombined into the original duct once through the division to avoid installing the damper required by this provision.

IR 3.7.3.1 Ducts or pipes with free sectional area of 0.075 m^2 or less need to be fitted with fire damper at their passage through Class "A" divisions in those cases indicated in 3.7.2.2 and 3.7.2.3. The fire damper can be omitted if the duct is arranged in compliance with the requirements of 3.7.2.4.2.1 and 3.7.2.4.2.2.

3.7.3.2 Ventilation ducts with a free cross-sectional area exceeding 0.02 [m^2] passing through "B" class bulkheads shall be lined with steel sheet sleeves of 900 [mm] in length, divided preferably into 450 [mm] on each side of the bulkheads unless the duct is of steel for this length.

IR 3.7.3.2 When a duct passing through a division is to be in accordance with 3.3.2 and 3.7.3.2, no clearance is to be allowed between the duct and the division.

3.7.3.3 All fire dampers are to be capable of manual operation. The dampers are to have a direct mechanical means of release or, alternatively, be closed by electrical, hydraulic, or pneumatic operation. All dampers are to be manually operable from both sides of the division. Automatic fire dampers, including those capable of remote operation, are to have a failsafe mechanism that will close the damper in a fire even upon loss of electrical power or hydraulic or pneumatic pressure loss. Remotely operated fire dampers are to be capable of being reopened manually at the damper.

3.7.4 Ventilation systems for passenger ships carrying more than 36 passengers

3.7.4.1 In addition to the requirements in sections 3.7.1, 3.7.2 and 3.7.3, the ventilation system of a passenger ship carrying more than 36 passengers is also to meet the following requirements.

3.7.4.2 In general, the ventilation fans are to be so arranged that the ducts reaching the various spaces remain within a main vertical zone.

3.7.4.3 Stairway enclosures are to be served by an independent ventilation fan and duct system (exhaust and supply) which is not to serve any other spaces in the ventilation systems.

3.7.4.4 A duct, irrespective of its cross-section, serving more than one 'tween-deck accommodation space, service space or control station, is to be fitted, near the penetration of each deck of such spaces, with an automatic smoke damper that is also to be capable of being closed manually from the protected deck above the damper. Where a fan serves more than one 'tween-deck space through separate ducts within a main vertical zone, each dedicated to a single 'tween-deck space, each duct is to be provided with a manually operated smoke damper fitted close to the fan.

3.7.4.5 Vertical ducts, if necessary are to, be insulated as required by tables 3.1 and 3.2. Ducts are to be insulated as required for decks between the space they serve and the space being considered, as applicable.

3.7.5 Exhaust ducts from galley ranges

3.7.5.1 Requirements for passenger ships carrying more than 36 passengers

3.7.5.1.1 In addition to the requirements in sections 3.7.1, 3.7.2 and 3.7.3, exhaust ducts from galley ranges are to be constructed in accordance with paragraphs 3.7.2.4.2.1 and 3.7.2.4.2.2 and insulated to "A-60" class standard throughout accommodation spaces, service spaces, or control stations they pass through. They are also to be fitted with:

.1 a grease trap readily removable for cleaning unless an alternative approved grease removal system is fitted;

.2 a fire damper located in the lower end of the duct at the junction between the duct and the galley range hood which is automatically and remotely operated and, in addition, a remotely operated fire damper located in the upper end of the duct close to the outlet of the duct;

.3 a fixed means for extinguishing a fire within the duct*;

(*Refer to the recommendations published by the International Organization for Standardization, in particular publication ISO 15371:2009, Ships and marine technology – Fire-extinguishing systems for protection of galley cooking equipment.)

.4 remote-control arrangements for shutting off the exhaust fans and supply fans, for operating the fire dampers mentioned in paragraph 3.7.5.1.1.2 and for operating the fire-extinguishing system, which is to be placed in a position outside the galley close to the entrance to the galley. Where a multi-branch system is installed, a remote means located with the above controls shall be provided to close all branches exhausting through the same main duct before an extinguishing medium is released into the system; and

.5 suitably located hatches for inspection and cleaning, including one provided close to the exhaust fan and one fitted in the lower end where grease accumulates.

3.7.5.1.2 Exhaust ducts from ranges for cooking equipment installed on open decks are to conform to paragraph 3.7.5.1.1, as applicable, when passing through accommodation spaces or spaces containing combustible materials.

3.7.5.2 Requirements for cargo ships and passenger ships carrying not more than 36 passengers

When passing through accommodation spaces or spaces containing combustible materials, the exhaust ducts from galley ranges are to be constructed in accordance with paragraphs 3.7.2.4.1.1 and 3.7.2.4.1.2. Each exhaust duct is to be fitted with:

.1 a grease trap readily removable for cleaning;

.2 an automatically and remotely operated fire damper located in the lower end of the duct at the junction between the duct and the galley range hood and, in addition, a remotely operated fire damper in the upper end of the duct close to the outlet of the duct;

.3 arrangements, operable from within the galley, for shutting off the exhaust and supply fans; and

.4 fixed means for extinguishing a fire within the duct.*

(*Refer to the recommendations published by the International Organization for Standardization, in particular publication ISO 15371:2009, Ships and marine technology – Fire-extinguishing systems for protection of galley cooking equipment.)

3.7.6 Ventilation rooms serving machinery spaces of category A containing internal combustion machinery

3.7.6.1 Where a ventilation room serves only such an adjacent machinery space and there is no fire division between the ventilation room and the machinery space, the means for closing the ventilation duct or ducts serving the machinery space shall be located outside of the ventilation room and machinery space.

3.7.6.2 Where a ventilation room serves such a machinery space as well as other spaces and is separated from the machinery space by a "A-0" class division, including penetrations, the means for closing the ventilation duct or ducts for the machinery space can be located in the ventilation room.

3.7.7 Ventilation systems for laundries in passenger ships carrying more than 36 passengers

Exhaust ducts from laundries and drying rooms of category (13) spaces as defined in paragraph 3.2.2.3.2.2 are to be fitted with:

.1 filters readily removable for cleaning purposes;

.2 a fire damper located in the lower end of the duct which is automatically and remotely operated;

.3 remote-control arrangements for shutting off the exhaust fans and supply fans from within the space and for operating the fire damper mentioned in paragraph 3.7.7.2; and

.4 suitably located hatches for inspection and cleaning.

Section 4

Fire Fighting

4.1 Purpose

4.1.1 The purpose of this section is to suppress and swiftly extinguish a fire in the space of origin, except for 4.1.2. For this purpose, the following functional requirements are to be met:

.1 fixed fire extinguishing systems are to be installed having due regard to the fire growth potential of the protected spaces; and

.2 fire extinguishing appliances are to be readily available.

4.1.2 For open-top container holds* and on deck container stowage areas on ships designed to carry containers on or above the weather deck, constructed on or after 1 January 2016, fire protection arrangements are to be provided for the purpose of containing a fire in the space or area of origin and cooling adjacent areas to prevent fire spread and structural damage.

(*For a definition of this term, refer to the Interim guidelines for open-top containerships (MSC/Circ.608/Rev.1).)

4.2 Water supply systems

Every ship is to be provided with fire pumps, fire mains, hydrants and hoses complying as applicable with the following requirements.

4.2.1 *Fire mains and hydrants*

4.2.1.1 *General*

Materials readily rendered ineffective by heat are not to be used for fire mains and hydrants unless adequately protected. The pipes and hydrants are to be so placed that the fire hoses may be easily coupled to them. The

arrangement of pipes and hydrants is to be such as to avoid the possibility of freezing. Suitable drainage arrangement is to be provided for fire main piping. Isolation valves are to be installed for all open deck fire main branches used for purposes other than fire fighting. In ships where deck cargo may be carried, the positions of the hydrants are to be such that they are always readily accessible and the pipes are to be arranged as far as practicable to avoid risk of damage by such cargo.

4.2.1.2 *Ready availability of water supply*

The arrangements for the ready availability of water supply is to be:

.1 in passenger ships:

a) of 1,000 gross tonnage and upwards such that at least one effective jet of water is immediately available from any hydrant in an interior location and so as to ensure the continuation of the output of water by the automatic starting of one required fire pump;

b) of less than 1,000 gross tonnage by automatic start of at least one fire pump or by remote starting from the navigation bridge of at least one fire pump. If the pump starts automatically or if the bottom valve cannot be opened from where the pump is remotely started, the bottom valve is to be always kept open; and

c) in passenger ships, if fitted with periodically unattended machinery spaces, the arrangements will be specially considered.

.2 in cargo ships:

a) to the satisfaction of IRS; and

b) with a periodically unattended machinery space or when only one person is required on watch there is to be immediate water delivery from the fire main system at a suitable pressure, either by remote starting of one of the main fire pumps with remote starting from the navigating bridge and fire control station, if any, or permanent pressurization of the fire main system by one of the main fire pumps, except that this requirement may be waived for cargo ships of less than 1,600 tons gross tonnage if the fire pump starting arrangement in the machinery space is in an easily accessible position;

c) For vessels intended for ice class notation, See also Pt.5.

4.2.1.3 *Diameter of fire mains*

The diameter of the fire main and water service pipes is to be sufficient for the effective distribution of the maximum required discharge from two fire pumps operating simultaneously, except that in the case of cargo ships, other than those included in 4.7.3.2, the diameter need only be sufficient for the discharge of 140 [m^3/hour]. (Also see 4.2.2.4.1, IR .2.1).

4.2.1.4 *Isolating valves and relief valves*

4.2.1.4.1 Isolating valves to separate the section of the fire main within the machinery space containing the main fire pump or pumps from the rest of the fire main are to be fitted in an easily accessible and tenable position outside the machinery spaces. The fire main is to be so arranged that when the isolating valves are shut all the hydrants on the ship, except those in the machinery space referred to above, can be supplied with water by another fire pump or an emergency fire pump. The emergency fire pump, its seawater inlet, and suction and delivery pipes and isolating valves are to be located outside the machinery space. If this arrangement cannot be made, the sea-chest may be fitted in the machinery space if the valve (i.e. sea inlet valve) is remotely controlled from a position in the same compartment as the emergency fire pump and the suction pipe is as short as practicable. Short lengths of suction or discharge piping may penetrate the machinery space, provided they are enclosed in a substantial steel casing, or are insulated to A-60 class standards. The pipes are to have substantial wall thickness, but in no case less than 11 [mm] and are to be welded except for the flanged connection to the sea inlet valve.

IR4.2.1.4.1

a) Any part of the fire main routed through a category ‘A’ machinery space, except for short lengths of suction or discharge piping complying with 4.2.1.4.1, is to be fitted with isolating valves outside the space. The arrangements of fire mains is to allow for fire water from the fire pumps or emergency fire pump to reach all hydrants outside the isolated space. Isolation requirements of 4.2.1.4.1 are not applicable to the piping from fire pumps

located in spaces other than category 'A' machinery spaces.

b) In cases where suction or discharge piping penetrating machinery spaces are required to be enclosed in a substantial steel casing, or insulated to "A-60" class standards, it is not necessary to enclose or insulate "sea inlet valves", "sea chests" and "distance pieces between the sea inlet valves and shell plating / sea chests";

c) The method for insulating pipes to ""A-60" class standards" is to be such that the pipes are covered/protected in a practical manner by insulation material which is approved as a part of "A-60" class divisions in accordance with the FTP Code; and

d) Where the sea inlet valve is in the machinery space, the valve is not to be a fail-close type. Where the sea inlet valve is in the machinery space and is not a fail-open type, measures are to be taken so that the valve can be opened in the event of fire, e.g. control piping, actuating devices and/or electric cables with fire resistant protection equivalent to "A-60" class standards.

e) In cases where main fire pumps are provided in a compartment outside machinery spaces and where the emergency fire pump suction or discharge piping penetrates such compartment, the above requirement is to be applied to the piping.

4.2.1.4.2 A valve is to be fitted to serve each fire hydrant so that any fire hose may be removed while the fire pumps are at work.

4.2.1.4.3 Relief valves are to be provided in conjunction with all fire pumps if the pumps are capable of developing a pressure exceeding the design pressure of the water service pipes, hydrants and hoses. These valves are to be so placed and adjusted as to prevent excessive pressure in any part of the fire main system.

4.2.1.4.4 In tankers isolation valves are to be fitted in the fire main at poop front in a protected position and on the tank deck at intervals of not more than 40 [m] to preserve the integrity of the fire main system in case of fire or explosion.

4.2.1.5 *Number and position of hydrants*

4.2.1.5.1 The number and position of hydrants are to be such that at least two jets of water not emanating from the same hydrant, one of which is to be from a single length of hose, may reach any part of the ship normally accessible to the passengers or crew while the ship is being navigated and any part of any cargo space when empty, any ro-ro space or any vehicle space in which latter case the two jets is to reach any part of the space, each from a single length of hose. Furthermore, such hydrants are to be positioned near the accesses to the protected spaces.

IR4.2.1.5.1 In ships of 1000 tons gross tonnage and over, at least two hydrants are to be provided in the machinery spaces.

4.2.1.5.2 In addition to the requirements in 4.2.1.5.1, passenger ships are to comply with the following:

.1 in the accommodation, service and machinery spaces the number and position of hydrants are to be such that the requirements of 4.2.1.5.1 may be complied with when all watertight doors and all doors in main vertical zone bulkheads are closed; and

.2 where access is provided to a machinery space of category A at a low level from an adjacent shaft tunnel, two hydrants are to be provided external to, but near the entrance to that machinery space. Where such access is provided from other spaces, in one of those spaces two hydrants are to be provided near the entrance to the machinery space of category A. Such provision need not be made where the tunnel or adjacent spaces are not part of the escape route.

IR4.2.1.5.3 In cargo ships of 2,000 tons gross tonnage and over, a hydrant is to be provided in the shaft tunnel adjacent to the engine room watertight door.

4.2.1.6 *Pressure at hydrants*

With the two pumps simultaneously delivering water through the nozzles specified in 4.2.3.3, with the quantity of water as specified in 4.2.1.3, through any adjacent hydrants, the following minimum pressures are to be maintained at all hydrants:

.1 for passenger ships:

4,000 gross tonnage and upwards 0.40 [N/mm^2] less than 4,000 gross tonnage 0.30 [N/mm^2];

.2 for cargo ships,

6,000 gross tonnage and upwards 0.27 [N/mm^2]
less than 6,000 gross tonnage; 0.25 [N/mm^2]; and

.3 the maximum pressure at any hydrant is not to exceed that at which the effective control of a fire hose can be demonstrated.

4.2.1.7 *International shore connection*

4.2.1.7.1 Ships of 500 gross tonnage and upwards is to be provided with at least one international shore connection complying with the Fire Safety Systems Code (Chapter 8).

4.2.1.7.2 Facilities are to be available enabling such a connection to be used on either side of the ship.

4.2.2 Fire pumps

4.2.2.1 *Pumps accepted as fire pumps*

Sanitary, ballast, bilge or general service pumps may be accepted as fire pumps, provided that they are not normally used for pumping oil and that if they are subject to occasional duty for the transfer or pumping of oil fuel, suitable change-over arrangements are fitted.

4.2.2.2 *Number of fire pumps*

Ships are to be provided with independently driven fire pumps as follows:

.1 in passenger ships of:

4,000 gross tonnage and upwards	:	at least three
less than 4,000 gross tonnage	:	at least two

.2 in cargo ships of:

1,000 gross tonnage and upwards	:	at least two

less than 1,000 gross tonnage : at least two power driven pumps, one of which is to be independently driven.

4.2.2.3 *Arrangement of fire pumps and fire mains*

4.2.2.3.1 *Fire pumps*

The arrangement of sea connections, fire pumps and their sources of power are to be such as to ensure that:

.1 in passenger ships of 1,000 gross tonnage and upwards, in the event of a fire in any one compartment all the fire pumps will not be put out of action; and

.2 in passenger ships of less than 1,000 gross tonnage and in cargo ships of 500 gross tonnage and upwards, if a fire in any one compartment could put all the pumps out of action, there is to be an alternative means consisting of an emergency fire pump complying with the provisions of the Fire Safety Systems Code (Chapter 8) with its source of power and sea connection located outside the space where the main fire pumps or their sources of power are located. (See also 4.2.1.4.1).

IR.2.1 Unless the main fire pumps, their sea suctions and the fuel supply or source of power for each pump are situated within compartments separated at least by A-0 divisions, it is considered for the purpose of para 2 above, that the fire in any one compartment would put the pumps out of action.

IR .2.2 An arrangement in which two main fire pumps are located in adjacent compartments which share more than one boundary will also require an emergency fire pump.

4.2.2.3.2 *Requirements for the space containing the emergency fire pump*

.1 *Location of the space*

The space containing the fire pump are not to be contiguous to the boundaries of machinery spaces of category A or those spaces containing main fire pumps. Where this is not practicable, the common bulkhead between the two spaces are to be insulated to a standard of structural fire protection equivalent to that required for a control station in 3.2.3.3. The insulation is to extend at least 450 [mm] outside the area of the common boundary.

.2 *Access to the emergency fire pump*

No direct access is to be permitted between the machinery space and the space containing the emergency fire pump and its source of power. When this is impracticable, IRS may accept an arrangement where the access is by

means of an airlock with the door of the machinery space being of A-60 class standard, and the other door being at least steel, both reasonably gastight, self-closing and without any hold back arrangements. Alternatively, the access may be through a watertight door capable of being operated from a space remote from the machinery space and the space containing the emergency fire pump and unlikely to be cut off in the event of fire in those spaces. In such cases, a second means of access to the space containing the emergency fire pump and its source of power is to be provided.

IR.2 When a single access to the emergency fire pump room is through another space adjoining a machinery space of category 'A' or the spaces containing the main fire pumps, class 'A-60' boundary is to be provided between that other space and the machinery space of category 'A' or the spaces containing main fire pumps.

.3 Lighting and v*entilation of the emergency fire pump space*

Ventilation arrangements to the space containing the independent source of power for the emergency fire pump are to be such as to preclude, as far as practicable, the possibility of smoke from a machinery space fire entering or being drawn into that space.

IR.3 The room where the emergency fire pump prime mover is located is to be illuminated from the emergency source of supply and is to be well ventilated. If the room is to be mechanically ventilated, the power is to be supplied by the emergency source.

IR .4 Maintenance / inspection

The room(s) where the pump and prime mover are installed is/are to have adequate space for maintenance work and inspections.

4.2.2.3.3 *Additional pumps for cargo ships*

In addition, in cargo ships where other pumps, such as general service, bilge and ballast, etc., are fitted in a machinery space, arrangements are to be made to ensure that at least one of these pumps, having the capacity and pressure required by 4.2.1.6.2 and 4.2.2.4.2, is capable of providing water to the fire main.

IR4.2.2.3.3 However, in cases where the required number and capacity of fire pumps is already available otherwise, the capacity and pressure characteristics of the general service/bilge/ballast pumps required to be connected as per 4.2.2.3.3, would be specially considered in view of the optimal characteristics required for their primarily intended services.

IR4.2.2.3.4 Where the emergency fire pump is electrically driven, the power is to be supplied by a source other than that supplying the main fire pump and be located outside the engine room, and separated from it by an A class division. The relevant electrical cables are not to pass through the compartment containing the main fire pump.

4.2.2.4 *Capacity of fire pumps*

4.2.2.4.1 *Total capacity of required fire pumps*

The required fire pumps are to be capable of delivering for fire-fighting purposes a quantity of water, at the pressure specified in 4.2.1.6, as follows:

.1 pumps in passenger ships, the quantity of water is not less than two thirds of the quantity required to be dealt with by the bilge pumps (See Pt.4, Ch.3, Sec.2 for capacity and number of bilge pumps) when employed for bilge pumping; and

.2 pumps in cargo ships, other than any emergency pump, the quantity of water is not less than four thirds of the quantity required to be dealt with by each of the independent bilge pumps when employed for bilge pumping, except that in no cargo ship, other than those included in 4.7.3.2, need the total required capacity of the fire pumps exceed 180 [m^3/h]. (See Pt.4, Ch.3, Sec.2 for capacity of bilge pumps).

IR.2.1 On board cargo ships designed to carry five or more tiers of containers on or above the weather deck,

.1 in cases where the mobile water monitors are supplied by separate pumps and piping system, the total capacity of the main fire pumps need not exceed 180 [m^3/h] and the diameter of the fire main and water service pipes (pipework diameter) need only be sufficient for the discharge of 140 [m^3/h].

.2 in cases where the mobile water monitors are supplied by the main fire pumps; the total capacity of required

main fire pumps and the pipework diameter is to be sufficient for simultaneously supplying both the required number of fire hoses and mobile water monitors. However, the total capacity is not to be less than the following .1 or .2, whichever is smaller:

.1 four thirds of the quantity required under SOLAS II-1/35-1 to be dealt with by each of the independent bilge pumps in a passenger ship of the same dimension when employed in bilge pumping; or

.2 180 [m^3/h].

.3 in cases where the mobile water monitors and the “water spray system” (fixed arrangement of spraying nozzles or flooding the cargo space with water) required by Ch7, 2.3.1.3 (SOLAS II-2/19.3.1.3) are supplied by the main fire pumps, the total capacity of the main fire pumps and the pipework diameter need only be sufficient to supply whichever of the following is the greater:

.1 the mobile water monitors and the four nozzles required by Ch 7, 2.3.1.2 (SOLAS II-2/19.3.1.2); or

.2 the four nozzles required by Ch 7, 2.3.1.2 (SOLAS II-2/19.3.1.2) and the water spray system required by Ch 7, 2.3.1.3 (SOLAS II-2/19.3.1.3).

The total capacity, however, is not to be less than IR 2.1.2.1 or 2.1.2.2, whichever is smaller.

IR .2.2 On board cargo ships designed to carry five or more tiers of containers on or above the weather deck, the total capacity of the emergency fire pump need not exceed 72 [m^3/h].

4.2.2.4.2 *Capacity of each fire pump*

Each of the required fire pumps (other than any emergency pump required in 4.2.2.3.1.2 for cargo ships) are to have a capacity not less than 80% of the total required capacity divided by the minimum number of required fire pumps but in any case not less than 25 [m^3/h] and each such pump are in any event to be capable of delivering at least the two required jets of water. These fire pumps are to be capable of supplying the fire main system under the required conditions. Where more pumps than the minimum of required pumps are installed such additional pumps are to have a capacity of at least 25 [m^3/h] and are to be capable of delivering at least the two jets of water required in 4.2.1.5.1.

4.2.3 Fire hoses and nozzles

4.2.3.1 *General specifications*

4.2.3.1.1 Fire hoses are to be of approved non-perishable material and are to be sufficient in length to project a jet of water to any of the spaces in which they may be required to be used. Each hose is to be provided with a nozzle and the necessary couplings. Hoses specified in this chapter as "fire hoses" together with any necessary fittings and tools are to be kept ready for use in conspicuous positions near the water service hydrants or connections. Additionally, in interior locations in passenger ships carrying more than 36 passengers fire hoses are to be connected to the hydrants at all times. Fire hoses are to have a length of at least 10 [m], but not more than:

.1 15 [m] in machinery spaces;

.2 20 [m] in other spaces and open decks; and

.3 25 [m] for open decks on ships with a maximum breadth in excess of 30 [m].

4.2.3.1.2 Unless one hose and nozzle is provided for each hydrant in the ship, there is to be complete interchangeability of hose couplings and nozzles.

4.2.3.2 *Number and diameter of fire hoses*

4.2.3.2.1 Ships are to be provided with such number and diameter of hoses as are appropriate to the type of ship.

4.2.3.2.2 In passenger ships, there is to be at least one fire hose for each of the hydrants required by 4.2.1.5 and these hoses are to be used only for the purposes of extinguishing fires or testing the fire-extinguishing apparatus at fire drills and surveys.

4.2.3.2.3 In cargo ships:

.1 of 1,000 gross tonnage and upwards, the number of fire hoses to be provided is to be one for each 30 [m] length of the ship and one spare but in no case less than five in all. This number does not include any hoses required in any engine or boiler room. If necessary the number of hoses is to be increased so as to ensure that hoses in sufficient number are available and accessible at all times, having regard to the type of ship and the nature of trade in which the ship is employed. Ships carrying dangerous goods in accordance with Ch.7, Sec.2 are to be provided with 3 hoses and nozzles, in addition to those required above; and

.2 of less than 1,000 gross tonnage, the number of fire hoses to be provided are to be calculated in accordance with the provisions of 4.2.3.2.3.1. However, the number of hoses are in no case to be less than three.

IR.3 All hydrants in the machinery spaces of ships with oil fire boilers or internal combustion type propelling machinery are to be fitted with hoses having the nozzles in accordance with 4.2.3.3.

4.2.3.3 *Size and types of nozzles*

4.2.3.3.1 For the purposes of this part, standard nozzle sizes are to be 12 [mm], 16 [mm] and 19 [mm] or as near thereto as possible. Larger diameter nozzles may be permitted at the discretion of IRS.

4.2.3.3.2 For accommodation and service spaces, a nozzle size greater than 12 [mm] need not be used.

4.2.3.3.3 For machinery spaces and exterior locations, the nozzle sizes are to be such as to obtain the maximum discharge possible from two jets at the pressure mentioned in 4.2.1.6 from the smallest pump, provided that a nozzle size greater than 19 [mm] need not be used.

4.2.3.3.4 Nozzles are to be of an approved dual-purpose type (i.e., spray / jet type) incorporating a shutoff.

IR4.2.3.3.4 Aluminium alloys may be used for fire hose couplings and nozzles, except in open deck areas of oil tankers and chemical tankers.

4.3 Portable fire extinguishers

4.3.1 Type and design

Portable fire extinguishers are to comply with the requirements of the Fire Safety Systems Code (Chapter 8).

4.3.2 Arrangement of fire extinguishers (Also refer MSC.1/Circ.1275 'Unified Interpretations of SOLAS Chapter II-2 on the Number and Arrangement of Portable Fire Extinguishers on Board Ships') as corrected by MSC.1/Circ.1275/Corr.1.

4.3.2.1 Accommodation spaces, service spaces and control stations are to be provided with portable fire extinguishers of appropriate types and in sufficient number to the satisfaction of the Administration. Ships of 1,000 gross tonnage and upwards are to carry at least five portable fire extinguishers.

IR4.3.2.1 For ships of under 1,000 gross tonnage the above number of extinguishers is not be less than three.

4.3.2.2 One of the portable fire extinguishers intended for use in any space is to be stowed near the entrance to that space.

4.3.2.3 Carbon dioxide fire extinguishers are not to be placed in accommodation spaces. In control stations and other spaces containing electrical or electronic equipment or appliances necessary for the safety of the ship, fire extinguishers whose extinguishing media are neither electrically conductive nor harmful to the equipment and appliances are to be provided.

4.3.2.4 Fire extinguishers are to be situated ready for use at easily visible places, which can be reached quickly and easily at any time in the event of a fire, and in such a way that their serviceability is not impaired by the weather, vibration or other external factors. Portable fire extinguishers are to be provided with devices which indicate whether they have been used.

IR4.3.2.5 For galleys and for spaces containing domestic boilers, one portable fire extinguisher suitable for dealing with oil fires or fires in electric cooking equipment, as appropriate, is to be provided.

4.3.3 Spare charges

4.3.3.1 Spare charges are to be provided for 100% of the first 10 extinguishers and 50% of the remaining fire extinguishers capable of being recharged on board. Not more than 60 total spare charges are required. Instructions for recharging are to be carried on board.

4.3.3.2 For fire extinguishers which cannot be recharged onboard, additional portable fire extinguishers of the same quantity, type, capacity and number as determined in 4.3.3.1 above are to be provided in lieu of spare charges.

4.4 Fixed fire-extinguishing systems

4.4.1 Types of fixed fire extinguishing systems

4.4.1.1 A fixed fire extinguishing system required by 4.5 below may be any of the following:

.1 a fixed gas fire-extinguishing system complying with the provisions of the Fire Safety Systems Code (Chapter 8);

.2 a fixed high-expansion foam fire-extinguishing system complying with the provisions of the Fire Safety Systems Code (Chapter 8); and

.3 a fixed pressure water-spraying fire-extinguishing system complying with the provisions of the Fire Safety Systems Code (Chapter 8).

4.4.1.2 Where a fixed fire-extinguishing system not required by this part is installed, it is to meet the relevant requirement of this part and the Fire Safety Systems Code (Chapter 8).

4.4.1.3 Fire-extinguishing systems using Halon 1211, 1301, and 2402 and perfluorocarbons are to be prohibited.

4.4.1.4 Steam is not generally accepted as a fire-extinguishing medium in fixed fire-extinguishing systems. However, restricted use of steam is permitted as an addition to the required fire-extinguishing system and is to comply with the requirements of the Fire Safety System Code (Chapter 8).

4.4.1.5 On ships constructed before 1 July 2002, fixed carbon dioxide fire-extinguishing systems for the protection of machinery spaces and cargo pump-rooms shall comply with the provisions of 5.2.2.2 of Section 5 of Chapter 8 “Fire Safety Systems Code”, by the first scheduled dry-docking after 1 January 2010.

4.4.2 Closing appliances for fixed gas fire-extinguishing systems

Where a fixed gas fire-extinguishing system is used, openings which may admit air to, or allow gas to escape from, a protected space is to be capable of being closed from outside the protected space.

4.4.3 Storage rooms of fire-extinguishing medium

When the fire-extinguishing medium is stored outside a protected space, it is to be stored in a room which is located aft of the forward collision bulkhead, and is used for no other purposes. Any entrance to such a room is preferably to be from the open deck and is to be independent of the protected space.

Additionally, storage rooms for fixed gas fire extinguishing media are to meet the following requirements:

a) If the storage space is located below deck, it is to be located no more than one deck below the open deck and is to directly accessible by a stairway or ladder from the open deck.

b) Storage spaces located below deck or spaces located above deck but not provided with access from the open deck, are to be fitted with a mechanical ventilation system designed to take exhaust air from the bottom of the space and sized to provide at least 6 air changes per hour. Where located above deck and having direct access from the open deck, natural ventilation may suffice.

c) Access doors are to open outwards, and the bulkheads and decks including doors and other means of closing any opening therein, which form the boundaries between such rooms and adjacent enclosed spaces are to be gastight. For the purpose of the application of Table 3.1 to Table 3.8, such storage rooms are to be treated as fire control stations.

IR4.4.3 Fire extinguishing media protecting the cargo holds may be stored in a room located forward of the cargo holds but aft of the collision bulkheads, provided that both the local manual release mechanism and remote control(s) for the release of the media are fitted, and the latter is of robust construction or so protected as to remain operable in case of fire in protected spaces. The remote control is to be placed in the accommodation area in order to facilitate their ready accessibility by the crew. The capability to release different quantities of fire extinguishing media into different cargo holds so protected is to be included in the remote release arrangement.

4.4.4 Water pumps for other fire-extinguishing systems

Pumps, other than those serving the fire main, required for the provision of water for fire-extinguishing systems required by this part, their sources of power and their controls are to be installed outside the space or spaces protected by such systems and are to be so arranged that a fire in the space or spaces protected will not put any such system out of action.

4.5 Fire extinguishing arrangements in machinery spaces

4.5.1 Machinery spaces containing oil-fired boilers or oil fuel units (Also see Table 4.5.1)

4.5.1.1 *Fixed fire-extinguishing systems*

Machinery spaces of category A containing oil-fired boilers or oil fuel units are to be provided with any one of the fixed fire-extinguishing systems in 4.4.1. In each case, if the engine and boiler rooms are not entirely separate, or if fuel oil can drain from the boiler room into the engine-room, the combined engine and boiler rooms are to be considered as one compartment.

IR 4.5.1.1 Machinery spaces of Category A where oil fuel of flash point less than 60°C is used

The fixed installation is to be of gas type as in 4.4.1.1.1 in all cases where the flash point of oil fuel is less than 60°C. (See Ch.2, 1.2.1).

4.5.1.2 *Additional fire-extinguishing arrangements* (Also refer MSC.1/Circ.1275 'Unified Interpretations of SOLAS Chapter II-2 on the Number and Arrangement of Portable Fire Extinguishers on Board Ships' as corrected by MSC.1/Circ.1275/Corr.1).

4.5.1.2.1 There are to be in each boiler room or at an entrance outside of the boiler room at least one portable foam applicator unit complying with the provisions of the Fire Safety Systems Code.

4.5.1.2.2 There are to be at least two portable foam extinguishers or equivalent in each firing space in each boiler room and in each space in which a part of the oil fuel installation is situated. There is to be not less than one approved foam-type extinguisher of at least 135 litres capacity or equivalent in each boiler room. These extinguishers are to be provided with hoses on reels suitable for reaching any part of the boiler room. In the case of domestic boilers of less than 175 kW, or boilers protected by fixed water-based local application fire-extinguishing systems as required by 4.5.6, an approved foam-type extinguisher of at least 135 litres capacity is not required.

4.5.1.2.3 In each firing space there is to be a receptacle containing at least 0.1 [m^3] sand, sawdust impregnated with soda, or other approved dry material, along with a suitable shovel for spreading the material. An approved portable extinguisher may be substituted as an alternative.

Table 4.5.1 : Number of systems, appliances and extinguishers

Systems, appliances & extinguishers Category A machinery spaces	Fixed fire extinguishing system	Portable foam applicator *1	Portable foam extinguishers	Additional portable foam extinguishers	135 l foam extinguisher	45 l foam extinguishers *2	Sand boxes *3
Pt.6, Ch.3, Clause nos.	4.5.1.1 4.5.2.1	4.5.1.2.1 4.5.2.2.1	4.5.1.2.2	4.5.2.2.2	4.5.1.2.2	4.5.2.2.2	4.5.1.2.3
Boiler room containing:							
Oil-fired boilers	1	1	2N	NA	1*4	-	N
Oil-fired boilers and oil fuel units	1	1	2N + 2	NA	1*4	-	N
Engine room containing:							
Oil fuel units only	1	-	2	NA	-	-	-
Internal combustion machinery	1	1	x		-	Y	-
Internal combustion machinery and oil fuel units	1	1	x		-	y	-
Combined engine / boiler room containing:							
Internal combustion machinery, oil fired boilers and oil fuel units	1	1	(2N + 2) or x whichever is greater		1*4	y*5	N

N = number of firing spaces.
"2N" means that two extinguishers are to be located in each firing space.

x = sufficient number, minimum two in each space, so located that there are at least one portable fire extinguisher within 10 m walking distance from any point.

y = sufficient number to enable foam to be directed onto any part of the fuel and lubricating oil pressure systems, gearing and other fire hazards.

Notes:

*1 : May be located at outside of the entrance to the room.

*2 : May be arranged outside of the space concerned for smaller spaces of cargo ships.

*3 : The amount of sand is to be at least 0.1 m3. A shovel is to be provided. Sand boxes may be substituted by approved portable fire extinguishers.

*4 : Not required for such spaces in cargo ships wherein all boilers contained therein are for domestic services and are less than 175 kW, or boilers are protected by fixed water-based local application fire-extinguishing systems as required by 4.5.6.

*5 : In case of machinery spaces containing both boilers and internal combustion engines (case not explicitly considered in Clause 4.5. Clauses 4.5.1 and 4.5.2 apply, with the exception that one of the foam fire extinguishers of at least 45 l capacity or equivalent (required by 4.5.2.2.2) may be omitted on the condition that the 135 l extinguisher (required by 4.5.1.2.2) can protect efficiently and readily the area covered by the 45 l extinguisher.

*6 Oil fired machinery other than boilers such as fired inert gas generators, incinerators and waste disposal units are to be considered the same as boiler in so far as the required number and type of fire fighting appliances are concerned.

4.5.2 Machinery spaces of Category A containing internal combustion machinery (Also See Table 4.5.1)

Machinery spaces of category A containing internal combustion machinery are to be provided with one of the fixed fire-extinguishing systems in 4.4.1.

4.5.2.1 *Fixed fire-extinguishing systems*

4.5.2.2 *Additional fire-extinguishing arrangements* (Also refer MSC.1/Circ.1275 'Unified Interpretations of SOLAS Chapter II-2 on the Number and Arrangement of Portable Fire Extinguishers on Board Ships' as corrected by MSC.1/Circ.1275/Corr.1).

4.5.2.2.1 There is to be at least one portable foam applicator unit complying with the provisions of the Fire Safety Systems Code.

4.5.2.2.2 There are to be in each such space approved foam type fire extinguishers each of at least 45 litres capacity or equivalent sufficient in number to enable foam or its equivalent to be directed onto any part of the fuel and lubricating oil pressure systems, gearing and other fire hazards. In addition, there is to be provided a sufficient number of portable foam extinguishers or equivalent which are to be so located that an extinguisher is not more than 10 [m] walking distance from any point in the space; provided that there are to be at least two such extinguishers in each such space. For ships under 150 tons gross the provision of a 45 litre extinguisher may be waived.

4.5.3 Machinery spaces containing steam turbines or enclosed steam engines

4.5.3.1 *Fixed fire-extinguishing systems*

In spaces containing steam turbines or enclosed steam engines used for main propulsion or other purposes having in the aggregate a total output of not less than 375 [kW], one of the fire-extinguishing systems specified in 4.4.1 is to be provided if such spaces are periodically unattended.

4.5.3.2 *Additional fire-extinguishing arrangements*

4.5.3.2.1 There are to be approved foam fire extinguishers each of at least 45 *l* capacity or equivalent sufficient in number to enable foam or its equivalent to be directed on to any part of the pressure lubrication system, on to any part of the casings enclosing pressure lubricated parts of the turbines, engines or associated gearing, and any other fire hazards. However, such extinguishers are not required if protection, at least equivalent to that required by this subparagraph, is provided in such spaces by a fixed fire-extinguishing system fitted in compliance with 4.4.1.

4.5.3.2.2 There are to be a sufficient number of portable foam extinguishers or equivalent which are to be so located that no point in the space is more than 10 [m] walking distance from an extinguisher and that there are at least two such extinguishers in each such space, except that such extinguishers are not required in addition to any provided in compliance with 4.5.1.2.2. (Also refer MSC.1/Circ.1275 'Unified Interpretations of SOLAS Chapter II-2 on the Number and Arrangement of Portable Fire Extinguishers on Board Ships' as corrected by MSC.1/Circ.1275/Corr.1).

4.5.4 Other machinery spaces

Where a fire hazard exists in any machinery space for which no specific provisions for fire-extinguishing appliances are prescribed in 4.5.1, 4.5.2 and 4.5.3, there are to be provided in, or adjacent to, that space such a number of approved portable fire extinguishers or other means of fire extinction according to fire hazard in each space. (Also refer MSC.1/Circ.1275 'Unified Interpretations of SOLAS Chapter II-2 on the Number and Arrangement of Portable Fire Extinguishers on Board Ships' as corrected by MSC.1/Circ.1275/Corr.1).

4.5.5 Additional requirements for passenger ships

In passenger ships carrying more than 36 passengers, each machinery space of category A is to be provided with at least two water fog applicators consisting of a metal L-shaped pipe, the long limb being about 2 [m] in length capable of being fitted to a fire hose and the short limb being about 250 [mm] in length fitted with a fixed water fog nozzle or capable of being fitted with a water spray nozzle.

4.5.6 Fixed local application fire-fighting systems

4.5.6.1 Sub-section 4.5.6 applies to passenger ships of 500 gross tonnage and above and cargo ships of 2000 gross tonnage and above.

4.5.6.2 Machinery spaces of category A above 500 [m^3] in volume in addition to the fixed fire-extinguishing system required in 4.5.1.1 are to be protected by a type of fixed water-based or equivalent local application fire-fighting system approved by the National Statutory Authority. In the case of periodically unattended machinery spaces, the fire fighting system is to have both automatic and manual release capabilities. In the case of continuously

manned machinery spaces, the fire-fighting system is only required to have a manual release capability. (Refer to the Revised Guidelines for the approval of fixed water-based local application fire-fighting systems for use in category A machinery spaces (MSC.1/Circ.1387 and MSC.1/Circ.1387/Corr.1) and Unified Interpretations of SOLAS Chapter II-2 (MSC.1/Circ.1276/Rev.1)).

IR4.5.6.2 The automatic release of fire extinguishing medium is to be activated by a detection system capable of reliably identifying the local zones. Means are to be provided to prevent accidental release.

IR4.5.6.2.1 If the system installed deviates from the arrangement approved in accordance with MSC.1/Circ.1387 and MSC.1/Circ.1387/Corr.1, then such arrangement is to additionally pass the fire test based on the scenarios specified in the circular.

4.5.6.3 Fixed local application fire-fighting systems are to protect areas such as the following without the necessity of engine shutdown, personnel evacuation, or sealing of the spaces:

.1a) the fire hazard portions of all internal combustion machinery for ships constructed on or after 01 July, 2014 and

b) the fire hazard portions of internal combustion machinery used for the ship's main propulsion and power generation for ships constructed before 01 July, 2014.

IR.1 In multi-engine installations at least two sections are to be arranged to cover all internal combustion machinery.

.2 boiler fronts;

IR.2 (Boiler fronts in this context mean the boiler burner locations irrespective of the boiler design).

.3 the fire hazard portions of incinerators; and

.4 purifiers for heated fuel oil.

IR.5 oil fired equipment such as inert gas generators and thermal oil heaters.

4.5.6.4 Activation of any local application system is to give a visual and distinct audible alarm in the protected space and at continuously manned stations. The alarm is to indicate the specific system activated. The system alarm requirements described within this subsection are in addition to, and not a substitute for, the detection and fire alarm system required elsewhere in this chapter.

IR4.5.6.4 The alarms may be grouped together with provision for indication of the activated zone. Such alarms and indications are to be provided in wheel house in addition to protected space and engine control room. Audible alarms may use a single tone.

4.6 Fire-extinguishing arrangements in control stations, accommodation and service spaces

4.6.1 Sprinkler and water spray systems in passenger ships

4.6.1.1 Passenger ships carrying more than 36 passengers are to be equipped with an automatic sprinkler, fire detection and fire alarm system of an approved type complying with the requirements of the Fire Safety Systems Code (Chapter 8) in all control stations, accommo-dation and service spaces, including corridors and stairways. Alternatively, control stations, where water may cause damage to essential equipment, may be fitted with an approved fixed fire-extinguishing system of another type. Spaces having little or no fire risk such as voids, public toilets, carbon dioxide rooms and similar spaces need not be fitted with an automatic sprinkler system.

4.6.1.2 In passenger ships carrying not more than 36 passengers, when a fixed smoke detection and fire alarm system complying with the provisions of the Fire Safety Systems Code (Chapter 8) is provided only in corridors, stairways and escape routes within accommodation spaces, an automatic sprinkler system is to be installed in accordance with 1.5.3.2.

4.6.1.3 A fixed pressure water-spraying fire extinguishing system complying with the provisions of Ch8 is to be installed on cabin balconies of ships to which requirement of Ch.2, 2.3.4 applies, if furniture and furnishings on such balconies are not as defined in Ch.1, 3.40 a), b), c), f) and g).

4.6.2 Sprinkler systems for cargo ships

In cargo ships in which method IIC specified in 3.2.3.1.1.2 is adopted, an automatic sprinkler, fire detection and fire alarm system is to be fitted in accordance with the requirements in 1.5.5.2.

4.6.3 Spaces containing flammable liquid

4.6.3.1 Paint lockers are to be protected by any one of the following systems :
.1 a carbon dioxide system, designed to give a minimum volume of free gas equal to 40% of the gross volume of the protected space;

.2 a dry powder system, designed for at least 0.5 [kg powder/m^3];

.3 a water spraying or sprinkler system, designed for 5 [l/m^2 min]. Water spraying systems may be connected to the fire main of the ship; or

.4 a system providing equivalent protection, as determined by IRS.

In any case, the system is to be operable from outside the protected space.

4.6.3.2 Flammable liquid lockers are to be protected by an appropriate fire-extinguishing arrangement approved by IRS.

4.6.3.3 For lockers of a deck area of less than 4 [m^2], which do not give access to accommodation spaces, a carbon dioxide portable fire extinguisher sized to provide a minimum volume of free gas equal to 40% of the gross volume of the space may be accepted in lieu of a fixed system. A discharge port is to be arranged in the locker to allow the discharge of the extinguisher without having to enter into the protected space. The required portable fire extinguisher is to be stowed adjacent to the port. Alternatively, a port or hose connection may be provided to facilitate the use of fire main water.

IR4.6.3.3 The requirements given in 4.6.3.2 and 4.6.3.3 are not considered applicable for cargo service spaces intended for the stowage of cargo samples, when such spaces are positioned within the cargo area onboard tankers.

4.6.4 Deep-fat cooking equipment

Deep-fat cooking equipment installed in enclosed spaces or on open decks is to be fitted with the following:

.1 an automatic or manual extinguishing system tested to a recognised international standard; (Refer to the recommendations by the International Organization for Standardization, in particular, Publication ISO 15371:2000 on *Fire-extinguishing systems for protection of galley deep-fat cooking equipmen*t);

.2 a primary and backup thermostat with an alarm to alert the operator in the event of failure of either thermostat;

.3 arrangements for automatically shutting off the electrical power upon activation of the extinguishing system;

.4 an alarm for indicating operation of the extinguishing system in the galley where the equipment is installed; and

.5 controls for manual operation of the extinguishing system which are clearly labelled for ready use by the crew.

4.7 Fire extinguishing arrangements in cargo spaces

4.7.1 Fixed gas fire-extinguishing systems for general cargo

4.7.1.1 Except as provided for in 4.7.2, the cargo spaces of passenger ships of 1,000 gross tonnage and upwards are to be protected by a fixed carbon dioxide or inert gas fire-extinguishing system complying with the provisions of the Fire Safety Systems Code (Chapter 8) or by a fixed high expansion foam fire-extinguishing system which gives equivalent protection.

4.7.1.2 Where a passenger ship is engaged on voyages of such short duration that it would be unreasonable to apply the requirements of 4.7.1.1 and also in ships of less than 1,000 gross tonnage, the fire extinguishing arrangements in cargo spaces will be specially considered, provided that the ship is fitted with steel hatch covers and effective means of closing all ventilators and other openings leading to the cargo spaces.

4.7.1.3 Except for ro-ro and vehicle spaces, cargo spaces on cargo ships of 2,000 gross tonnage and upwards are to be protected by a fixed carbon dioxide or inert gas fire-extinguishing system complying with the Fire Safety Systems Code (Chapter 8), or by a fire-extinguishing system which gives equivalent protection.

IR4.7.1.3 In addition, ships of less than 2,000 tons gross tonnage carrying petroleum products having a flash point exceeding 60°C (c.c. test) are also not required to be fitted with a fixed fire extinguishing system.

4.7.1.4 The requirements of 4.7.1.3 and 4.7.2 may be waived for cargo spaces of any cargo ship if constructed, and solely intended for, the carriage of ore, coal, grain, unseasoned timber, non-combustible cargoes or cargoes which constitute a low fire risk. Such exemptions may be granted only if the ship is fitted with steel hatch covers and effective means of closing ventilators and other openings leading to the cargo spaces. (Refer to the IMSBC Code (resolution MSC.268(85)), as amended, appendix 1, entry for coal and to the List of solid bulk cargoes for which a fixed gas fire-extinguishing system may be exempted or for which a fixed gas fire-extinguishing system is ineffective (MSC.1/Circ.1395/Rev.6)).

4.7.2 Fixed gas fire-extinguishing systems for dangerous goods

A ship engaged in the carriage of dangerous goods in any cargo spaces is to be provided with a fixed carbon dioxide or inert gas fire-extinguishing system complying with the provisions of the Fire Safety Systems Code or with a fire-extinguishing system which gives equivalent protection for the cargoes carried.

IR4.7.2.1 Water supplies defined in Ch.7, 2.3.1.2 are considered as equivalent protection for cargoes listed in Table 2 of MSC.1/Circ.1395/Rev.6.

IR4.7.2.2 Clause 4.7.2 applies to the following ships engaged in the carriage of dangerous goods:

.1 Passenger ships constructed on or after 1 September 1984; and

.2 Cargo ships of 500 gross tonnage and upwards constructed on or after 1 September 1984;

.3 Cargo ships of less than 500 gross tonnage are not subject to Clause 4.7.2 even when such ships are engaged in the carriage of dangerous goods and document of compliance are issued to such ships according to Pt.6, Ch.7, Cl.2.4.

4.7.3 Firefighting for ships constructed on or after 1 January 2016 designed to carry containers on or above the weather deck

4.7.3.1 Ships are to carry, in addition to the equipment and arrangements required by 4.1 and 4.2, at least one water mist lance.

4.7.3.1.1 The water mist lance is to consist of a tube with a piercing nozzle which is capable of penetrating a container wall and producing water mist inside a confined space (container, etc.) when connected to the fire main.

4.7.3.2 Ships designed to carry five or more tiers of containers on or above the weather deck are to carry, in addition to the requirements of paragraph 4.7.3.1, mobile water monitors* as follows:

(*Refer to the Guidelines for the design, performance, testing and approval of mobile water monitors used for the protection of on-deck cargo areas of ships designed and constructed to carry five or more tiers of containers on or above the weather deck (MSC.1/Circ.1472).)

.1 ships with breadth less than 30 [m] at least two mobile water monitors; or

.2 ships with breadth of 30 [m] or more: at least four mobile water monitors.

4.7.3.2.1 The mobile water monitors, all necessary hoses, fittings and required fixing hardware are to be kept ready for use in a location outside the cargo space area not likely to be cut-off in the event of a fire in the cargo spaces.

4.7.3.2.2 A sufficient number of fire hydrants are to be provided such that:

.1 all provided mobile water monitors can be operated simultaneously for creating effective water barriers forward and aft of each container bay;

.2 the two jets of water required by paragraph 4.2.1.5.1 can be supplied at the pressure required by paragraph 4.2.1.6; and

.3 each of the required mobile water monitors can be supplied by separate hydrants at the pressure necessary to

reach the top tier of containers on deck.

4.7.3.2.3 The mobile water monitors may be supplied by the fire main, provided the capacity of fire pumps and fire main diameter are adequate to simultaneously operate the mobile water monitors and two jets of water from fire hoses at the required pressure values. If carrying dangerous goods, the capacity of fire pumps and fire main diameter is also to comply with Pt 6, Ch 7, Sec 2, and 2.3.1.5 as far as applicable to on-deck cargo areas. (Also see 4.2.2.4.1, IR .2.1)

4.7.3.2.4 The operational performance of each mobile water monitor is to be tested during initial survey on board the ship to the satisfaction of the Administration. The test is to verify that:

.1 the mobile water monitor can be securely fixed to the ship structure ensuring safe and effective operation; and

.2 the mobile water monitor jet reaches the top tier of containers with all required monitors and water jets from fire hoses operated simultaneously.

4.8 Cargo tank protection

4.8.1 Fixed deck foam systems

4.8.1.1 For tankers of 20,000 tonnes deadweight and upwards, a fixed deck foam system is to be provided in accordance with the Fire Safety Systems Code (Chapter 8). Other fixed installations if they afford equivalent protection may be accepted is lieu of above installations. The requirements for alternative fixed installations are to comply with 4.8.1.2.

4.8.1.2 To be considered equivalent, the system proposed in lieu of the deck foam system is to be capable of:

.1 extinguishing spill fires and also precluding ignition of spilled oil not yet ignited, and

.2 combating fires in ruptured tanks.

4.8.1.3 Tankers of less than 20,000 tonnes deadweight are to be provided with a deck foam system complying with the requirements of the Fire Safety Systems Code (Chapter 8).

IR4.8.1 Where an enclosed pipe trunk is situated within the cargo tanks deck area, the pipe trunk is to comply with following:

.1 it is to be protected by a fixed fire extinguishing system in accordance with 4.9. the extinguishing system is to be operated from a readily accessible position outside the pipe trunk;

.2 it is not considered as part of the cargo tanks deck area;

.3 the area of the pipe trunk need not be included in the calculation of the foam solution rate of supply for the deck foam system required by 4.8;

.4 it is to be adequately ventilated and protected in accordance with Pt.5, Ch.2, 6.4.3 and 6.4.4 and

.5 it is to contain no flammable gas sources other than pipes and flanges. If the pipe trunk contains any other source of flammable gas, i.e. valves and pumps, it is to be regarded as cargo pump room.

4.9 Protection of cargo pump rooms in tankers

4.9.1 Fixed fire-extinguishing systems

Each cargo pump-room in tankers of 500 gross tonnage and more is to be provided with one of the following fixed fire-extinguishing systems operated from a readily accessible position outside the pump-room. Cargo pump-rooms are to be provided with a system suitable for machinery spaces of category A.

4.9.1.1 A carbon dioxide system complying with the provisions the Fire Safety Systems Code (Chapter 8) and with the following:

.1 the alarms giving audible warning of the release of fire-extinguishing medium are to be safe for use in a flammable cargo vapour/air mixture; and

.2 a notice is to be exhibited at the controls stating that due to the electrostatic ignition hazard, the system is to be used only for fire extinguishing and not for inerting purposes.

4.9.1.2 A high-expansion foam system complying with the provisions of the Fire Safety Systems Code (Chapter 8), provided that the foam concentrate supply is suitable for

extinguishing fires involving the cargoes carried.

4.9.1.3 A fixed pressure water-spraying system complying with the provisions of the Fire Safety Systems Code (Chapter 8).

4.9.2 Quantity of fire-extinguishing medium

Where the extinguishing medium used in the cargo pump-room system is also used in systems serving other spaces, the quantity of medium provided or its delivery rate need not be more than the maximum required for the largest compartment.

IR4.9.3 In addition, two portable foam extinguishers or equivalent are to be provided, one at the pumps and one at the pump room entrance. (Refer 4.2.1.1.1 of Chapter 8 for capacity of foam extinguishers).

IR4.9.4 In ships of less than 500 tons gross tonnage, the fire extinguishing arrangements will be specially considered in each case.

4.10 Fire-fighter's outfits

4.10.1 Types of fire-fighter's outfits

4.10.1.1 Fire-fighter's outfits are to comply with the Fire Safety Systems Code (Chapter 8), and

4.10.1.2 Self-contained compressed air breathing apparatus of fire-fighter's outfits are to comply with paragraph 3.2.1.2.2 of the fire safety systems code (Chapter 8) by 1 July 2019.

4.10.2 Number of fire-fighter's outfits

4.10.2.1 Ships are to carry at least two fire-fighter's outfits.

4.10.2.2 In addition, in passenger ships there are to be provided:

.1 for every 80 [m], or part thereof, of the aggregate of the lengths of all passenger spaces and service spaces on the deck which carries such spaces or, if there is more than one such deck, on the deck which has the largest aggregate of such lengths, two fire-fighter's outfits and two sets of personal equipment, each set comprising the items stipulated in the Fire Safety Systems Code (Chapter 8). In passenger ships carrying more than 36 passengers, two additional fire-fighter's outfits are to be provided for each main vertical zone. However, for stairway enclosures which constitute individual main vertical zones and for the main vertical zones in the fore or aft end of a ship which do not contain spaces of categories (6), (7), (8) or (12) defined in 3.2.2.3, no additional fire-fighter's outfits are required; and

.2 ships carrying more than 36 passengers, for each pair of breathing apparatus there is to be provided one water fog applicator which is to be stored adjacent to such apparatus.

4.10.2.3 In addition, in tankers, two fire-fighter's outfits are provided.

4.10.2.4 Additional sets of personal equipment and breathing apparatus may be required, having due regard to the size and type of the ship.

4.10.2.5 Two spare charges are to be provided for each required breathing apparatus. Passenger ships carrying not more than 36 passengers and cargo ships that are equipped with suitably located means for fully recharging the air cylinders free from contamination, need carry only one spare charge for each required apparatus. In passenger ships carrying more than 36 passengers, at least two spare charges for each breathing apparatus are to be provided.

4.10.2.6 Passenger ships carrying more than 36 passengers constructed on or after 1 July 2010 are to be fitted with a suitably located means for fully recharging breathing air cylinders, free from contamination. The means for recharging are to be either:

.1 breathing air compressors supplied from the main and emergency switchboard, or independently driven, with a minimum capacity of 60 l/min per required breathing apparatus, not to exceed 420 l/min; or

.2 self-contained high-pressure storage systems of suitable pressure to recharge the breathing apparatus used on board, with a capacity of at least 1,200 l per required breathing apparatus, not to exceed 50,000 l of free air.

4.10.3 Storage of fire-fighter's outfits

4.10.3.1 The fire-fighter's outfits or sets of personal equipment are to be kept ready for use in an easily accessible location that is

permanently and clearly marked and, where more than one fire-fighter's outfit or more than one set of personal equipment is carried, they are to be stored in widely separated positions.

4.10.3.2 In passenger ships, at least two fire-fighter's outfits and, in addition, one set of personal equipment are to be available at any one position. At least two fire-fighter's outfits are to be stored in each main vertical zone.

4.10.4 Fire-fighter's communication

4.10.4.1 For ships constructed on or after 1 July 2014, a minimum of two exclusive two-way portable radiotelephone apparatus for each fire party for fire-fighter's communication shall be carried on board. Those two-way portable radiotelephone apparatus shall be of an explosion-proof type or intrinsically safe. Ships constructed before 1 July 2014 shall comply with the requirements of this paragraph not later than the first survey after 1 July 2018.

IR4.10.4.1 The two-way portable radio telephone apparatus for fire-fighter's communication, required by 4.10.4.1 is to be of certified safe type suitable for use in Zone 1 hazardous areas as defined in IEC Publication 600079. The minimum requirements in respect to the apparatus group and temperature class are to be consistent with the most restrictive requirements for the hazardous area zone on board which is accessible to fire party.

IR4.11 Ships not fitted with propelling machinery

A power pump or hand pump and fire hose and nozzle are to be fitted, having suction from the sea and capable of producing a jet of water on deck with a throw of not less than 6 [m].
Where oil fuel is used for generation of power, fire extinguishing appliances suitable for fighting oil fires are to be provided to the satisfaction of the Surveyors.

Additional fire extinguishing equipment may be required in accommodation spaces or cargo spaces depending upon the potential fire hazard afforded by the equipment and materials carried on in these spaces.

Section 5

Structural Integrity

5.1 Purpose

The purpose of this regulation is to maintain structural integrity of the ship preventing partial or whole collapse of the ship structures due to strength deterioration by heat. For this purpose, materials used in the ships' structure are to ensure that the structural integrity is not degraded due to fire.

5.2 Material of hull, superstructures, structural bulkheads, decks and deckhouses

The hull, superstructures, structural bulkheads, decks and deckhouses are to be constructed of steel or other equivalent material. For the purpose of applying the definition of steel or other equivalent material as given in Ch.1, 3.43 the "applicable fire exposure" is to be according to the integrity and insulation standards given in Table 3.1 to Table 3.4. For example, where divisions such as decks or sides and ends of deckhouses are permitted to have "B-0" fire integrity, the "applicable fire exposure" is to be half an hour.

5.3 Structure of aluminium alloy

Aluminium alloys will be specially considered giving due regard to the fire protection method adopted to ensure:

.1 the insulation of aluminium alloy components of 'A' or 'B' class divisions except structures, which in the opinion of IRS are non- load bearing, is to be such that the temperature of the structural core does not rise more than 200°C above the ambient temperature at any time during the applicable fire exposure to the standard fire test.

IR.1 If an aluminium deck is tested with insulation installed below the deck, then the result is to apply to decks which are bare on the top. Aluminium decks are not to be

provided with deck coverings or insulation on the top unless tested with the deck covering or insulation included, to verify that the 200°C temperature of the aluminium is not exceeded.

.2 special attention is to be given to the insulation of aluminium alloy components of columns, stanchions and other structural members required to support lifeboat and liferaft stowage, launching and embarkation areas, and 'A' and 'B' class divisions to ensure:

.2.1 that for such members supporting lifeboat and liferaft areas and 'A' class divisions, the temperature rise limitation specified in (5.3.1) is to apply at the end of one hour, and

.2.2 that for such members required to support 'B' class divisions, the temperature rise limitation specified in (5.3.1) is to apply at the end of half an hour.

5.4 Machinery spaces of category A

5.4.1 Crowns and casings

Crowns and casings of machinery spaces of category A is to be of steel construction and are to be insulated as required by Table 3.5a and Table 3.7, as appropriate.

5.4.2 Floor plating

The floor plating of normal passageways in machinery spaces of category A are to be made of steel.

5.5 Materials of overboard fittings

Materials readily rendered ineffective by heat are not to be used for overboard scuppers, sanitary discharges and other outlets which are close to the waterline and where the failure of the material in the event of fire would give rise to danger of flooding.

5.6 Protection of cargo tank structure against pressure or vacuum in tankers

5.6.1 General

Refer Pt.5, Ch.2, 8.1.4a) and b) for venting of small and large volumes.

5.6.2 Openings for small flow by thermal variations

Refer Pt.5, Ch.2, 8.1.14a) and b).

5.6.3 Safety measures in cargo tanks

5.6.3.1 *Preventive measures against liquid rising in the venting system*

Refer Pt.5, Ch.2, 8.1.5.

5.6.3.2 *Secondary means for pressure/vacuum relief*

Refer Pt.5, Ch.2, 8.1.4 c).

5.6.3.3 *Bypasses in vent mains*

Refer Pt.5, Ch.2, 8.1.9.

5.6.3.4 *Pressure/vacuum-breaking devices*

Refer Pt.5, Ch.2, 8.2.4.

5.6.4 Size of vent outlets

Large volume vent outlets for cargo loading, discharging and ballasting required by 5.6.1 are to be designed as given in Pt.5, Ch.2, 8.1.10. The master is to provided with information as given in Pt.5, Ch.2, 8.1.15 e).

End of Chapter

Chapter 4

Escape

Contents

Section

1 *Notification of Crew and Passengers*

2 *Means of Escape*

Section 1

Notification of Crew and Passengers

1.1 Purpose

The purpose of this section is to notify crew and passengers of a fire for safe evacuation. For this purpose, a general emergency alarm system and a public address system are to be provided.

1.2 General emergency alarm system

A general emergency alarm system is to be used for notifying crew and passengers of a fire.

1.3 Public address systems in passenger ships

A public address system or other effective means of communication are to be available throughout the accommodation and service spaces and control stations and open decks.

Section 2

Means of Escape

2.1 Purpose

2.1.1 The purpose of this regulation is to provide means of escape so that persons onboard can safely and swiftly escape to the lifeboat and liferaft embarkation deck. For this purpose, the following functional requirements are to be met:

.1 safe escape routes are to be provided;

.2 escape routes are to be maintained in a safe condition, clear of obstacles; and

.3 additional aids for escape are to be provided as necessary to ensure accessibility, clear marking, and adequate design for emergency situations.

IR2.1.1 To facilitate a swift and safe means of escape to the lifeboat and liferaft embarkation deck, the following provisions apply to overhead hatches fitted along the escape routes.

.1 the securing devices shall be of a type which can be opened from both sides;

.2 the maximum force needed to open the hatch cover should not exceed 150 N; and

.3 the use of a spring equalizing, counterbalance or other suitable device on the hinge side to reduce the force needed for opening is acceptable.

2.2 General requirements

2.2.1 Unless expressly provided otherwise in this section, at least two widely separated and ready means of escape are to be provided from all spaces or group of spaces.

2.2.2 Lifts are not to be considered as forming one of the means of escape as required by this section.

2.3 Means of escape from control stations, accommodation and service spaces

2.3.1 General requirements

2.3.1.1 Stairways and ladders are to be so arranged as to provide ready means of escape to the lifeboat and liferaft embarkation deck from passenger and crew accommodation spaces and from spaces in which the crew is normally employed, other than machinery spaces.

2.3.1.2 Unless expressly provided otherwise in this section, a corridor, lobby, or part of a corridor from which there is only one route of escape is to be prohibited. Dead-end corridors used in service areas which are necessary for the practical utility of the ship, such as fuel oil stations and athwartship supply corridors, may be permitted, provided such dead-end corridors are separated from crew accommodation areas and are inaccessible from passenger accommodation areas. Also, a part of a corridor that has a depth not exceeding its width is considered a recess or local extension and is permitted.

2.3.1.3 All stairways in accommodation and service spaces and control stations are to be of steel frame construction except where the use of other equivalent material is specially approved.

2.3.1.4 If a radiotelegraph station has no direct access to the open deck, two means of escape from or access to such station are to be provided, one of which may be a porthole or window of sufficient size.

2.3.1.5 Doors in escape routes are to, in general, open in-way of the direction of escape, except that:

.1 individual cabin doors may open into the cabins in order to avoid injury to persons in the corridor when the door is opened; and

.2 doors in vertical emergency escape trunks may open out of the trunk in order to permit the trunk to be used both for escape and for access.

2.3.2 Means of escape in passenger ships

2.3.2.1 *Escape from spaces below the bulkhead deck*

2.3.2.1.1 Below the bulkhead deck two means of escape, at least one of which is to be independent of watertight doors, are to be provided from each watertight compartment or similarly restricted space or group of spaces. Exceptionally, IRS may dispense with one of the means of escape for crew spaces that are entered only occasionally, if the required escape route is independent of watertight doors.

2.3.2.1.2 Where dispensation is given under the provisions of 2.3.2.1.1, this sole means of escape is to provide safe escape. However, stairways are not to be less than 800 [mm] in clear width with handrails on both sides.

2.3.2.2 *Escape from spaces above the bulkhead deck*

Above the bulkhead deck there are to be at least two means of escape from each main vertical zone or similarly restricted space or group of spaces, at least one of which is to give access to a stairway forming a vertical escape.

2.3.2.3 *Direct access to stairway enclosures*

Stairway enclosures in accommodation and service spaces are to have direct access from the corridors and be of a sufficient area to prevent congestion, having in view the number of persons likely to use them in an emergency. Within the perimeter of such stairway enclosures, only public toilets, lockers of non-combustible material providing storage for non-hazardous safety equipment and open information counters are permitted. Only corridors, lifts, public toilets, special category spaces and open ro-ro spaces to which any passengers carried can have access, other escape stairways required by 2.3.2.4.1 and external areas are permitted to have direct access to these stairway enclosures. Public spaces may also have direct access to stairway enclosures except for the backstage of a theatre. Small corridors or "lobbies" used to separate an enclosed stairway from galleys or main laundries may have direct access to the stairway provided they have a minimum

deck area of 4.5 [m^2], a width of not less than 900 [mm] and contain a fire hose station.

2.3.2.4 *Details of means of escape*

2.3.2.4.1 At least one of the means of escape required by 2.3.2.1.1 and 2.3.2.2 is to consist of a readily accessible enclosed stairway, which will provide continuous fire shelter from the level of its origin to the appropriate lifeboat and liferaft embarkation decks, or to the uppermost weather deck if the embarkation deck does not extend to the main vertical zone being considered. In the latter case, direct access to the embarkation deck by way of external open stairways and passageways will be provided and will have emergency lighting and slip-free surfaces underfoot. Boundaries facing external open stairways and passageways forming part of an escape route and boundaries in such a position that their failure during a fire would impede escape to the embarkation deck is to have fire integrity, including insulation values, in accordance with Table 3.1 to Table 3.4 of Part 6, Chapter 3, as appropriate.

2.3.2.4.2 Protection of access from the stairway enclosures to the lifeboat and liferaft embarkation areas is to be provided either directly or through protected internal routes which have fire integrity and insulation values for stairway enclosures as determined by Table 3.1 to Table 3.4 of Part 6, Chapter 3, as appropriate.

2.3.2.4.3 Stairways serving only a space and a balcony in that space is not to be considered as forming one of the required means of escape.

2.3.2.4.4 Each level within an atrium is to have two means of escape, one of which will give direct access to an enclosed vertical means of escape meeting the requirements of 2.3.2.4.1.

2.3.2.4.5 The widths, number and continuity of escapes are to be in accordance with the requirements in the Fire Safety Systems Code (Chapter 8).

2.3.2.5 *Marking of escape routes*

2.3.2.5.1 In addition to the emergency lighting the means of escape, including stairways and exits, are to be marked by lighting or photo-luminescent strip indicators placed not more than 300 [mm] above the deck at all points of the escape route including angles and intersections. The marking is to enable passengers to identify the routes of escape and readily identify the escape exits. If electric illumination is used, it is to be supplied by the emergency source of power and it is to be so arranged that the failure of any single light or cut in a lighting strip will not result in the marking being ineffective. Additionally, escape route signs and fire equipment location markings is to be of photoluminescent material or marked by lighting. Such lighting or photoluminescent equipment are to be evaluated, tested and applied in accordance with the Fire Safety Systems Code.

2.3.2.5.2 In passenger ships carrying more than 36 passengers, the requirements of 2.3.2.5.1 are to also apply to the crew accommodation areas.

2.3.2.5.3 In lieu of the escape route lighting system required by 2.3.2.5.1, alternative evacuation guidance systems may be accepted if approved by IRS based on the guidelines developed by the IMO*.

* Refer to the functional requirements and performance standards for the assessment of evacuation guidance systems (MSC1/Circ.1167) and the interim guidelines for the testing, approval and maintenance of evacuation guidance systems used as an alternative to low-location lighting systems (MSC1/Circ.1168).

2.3.2.6 *Normally locked doors that form part of an escape route*

2.3.2.6.1 Cabin and stateroom doors are not to require keys to unlock them from inside the room. There are not to be any doors along any designated escape route which require keys to unlock them when moving in the direction of escape.

2.3.2.6.2 Escape doors from public spaces that are normally latched are to be fitted with a means of quick release. Such means are to consist of a door-latching mechanism incorporating a device that releases the latch upon the application of a force in the direction of escape flow. Quick release mechanisms is to be designed and installed to the satisfaction of IRS and in particular:

.1 consist of bars or panels, the actuating portion of which extends across at least one half of the width of the door leaf, at least 760

[mm] and not more than 1120 [mm] above the deck;

.2 cause the latch to release when a force not exceeding 67 [N] is applied; and

.3 not be equipped with any locking device, set screw or other arrangement that prevents the release of the latch when pressure is applied to the releasing device.

2.3.2.7 Evacuation analysis for passenger ships

(Refer to the *Revised Guidelines on evacuation analyses for new and existing passenger ships* (MSC.1/Circ.1533), as may be amended.)

2.3.2.7.1 Escape routes are to be evaluated by an evacuation analysis early in the design process. This analysis applies to:

.1 ro-ro passenger ships constructed on or after 1 July 1999; and

.2 other passenger ships constructed on or after 1 January 2020 carrying more than 36 passengers.

2.3.2.7.2 The analysis is to be used to identify and eliminate, as far as practicable, congestion which may develop during an abandonment, due to normal movement of passengers and crew along escape routes, including the possibility that crew may need to move along these routes in a direction opposite to the movement of passengers. In addition, the analysis is to be used to demonstrate that escape arrangements are sufficiently flexible to provide for the possibility that certain escape routes, assembly stations, embarkation stations or survival craft may not be available as a result of a casualty.

2.3.3 Means of escape in cargo ships

2.3.3.1 *General*

At all levels of accommodation there are to be provided at least two widely separated means of escape from each restricted space or group of spaces.

2.3.3.2 *Escape from spaces below the lowest open deck*

Below the lowest open deck the main means of escape are to be a stairway and the second escape may be a trunk or a stairway.

2.3.3.3 *Escape from spaces above the lowest open deck*

Above the lowest open deck the means of escape are to be stairways or doors to an open deck or a combination thereof.

IR2.3.3.3 The “lowest open deck” is to be a category (10) “Open deck” (as defined in Chapter 3, Section 3, Cl.3.2.3.3.2.2 and Cl.3.2.4.2.2.2) at the lowest height from baseline in way of accommodation spaces.

2.3.3.4 *Dead-end corridors*

No dead-end corridors having a length of more than 7 [m] will be accepted. A dead-end corridor is a corridor or part of the corridor from which there is only one escape route.

2.3.3.5 *Width and continuity of escape routes*

The width, number and continuity of escape routes are to be in accordance with the requirements in the Fire Safety Systems Code (Chapter 8).

2.3.3.6 *Dispensation from two means of escape*

Exceptionally, one of the means of escape may be dispensed with, for crew spaces that are entered only occasionally, if the required escape route is independent of watertight doors.

2.3.4 Emergency escape breathing devices*

(* Refer to the Guidelines for the performance, location, use and care of emergency escape breathing devices (MSC/Circ.849)).

2.3.4.1 Emergency escape breathing devices are to comply with the Fire Safety Systems Code (Chapter 8). Spare emergency escape breathing devices are to be kept onboard.

2.3.4.2 All ships are to carry at least two emergency escape breathing devices within accommodation spaces.

2.3.4.3 In passenger ships, at least two emergency escape breathing devices are to be carried in each main vertical zone.

2.3.4.4 In passenger ships carrying more than 36 passengers, two emergency escape breathing devices, in addition to those required

in 2.3.4.3 above, are to be carried in each main vertical zone.

2.3.4.5 However, 2.3.4.3 and 2.3.4.4 do not apply to stairway enclosures which constitute individual main vertical zones and for the main vertical zones in the fore or aft end of a ship which do not contain spaces of categories (6), (7), (8) or (12) defined in Ch.3, 3.2.2.3.

2.4 Means of escape from machinery spaces

2.4.1 Means of escape on passenger ships

Means of escape from each machinery space in passenger ships are to comply with the following provisions.

2.4.1.1 *Escape from spaces below the bulkhead deck*

Where the space is below the bulkhead deck the two means of escape is to consist of either:

.1 two sets of steel ladders as widely separated as possible, leading to doors in the upper part of the space similarly separated and from which access is provided to the appropriate lifeboat and liferaft embarkation decks. One of these ladders are to be located within a protected enclosure that satisfies Ch.3, 3.2.2.3, category (2), or Ch.3, 3.2.2.4, category (4), as appropriate, from the lower part of the space it serves to a safe position outside the space. Self-closing fire doors of the same fire integrity standards are to be fitted in the enclosure. The ladder is to be fixed in such a way that heat is not transferred into the enclosure through non-insulated fixing points. The protected enclosure is to have minimum internal dimensions of at least 800 [mm] x 800 [mm], and is to have emergency lighting provisions; or

.2 one steel ladder leading to a door in the upper part of the space from which access is provided to the embarkation deck and additionally, in the lower part of the space and in a position well separated from the ladder referred to, a steel door capable of being operated from each side and which provides access to a safe escape route from the lower part of the space to the embarkation deck.

2.4.1.2 *Escape from spaces above the bulkhead deck*

Where the space is above the bulkhead deck, the two means of escape are to be as widely separated as possible and the doors leading from such means of escape are to be in a position from which access is provided to the appropriate lifeboat and liferaft embarkation decks. Where such means of escape require the use of ladders, these are to be of steel.

2.4.1.3 *Dispensation from two means of escape*

In a ship of less than 1,000 gross tonnage, one of the means of escape may be dispensed with due regard being paid to the width and disposition of the upper part of the space. In a ship of 1,000 gross tonnage and above, one means of escape from any such space, including a normally unattended auxiliary machinery space may be dispensed with, so long as either a door or a steel ladder provides a safe escape route to the embarkation deck, due regard being paid to the nature and location of the space and whether persons are normally employed in that space. In the steering gear space, a second means of escape is to be provided when the emergency steering position is located in that space unless there is direct access to the open deck.

IR2.4.1.3 The requirement of dispensing with second means of escape, in a ship of 1000 gross tonnage and above, as given in 2.4.1.3 applies only to auxiliary machinery spaces where persons are not normally employed.

2.4.1.4 *Escape from machinery control rooms*

Two means of escape are to be provided from a machinery control room located within a machinery space, at least one of which will provide continuous fire shelter to a safe position outside the machinery space.

IR2.4.1 The above clauses (2.4.1.1, 2.4.1.2 & 2.4.1.4) are to be interpreted as follows:

.1 A “safe position” can be any space, excluding lockers and storerooms irrespective of their area, cargo spaces and spaces where flammable liquids are stowed, but including special category spaces and ro-ro spaces, from which access is provided and maintained clear of obstacles to the embarkation decks (Cl. 2.4.1.1 and 2.4.1.4)

.2 Inclined ladders/stairways in machinery spaces being part of, or providing access to, escape routes but not located within a

protected enclosure are not to have an inclination greater than 60° and are not to be less than 600 [mm] in clear width. Such requirement need not be applied to ladders/stairways not forming part of an escape route, only provided for access to equipment or components, or similar areas, from one of the main platforms or deck levels within such spaces (Cl. 2.4.1).

.3 Machinery spaces may include working platforms and passageways, or intermediate decks at more than one deck level. In such case, the lower part of the space is to be regarded as the lowest deck level, platform or passageway within the space. At deck levels, other than the lowest one, where only one means of escape other than the protected enclosure is provided, self-closing fire doors are to be fitted in the protected enclosure at that deck level. Smaller working platforms in-between deck levels, or only for access to equipment or components, need not be provided with two means of escape (Cl. 2.4.1.1).

.4 A protected enclosure providing escape from machinery spaces to an open deck may be fitted with a hatch as means of egress from the enclosure to the open deck. The hatch is to have minimum internal dimensions of 800 [mm] x 800 [mm] (Cl. 2.4.1.1.1).

.5 Internal dimensions are to be interpreted as clear width, so that a passage having diameter of 800 mm is available throughout the vertical enclosure, as shown in Figure 2.4.1.4.1, clear of ship's structure, with insulation and equipment, if any. The ladder within the enclosure can be included in the internal dimensions of the enclosure. When protected enclosures include horizontal portions their clear width is not to be less than 600 [mm]. Figure 2.4.1.4.1 is given as example of some possible arrangements which may be in line with the above interpretation (Cl. 2.4.1.1.1).

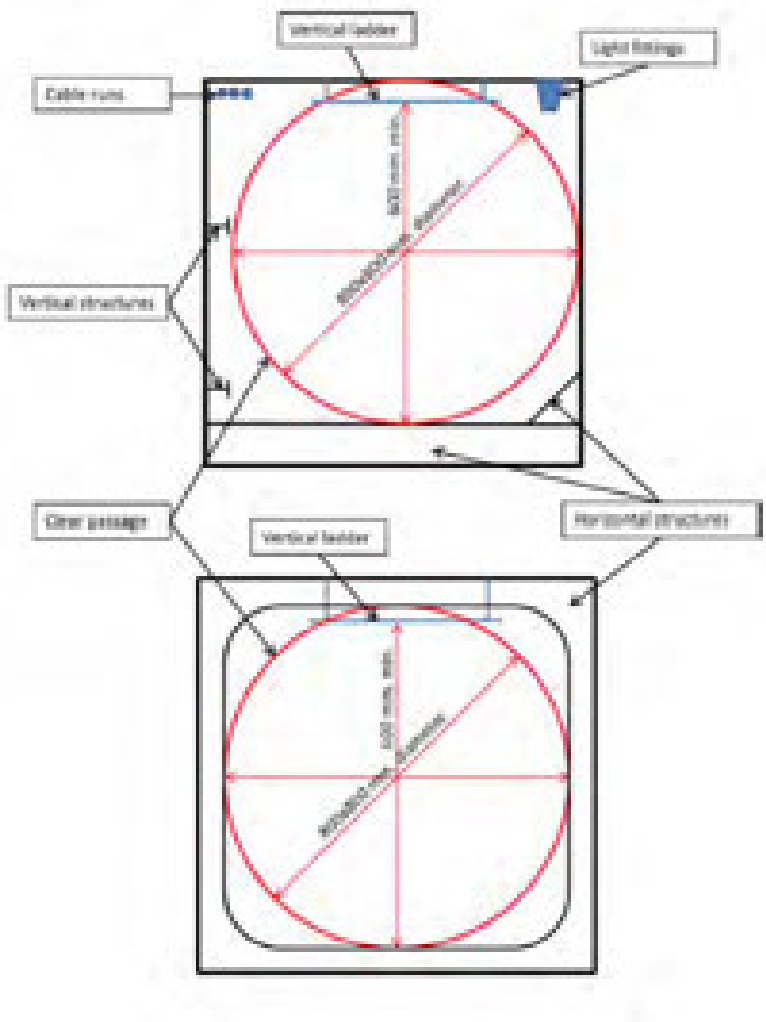

Fig.2.4.1.4.1 : Interpretation of Internal Dimensions – Possible Arrangements

2.4.1.5 *Inclined ladders and stairways*

All inclined ladders/stairways fitted to comply with 2.4.1.1 with open treads in machinery spaces being part of or providing access to escape routes but not located within a protected enclosure are to be made of steel. Such ladders/stairways are to be fitted with steel shields attached to their undersides, such as to provide escaping personnel protection against heat and flame from beneath.

2.4.1.6 *Escape from main workshops within machinery spaces*

Two means of escape are to be provided from the main workshop within a machinery space. At least one of these escape routes is to provide a continuous fire shelter to a safe position outside the machinery space.

2.4.2 Means of escape on cargo ships

Means of escape from each machinery space in cargo ships are to comply with the following provisions.

2.4.2.1 *Escape from machinery spaces of category A*

Except as provided in 2.4.2.2, two means of escape are to be provided from each machinery space of category A. In particular, one of the following provisions is to be complied with:

.1 two sets of steel ladders as widely separated as possible leading to doors in the upper part of the space similarly separated and from which access is provided to the open deck. One of these ladders is to be located within a protected enclosure that satisfies Ch.3, 3.2.3.3, category (4), from the lower part of the space it serves to a safe position outside the space. Self-closing fire doors of the same fire integrity standards are to be fitted in the enclosure. The ladder is to be fixed in such a way that heat is not transferred into the enclosure through non-insulated fixing points. The enclosure is to have minimum internal dimensions of at least 800 [mm] x 800 [mm], and is to have emergency lighting provisions; or

.2 one steel ladder leading to a door in the upper part of the space from which access is provided to the open deck and, additionally, in the lower part of the space and in a position well separated from the ladder referred to, a steel door capable of being operated from each side and which provides access to a safe escape route from the lower part of the space to the open deck.

2.4.2.2 *Dispensation from two means of escape*

In a ship of less than 1,000 gross tonnage, one of the means of escape required under 2.4.2.1 may be dispensed with, due regard being paid to the dimension and disposition of the upper part of the space. In addition, the means of escape from machinery spaces of category A need not comply with the requirement for an enclosed fire shelter listed in 2.4.2.1.1. In the steering gear space, a second means of escape is to be provided when the emergency steering position is located in that space unless there is direct access to the open deck.

IR2.4.2.2.1 Steering gear spaces which do not contain the emergency steering position need only have one means of escape.

.2 Steering gear spaces containing the emergency steering position can have one means of escape provided it leads directly onto the open deck. Otherwise, two means of escape are to be provided but they do not need to lead directly onto the open deck.

.3 Escape routes that pass only through stairways and/or corridors are considered as providing a “direct access to the open deck”, provided that the escape routes from the steering gear spaces have fire integrity protection equivalent to:

- steering gear spaces; or
- stairways/corridors,

whichever is more stringent.

2.4.2.3 *Escape from machinery spaces other than those of category A*

From machinery spaces other than those of category A, two escape routes are to be provided except that a single escape route may be accepted for spaces that are entered only occasionally, and for spaces where the maximum travel distance to the door is 5 [m] or less.

IR2.4.2 The above clauses (2.4.2.1 & 2.4.2.3) are to be interpreted as follows:

.1 A “safe position” can be any space, excluding cargo spaces, lockers and storerooms irrespective of their area, cargo pump-rooms and spaces where flammable liquids are stowed, but including vehicle and ro-ro spaces, from which access is provided and maintained clear of obstacles to the open deck (Cl. 2.4.2.1.1).

.2 Inclined ladders/stairways in machinery spaces being part of, or providing access to, escape routes, but not located within a protected enclosure are not to have an inclination greater than 60° and are not to be less than 600 [mm] in clear width. Such requirement need not be applied to ladders/stairways not forming part of an escape route, only provided for access to equipment or components, or similar areas, from one of the main platforms or deck levels within such spaces (Cl. 2.4.2.1).

.3 Machinery spaces of category A may include working platforms and passageways, or intermediate decks at more than one deck level. In such case, the lower part of the space is to be regarded as the lowest deck level, platform or passageway within the space.
At deck levels, other than the lowest one, where only one means of escape other than the protected enclosure is provided, self-closing fire doors are to be fitted in the protected enclosure at that deck level. Smaller working platforms in-between deck levels, or only for access to equipment or components, need not be provided with two means of escape (Cl. 2.4.2.1).

.4 A protected enclosure providing escape from machinery spaces of category A to an open deck may be fitted with a hatch as means of egress from the enclosure to the open deck. The hatch is to have minimum internal dimensions of 800 [mm] x 800 [mm] (Cl. 2.4.2.1.1).

.5 Internal dimensions are to be interpreted as clear width, so that a passage having diameter of 800 [mm] is available throughout the vertical enclosure, as shown in Fig. 2.4.1.4.1, clear of ship’s structure, with insulation and equipment, if any. The ladder within the enclosure can be included in the internal dimensions of the enclosure. When protected enclosures include horizontal portions their clear width is not to be less than 600 [mm]. Figure 2.4.1.4.1 is given as an example of some possible arrangements which may be in line with the above interpretation (Cl. 2.4.2.1.1).

.6 In machinery spaces other than those of category A, which are not entered only occasionally, the travel distance is to be measured from any point normally accessible to the crew, taking into account machinery and equipment within the space (Cl. 2.4.2.3).

2.4.2.4 Inclined ladders and stairways

All inclined ladders/stairways fitted to comply with 2.4.2.1 with open treads in machinery spaces being part of or providing access to escape routes but not located within a protected enclosure are to be made of steel. Such ladders/stairways are to be fitted with steel shields attached to their undersides, such as to provide escaping personnel protection against heat and flame from beneath.

2.4.2.5 Escape from machinery control rooms in machinery spaces of category "A"

Two means of escape are to be provided from the machinery control room located within a machinery space. At least one of these escape routes is to provide a continuous fire shelter to a safe position outside the machinery space.

2.4.2.6 Escape from main workshops in machinery spaces of category "A"

Two means of escape are to be provided from the main workshop within a machinery space. At least one of these escape routes is to provide a continuous fire shelter to a safe position outside the machinery space.

2.4.3 Emergency escape breathing devices

2.4.3.1 On all ships, within the machinery spaces, emergency escape breathing devices are to be situated ready for use at easily

visible places, which can be reached quickly and easily at any time in the event of fire. The location of emergency escape breathing devices is to take into account the layout of the machinery space and the number of persons normally working in the spaces. (Refer to the Guidelines for the performance, location, use and care of emergency escape breathing devices (MSC/Circ.849)).

2.4.3.2 The number and location of these devices are to be indicated in the fire control plan required in Ch.5, 2.2.4.

2.4.3.3 Emergency escape breathing devices are to comply with the Fire Safety Systems Code (Chapter 8).

2.5 Means of escape on passenger ships from special category and open ro-ro spaces to which any passengers carried can have access

2.5.1 In special category and open ro-ro spaces to which any passengers carried can have access, the number and locations of the means of escape both below and above the bulkhead deck are to be to the satisfaction of IRS and, in general, the safety of access to the embarkation deck is to be at least equivalent to that provided for under 2.3.2.1.1, 2.3.2.2, 2.3.2.4.1 and 2.3.2.4.2. Such spaces are to be provided with designated walkways to the means of escape with a breadth of at least 600 mm. The parking arrangements for the vehicles are to maintain the walkways clear at all times.

2.5.2 One of the escape routes from the machinery spaces where the crew is normally employed is to avoid direct access to any special category space.

2.6 Means of escape from ro-ro spaces

At least two means of escape are to be provided in ro-ro spaces where the crew are normally employed. The escape routes are to provide a safe escape to the lifeboat and liferaft embarkation decks and are to be located at the fore and aft ends of the space.

2.7 Additional requirements for ro-ro passenger ships

2.7.1 *General*

2.7.1.1 Escape routes are to be provided from every normally occupied space on the ship to an assembly station. These escape routes are to be arranged so as to provide the most direct route possible to the assembly station*, and are to be marked with symbols approved by the National Statutory Authority**.

(* Refer to the Indication of the "assembly stations" in passenger ships (MSC/Circ.777)).

(** Refer to the Symbols related to life-saving appliances and arrangements adopted by IMO by Resolution A.760(18)).

2.7.1.2 The escape route from cabins to stairway enclosures are to be as direct as possible, with a minimum number of changes in direction. It is not to be necessary to cross from one side of the ship to the other to reach an escape route. It is not to be necessary to climb more than two decks up or down in order to reach an assembly station or open deck from any passenger space.

2.7.1.3 External routes are to be provided from open decks, as referred to in 2.7.1.2, to the survival craft embarkation stations.

2.7.1.4 Where enclosed spaces adjoin an open deck, openings from the enclosed space to the open deck are, where practicable to be capable of being used as an emergency exit.

2.7.1.5 Escape routes are not to be obstructed by furniture and other obstructions. With the exception of tables and chairs which may be cleared to provide open space, cabinets and other heavy furnishings in public spaces and along escape routes are to be secured in place to prevent shifting if the ship rolls or lists. Floor coverings are also to be secured in place. When the ship is underway, escape routes are to be kept clear of obstructions such as cleaning carts, bedding, luggage and boxes of goods.

2.7.2 Instruction for safe escape

2.7.2.1 Decks are to be sequentially numbered, starting with "1" at the tank top or lowest deck. These numbers are to be prominently displayed at stair landings and lift lobbies. Decks may also be named, but the deck number is always to be displayed with the name.

2.7.2.2 Simple "mimic" plans showing the "you are here" position and escape routes marked by arrows, are to be prominently displayed on the inside of each cabin door and in public

spaces. The plan is to show the directions of escape, and is to be properly oriented in relation to its position on the ship.

2.7.3 Strength of handrails and corridors

2.7.3.1 Handrails or other handholds are to be provided in all corridors along the entire escape route, so that a firm handhold is available at every step of the way, where possible, to the assembly stations and embarkation stations. Such handrails are to be provided on both sides of longitudinal corridors more than 1.8 [m] in width and transverse corridors more than 1 [m] in width. Particular attention is to be paid to the need to be able to cross lobbies, atriums and other large open spaces along escape routes. Handrails and other handholds are to be of such strength as to withstand a distributed horizontal load of 750 [N/m] applied in the direction of the centre of the corridor or space, and a distributed vertical load of 750 [N/m] applied in the downward direction. The two loads need not be applied simultaneously.

2.7.3.2 The lowest 0.5 [m] of bulkheads and other partitions forming vertical divisions along escape routes are to be able to sustain a load of 750 [N/m] to allow them to be used as walking surfaces from the side of the escape route with the ship at large angles of heel.

3 *Operations*

Section 1

Operational Readiness and Maintenance

1.1 Purpose

The purpose of this section is to maintain and monitor the effectiveness of the fire safety measures the ship is provided with. For this purpose, the following functional requirements are to be met:

.1 fire protection systems and fire-fighting systems and appliances are to be maintained ready for use; and

.2 fire protection systems and fire-fighting systems and appliances are to be properly tested and inspected.

1.2 General requirements

At all times while the ship is in service, the requirements of 1.1.1 are to be complied with. A ship is not in service when:

.1 it is in for repairs or lay-up (either at anchor or in port) or in dry-dock;

.2 it is declared not in service by the owner or the owner's representative; and

.3 in the case of passenger ships, there are no passengers on board. However, in this case, the vessel is to satisfy the requirements of 1.1.1 as for a cargo ship.

1.2.1 Operational readiness

1.2.1.1 The following fire protection systems are to be kept in good order so as to ensure their required performance if a fire occurs:

.1 structural fire protection including fire resisting divisions, and protection of openings and penetrations in these divisions;

.2 fire detection and fire alarm systems; and

.3 means of escape systems and appliances.

1.2.1.2 Fire-fighting systems and appliances are to be kept in good working order and readily available for immediate use. Portable extinguishers which have been discharged are to be immediately recharged or replaced with an equivalent unit.

1.2.2 Maintenance, testing and inspections

1.2.2.1 Maintenance, testing and inspections are to be carried out based on the requirements approved by the National Statutory Authority and in a manner having due regard to ensuring the reliability of fire-fighting systems and appliances. (Refer to the Guidelines on maintenance and inspection of fire protection systems and appliances (MSC/Circ.850)).

1.2.2.2 The maintenance plan is to be kept on board the ship and is to be available for inspection whenever required.

1.2.2.3 The maintenance plan is to include at least the following fire protection systems and fire-fighting systems and appliances, where installed:

.1 fire mains, fire pumps and hydrants including hoses, nozzles and international shore connections;

.2 fixed fire detection and fire alarm systems;

.3 fixed fire-extinguishing systems and other fire extinguishing appliances;

.4 automatic sprinkler, fire detection and fire alarm systems;

.5 ventilation systems including fire and smoke dampers, fans and their controls;

.6 emergency shut down of fuel supply;

.7 fire doors including their controls;

.8 general emergency alarm systems;

.9 emergency escape breathing devices;

.10 portable fire extinguishers including spare charges; and

.11 fire-fighter's outfits.

1.2.2.4 The maintenance programme may be computer-based.

1.3 Additional requirements for passenger ships

In addition to the fire protection systems and appliances listed in 1.2.2.3, ships carrying more than 36 passengers are to develop a maintenance plan for low-location lighting and public address systems.

1.4 Additional requirements for tankers

In addition to the fire protection systems and appliances listed in 1.2.2.3, tankers are to develop a maintenance plan for:

.1 inert gas systems;

.2 deck foam systems;

.3 fire safety arrangements in cargo pump rooms; and

.4 flammable gas detectors.

Section 2

Instructions, Onboard Training and Drills

2.1 Purpose

The purpose of this regulation is to mitigate the consequences of fire by means of proper instructions for training and drills of persons onboard in correct procedures under emergency conditions. For this purpose, the crew are to have the necessary knowledge and skills to handle fire emergency cases, including passenger care.

2.2 General requirements

2.2.1 Instructions, duties and organization

2.2.1.1 Crew members are to receive instruction on fire safety onboard the ship.

2.2.1.2 Crew members are to receive instructions on their assigned duties.

2.2.1.3 Parties responsible for fire-extinguishing are to be organized. These parties are to have the capability to complete their duties at all times while the ship is in service.

2.2.2 Onboard training and drills

2.2.2.1 Crew members are to be trained to be familiar with the arrangements of the ship as well as the location and operation of any fire-fighting systems and appliances that they may be called upon to use.

2.2.2.2 Training in the use of the emergency escape breathing devices is to be considered as part of on board training.

2.2.2.3 Performance of crew members assigned fire-fighting duties is to be

periodically evaluated by conducting onboard training and drills to identify areas in need of improvement, to ensure competency in fire-fighting skills is maintained, and to ensure the operational readiness of the fire-fighting organization.

2.2.2.4 Onboard training in the use of the ship's fire-extinguishing systems and appliances is to be planned and conducted in accordance with provisions of SOLAS Reg. III/19.4.1.

2.2.2.5 Fire drills are to be conducted and recorded in accordance with the provisions of SOLAS Reg. III/19.3 and III/19.5.

2.2.2.6 An onboard means of recharging breathing apparatus cylinders used during drills shall be provided or a suitable number of spare cylinders shall be carried on board to replace those used.

IR2.2.2.6 "A suitable number of spare cylinders" to be carried onboard to replace those used for fire drills shall be at least one 'set of cylinders' for each mandatory breathing apparatus unless additional spare cylinders are required by the shipboard safety management system (SMS). 'Set of cylinders' means the number of cylinders which are required to operate the breathing apparatus. No additional cylinders are required for fire drills for breathing apparatus sets required by SOLAS Reg. II-2/19 (Pt. 6, Ch. 7), IMSBC Code, the IBC Code (Pt. 5, Ch. 3) or IGC Code (Pt. 5, Ch. 4).

2.2.3 Training manuals

2.2.3.1 A training manual is to be provided in each crew mess room and recreation room or in each crew cabin.

2.2.3.2 The training manual is to be written in the working language of the ship.

2.2.3.3 The training manual, which may comprise several volumes, is to contain the instructions and information required in 2.2.3.4 in easily understood terms and illustrated wherever possible. Any part of such information may be provided in the form of audio-visual aides in lieu of the manual.

2.2.3.4 The training manual is to explain the following in detail:

.1 general fire safety practice and precautions related to the dangers of smoking, electrical hazards, flammable liquids and similar common shipboard hazards;

.2 general instructions on fire-fighting activities and fire-fighting procedures including procedures for notification of a fire and use of manually operated call points;

.3 meanings of the ship's alarms;

.4 operation and use of fire-fighting systems and appliances;

.5 operation and use of fire doors;

.6 operation and use of fire and smoke dampers; and

.7 escape systems and appliances.

2.2.4 Fire control plans

(Refer to the Graphical symbols for fire control plans, adopted by IMO by resolution A.952(23). Resolution A.1116 (30) is to be used in combination with resolution A.952 (23) for the preparation of the shipboard fire control plans).

2.2.4.1 In all ships, fire control plans as given below are to be approved and permanently displayed for the guidance of ship's officers.

A general arrangement plan is to show clearly for each deck:

a) the control stations;

b) various fire sections enclosed by 'A' and 'B' class divisions together with particulars of fire detection and alarm systems;

c) the sprinkler installation;

d) the fire extinguishing appliances;

e) means of access to different compartments, etc.;

f) the ventilation system including particulars of the fan control positions, position of dampers and identification numbers of the ventilating fans serving each section.

Alternatively, the above mentioned details may be set out in a booklet, a copy of which is to be supplied to each officer, and at least one copy is to be available at all times on board in an accessible position.

Plans and booklets are to be kept up to date, any alterations being recorded thereon as soon as practicable. Description in such plans and booklets is to be in English and official language of the flag state.

2.2.4.2 A duplicate set of fire control plans or a booklet containing such plans is to be permanently stored in a prominently marked weathertight enclosure outside the deckhouse for the assistance of shore-side fire-fighting personnel. (Refer to the Guidance concerning the location of fire control plans for assistance of shoreside fire-fighting personnel (MSC/ Circ.451)).

2.3 Additional requirements for passenger ships

2.3.1 Fire drills

In addition to the requirement of 2.2.2.3, fire drills are to be conducted in accordance with the provision of SOLAS Reg.III/30 having due regard to notification of passengers and movement of passengers to assembly stations and embarkation decks.

2.3.2 Fire control plans

In ships carrying more than 36 passengers, plans and booklets required by this regulation is to provide information regarding fire protection, fire detection and fire extinction based on the requirements of the National Statutory Authority. (Refer to the Guidelines on the information to be provided with fire control plans and booklets required by SOLAS regulations II-2/20 and 41-2, adopted by the Organization by resolution A.756(18)).

Section 3

Operations

3.1 Purpose

The purpose of this regulation is to provide information and instructions for proper ship and cargo handling operations in relation to fire safety. For this purpose, the following functional requirements are to be met:

.1 fire safety operational booklets is to be provided on board; and

.2 flammable vapour releases from cargo tank venting is to be controlled.

3.2 Fire safety operational booklets

3.2.1 The required fire safety operational booklet is to contain the necessary information and instructions for the safe operation of the ship and cargo handling operations in relation to fire safety. The booklet is to include information concerning the crew's responsibilities for the general fire safety of the ship while loading and discharging cargo and while underway. Necessary fire safety precautions for handling general cargoes are to be explained. For ships carrying dangerous goods and flammable bulk cargoes, the fire safety operational booklet are also to provide reference to the pertinent fire-fighting and emergency cargo handling instructions contained in the International Maritime Solid Bulk Cargoes (IMSBC) Code the International Bulk Chemical Code, the International Gas Carrier Code and the International Maritime Dangerous Goods Code, as appropriate.

3.2.2 The fire safety operational booklet is to be provided in each crew mess room and recreation room or in each crew cabin.

3.2.3 The fire safety operational booklet is to be written in the working language of the ship.

3.2.4 The fire safety operational booklet may be combined with the training manuals required in 2.2.3.

3.3 Additional requirements for tankers

3.3.1 General

The fire safety operational booklet referred to in 3.2 is to include provisions for preventing fire spread to the cargo area due to ignition of flammable vapours and include procedures of

cargo tank gas-purging and/or gas-freeing taking into account the provisions in 3.3.2.

3.3.2 Procedures for cargo tank purging and/or gas-freeing

3.3.2.1 When the ship is provided with an inert gas system, the cargo tanks are first to be purged in accordance with the provisions of Ch.2, 1.5.6 until the concentration of hydrocarbon vapours in the cargo tanks has been reduced to less than 2% by volume. Thereafter, gas-freeing may take place at the cargo tank deck level.

3.3.2.2 When the ship is not provided with an inert gas system, the operation is to be such that the flammable vapour is discharged initially through:

.1 the vent outlets as specified in Ch.2, 1.5.3.4;

.2 outlets at least 2 [m] above the cargo tank deck level with a vertical efflux velocity of at least 30 [m/s] maintained during the gas-freeing operation; or

.3 outlets at least 2 [m] above the cargo tank deck level with a vertical efflux velocity of at least 20 [m/s] and which are protected by suitable devices to prevent the passage of flame.

The above outlets are to be located not less than 10 [m] measured horizontally from the nearest air intakes and openings to enclosed spaces containing a source of ignition and from deck machinery, which may include anchor windlass and chain locker openings, and equipment which may constitute an ignition hazard.

When the flammable vapour concentration at the outlet has been reduced to 30% of the lower flammable limit, gas-freeing may be continued at cargo tank deck level.

3.3.3 Operation of inert gas system

3.3.3.1 The inert gas system for tankers required in accordance with Pt6, Ch2, 1.5.5.1 is to be so operated as to render and maintain the atmosphere of the cargo tanks non-flammable, except when such tanks are required to be gas-free.

3.3.3.2 Notwithstanding the above, for chemical tankers, the application of inert gas, may take place after the cargo tank has been loaded, but before commencement of unloading and shall continue to be applied until that cargo tank has been purged of all flammable vapours before gas-freeing. Only nitrogen is acceptable as inert gas under this provision.

3.3.3.3 Notwithstanding Pt 6, Ch 1, 1.3.2, the provisions of this paragraph shall only apply to tankers constructed on or after 1 January 2016. If the oxygen content of the inert gas exceeds 5% by volume, immediate action is to be taken to improve the gas quality. Unless the quality of the gas improves, all operations in those cargo tanks to which inert gas is being supplied are to be suspended so as to avoid air being drawn into the cargo tanks, the gas regulating valve, if fitted, is to be closed and the off-specification gas is to be vented to atmosphere.

3.3.3.4 In the event that the inert gas system is unable to meet the requirement in paragraph 3.3.3.1 and it has been assessed that it is impractical to effect a repair, then cargo discharge and cleaning of those cargo tanks requiring inerting shall only be resumed when suitable emergency procedures have been followed, taking into account guidelines developed by IMO*.

(*Refer to the *Clarification of inert gas system requirements under the Convention* (MSC/Circ.485) and to the *Revised Guidelines for inert gas systems* (MSC/Circ.353), as amended by MSC/Circ.387.)

End of Chapter

Chapter 6

Alternative Design and Arrangements

Contents

Section	
1	*Alternative Design and Arrangements*

Section 1

Alternative Design and Arrangements

1.1 Purpose

The purpose of this section is to provide a methodology for alternative design and arrangements for fire safety.

1.2 General

1.2.1 Fire safety design and arrangements may deviate from the prescriptive requirements set out in Chapters 2, 3, 4, 5 or 7, provided that the design and arrangements meet the fire safety objectives and the functional requirements.

1.2.2 When fire safety design or arrangements deviate from the prescriptive requirements of this part, engineering analysis, evaluation and approval of the alternative design and arrangements are to be carried out in accordance with this section.
Note: Interim guidelines for use of fibre reinforced plastic (FRP) elements within ship structures (*MSC.1/ Circ. 1574*) may be referred whilst approving FRP elements as part of alternative design and arrangements of fire safety.

1.3 Engineering analysis

The engineering analysis is to be prepared and submitted to IRS (Refer to MSC/Circ.1002 as corrected by Corr.1, Corr.2, Corr.3 and amended by MSC.1/ Circ. 1552) and is to include, as a minimum, the following elements:

.1 determination of the ship type and space(s) concerned;

.2 identification of prescriptive requirement(s) with which the ship or the space(s) will not comply;

.3 identification of the fire and explosion hazards of the ship or the space(s) concerned;

.3.1 identification of the possible ignition sources;

.3.2 identification of the fire growth potential of each space concerned;

.3.3 identification of the smoke and toxic effluent generation potential for each space concerned;

.3.4 identification of the potential for the spread of fire, smoke or of toxic effluents from the space(s) concerned to other spaces;

.4 determination of the required fire safety performance criteria for the ships or the space(s) concerned addressed by the prescriptive requirement(s);

.4.1 performance criteria is to be based on the fire safety objectives and on the functional requirements of this part;

.4.2 performance criteria are to provide a degree of safety not less than that achieved by using the prescriptive requirements; and

.4.3 performance criteria is to be quantifiable and measurable;

.5 detailed description of the alternative design and arrangements, including a list of the assumptions used in the design and any proposed operational restrictions or conditions; and

.6 technical justification demonstrating that the alternative design and arrangements meet the required fire safety performance criteria.

1.4 Evaluation of the alternative design and arrangements

1.4.1 The engineering analysis required in 1.3 is to be evaluated and approved by IRS taking into account the requirements of the National Statutory Authority (Refer to MSC/Circ.1002 as corrected by Corr.1, Corr.2, Corr.3 and amended by MSC.1/ Circ. 1552).

1.4.2 A copy of the documentation, as approved by IRS, indicating that the alternative design and arrangements comply with this chapter is to be carried onboard the ship.

1.5 Exchange of information

Note : The Administration is to communicate to IMO pertinent information concerning alternative design and arrangements approved by them for circulation to all contracting governments.

1.6 Re-evaluation due to change of conditions

If the assumptions, and operational restrictions that were stipulated in the alternative design and arrangements are changed, the engineering analysis is to be carried out under the changed condition and is to be approved by IRS.

6	*Design Criteria for Systems to Remain Operational after a Fire Casualty*
7	*Safety Centre on Passenger Ships*

Section 1

Helicopter Facilities

1.1 Purpose

The purpose of this section is to provide additional measures in order to address the fire safety objectives of this part for ships fitted with special facilities for helicopters. For this purpose, the following functional requirements are to be met:

.1 helideck structure is to be adequate to protect the ship from the fire hazards associated with helicopter operations;

.2 fire fighting appliances are to be provided to adequately protect the ship from the fire hazards associated with helicopter operations;

.3 refuelling and hangar facilities and operations are to provide the necessary measures to protect the ship from the fire hazards associated with helicopter operations; and

.4 operation manuals and training are to be provided.

1.2 Application

1.2.1 In addition to complying with the requirements of Chapters 2, 3, 4 and 5, as appropriate, ships equipped with helidecks are to comply with the requirements of this section.

1.2.2 Where helicopters land or conduct winching operations on an occasional or emergency basis on ships without helidecks, fire-fighting equipment fitted in accordance with the requirements in Ch.3 may be used. This equipment is to be made readily available in close proximity to the landing or winching areas during helicopter operations.

1.2.3 Notwithstanding the requirements of paragraph 1.2.2 above, ships constructed on or after 1 January 2020, having a helicopter landing area, are to be provided with foam firefighting appliances which comply with the relevant provisions of Ch.8, Sec.17.

1.2.4 Notwithstanding the requirements of 1.2.2 or 1.2.3 above, ro-ro passenger ships without helidecks are to comply with SOLAS Reg.III/28.

1.3 Structure

1.3.1 Construction of steel or other equivalent material

In general, the construction of the helidecks is to be of steel or other equivalent materials. If the helideck forms the deckhead of a deckhouse or superstructure, it is to be insulated to "A-60" class standard.

1.3.2 Construction of aluminium or other low melting point metals

1.3.2.1 If helideck platform of such construction located above the ship's deckhouse or similar structure:

- The deckhouse top and bulkheads under the platform are to have no openings; and
- Windows under the platform are to be provided with steel shutters.

1.3.2.2 After each fire on the platform or in close proximity its suitability for further use will be specially considered in each case.

1.4 Means of escape

A helideck is to be provided with both a main and an emergency means of escape and access for fire fighting and rescue personnel. These are to be located as far apart from each other as is practicable and preferably on opposite sides of the helideck.

1.5 Fire-fighting appliances

1.5.1 In close proximity to the helideck, the following fire-fighting appliances are to be provided and stored near the means of access to that helideck (Also refer MSC.1/Circ.1275 'Unified Interpretations of SOLAS Chapter II-2 on the Number and Arrangement of Portable fire extinguishers on board ships'):

.1 at least two dry powder extinguishers having a total capacity of not less than 45 [kg];

.2 carbon dioxide extinguishers of a total capacity of not less than 18 [kg] or equivalent;

.3 a suitable foam application system consisting of monitors or foam making branch pipes capable of delivering foam to all parts of the helideck in all weather conditions in which helicopters can operate. The system is to be capable of delivering a discharge rate as required in Table 1.1 for at least five minutes;

Table 1.1 : Foam discharge rates

Category	Helicopter overall length	Discharge rate foam solution [l/min.]
H1	up to but not including 15 [m]	250
H2	from 15 [m] up to but not including 24 [m]	500
H3	from 24 [m] up to but not including 35 [m]	800

.4 the principal agent is to be suitable for use with salt water and conform to performance standards not inferior to those acceptable to the National Statutory Authority. (Refer to the International Civil Aviation Organization Airport Services Manual, Part 1 - Rescue and Fire fighting, Chapter 8 - Extinguishing Agent Characteristics, Paragraph 8.1.5 - Foam Specifications Table 8-1, Level 'B'));

.5 at least two nozzles of an approved dual-purpose type (jet/spray) and hoses sufficient to reach any part of the helideck;

.6 in lieu of the requirements of paragraphs .3 through .5, on ships constructed on or after 1 January 2020 having a helideck, foam firefighting appliances which comply with the provisions of the Chapter 8.

.7 in addition to the requirements of Ch.3, 4.10, two sets of fire-fighter's outfits; and

.8 at least the following equipment are to be stored in a manner that provides for immediate use and protection from the elements:

- adjustable wrench;
- blanket, fire resistant;
- cutters, bolt 60 [cm];
- hook, grab or salving;
- hacksaw, heavy duty complete with 6 spare blades;
- ladder;
- lift line 5 [mm] diameter x 15 [m] in length;

- pliers, side cutting;
- set of assorted screwdrivers; and
- harness knife complete with sheath.

1.6 Drainage facilities

Drainage facilities in way of helidecks are to be constructed of steel and are to lead directly overboard independent of any other system and is to be designed so that drainage does not fall onto any part of the ship.

1.7 Helicopter refuelling and hangar facilities

Where the ship has helicopter refuelling and hangar facilities, the following requirements are to be complied with:

.1 a designated area is to be provided for the storage of fuel tanks which is to be:

.1.1 as remote as is practicable from accommodation spaces, escape routes and embarkation stations; and

.1.2 isolated from areas containing a source of vapour ignition;

.2 the fuel storage area is to be provided with arrangements whereby fuel spillage may be collected and drained to a safe location;

.3 tanks and associated equipment are to be protected against physical damage and from a fire in an adjacent space or area;

.4 where portable fuel storage tanks are used, special attention is to be given to:

.4.1 design of the tank for its intended purpose;

.4.2 mounting and securing arrangements;

.4.3 electric bonding; and

.4.4 inspection procedures;

.5 storage tank fuel pumps are to be provided with means which permit shutdown from a safe remote location in the event of a fire. Where a gravity fuelling system is installed, equivalent closing arrangements are to be provided to isolate the fuel source;

.6 the fuel pumping unit is to be connected to one tank at a time. The piping between the tank and the pumping unit is to be of steel or equivalent material, as short as possible, and protected against damage;

.7 electrical fuel pumping units and associated control equipment is to be of a type suitable for the location and potential hazards;

.8 fuel pumping units are to incorporate a device which will prevent over-pressurization of the delivery or filling hose;

.9 equipment used in refuelling operations is to be electrically bonded;

.10 "NO SMOKING" signs are to be displayed at appropriate locations;

.11 hangar, refuelling and maintenance facilities are to be treated as category ‘A’ machinery spaces with regard to structural fire protection, fixed fire-extinguishing and detection system requirements;

.12 enclosed hangar facilities or enclosed spaces containing refuelling installations are to be provided with mechanical ventilation, as required by 3.3 for closed ro-ro spaces of cargo ships. Ventilation fans are to be of non-sparking type; and

.13 electric equipment and wiring in enclosed hangar or enclosed spaces containing refuelling installations are to comply with 3.3.2, 3.3.3 and 3.3.4.

1.8 Operations manual and fire-fighting service

1.8.1 Each helicopter facility is to have an operations manual, including a description and a checklist of safety precautions, procedures and equipment requirements. This manual may be part of the ship’s emergency response procedures.

1.8.2 The procedures and precautions to be followed during refuelling operations are to be in accordance with recognized safe practices and contained in the operations manual.

1.8.3 Fire-fighting personnel consisting of at least two persons trained for rescue and fire-fighting duties and fire-fighting equipment are to be immediately available at all times when helicopter operations are expected.

1.8.4 Fire-fighting personnel are to be present during refuelling operations. However, the fire-

fighting personnel are not to be involved with refuelling activities.

1.8.5 On-board refresher training is to be carried out and additional supplies of fire-fighting media is to be provided for training and testing of the equipment.

Section 2

Carriage of Dangerous Goods*

2.1 Purpose

The purpose of this section is to provide additional safety measures in order to address the fire safety objectives of this part for ships carrying dangerous goods. For this purpose, the following functional requirements are to be met:

.1 fire protection systems are to be provided to protect the ship from the added fire hazards associated with carriage of dangerous goods;

.2 dangerous goods are to be adequately separated from ignition sources; and

.3 appropriate personnel protective equipment are to be provided for the hazards associated with the carriage of dangerous goods.

2.2 General requirements

2.2.1 In addition to complying with the requirements of Chapters 2, 3, 4, 5 and sections 1 and 3**, as appropriate, ship types and cargo spaces, referred to in 2.2.2, intended for the carriage of dangerous goods are to comply with the requirements of this section, as appropriate, except when carrying dangerous goods in limited quantities*** and excepted quantities**** unless such requirements have already been met by compliance with the requirements elsewhere in this chapter. The types of ships and modes of carriage of dangerous goods are referred to in 2.2.2 and in Table 2.1. Cargo ships of less than 500 gross tonnage are to comply with this section, but Administrations may reduce the requirements and such reduced requirements are to be recorded in the document of compliance referred to in 2.4.

* Refer also to the Interim guidelines for open top containerships (MSC/Circ.608/Rev.1).

** Refer to part 7 of the International Maritime Dangerous Goods Code.

*** Refer to chapter 3.4 of the International Maritime Dangerous Goods Code.

**** Refer to chapter 3.5 of the IMDG Code.

2.2.2 The following ship types and cargo spaces are to govern the application of Table 2.1 and Table 2.2:

.1 ships and cargo spaces not specifically designed for the carriage of freight containers, but intended for the carriage of dangerous goods in packaged form including goods in freight containers and portable tanks;

.2 purpose-built container ships and cargo spaces intended for the carriage of dangerous goods in freight containers and portable tanks;

IR.2 A purpose built container space is a cargo space fitted with cell guides for stowage securing of containers.

.3 ro-ro ships and ro-ro spaces intended for the carriage of dangerous goods;

IR.3 Ro-ro spaces include special category spaces (refer Ch.1, 3.46) and vehicle spaces (refer Ch.1, 3.49).

.4 ships and cargo spaces intended for the carriage of solid dangerous goods in bulk; and

.5 ships and cargo spaces intended for carriage of dangerous goods other than liquids and gases in bulk in shipborne barges.

2.3 Special requirements

Unless otherwise specified, the following requirements (2.3.1 to 2.3.10) are to govern the application of Table 2.1, Table 2.2 and Table 2.3 to both "on-deck" and "under-deck" stowage of dangerous goods where the numbers of the following paragraphs are indicated in the first column of the tables.

2.3.1 Water supplies

2.3.1.1 Arrangements are to be made to ensure immediate availability of a supply of water from the fire main at the required pressure either by permanent pressurization or by suitably placed remote arrangements for the fire pumps.

2.3.1.2 The quantity of water delivered is to be capable of supplying four nozzles of a size and at pressures as specified in Ch.3, 4.2, capable of being trained on any part of the cargo space when empty. (Also see Ch.3, 4.2.2.4.1, IR.2.1) This amount of water may be applied by equivalent means to the satisfaction of IRS.

IR 2.3.1.2 The number and position of hydrants are to be such that at least two of the required four jets of water, when supplied by single lengths of hose, may reach any part of the cargo space when empty; and all four jets of water, each supplied by single lengths of hose may reach any part of ro-ro cargo spaces.

2.3.1.3 Means of effectively cooling the designated underdeck cargo space by at least 5 l/min per square metre of the horizontal area of cargo spaces, either by a fixed arrangement of spraying nozzles or flooding the cargo space with water are to be provided. Hoses may be used for this purpose in small cargo spaces and in small areas of larger cargo spaces at the discretion of IRS. However, the drainage and pumping arrangements are to be such as to prevent the build-up of free surfaces. The drainage system is to be sized to remove no less than 125% of the combined capacity of both the water spraying system pumps and the required number of fire hose nozzles. The drainage system valves are to be operable from outside the protected space at a position in the vicinity of the extinguishing system controls. Bilge wells are to be of sufficient holding capacity and are to be arranged at the side shell of the ship at a distance from each other of not more than 40 [m] in each watertight compartment. If this is not possible, the adverse effect upon stability of the added weight and free surface of water is to be taken into account to the extent deemed necessary during appraisal of stability information. (Refer to the Recommendation on fixed fire-extinguishing systems for special cargo spaces adopted by IMO by resolution A.123(V)). (Also see Ch.3, 4.2.2.4.1, IR .2.1).

2.3.1.4 Provision to flood a designated under-deck cargo space with suitable specified media may be substituted for the requirements in 3.1.3.

IR2.3.1.4 A high expansion foam system complying with Fire Safety Systems Code (Chapter 8) is acceptable except if cargoes dangerously react with water (see the IMDG Code, paragraph 16.2.2 of Section 16).

2.3.1.5 The total required capacity of the water supply is to satisfy 2.3.1.2 and 2.3.1.3, if applicable, simultaneously calculated for the largest designated cargo space. The capacity requirements of 2.3.1.2 are to be met by the total capacity of the main fire pump(s) not including the capacity of the emergency fire pump, if fitted. If a drencher system is used to satisfy 2.3.1.3, the drencher pump is also be taken into account in this total capacity calculation. (Also see Ch.3, 4.2.2.4.1, IR .2.1).
.
IR2.3.1.5 a) The water spray system required by paragraphs 9.2, 9.3 and 9.4 of MSC/Circ.608/ Rev.1 “Interim guidelines for open top container ships” will also satisfy the requirements for dangerous goods.

b) The amount of water required for fire fighting purposes in the largest hold is to allow simultaneous use of the water spray system plus the four jets of water from hose nozzles.

2.3.2 Sources of ignition

Electrical equipment and wiring is not to be fitted in enclosed cargo spaces or vehicle spaces unless it is considered essential for operational purposes. However, if electrical equipment is fitted in such spaces, it is to be of a certified safe type for use in the dangerous environments to which it may be exposed unless it is possible to completely isolate the electrical system (e.g. by removal of links in the system, other than fuses). Cable penetrations of the decks and bulkheads are to be sealed against the passage of gas or vapour. Through runs of cables and cables within the cargo spaces are to be protected against damage from impact. Any other equipment which may constitute a source of ignition of flammable vapour will not be permitted.

IR2.3.2 Notes for 2.3.2 :

1) Reference is to be made to IEC 60092-506:2003.

2) For pipes having open ends (e.g. ventilation and bilge pipes, etc.) in a hazardous area, the pipe itself is to be classified as hazardous area. See IEC 60092-506:2003 table B1, item B.

3) When carrying flammable liquids having flashpoints less than 23 [˚C] as Class 3, 6.1 or 8 in cargo spaces, the bilge pipes with flanges, valves, pumps, etc. constitute a source of release and the enclosing spaces (e.g. pipe tunnels, bilge pump rooms, etc.) are to be classified as an extended hazardous area (comparable with Zone 2) unless these spaces are continuously mechanically ventilated with a capacity for at least six air changes per hour. Except where the space is protected with redundant mechanical ventilation capable of starting automatically, equipment not certified for Zone 2 are to be automatically disconnected following loss of ventilation while essential systems such as bilge and ballast systems are to be certified for Zone 2. Where redundant mechanical ventilation is employed, equipment and essential systems not certified for Zone 2 are to be interlocked so as to prevent inadvertent operation if the ventilation is not operational. Audible and visible alarms are to be provided at a manned station if failure occurs.

2.3.3 Detection system

Ro-ro spaces are to be fitted with a fixed fire detection and fire alarm system complying with the requirements of the Fire Safety Systems Code (Chapter 8). All other types of cargo spaces are to be fitted with either a fixed fire detection and fire alarm system or a sample extraction smoke detection system complying with the requirements of the Fire Safety Systems Code. If a sample extraction smoke detection system is fitted, particular attention is to be made to the Fire Safety Systems Code (Chapter 8, Clause 10.2.1.3 in Sec.10) in order to prevent the leakage of toxic fumes into occupied areas.

2.3.4 Ventilation arrangement

2.3.4.1 Adequate power ventilation is to be provided in enclosed cargo spaces. The arrangement is to be such as to provide for at least six air changes per hour in the cargo space based on an empty cargo space and for removal of vapours from the upper or lower parts of the cargo space, as appropriate.

IR 2.3.4.1.1 The reduced air changes per hour as per Note 1 of Table 2.1 apply equally to the ventilation air changes requirements in 2.3.4.1 above, when the bilge pump is located directly inside a container cargo space.

IR 2.3.4.1.2 In such a case, where several container cargo spaces are served by the same bilge pump, the bilge pump is to be installed in the container cargo space with the highest ventilation rate, compared to the other container cargo spaces.

2.3.4.2 The fans are to be of non-sparking type, as per Pt.5, Ch.2, Cl.6.5. Suitable wire mesh guards are to be fitted over inlet and outlet ventilation openings to prevent foreign objects from entering into the fan casing.

2.3.4.3 Natural ventilation is to be provided in enclosed cargo spaces intended for the carriage of solid dangerous goods in bulk, where there is no provision for mechanical ventilation.

IR2.3.4.4 If adjacent spaces are not separated from cargo spaces by gastight bulkheads or decks, then they are considered as part of the enclosed cargo space and the ventilation requirements are to apply to the adjacent space as for the enclosed cargo space itself.

IR2.3.4.5 Where the IMSBC Code requires continuous ventilation in cargo holds, the ventilation openings are to comply with the requirements of Pt.3, Ch.13, Sec.2 for openings not fitted with means of closure. This does not prevent ventilators from being fitted with a means of closure as required for fire protection purposes as per Pt.6, Ch.2, Cl. 2.2.1.1 provided the minimum height to the ventilator opening is in accordance with Pt.3, Ch.13, Sec.2 (4.5.m for Position 1 and 2.3 m for Position 2).

The requirements for continuous ventilation apply to the following cargoes as per the IMSBC code:

ALUMINIUM FERROSILICON POWDER
UN 1395

ALUMINIUM SILICON POWDER, UNCOATED UN 1398
ALUMINIUM SMELTING/REMELTING BY-PRODUCTS, PROCESSED
ALUMINIUM SMELTING BY-PRODUCTS or ALUMINIUM REMELTING BYPRODUCTS UN 3170
FERROPHOSPHORUS (including BRIQUETTES)
FERROSILICON (25% ≤ Silicon ≤ 30% or ≥ 90% Silicon)
FERROSILICON UN 1408 (30% ≤ Silicon < 90%)
ZINC ASHES UN 1435

IR2.3.4.6 Where two fans per hold are required in the IMSBC Code, a common ventilation system with two fans connected is acceptable.

IR2.3.4.7 For open top container holds, power ventilation is required only for the lower part of the cargo hold for which purpose ducting is required. The ventilation capacity is to be at least 2 air changes per hour based on the empty hold volume below weather deck.

2.3.5 Bilge pumping

2.3.5.1 Where it is intended to carry flammable or toxic liquids in enclosed cargo spaces, the bilge pumping system is to be designed to protect against inadvertent pumping of such liquids through machinery space piping or pumps. Where large quantities of such liquids are carried, consideration is to be given to the provision of additional means of draining those cargo spaces. These means are to be specially examined and approved.

2.3.5.2 If the bilge drainage system for cargo spaces is additional to the system served by pumps in the machinery space, the capacity of the system is to be not less than 10 [m^3/hr] per cargo space served. If the additional system is common, the capacity need not exceed 25 [m^3/h]. The additional bilge system need not be arranged with redundancy.

2.3.5.3 Whenever flammable or toxic liquids are carried, the bilge line into the machinery space is to be isolated either by fitting a blank flange or by a closed lockable valve.

2.3.5.4 Enclosed spaces outside of machinery spaces containing bilge pumps serving cargo spaces intended for carriage of flammable or toxic liquids are to be fitted with separate mechanical ventilation giving at least 6 air changes per hour. If the space has access from another enclosed space, the door is to be self closing.

IR 2.3.5.4.1 Electrical equipment in the space is to be according to Pt.4, Ch.8.

IR 2.3.5.4.2 The reduced air changes per hour as per Note 1 of Table 2.1 apply equally to the ventilation air changes requirements in 2.3.5.4 above, when the bilge pump is located directly inside a container cargo spaces.

IR 2.3.5.4.3 In such a case, where several container cargo spaces are served by the same bilge pump, the bilge pump is to be installed in the container cargo space with the highest ventilation rate, compared to the other container cargo spaces.

2.3.5.5 If bilge drainage of cargo spaces is arranged by gravity drainage, the drainage is to be either led directly overboard or to a closed drain tank located outside the machinery spaces. The tank is to be provided with a vent pipe to a safe location on the open deck.

IR2.3.5.6 Cargo spaces intended for carriage of flammable liquids with flash point less than 23°C or toxic liquids are to be fitted with a fixed bilge drainage system independent or separated from the bilge system in machinery space and located outside of the machinery space.

If a single bilge drainage system completely independent of the machinery space is provided, the system is to comply with the Rule requirement to redundancy and capacity based on the size of the space or spaces which it serves.

IR2.3.5.7 Drainage from a cargo space into bilge wells in a lower space is only permitted if that space satisfies the same requirements as the cargo space above.

IR2.3.5.8 Bilge systems for open top container ship cargo holds are to be independent of machinery space bilge system and be located outside machinery space.

2.3.6 Personnel protection

2.3.6.1 Four sets of full protective clothing resistant to chemical attack are to be provided in addition to the fireman's outfits required by Ch.3, 4.10 and are to be selected taking into

account the hazards associated with the chemicals being transported and the standards developed by IMO according to the class and physical state. (See Note 2 in IR2.3.6.1). The protective clothing is to cover all skin, so that no part of the body is unprotected.

IR2.3.6.1 Notes for 2.3.6.1:

1) The required protective clothing is for emergency purposes.

2) For solid bulk cargoes the protective clothing is to satisfy the equipment requirements specified in the respective schedules of the IMSBC Code for the individual substances. For packaged goods, the protective clothing is to satisfy the equipment requirements specified in emergency procedures (EmS) of the Supplement to IMDG Code for the individual substances

2.3.6.2 At least two self-contained breathing apparatuses additional to those required by Ch.3, Sec.4 is to be provided. Passenger ships carrying not more than 36 passengers and cargo ships that are equipped with suitably located means for fully recharging the air cylinders free from contamination, need carry only one spare charge for each required apparatus.

IR2.3.6.2 For each of the breathing apparatuses, two complete sets of air bottles are to be provided. These spare bottles are in addition to the spare bottles required for fire fighter's outfit.

2.3.7 Portable fire extinguishers

Portable fire extinguishers with a total capacity of at least 12 [kg] of dry powder or equivalent are to be provided for the cargo spaces. These extinguishers are to be in addition to any portable fire extinguishers required elsewhere in this part. (Also refer MSC.1/Circ.1275 'Unified Interpretations of SOLAS Chapter II-2 on the Number and Arrangement of Portable fire extinguishers on board ships')

2.3.8 Insulation of machinery space boundaries

Bulkheads forming boundaries between cargo spaces and machinery spaces of category A are to be insulated to "A-60" class standard, unless the dangerous goods are stowed at least 3 [m] horizontally away from such bulkheads. Other boundaries between such spaces are to be insulated to "A-60" class standard.

IR2.3.8 In the case of a closed or semi-closed cargo space located partly above a machinery space and the deck above the machinery space not insulated, dangerous goods are not to be carried in the whole of that cargo space. If un-insulated deck above the machinery space is a weather deck, dangerous goods are not to be carried in the portion of the deck above the machinery space.

2.3.9 Water spray system

Each open ro-ro space having a deck above it and each space deemed to be a closed ro-ro space not capable of being sealed, is to be fitted with an approved fixed pressure water-spraying system for manual operation which is to protect all parts of any deck and vehicle platform in the space. Use of any other fixed fire-extinguishing system that has been shown by full-scale test to be no less effective may be considered. However, the drainage and pumping arrangements are to be such as to prevent the build-up of free surfaces. The drainage system is to be sized to remove no less than 125% of the combined capacity of both the water spraying system pumps and the required number of fire hose nozzles. The drainage system valves are to be operable from outside the protected space at a position in the vicinity of the extinguishing system controls. Bilge wells are to be of sufficient holding capacity and are to be arranged at the side shell of the ship at a distance from each other of not more than 40 [m] in each watertight compartment. If this is not possible the adverse effect upon stability of the added weight and free surface of water is to be taken into account during appraisal the stability information. (Refer to the Recommendation on fixed fire-extinguishing systems for special cargo spaces adopted by IMO by resolution A.123(V)).

2.3.10 Separation of ro-ro spaces

2.3.10.1 In ships having ro-ro spaces, a separation is to be provided between a closed ro-ro space and an adjacent open ro-ro space. The separation is to be such as to minimize the passage of dangerous vapours and liquids between such spaces. Alternatively, such separation need not be provided if the ro-ro space is considered to be a closed cargo space over its entire length and is to fully

comply with the relevant special requirements of this section.

2.3.10.2 In ships having ro-ro spaces, a separation is to be provided between a closed ro-ro space and the adjacent weather deck. The separation is to be such as to minimize the passage of dangerous vapours and liquids between such spaces. Alternatively, a separation need not be provided if the arrangements of the closed ro-ro spaces are in accordance with those required for the dangerous goods carried on adjacent weather deck.

2.4 Document of compliance

(Refer to the Document of compliance with the special requirements for ships carrying dangerous goods under the provisions of regulation II-2/19 of SOLAS 74, as amended (MSC/Circ.1266)).

If requested and authorised by statutory authority IRS will provide the ship with an appropriate document as evidence of compliance of construction and equipment with the requirement of this section. Certification for carriage of solid dangerous bulk cargoes covers only those cargoes listed in Group B of the IMSBC Code except cargoes classified solely as MHB (Materials Hazardous only in Bulk) Other solid dangerous bulk cargoes may be certified subject to acceptance by the relevant statutory authority.

IR2.4 Notes regarding statutory document of compliance given in 2.4:

1) Ships constructed on or after 1 July 2002 are to comply with SOLAS Reg. II-2/19 and all the requirements introduced with 2000 SOLAS amendments and will be issued DoC in pursuance of regulation II-2/19.

2) Ships constructed on or after 1 July 1998 and before 1 July 2002 are to comply with SOLAS Reg. II-2/54 and all the requirements introduced with 1996 SOLAS amendments and will be issued DoC in pursuance of regulation II-2/54.

   (See Ch.1 Cl. 1.3.4 regarding retroactive application of SOLAS Reg.II-2/19 to such ships).

3) Ships constructed on or after 1 September 1984 and before 1 July 1998 are to comply with SOLAS Reg. II-2/54 and all the requirements introduced with 1981 SOLAS amendments and will be issued DoC in pursuance of regulation II-2/54.

   (See Ch.1 Cl. 1.3.4 regarding retroactive application of SOLAS Reg.II-2/19 to such ships).

4) Ships constructed before 1 September 1984, upon request of the Owner, will be issued DoC in pursuance of regulation II-2/54 provided they comply with the requirements of regulation II-2/54 and other regulations referred to in reg. II-2/54.

Table 2.1 : Application of the requirements to different modes of carriage of dangerous goods in ships and cargo spaces

Wherever X appears in Table 2.1 it means that this requirement is applicable to all classes of dangerous goods as given in the appropriate line of Table 2.3, except as indicated by the notes.

Clause 2.2.2		**.1**	**.2**	**.3**		**.4**	**.5**
Clause 2.3	**Weather decks .1 to .5 inclusive**	**Not specifi-cally designed**	**Container cargo spaces**	**Closed ro-ro cargo spaces[5]**	**Open ro-ro cargo spaces#**	**Solid dangerous goods in bulk**	**Shipbor-ne barges**
.1.1	X	X	X	X	X	For application of requirements of Sec.2 to different classes of dangerous goods, see Table 2.2	X

.10.1	-	-	-	X	-		-
.10.2	-	-	-	X	-		-

Notes:

1 For classes 4 and 5.1 solids not applicable to closed freight containers.
For classes 2, 3, 6.1 and 8 when carried in closed freight containers, the ventilation rate may be reduced to not less than two air changes per hour. For classes 4 and 5.1 liquids when carried in closed freight containers, the ventilation rate may be reduced to not less than two air changes per hour. For the purpose of this requirement a portable tank is a closed freight container.

2 Applicable to decks only.

3 Applies only to closed ro-ro cargo spaces, not capable of being sealed.

4 In the special case where the barges are capable of containing flammable vapours or alternatively if they are capable of discharging flammable vapours to a safe space outside the barge carrier compartment by means of ventilation ducts connected to the barges, these requirements may be reduced or waived to the satisfaction of IRS.

5 Special category spaces are to be treated as closed ro-ro cargo spaces when dangerous goods are carried.

For the purposes of Section 5.6 a ro-ro space fully open above and with full openings in both ends may be treated as a weather deck.

* Classes are as defined in International Maritime Dangerous Goods Code.

Notes:

6 The hazards of substances in this class which may be carried in bulk are such that special consideration must be given by IRS to the construction and equipment of the ship involved in addition to meeting the requirements enumerated in this table.

7 Only applicable to –

- Seedcake containing solvent extractions
- Ammonium nitrate
- Ammonium nitrate fertilizers.

8 Only applicable to Ammonium nitrate and to Ammonium nitrate fertilizers. However, a degree of protection in accordance with standards contained in the International Electro-technical Commission, publication 60079 - Electrical Apparatus for Explosive Gas Atmospheres, is sufficient.

9 Only suitable wire mesh guards are required.

10 The requirements of the International Maritime Solid Bulk Cargoes (IMSBC) Code, as amended, are sufficient.

* Classes are as defined in International Maritime Dangerous Goods Code.

Table 2.3 - Notes:

11 When "mechanically ventilated spaces" are required by the International Maritime Dangerous Goods Code, as amended.

12 Stow 3 [m] horizontally away from the machinery space boundaries in all cases.

13 Refer to the International Maritime Dangerous Goods Code.

14 As appropriate to the goods being carried.

15 FP refers to flashpoint.

16 Under the provisions of the IMDG Code, stowage of class 5.2 dangerous goods under deck or in enclosed ro-ro spaces is prohibited.

17 Only applicable to dangerous goods evolving flammable vapour listed in the IMDG Code.

18 Only applicable to dangerous goods having a flashpoint less than 23°C listed in the IMDG Code.

19 Only applicable to dangerous goods having a subsidiary risk class 6.1.

20 Under the provisions of the IMDG Code, stowage of class 2.3 having subsidiary risk class 2.1 under deck or in enclosed ro-ro spaces is prohibited.

21 Under the provisions of the IMDG Code, stowage of class 4.3 liquids having a flashpoint less than 23°C under deck or in enclosed ro-ro spaces is prohibited.

Section 3

Protection of Vehicle, Special Category and Ro-ro Spaces

3.1 Purpose

The purpose of this section is to provide additional safety measures in order to address the fire safety objectives of this part for ships fitted with vehicle, special category and ro-ro spaces. For this purpose, the following functional requirements are to be met:

.1 fire protection systems are to be provided to adequately protect the ship from the fire hazards associated with vehicle, special category and ro-ro spaces;

.2 ignition sources are to be separated from vehicle, special category and ro-ro spaces; and

.3 vehicle, special category and ro-ro spaces are to be adequately ventilated.

3.2 General requirements

3.2.1 Application

3.2.1.1 In addition to complying with the requirements of Chapters 2, 3, 4 and 5, as appropriate, vehicle, special category and ro-ro spaces are to comply with the requirements of this section.

3.2.1.2 On all ships, vehicles with fuel in their tanks for their own propulsion may be carried in cargo spaces other than vehicle, special category or ro-ro spaces, provided that all the following conditions are met:

.1 the vehicles do not use their own propulsion within the cargo spaces;

.2 the cargo spaces are in compliance with the appropriate requirements of Section 2; and

.3 the vehicles are carried in accordance with the IMDG Code, as defined in SOLAS regulation VII/1.1.

3.2.2 Basic principles for passenger ships

3.2.2.1 The basic principle underlying the provisions of this section is that the main vertical zoning required by Ch.3, 3.2 may not be practicable in vehicle spaces of passenger ships and, therefore, equivalent protection must be obtained in such spaces on the basis of a horizontal zone concept and by the provision of an efficient fixed fire-extinguishing system. Based on this concept, a horizontal zone for the purpose of these requirements may include special category spaces on more than one deck provided that the total overall clear height for vehicles does not exceed 10 [m]. The "Total overall clear height" is the sum of distances between deck and web frames of the decks forming one horizontal zone.

3.2.2.2 The basic principle underlying the provisions of 3.2.2.1 are also applicable to ro-ro spaces.

3.2.2.3 The requirements of ventilation systems, openings in "A" class divisions and penetrations in "A" class divisions for maintaining the integrity of vertical zones in this part are to be applied equally to decks and bulkheads forming the boundaries separating horizontal zones from each other and from the remainder of the ship.

3.3 Precaution against ignition of flammable vapours in closed vehicle spaces, closed ro-ro spaces and special category spaces

3.3.1 Ventilation systems

3.3.1.1 Capacity of ventilation systems

There are to be provided an effective power ventilation system sufficient to give at least the following air changes:

.1	Passenger ships	
	Special category spaces	10 air changes per hour
	Closed ro-ro and vehicle spaces other than special category spaces for ships carrying more than 36 passengers	10 air changes per hour
	Closed ro-ro and vehicle spaces other than special category spaces for ships carrying not more than 36 passengers	6 air changes per hour
.2	Cargo ships	6 air changes per hour

An increased number of air changes may be required when vehicles are being loaded and unloaded.

3.3.1.2 *Performance of ventilation systems*

3.3.1.2.1 In passenger ships, the power ventilation system is to be separate from other ventilation systems. The power ventilation system is to be operated to give at least the number of air changes required in 3.3.1.1 at all times when vehicles are in such spaces, except where an air quality control system in accordance with 3.3.1.2.4 is provided. Ventilation ducts serving such cargo spaces capable of being effectively sealed are to be separated for each such space. The system is to be capable of being controlled from a position outside such spaces.

3.3.1.2.2 In cargo ships, ventilation fans are to normally be run continuously and give at least the number of air changes required in 3.3.1.1 whenever vehicles are on board, except where an air quality control system in accordance with 3.3.1.2.4 is provided. Where this is impracticable, they are to be operated for a limited period daily as weather permits and in any case for a reasonable period prior to discharge, after which period the ro-ro or vehicle space are to be proved gas-free. One or more portable combustible gas detecting instruments is to be carried for this purpose. The system is to be entirely separate from other ventilating systems. Ventilation ducts serving ro-ro or vehicle spaces are to be capable of being effectively sealed for each cargo space. The system is to be capable of being controlled from a position outside such spaces.

3.3.1.2.3 The ventilation system is to be such as to prevent air stratification and the formation of air pockets.

3.3.1.2.4 For all ships, where an air quality control system is provided based on the IMO guidelines*, the ventilation system may be operated at a decreased number of air changes and/or a decreased amount of ventilation. This relaxation does not apply to spaces to which at least ten air changes per hour is required by paragraph 3.3.2.2 of this regulation and spaces subject to regulations 2.3.4.1 and Section 4.

Note:

* *Refer to the revised design guidelines and operational recommendations for ventilation systems in ro-ro cargo spaces (MSC.1/Circ.1515).*

3.3.1.3 *Indication of ventilation systems*

Means is to be provided on the navigation bridge to indicate any loss of the required ventilating capacity.

IR3.3.1.3 Alarm provided on the bridge and initiated by tripping of starter relay of fan motor is considered to meet the requirement of 3.3.1.3.

3.3.1.4 *Closing appliances and ducts*

3.3.1.4.1 Arrangements are to be provided to permit a rapid shutdown and effective closure of the ventilation system from outside of the space in case of fire, taking into account the weather and sea conditions.

IR3.3.1.4.1 Access routes to the controls for closure of the ventilation system are considered to "permit a rapid shutdown" and adequately "take into account the weather and sea conditions" if the routes:
- are at least 600 mm clear width;
- are provided with a single handrail or wire rope lifeline not less than 10 mm in diameter, supported by stanchions not more than 10 m apart in way of any route which involves traversing a deck exposed to weather; and
- are fitted with appropriate means of access (such as ladders or steps) to the closing devices of ventilators located in high positions.

Alternatively, remote closing and position indicator arrangements from the bridge or a fire control station for those ventilator closures are considered acceptable.

3.3.1.4.2 Ventilation ducts, including dampers, within a common horizontal zone are to be made of steel. In passenger ships, ventilation ducts that pass through other horizontal zones or machinery spaces are to be “A-60” class steel ducts constructed in accordance with Ch.3, 3.7.2.4.1.1 and Ch.3, 3.7.2.4.1.2.

3.3.1.5 *Permanent openings*

Permanent openings in the side plating, the ends or deckhead of the space are to be so situated that a fire in the cargo space does not endanger stowage areas and embarkation stations for survival craft and accommodation spaces, service spaces and control stations in superstructures and deckhouses above the cargo spaces.

3.3.2 Electrical equipment and wiring

3.3.2.1 Except as provided in 3.3.2.2, electrical equipment and wiring are to be of a type suitable for use in an explosive petrol and air mixture.

IR3.3.2.1 Certified safe electrical equipment suitable for use in Zone 1 areas as defined in IEC 60079-10-1:2015 (Gas Group IIA and Temperature class T3) is considered to satisfy the requirement given in 3.3.2.1. Refer IEC 60079-14:2013 for types of protection suitable for use in Zone 1 areas.

3.3.2.2 In case of other than special category spaces below the bulkhead deck, notwithstanding the provisions in 3.3.2.1, above a height of 450 [mm] from the deck and from each platform for vehicles, if fitted, except platforms with openings of sufficient size permitting penetration of petrol gases downwards, electrical equipment of a type so enclosed and protected as to prevent the escape of sparks will be permitted as an alternative on condition that the ventilation system is so designed and operated as to provide continuous ventilation of the cargo spaces at the rate of at least ten air changes per hour whenever vehicles are on board.

IR3.3.2.2 Electrical equipment provided with at least IP55 enclosure or apparatus suitable for use in Zone 2 areas as defined in IEC 60079-10-1:2015 is considered to satisfy the requirement given in 3.3.2.2. Refer IEC 60079-14:2013 for types of protection suitable for use in Zone 2 areas.

3.3.3 Electrical equipment and wiring in exhaust ventilation ducts

Electrical equipment and wiring, if installed in an exhaust ventilation duct, is to be of a type approved for use in explosive petrol and air mixtures and the outlet from any exhaust duct is to be sited in a safe position, having regard to other possible sources of ignition.

IR3.3.3 Certified safe electrical equipment suitable for use in Zone 1 areas as defined in IEC 60079-10-1:2015 (Gas Group IIA and Temperature class T3) is considered to satisfy the requirement given in 3.3.3. Refer IEC 60079-14:2013 for types of protection suitable for use in Zone 1 areas.

3.3.4 Other ignition sources

Other equipment which may constitute a source of ignition of flammable vapours will not be permitted.

3.3.5 Scuppers and discharges

Scuppers are not to be led to machinery or other spaces where sources of ignition may be present.

3.4 Detection and alarm

3.4.1 Fixed fire detection and fire alarm systems

Except as provided in 3.4.3.1, there is to be provided a fixed fire detection and fire alarm system complying with the requirements of the Fire Safety Systems Code (Chapter 8). The fixed fire detection system is to be capable of rapidly detecting the onset of fire. The type of detectors and their spacing and location is to be to the satisfaction of IRS taking into account the effects of ventilation and other relevant factors. After being installed the system is to be tested under normal ventilation conditions and is to give an overall response time to the satisfaction of IRS.

IR3.4.1 The requirement of 3.4.1 need not apply to weather decks used for the carriage of vehicle for fuel in their tanks.

3.4.2 Sample extraction smoke detection systems

Except open ro-ro spaces, open vehicle spaces and special category spaces, a sample extraction smoke detection system complying with the requirements of the Fire Safety Systems Code may be used as an alternative of the fixed fire detection and fire alarm system required in 3.4.1.

3.4.3 Special category spaces

3.4.3.1 An efficient fire patrol system is to be maintained in special category spaces. However, if an efficient fire patrol system is maintained by a continuous fire watch at all times during the voyage, a fixed fire detection and fire alarm systems is not required.

3.4.3.2 Manually operated call points are to be spaced so that no part of the space is more than 20 [m] from a manually operated call point, and one is to be placed close to each exit from such spaces.

3.5 Structural protection

Notwithstanding the provisions of Ch.3, 3.2.2, in passenger ships carrying more than 36 passengers, the boundary bulkheads and decks of special category spaces and ro-ro spaces are to be insulated to "A-60" class standard. However, where a category (5), (9) and (10) space, as defined in Ch.3, 3.2.2.3, is on one side of the division the standard may be reduced to "A-0". Where fuel oil tanks are below a special category space or a ro-ro space, the integrity of the deck between such spaces, may be reduced to "A-0" standard.

3.6 Fire-extinction

3.6.1 Fixed fire-extinguishing systems

(*The requirements of 3.6.1.1 and 3.6.1.2 apply to ships constructed on or after 1 July 2014. Ships constructed before 1 July 2014 are to comply with the previously applicable requirements of paragraphs 3.6.1.1 and 3.6.1.2)*

3.6.1.1 Vehicle spaces and ro-ro spaces which are not special category spaces and are capable of being sealed from a location outside of the cargo spaces are to be fitted with one of the following fixed fire-extinguishing systems:

.1 a fixed gas fire extinguishing system complying with the requirements of Chapter 8;

.2 a fixed high expansion foam fire-extinguishing system complying with the requirements of Chapter 8; or

.3 a fixed water-based fire fighting system for complying with the provisions of Ch 8, 7.2.4 and paragraphs 3.6.1.2.1 to 3.6.1.2.4.

3.6.1.2 Ro-ro and vehicle spaces not capable of being sealed and special category spaces are to be fitted with a fixed water-based fire fighting system complying with the requirements of Ch 8, 7.2.4, which will protect all parts of any deck and vehicle platform in such spaces.

Such a water-based fire-fighting system is to have:

.1 a pressure gauge on the valve manifold;

.2 clear marking on each manifold valve indicating the spaces served;

.3 instructions for maintenance and operation located in the valve room; and

.4 a sufficient number of drainage valves to ensure complete drainage of the system.

3.6.1.3 Use of any other fixed fire-extinguishing system may be permitted if it is shown that it is not less effective by a full-scale test in conditions simulating a flowing petrol fire in a vehicle space or a ro-ro space in controlling fires likely to occur in such a space. (Refer to the Revised Guidelines for the design and approval of fixed water-based fire-fighting systems for ro-ro spaces and special category spaces (MSC.1/Circ.1430,Rev.3)).

3.6.1.4 The requirements of this paragraph apply to ships constructed on or after 1 January 2010. Ships constructed on or after 1 July 2002 and before 1 January 2010 are to comply with the previously applicable version of this paragraph. When fixed pressure water-spraying systems are provided, in view of the serious loss of stability which could arise due to large quantities of water accumulating on the deck or decks during the operation of the fixed pressure water-spraying system, the following arrangements are to be provided:

.1 in passenger ships:

.1.1 in the spaces above the bulkhead deck, scuppers are to be fitted so as to ensure that such water is rapidly discharged directly overboard, taking into account MSC.1/ Circ.1320 “Guidelines for the drainage of fire-fighting water from closed vehicle and ro-ro spaces and special category spaces of passenger and cargo ships”;

.1.2.1 in ro-ro passenger ships discharge valves for scuppers, fitted with positive means of closing operable from a position above the bulkhead deck in accordance with the requirements of the International Convention on Load Lines in force, are to be kept open while the ships are at sea;

.1.2.2 any operation of valves referred to in 3.6.1.4.1.2.1 is to be recorded in the log-book;

.1.3 in the spaces below the bulkhead deck, IRS may require pumping and drainage facilities to be provided additional to the requirements of Pt.4, Ch.3, Sec.2. In such case, the drainage system is to be sized to remove no less than 125% of the combined capacity of both the water spraying system pumps and the required number of fire hose nozzles, taking into account MSC.1/Circ.1320 “Guidelines for the drainage of fire-fighting water from closed vehicle and ro-ro spaces and special category spaces of passenger and cargo ships”. The drainage system valves are to be operable from outside the protected space at a position in the vicinity of the extinguishing system controls. Bilge wells are to be of sufficient holding capacity and are to be arranged at the side shell of the ship at a distance from each other of not more than 40 [m] in each watertight compartment;

.2 in cargo ships, the drainage and pumping arrangements are to be such as to prevent the build-up of free surfaces. In such case, the drainage system is to be sized to remove no less than 125% of the combined capacity of both the water spraying system pumps and the required number of fire hose nozzles, taking into account MSC.1/Circ.1320 “Guidelines for the drainage of fire-fighting water from closed vehicle and ro-ro spaces and special category spaces of passenger and cargo ships”. The drainage system valves are to be operable from outside the protected space at a position in the vicinity of the extinguishing system controls. Bilge wells are to be of sufficient holding capacity and are to be arranged at the side shell of the ship at a distance from each other of not more than 40 [m] in each watertight compartment. If this is not possible the adverse effect upon stability of the added weight and free surface of water is to be taken into account to the extent deemed necessary. This information is to be included in the stability information supplied to the master.

3.6.1.5 On all ships, for closed vehicles and ro-ro spaces and special category spaces, where fixed pressure water-spraying systems are fitted, means shall be provided to prevent

the blockage of drainage arrangements, taking into account MSC.1/Circ.1320 “Guidelines for the drainage of fire-fighting water from closed vehicle and ro-ro spaces and special category spaces of passenger and cargo ships”. Ships constructed before 1 January 2010 are to comply with the requirements of this paragraph by the first survey after 1 January 2010.

IR3.6.1.5 The requirements for fixed fire extinguishing system, portable fire extinguishers and foam applicators given in 3.6.1 and 3.6.2 need not apply to weather decks used for the carriage of vehicle with fuel in their tanks.

3.6.2 Portable fire extinguishers

3.6.2.1 Portable extinguishers are to be provided at each deck level in each hold or compartment where vehicles are carried, spaced not more than 20 [m] apart on both sides of the space. At least one portable fire-extinguisher is to be located at each access to such a cargo space. (Also refer MSC.1/Circ.1275 ‘Unified Interpretations of SOLAS Chapter II-2 on the Number and Arrangement of Portable fire extinguishers on board ships’).

3.6.2.2 In addition to the provision of 3.6.2.1, the following fire extinguishing appliances are to be provided in vehicle, ro-ro and special category spaces intended for the carriage of motor vehicles with fuel in their tanks for their own propulsion:

.1 at least three water-fog applicators; and

.2 one portable foam applicator unit complying with the provisions of the Fire Safety Systems Code (Chapter 8), provided that at least two such units are available in the ship for use in such ro-ro spaces.

IR3.6.2.3 Also refer IR3.6.1.5.

IR3.6.2.4 Cargo holds, loaded with vehicles with fuel in their tanks and stowed in open or closed containers need not be provided with the portable fire extinguishers, water-fog applicators and foam applicator unit as given in 3.6.2.1 and 3.6.2.2.

Section 4

Requirements for vehicles carriers carrying as cargo motor vehicles with compressed hydrogen or natural gas in their tanks for their own propulsion

4.1 Purpose

4.1.1 The purpose of this section is to provide additional safety measures in order to address the fire safety objectives of this chapter for vehicle carriers with vehicle and ro-ro spaces intended for carriage as cargo motor vehicles with compressed hydrogen or compressed natural gas in their tanks for their own propulsion.

4.2 Application

4.2.1 In addition to complying with the requirements of section 3, as appropriate, vehicle carriers constructed on or after 1 January 2016 intended for the carriage of motor vehicles with compressed hydrogen or compressed natural gas in their tanks for their own propulsion as cargo are to comply with the requirements in 4.3 to 4.5.

4.2.2 In addition to complying with the requirements of Sec 3, as appropriate, vehicle carriers constructed before 1 January 2016, including those constructed before 1 July 2012*, are to comply with the requirements in 4.5 of this section.

(*Refer to the recommendation on safety measures for existing vehicle carriers carrying as cargo motor vehicles with compressed hydrogen or natural gas in their tanks for their own propulsion MSC.1/Circ.1471.)

4.3 Requirements for spaces intended for carriage of motor vehicles with compressed natural gas in their tanks for their own propulsion as cargo

4.3.1 Electrical equipment and wiring

All electrical equipment and wiring are to be of a certified safe type for use in an explosive methane and air mixture*.

(* Refer to the recommendations of the International Electrotechnical Commission, in particular, publication IEC 60079)

4.3.2 Ventilation arrangement

4.3.2.1 Electrical equipment and wiring, if installed in any ventilation duct, are to be of a certified safe type for use in explosive methane and air mixtures.

4.3.2.2 The fans are to be such as to avoid the possibility of ignition of methane and air mixtures. Suitable wire mesh guards are to be fitted over inlet and outlet ventilation openings.

4.3.3 Other ignition sources

Other equipment which may constitute a source of ignition of methane and air mixtures are not to be permitted.

4.4 Requirements for spaces intended for carriage of motor vehicles with compressed hydrogen in their tanks for their own propulsion as cargo

4.4.1 Electrical equipment and wiring

All electrical equipment and wiring are to be of a certified safe type for use in an explosive hydrogen and air mixture*.

(*Refer to the recommendations of the International Electrotechnical Commission, in particular, publication IEC 60079.)

4.4.2 Ventilation arrangement

4.4.2.1 Electrical equipment and wiring, if installed in any ventilation duct, are to be of a certified safe type for use in explosive hydrogen and air mixtures and the outlet from any exhaust duct are to be sited in a safe position, having regard to other possible sources of ignition.

4.4.2.2 The fans are to be designed such as to avoid the possibility of ignition of hydrogen and air mixtures. Suitable wire mesh guards are to be fitted over inlet and outlet ventilation openings.

4.4.3 Other ignition sources

Other equipment which may constitute a source of ignition of hydrogen and air mixtures are not to be permitted.

4.5 Detection

When a vehicle carrier carries as cargo one or more motor vehicles with either compressed hydrogen or compressed natural gas in their tanks for their own propulsion, at least two portable gas detectors are to be provided. Such detectors are to be suitable for the detection of the gas fuel and be of a certified safe type for use in the explosive gas and air mixture.

Section 5

Casualty Threshold, Safe Return to Port and Safe Areas

5.1 Application

5.1.1 Passenger ships constructed on or after 1 July 2010 having loadline length, as defined in Pt.3, Ch.1, of 120 [m] or more or having three or more main vertical zones are to comply with the provisions of this section.

5.2 Purpose

5.2.1 The purpose of this section is to establish design criteria for a ship's safe return to port under its own propulsion after a casualty that does not exceed the casualty threshold stipulated in 5.3 and also provides functional requirements and performance standards for safe areas.

5.3 Casualty threshold

5.3.1 The casualty threshold, in the context of a fire, includes:

a) loss of space of origin upto the nearest "A" class boundaries, which may be a part of the space of origin, if the space of origin is protected by a fixed fire extinguishing system; or

b) loss of the space of origin and adjacent spaces upto the nearest "A" class boundaries, which are not part of the space of origin.

5.4 Safe return to port*

5.4.1 When fire damage does not exceed the casualty threshold indicated in 5.3, the ship is to be capable of returning to port while providing a safe area as defined in Ch.1, Sec.3. To be deemed capable of returning to port, the following systems are to remain operational in the remaining part of the ship not affected by fire:

.1 propulsion;

.2 steering systems and steering-control systems;

.3 navigational systems;

.4 systems for fill, transfer and service of fuel oil;

.5 internal communication between the bridge, engineering spaces, safety centre, fire-fighting and damage control teams and as required for passenger and crew notification and mustering;

.6 external communication;

.7 fire main system;

.8 fixed fire-extinguishing systems;

.9 fire and smoke detection system;

.10 bilge and ballast system;

.11 power-operated watertight and semi-watertight doors;

.12 systems intended to support "safe areas" as indicated in paragraph 4.5.1.2;

.13 flooding detection systems; and

.14 other systems determined by IRS to be vital to damage control efforts.

* Refer to MSC.1 Circ. 1369 as amended by MSC.1/ Circ. 1369/Add.1 "Interim explanatory notes for the assessment of passenger ship systems' capabilities after a fire or flooding casualty".

IR5.4.1 Qualitative failure analysis for propulsion and steering on passenger ships

IR5.4.1.1 Scope

This clause (IR 5.4.1) gives details of a qualitative failure analysis for propulsion and steering for new passenger ships including those having a length of 120 [m] or more or having three or more main vertical zones.

IR5.4.1.2 Note

This may be considered as the first step for demonstrating compliance with the revised SOLAS Chapter II-2, Regulation 21 – SOLAS 2006 Amendments, Resolution MSC.216(82), Annex 3.

IR5.4.1.3 Objectives

a) For ships having at least two independent means of propulsion and steering, to comply with SOLAS requirements for a safe return to port, items (a) and (b) below are applicable:

- Provide knowledge of the effects of failure in all the equipment and systems due to fire in any space, or flooding of any watertight compartment that could affect the availability of the propulsion and steering.

- Provide solutions to ensure the availability of propulsion and steering upon such failures in item (a).

b) Ships not required to satisfy the safe return to port concept will require the analysis of failure in single equipment and fire in any space to provide knowledge and possible solutions for enhancing availability of propulsion and steering.

IR5.4.1.4 Systems to be considered

The qualitative failure analysis is to consider the propulsion and steering equipment and all its associated systems which might impair the availability of propulsion and steering.

The qualitative failure analysis should include:

a) Propulsion and electrical power prime movers e.g.
   - Diesel engines
   - Electric motors

b) Power transmission systems, e.g.

- Shafting
- Bearings
- Power converters
- Transformers
- Slip ring systems

c) Steering gear

- Rudder actuator or equivalent for azimuthing propulsor
- Rudder stock with bearings and seals
- Rudder
- Power unit and control gear
- Local control systems and indicators
- Remote control systems and indicators
- Communication equipment

d) Propulsors, e.g.

- Propeller
- Azimuthing thruster
- Water jet

e) Main power supply systems, e.g.

- Electrical generators and distribution systems
- Cable runs
- Hydraulic
- Pneumatic

f) Essential auxiliary systems, e.g.

- Compressed air
- Oil fuel
- Lubricating oil
- Cooling water
- Ventilation
- Fuel storage and supply systems

g) Control and monitoring systems, e.g.

- Electrical auxiliary circuits
- Power supplies
- Protective safety systems
- Power management systems
- Automation and control systems

h) Support systems, e.g.

- Lighting
- Ventilation.

To consider the effects of fire or flooding in a single compartment, the analysis is to address the location and layout of equipment and systems.

IR5.4.1.5 Failure criteria

a) Failures are deviations from normal operating conditions such as loss or malfunction of a component or system such that it cannot perform an intended or required function.

b) The qualitative failure analysis is to be based on single failure criteria (not two independent failures occurring simultaneously).

c) Where a single failure causes results in failure of more than one component in a system (common cause failure), all the resulting failures are to be considered together.

d) Where the occurrence of a failure leads directly to further failures, all those failures are to be considered together.

IR5.4.1.6 Verification of solutions

a) The shipyard is to submit a report to IRS that identifies how the objectives have been addressed. The report is to include the following information:

- Identify the standards used for analysis of the design.
- Identify the objectives of the analysis.
- Identify any assumptions made in the analysis.
- Identify the equipment, system or sub-system, mode of operation of the equipment.
- Identify probable failure modes and acceptable deviations from the intended or required function.
- Evaluate the local effects (e.g. fuel injection failure) and the effects on the system as a whole (e.g. loss of propulsion power) of each failure mode as applicable.
- Identify trials and testing necessary to prove conclusions.

Note : All stakeholders (e.g. IRS, owners, shipyard and manufacturers) should as far as possible be involved in the development of the report.

b) The report is to be submitted prior to approval of detailed design plans. The report may be submitted in two parts:

- A preliminary analysis as soon as the initial arrangements of different compartments and propulsion plant are known which can form the basis of discussion. This is to include a structured assessment of all essential systems supporting the propulsion plant after a failure in equipment, fire or flooding in any compartment casualty.

- A final report detailing the final design with a detailed assessment of any critical system identified in the preliminary report.

c) Conclusions of the report are to be agreed between IRS and the shipyard.

IR5.4.1.13 Flooding detection systems

.1 A flooding detection system is to be fitted in all watertight spaces below the bulkhead deck that:

a) have a volume, in cubic metres [m^3], that is more than the ship's moulded displacement per centimeter immersion at the deepest subdivision draught; or

b) have a volume more than 30 [m^3], whichever is the greater.

whichever is the greater.

.2 Any watertight spaces that are separately equipped with a liquid level monitoring system (such as fresh water, ballast water, fuel, etc.), with an indicator panel or other means of monitoring at the navigation bridge (and the safety centre if located in a separate space from the navigation bridge), are excluded from these requirements.

.3 For passenger ships (contracted for construction on or after 01 July 2019) carrying 36 or more persons and subject to 5.1.1, the safe return to port requirements of 5.4.1 apply to both:

.1 the flooding detection systems in the spaces as defined in IR5.4.1.13.1

.2 the liquid level monitoring systems, which are used as, or replace, the flooding detection systems, as specified in IR5.4.1.13.2.

For systems noted in IR5.4.1.13.2 above, the phrase '*excluded from these requirements*' is not an exclusion from the general provisions in 5.4.1 (remain operational in the event of fire). This exclusion pertains only to the detailed provisions of MSC.1/Circ. 1291, 'Guidelines for flooding detection systems on passenger ships'.

5.5 Safe area(s)

5.5.1 Functional requirements:

a) the safe area(s) are generally to be internal space(s); however, the use of an external space as a safe area may be allowed by IRS taking into account any restriction due to the area of operation and relevant expected environmental conditions;

b) the safe area(s) are to provide all occupants with the following basic services* to ensure that the health of passengers and crew is maintained:

  - sanitation;
  - water;
  - food;
  - alternate space for medical care;
  - shelter from the weather;
  - means of preventing heat stress and hypothermia;
  - light; and
  - ventilation.

c) ventilation design is to reduce the risk of smoke and hot gases affecting the use of the safe area(s); and

d) means of access to life-saving appliances are to be provided from each area identified or used as a safe area, taking into account that a main vertical zone may not be available for internal transit.

* Refer to MSC.1 Circ. 1369 "Interim explanatory notes for the assessment of passenger ship systems' capabilities after a fire or flooding casualty".

5.5.2 Alternate space for medical care

Alternate space for medical care is to conform to a standard acceptable to IRS**.

** Refer to the Guidance on the establishment of medical and sanitation related programmes for passenger ships (MSC/Circ.1129).

Section 6

Design Criteria for Systems to Remain Operational after a Fire Casualty

6.1 Application

6.1.1 Passenger ships constructed on or after 1 July 2010 having loadline length, as defined in Pt.3, Ch.1, of 120 [m] or more or having three or more main vertical zones are to comply with the provisions of this section.

6.2 Purpose

6.2.1 The purpose of this regulation is to provide design criteria for systems required to remain operational for supporting the orderly evacuation and abandonment of a ship, if the casualty threshold, as defined in 5.3 is exceeded.

6.3 Systems*

6.3.1 In case any one main vertical zone is unserviceable due to fire, the following systems are to be so arranged and segregated as to remain operational:

- fire main;
- internal communications (in support of fire-fighting as required for passenger and crew notification and evacuation);
- means of external communications;
- bilge systems for removal of fire-fighting water;
- lighting along escape routes, at assembly stations and at embarkation stations of life-saving appliances; and
- guidance systems for evacuation are to be available.

* Refer to MSC.1 Circ. 1369 “Interim explanatory notes for the assessment of passenger ship systems’ capabilities after a fire or flooding casualty”.

6.3.2 The above systems are to be capable of operation for at least 3 hours based on the assumption of no damage outside the unserviceable main vertical zone. These systems are not required to remain operational within the unserviceable main vertical zones.

6.3.3 Cabling and piping within a trunk constructed to an “A-60” standard are deemed to remain intact and serviceable while passing through the unserviceable main vertical zone for the purposes of 6.3.1. An equivalent degree of protection for cabling and piping may be approved by IRS.

Section 7

Safety Centre on Passenger Ships

7.1 Application

7.1.1 Passenger ships constructed on or after 1 July 2010 are to have on board a safety centre complying with the requirements of this regulation.

7.2 Purpose

7.2.1 The purpose of this regulation is to provide a space to assist with the management of emergency situations.

7.3 Location and arrangement

7.3.1 The safety centre are either to be a part of the navigation bridge or be located in a separate space adjacent to and having direct access to the navigation bridge, so that the management of emergencies can be performed without distracting watch officers from their navigational duties.

7.4 Layout and ergonomic design

7.4.1 The layout and ergonomic design of the safety centre are to take into account the guidelines developed by IMO*, as appropriate.

* Refer to MSC.1 Circ. 1369 “Interim explanatory notes for the assessment of passenger ship systems’ capabilities after a fire or flooding casualty”.

7.5 Communications

7.5.1 Means of communication is to be provided between the safety centre, the central control station, the navigation bridge, the engine control room, the storage room(s) for fire extinguishing system(s) and fire equipment lockers.

7.6 Control and monitoring of safety systems

7.6.1 Notwithstanding the requirements set out elsewhere in the part of the rules, the full functionality (operation, control, monitoring or any combination thereof, as required) of the safety systems listed below shall be available from the safety centre:

- all powered ventilation systems;
- fire doors;
- general emergency alarm system;
- public address system;
- electrically powered evacuation guidance systems;
- watertight and semi-watertight doors;
- indicators for shell doors, loading doors and other closing appliances;
- water leakage of inner/outer bow doors, stern doors and any other shell door;
- television surveillance system;
- fire detection and alarm system;
- fixed fire-fighting local application system(s);
- sprinkler and equivalent systems;
- water-based systems for machinery spaces;
- alarm to summon the crew;
- atrium smoke extraction system;
- flooding detection systems; and
- fire pumps and emergency fire pumps.

Preamble

1. The purpose of this Code is to provide international standards of specific engineering specifications for fire safety systems required by Chapter 1 to 7 of this part of rules.

2. This code will be applicable on or after 1 July 2002.

Section 1

General

1.1 Application

1.1.1 This chapter is applicable to fire safety systems as referred to in Chapters 1 to 7 of this part of Rules.

1.1.2 Unless expressly provided otherwise, this Chapter is applicable for the fire safety systems of ships the keels of which are laid or which are at a similar stage of construction on or after 1 July 2002. However, amendments to

this chapter adopted after 1 July 2002 will apply only to ships the keels of which are laid or which are at a similar stage of construction, on or after the date on which the amendments enter into force, unless expressly provided otherwise.

1.2 Definitions

1.2.1 *Administration* means the Government of the State whose flag the ship is entitled to fly.

1.2.2 *Convention* means the International Convention for the Safety of Life at Sea, 1974, as amended.

1.2.3 *Fire Safety Systems Code (this chapter)* means the International Code for Fire Safety Systems as defined in Ch.1, 3.22.

1.2.4 For the purpose of this Chapter, definitions provided in Ch.1, Sec.3 also apply.

1.3 Use of equivalents and modern technology

In order to allow modern technology and development of fire safety systems, IRS may approve fire safety systems which are not specified in this Chapter if the requirements of Ch.6 are fulfilled.

1.4 Use of toxic extinguishing media

The use of a fire-extinguishing medium which either by itself or under expected conditions of use gives off toxic gases, liquids and other substances in such quantities as to endanger persons is not permitted.

Section 2

International Shore Connections

2.1 Application

This section details the specifications for international shore connections as required by Ch.3, 4.2.1.7.

2.2 Engineering specifications

2.2.1 Standard dimensions

The international shore connection is to be in accordance with the following specifications. (see Fig.2.1).

Standard dimensions of flanges for the international shore connection are to be in accordance with Table 2.1.

The flange is to have a flat face on one side and on the other side there is to be a permanently attached coupling that will fit the ships hydrants and hoses. The shore connection complete with gasket, four 16 [mm] bolts, 50 [mm] in length and 8 washers are to be stowed together in an easily accessible position along with other items of fire fighting outfit on board.

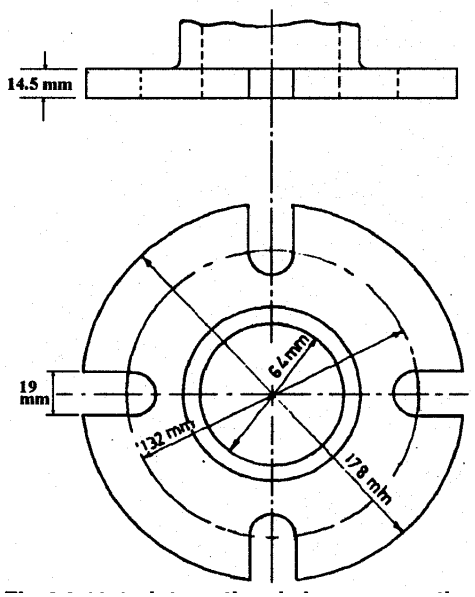

Fig.2.1 : International shore connection

Table 2.1 : Standard dimensions for international shore connections	
Description	**Dimension**
External diameter	178 [mm]
Internal diameter	64 [mm]
Bolt circle diameter	132 [mm]
Slots in flange	4 holes of 19 [mm] diameter equidistantly placed on the bolt circle, slotted to the flange periphery
Flange thickness	14.5 [mm] minimum
Bolts and nuts	4 each of 16 [mm] diameter, 50 [mm] in length
Material	steel or any other suitable material and designed for 1.0 [N/mm^2] service
Gasket Material	any material suitable for 1.0 [N/mm^2] pressure service

Section 3

Personnel Protection

3.1 Application

This section details the specifications for personnel protection as required by this part of the Rules.

3.2 Engineering specifications

3.2.1 Fire-fighter's outfit

A fire-fighter's outfit is to consist of a set of personal equipment and a breathing apparatus.

3.2.1.1 Personal equipment

Personal equipment is to consist of the following:

.1 protective clothing of material to protect the skin from the heat radiating from the fire and from burns and scalding by steam. The outer surface is to be water-resistant;

.2 boots of rubber or other electrically non-conducting material;

.3 rigid helmet providing effective protection against impact;

.4 electric safety lamp (hand lantern) of an approved type with a minimum burning period of 3 h. Electric safety lamps on tankers and those intended to be used in hazardous areas are to be of an explosion-proof type; and

.5 axe with a handle provided with high-voltage insulation.

3.2.1.2 Breathing apparatus

.1 Breathing apparatus is to be a self-contained compressed air-operated breathing apparatus for which the volume of air contained in the cylinders is to be at least 1,200 litres, or other self-contained breathing apparatus which is to be capable of functioning for at least 30 min. All air cylinders for breathing apparatus are to be interchangeable.

.2 Compressed air breathing apparatus is to be fitted with an audible alarm and a visual or other device which will alert the user before the volume of the air in the cylinder has been reduced to no less than 200 litres.

3.2.1.3 Lifeline

For each breathing apparatus a fireproof lifeline of at least 30 [m] in length is to be provided. The lifeline is to successfully pass an approval test by statical load of 3.5 [kN] for 5 min without failure. The lifeline is to be

capable of being attached by means of a snap-hook to the harness of the apparatus or to a separate belt in order to prevent the breathing apparatus becoming detached when the lifeline is operated.

3.2.2 Emergency escape breathing devices (EEBD)

3.2.2.1 General

3.2.2.1.1 An EEBD is a supplied air or oxygen device only used for escape from a compartment that has a hazardous atmosphere and is to be of an approved type.

3.2.2.1.2 EEBDs are not to be used for fighting fires, entering oxygen deficient voids or tanks, or worn by fire-fighters. In these events, a self-contained breathing apparatus, which is specifically suited for such applications, are to be used.

3.2.2.2 Definitions

3.2.2.2.1 Face piece means a face covering that is designed to form a complete seal around the eyes, nose and mouth which is secured in position by a suitable means.

3.2.2.2.2 Hood means a head covering which completely covers the head, neck, and may cover portions of the shoulders.

3.2.2.2.3 Hazardous atmosphere means any atmosphere that is immediately dangerous to life or health.

3.2.2.3 Particulars

3.2.2.3.1 The EEBD are to have a service duration of at least 10 min.

3.2.2.3.2 The EEBD is to include a hood or full face piece, as appropriate, to protect the eyes, nose and mouth during escape. Hoods and face pieces are to be constructed of flame resistant materials and include a clear window for viewing.

3.2.2.3.3 An inactivated EEBD is to be capable of being carried hands-free.

3.2.2.3.4 An EEBD, when stored, is to be suitably protected from the environment.

3.2.2.3.5 Brief instructions or diagrams clearly illustrating their use is to be clearly printed on the EEBD. The donning procedures are to be quick and easy to allow for situations where there is little time to seek safety from a hazardous atmosphere.

3.2.2.4 Markings

Maintenance requirements, manufacturer's trademark and serial number, shelf life with accompanying manufacture date and name of approving authority are to be printed on each EEBD. All EEBD training units are to be clearly marked.

Section 4

Fire Extinguishers

4.1 Application

4.1.1 This section details the specifications for fire extinguishers as required by Ch.1 to 7.

4.1.2 Type approval

All fire extinguishers are to be of approved types and designs based on the requirements of the National Statutory Authority. (Refer to the Improved Guidelines for marine portable fire extinguishers adopted by IMO resolution A. 951(23)).

4.2 Engineering specifications

4.2.1 Fire extinguisher

4.2.1.1 Quantity of medium

4.2.1.1.1 Each powder or carbon dioxide extinguisher is to have a capacity of at least 5 [kg] and each foam extinguisher is to have a capacity of at least 9 [*l*]. The mass of all portable fire extinguishers is not to exceed 23 [kg] and they are to have a fire-extinguishing capability at least equivalent to that of a 9*l* fluid extinguisher.

4.2.1.2 Recharging

Only refills approved for the fire extinguisher in question is to be used for recharging.

4.2.2 Portable foam applicators

4.2.2.1 A portable foam applicator unit is to consist of foam nozzle/branch pipe, either of a self-inducting type or in combination with a separate inductor capable of being connected to the fire main by a fire hose together with a portable tank containing at least 20 litres of foam concentrate and at least one spare tank of foam concentrate of the same capacity.

4.2.2.2 System performance

4.2.2.2.1 The nozzle branch pipe and inductor are to be capable of producing effective foam suitable for extinguishing an oil fire at a foam solution flow rate of at least 200 l/min. at the nominal pressure in the fire main.

4.2.2.2.2 The foam concentrate is to be approved by IRS based on the guidelines developed by IMO (Guidelines for the performance and testing criteria and surveys of low-expansion foam concentrates for fixed fire extinguishing systems (MSC.1/Circ.1312 and MSC.1/Circ.1312/Corr.1).

4.2.2.2.3 The values of the foam expansion and drainage time of the foam produced by the portable foam applicator unit is not to differ more than 10% of that determined in 4.2.2.2.2.

4.2.2.2.4 The portable foam applicator unit is to be designed to withstand clogging, ambient temperature changes, vibration, humidity, shock, impact and corrosion normally encountered on ships.

Section 5

Fixed Gas Fire-Extinguishing Systems

5.1 Application

This section details the specifications for fixed gas fire-extinguishing systems as required by Ch.3, Sec.4.

5.2 Engineering specifications

5.2.1 General

5.2.1.1 Fire-extinguishing medium

5.2.1.1.1 Where the quantity of the fire-extinguishing medium is required to protect more than one space, the quantity of medium available need not be more than the largest quantity required for any one space so protected. The system is to be fitted with normally closed control valves arranged to direct the medium into the appropriate space. Adjacent spaces with independent ventilation systems not separated by atleast A-0 class divisions are to be considered as the same space.

5.2.1.1.2 The volume of starting air receivers, converted to free air volume, is to be added to the gross volume of the machinery space when calculating the necessary quantity of the fire-extinguishing medium. Alternatively, a discharge pipe from the safety valves may be fitted and led directly to the open air.

5.2.1.1.3 Means are to be provided for the crew to safely check the quantity of the fire-extinguishing medium in the containers. It is not to be necessary to move the containers completely from their fixing position for this purpose. For carbon dioxide systems, hanging bars for a weighing device above each bottle row, or other means are to be provided. For other types of extinguishing media, suitable surface indicators may be used

5.2.1.1.4 Containers for the storage of fire-extinguishing medium and associated pressure components are to be designed to pressure codes of practice to the satisfaction of IRS having regard to their locations and maximum ambient temperature expected in service*.

* Publication ISO – 9809/1 : Refillable seamless steel gas cylinders (design, construction and testing);
ISO – 3500 : Seamless steel CO_2 cylinders. For fixed fire-fighting installations on ships, specifying the principal external dimensions, accessories, filling ratio and marking for seamless steel CO_2 cylinders used in fixed

fire-fighting installations on ships, in order to facilitate their interchange ability;
ISO – 13769 : Gas cylinders – Stamp marking;
ISO – 6406 : Periodic inspection and testing of seamless steel gas cylinders.
ISO – 9329 Part 1 : Seamless steel tubes for pressure purpose – Technical delivery conditions – Part 1 – Unalloyed steels with specified room temperature properties;
ISO – 9329 Part 2 – Seamless steel tubes for pressure purposes – Technical delivery conditions – Part 2 – Unalloyed and alloyed steels with specified elevated temperature properties;
ISO – 9330 Part 1 – Welded steel tubes for pressure purposes – Technical delivery conditions – Part 1 – Unalloyed steel tubes with specified room temperature properties;
ISO 9330 Part 2 – Welded steel tubes for pressure purposes – Technical delivery conditions – Part 2 – Electric resistance and induction welded unalloyed and alloyed steel tubes with specified elevated temperature properties.

5.2.1.2 Installation requirements

5.2.1.2.1 The piping for the distribution of fire-extinguishing medium is to be arranged and discharge nozzles so positioned that a uniform distribution of the medium is obtained. System flow calculations are to be performed to ensure uniform distribution and submitted for consideration of IRS.

5.2.1.2.2 Except as otherwise permitted by IRS, pressure containers required for the storage of fire-extinguishing medium, other than steam, is to be located outside the protected spaces in accordance with Ch.3, 4.4.3.

5.2.1.2.3 Sufficient spare parts for the system are to be stored on board, and the proposals, in each case, will be specially considered by IRS.

IR5.2.1.2.3 The piping is to be of adequate size and so arranged as to provide effective distribution of gas. In holds exceeding 18 [m] in length, there are to be at least two pipes, one of which is to be fitted in the forward part and one in the after part. Separate pipes are to be provided for lower hold and tween decks. All pipes are to be arranged to be self draining and are not to be led through refrigerated spaces unless the pipes are specially insulated.

5.2.1.2.4 In piping sections where valve arrangements introduce sections of closed piping, such sections are to be fitted with a pressure relief valve and the outlet of the valve is to be led to open deck.

IR5.2.1.2.4 Where carbon dioxide is used, all steel pipes are to be galvanized, at least internally.

5.2.1.2.5 All discharge piping, fittings and nozzles in the protected spaces are to be constructed of materials having a melting temperature which exceeds 925°C. The piping and associated equipment is to be adequately supported.

IR5.2.1.2.5 Distribution pipes are not to be smaller than 25 [mm] bore for inert gas and 20 [mm] bore for carbon dioxide.

5.2.1.2.6 A connection is to be installed in the discharge piping to permit the air testing as required by paragraph 5.2.2.3.1.

IR5.2.1.2.6 The minimum wall thicknesses of steel pipes of carbon dioxide systems are given in Table 5.2.1.2.5.

IR5.2.1.2.7 Slightly smaller thicknesses will be accepted where these meet recognized National Standards.

IR5.2.1.2.8 Where threaded pipes are used, the minimum wall thicknesses given in Table 5.2.1.2.5 are to be measured at the bottom of the thread.

IR5.2.1.2.9 For pipes of diameter larger than those shown in Table 5.2.1.2.5 the thickness will be specially considered.

Table 5.2.1.2.5 : Minimum thickness of steel pipes		
External diameter D, [mm]	**Thickness [mm]**	
	From bottles to distribution valve	**From distribution valve to nozzles**
21.2 to 26.9	3.2	2.6
30.0 to 48.3	4.0	3.2
51.0 to 60.3	4.5	3.6
63.5 to 76.1	5.0	3.6
82.5 to 88.9	5.6	4.0
101.6	6.3	4.0
108.0 to 114.3	7.1	4.5
127.0	8.0	4.5
133.0 to 139.7	8.0	5.0
152.4 to 168.3	8.8	5.6

IR5.2.1.2.10 In general, the minimum thickness given in Table 5.2.1.2.5 is the nominal wall thickness, and no allowance need be made for negative tolerance and reduction in thickness due to bending.

IR5.2.1.2.11 For systems using carbon dioxide, the distribution manifolds and the pipes between the storage cylinders and the distribution valve are to be guaranteed by the manufacturers to have been satisfactorily hydraulically tested to a pressure of at least 12.2 [N/mm^2]. The manufacturers are to guarantee that at least 10 per cent of the pipes from the distribution valve to the discharge nozzles have been satisfactorily hydraulically tested to a pressure of at least 1.0 [N/mm^2]. On completion of the installation the joints are to be tested pneumatically to a pressure of atleast 0.69 [N/mm^2] with the discharge openings closed.

5.2.1.3 System control requirements

5.2.1.3.1 The necessary pipes for conveying fire-extinguishing medium into the protected spaces are to be provided with control valves so marked as to indicate clearly the spaces to which the pipes are led. Suitable provision is to be made to prevent inadvertent release of the medium into the space. Where a cargo space fitted with a gas fire-extinguishing system is used as a passenger space, the gas connection is to be blanked during such use. Blank flanges fitted in gas distribution pipes are to be of the 'spectacle' type. The nuts for the securing bolts are to be of non-corrodible metal. The pipes may pass through accommodations provided that they are of substantial thickness and that their tightness is verified with a pressure test, after their installation, at a pressure head not less than 5 [N/mm^2]. In addition, pipes passing through accommodation areas are to be joined only by welding and are not to be fitted with drains or other openings within such spaces. The pipes are not to pass through refrigerated spaces.

5.2.1.3.2 Means are to be provided for automatically giving audible and visual warning of the release of fire extinguishing medium into any ro-ro spaces, container holds equipped with integral reefer containers, spaces accessible by doors or hatches and other spaces in which personnel normally work or to which they have access. The audible alarms are to be located so as to be audible throughout the protected space with all machinery operating and the alarms are to be capable of being distinguished from other audible alarms by adjustment of sound pressure or sound patterns. The pre-discharge alarm is to be automatically activated (e.g. by opening of the release cabinet door). The alarm is to operate for the length of time needed to evacuate the space, but not less than 20 [s], before the medium is released. Conventional cargo spaces and small spaces (such as compressor rooms, paint lockers, etc.) with only a local release need not be provided with such alarm.

IR5.2.1.3.2 a) Reference is made to the Code on alerts and Indicators (AI Code), 1995 (Resolution A.1021(26)). The pre-discharge alarms may be pneumatically (by the

extinguishing medium or by air) or electrically operated, with requirements as follows:

- If electrically operated, the alarms are to be supplied with power from the main and an emergency source of power.

- If pneumatically operated by air, the air supplied is to be dry and clean and the supply reservoir is to be fitted with a low pressure alarm. The air supply may be taken from the starting air receivers. Any stop valve fitted in the air supply line is to be locked or sealed in the open position. Any electrical components associated with the pneumatic system are to be powered from the main and an emergency source of electrical power.

IR5.2.1.3.2 b) Conventional cargo spaces means cargo spaces other than ro-ro spaces or container holds equipped with integral reefer containers, and they need not be provided with means for automatically giving audible and visual warning of the release.

IR5.2.1.3.2 c) The requirements mentioned in 5.2.2.2 are also applicable for the spaces mentioned in 5.2.1.3.2.

5.2.1.3.3 The means of control of any fixed gas fire-extinguishing system are to be readily accessible, simple to operate and are to be grouped together in as few locations as possible at positions not likely to be cut off by a fire in a protected space. At each location there are to be clear instructions relating to the operation of the system having regard to the safety of personnel.

IR5.2.1.3.3 For control of fixed gas fire extinguishing media stored in a room located forward of cargo holds and intended for protecting cargo holds, refer Ch.3, IR4.4.3.

5.2.1.3.4 Automatic release of fire-extinguishing medium is not to be permitted, except as permitted by IRS.

IR5.2.1.4 Alarms in pump room.

IR5.2.1.4.1 The audible alarms fitted in cargo pump rooms of ships intended for the carriage of cargo oil having a flash point below 60°C (closed cup test), to warn of the release of extinguishing medium in such spaces, may be of the pneumatic or electrical type.

IR5.2.1.4.2 Where pneumatically operated alarms are fitted which require periodic testing, carbon dioxide is not to be used as an operating medium. Air operated alarms may be used provided that the air supply is clean and dry.

IR5.2.1.4.3 Where electrically operated alarms are used, the arrangements are to be such that the electric operating mechanism is located outside the pump room except where alarms are certified intrinsically safe.

5.2.2 Carbon dioxide systems

5.2.2.1 Quantity of fire extinguishing medium

5.2.2.1.1 For cargo spaces the quantity of carbon dioxide available, unless otherwise provided, is to be sufficient to give a minimum volume of free gas equal to 30% of the gross volume of the largest cargo space to be protected in the ship.

5.2.2.1.2 For vehicle spaces and ro-ro spaces which are not special category spaces, the quantity of carbon dioxide available are to be at least sufficient to give a minimum volume of free gas equal to 45% of the gross volume of the largest such cargo space which is capable of being sealed, and the arrangements are to be such as to ensure that at least two thirds of the gas required for the relevant space is introduced within 10 min. Carbon dioxide systems are not to be used for the protection of special category spaces.

5.2.2.1.3 For machinery spaces the quantity of carbon dioxide carried is to be sufficient to give a minimum volume of free gas equal to the larger of the following volumes, either:

.1 40% of the gross volume of the largest machinery space so protected, the volume to exclude that part of the casing above the level at which the horizontal area of the casing is 40% or less of the horizontal area of the space concerned taken midway between the tank top and the lowest part of the casing; or

.2 35% of the gross volume of the largest machinery space protected, including the casing.

5.2.2.1.4 The percentages in 5.2.2.1.3 above may be reduced to 35% and 30%, respectively, for cargo ships of less than 2,000 gross tonnage where two or more machinery

spaces, which are not entirely separate, are considered as forming one space.

5.2.2.1.5 The volume of free carbon dioxide is to be calculated at 0.56 [m^3/kg].

5.2.2.1.6 For machinery spaces the fixed piping system is to be such that 85 per cent of the gas can be discharged into the space within 2 minutes. Calculation to prove the discharge time may be submitted for consideration of IRS.

5.2.2.1.7 For container and general cargo spaces (primarily intended to carry a variety of cargoes separately secured or packed) the fixed piping system is to be such that at least two thirds of the gas can be discharged into the space within 10 min. For solid bulk cargo spaces the fixed piping system is to be such that at least two thirds of the gas can be discharged into the space within 20 min. The system controls are to be arranged to allow one third, two thirds or the entire quantity of gas to be discharged based on the loading condition of the hold.

5.2.2.2 Controls

Carbon dioxide systems for the protection of ro-ro spaces, container holds equipped with integral reefer containers, spaces accessible by doors or hatches, and other spaces in which personnel normally work or to which they have access are to comply with the following requirements:

.1 Two separate controls are to be provided for releasing carbon dioxide into a protected space and to ensure the activation of the alarm. One control is to be used for opening the valve of the piping which conveys the gas into the protected space and a second control is to be used to discharge the gas from its storage containers. Positive means are to be provided so they can only be operated in that order; and

IR.1 The pre-discharge alarm may be activated before the two separate system release controls are operated (e.g. by a micro-switch that activates the pre-discharge alarm upon opening the release cabinet door as per 5.2.1.3.2). Therefore, the two separate controls for releasing carbon dioxide into the protected space (i.e. one control to open the valve of the piping which conveys the gas into the protected space and a second control used to discharge the gas from its storage containers) as per 5.2.2.2.1 can be independent of the control for activating the alarm (provided the minimum length of time required for operation of the alarm before the release of the medium is as per 5.2.1.3.2).

A single control for activation of the alarm is sufficient.

The “positive means” referred to in 5.2.2.2.1 for the correct sequential operation of the controls, is to be achieved by a mechanical and/or electrical interlock that does not depend on any operational procedure to achieve the correct sequence of operation.

.2 The two controls are to be located inside a release box clearly identified for the particular space. If the box containing the controls is to be locked, a key to the box is to be in a break-glass-type enclosure conspicuously located adjacent to the box.

IR.2 The above requirements for controls apply to the spaces requiring audible warning identified in 5.2.1.3.2 and IR5.2.1.3.2 b).

5.2.2.3 Testing of the installation

When the system has been installed, pressure-tested and inspected, the following is to be carried out:

.1 a test of the free air flow in all pipes and nozzles; and

.2 a functional test of the alarm equipment.

5.2.3 Requirements of steam systems

5.2.3.1 Steam is not generally accepted as a fire extinguishing medium in fixed-fire extinguishing systems. However restricted use of steam is permitted as an addition to the required fire extinguishing medium.

5.2.3.2 The boiler or boilers available for supplying steam are to have an evaporation of at least 1 [kg] of steam per hour for each 0.75 [m^3] of the gross volume of the largest space so protected. In addition to complying with the foregoing requirements, the systems in all respects are to be to the satisfaction of IRS. (Refer Part 4 of the Rules).

5.2.3.3 Steam is not to be used in spaces containing explosives.

5.2.3.4 Steam used for fire extinguishing purposes is not to be obtained from a supply of superheated steam.

5.2.4 Equivalent fixed gas fire-extinguishing systems for machinery spaces and cargo pump rooms

Fixed gas fire-extinguishing systems equivalent to those specified in 5.2.2 and 5.2.3 will be approved by IRS based on the requirements of the National Statutory Authority. (Refer to the Revised guidelines for the approval of equivalent fixed gas fire-extinguishing systems, as referred to in SOLAS 74, for machinery spaces and cargo pump rooms (MSC/Circ.848 *amended by MSC.1/Circ.1267)* and the Guidelines for the approval of fixed aerosol fire-extinguishing systems equivalent to fixed gas fire-extinguishing systems, as referred to in SOLAS 74, for machinery spaces (MSC.1/Circ.1270 and MSC.1/Circ.1270/ Corr.1)).

IR5.2.4 Container storage arrangement for equivalent fixed gas fire extinguishing systems

Agent containers having / filled with fire extinguishing medium, stored in a protected space are to be distributed throughout the space with bottles or groups of bottles located in at least six separate locations. Duplicate power release lines are to be arranged to release all bottles simultaneously. The release lines are to be so arranged that in the event of damage to any power release line, five sixth of the fire extinguishing gas can still be discharged. The bottle valves are considered to be part of the release lines and a single failure are to include also failure of the bottle valve.

For systems that need less than six cylinders (using the smallest bottles available), the total amount of extinguishing gas on the bottles are to be such that in the event of a single failure to one of the release lines (including bottle valve), five sixth of the fire extinguishing gas can still be discharged. This may be achieved by for instance using more extinguishing gas than required so that if one bottle is not discharging due to a single fault, the remaining bottles will discharge the minimum five sixth of the required amount of gas. This can be achieved with minimum two bottles. However, NOAEL values calculated at the highest expected engine room temperature are not to be exceeded when discharging the total amount of extinguishing gas simultaneously.

Systems that can not comply with the above, for instance systems using only one bottle located inside the protected space, can not be accepted. Such systems are to be designed with the bottle(s) located outside the protected space, in a dedicated room in compliance with Ch.3, 4.4.3.

IR5.2.5 Low-pressure carbon dioxide smothering systems

5.2.5.1 General

a) The rated amount of carbon dioxide, time of discharge into the protected space, location of nozzles in the protected spaces and signals warning that the smothering system is activated is to comply with the requirements of 5.2.2 relating to CO_2 high-pressure systems.

b) Vessel(s), refrigerating plants, control devices and other equipment of the smothering system are to be located in a space complying with rules applying to CO_2 high-pressure systems. The system control devices and the refrigerating plants are to be located within the same room where the pressure vessels are stored.

5.2.5.2 Vessel(s) and relevant devices

a) The rated amount of liquid carbon dioxide is to be stored in vessel(s) under the working pressure in the range of 18 to 22 bar. The normal liquid charge in the container is to be limited to provide sufficient vapour space to allow for expansion of the liquid under the maximum storage temperatures than can be obtained corresponding to the setting of the pressure relief valves but is not to exceed 95% of the volumetric capacity of the container.

b) The vessel(s) is to be designed, constructed and tested in accordance with the requirements of Pt.4, Ch.5 for pressure vessels. For this purpose the design pressure is to be taken not less than the relief valve setting. Besides, provision is to be made for:

   - pressure gauge

   - high pressure alarm: not more than setting of the relief valve

- low pressure alarm: not less than 18 bar

- branch pipes with stop valves for filling the vessel

- discharge pipes

- liquid CO_2 level indicator, fitted on the vessel(s)

- two safety relief valves arranged so that either valve can be shut off while the other is connected to the vessel. The setting of the relief valves is to be not less than 1.1 times working pressure. The capacity of each valve is to be such that the vapours generated under fire condition can be discharged with a pressure rise not more than 20% above the setting pressure. The discharge from the safety valves is to be led to the open.

c) The vessel(s) and outgoing pipes permanently filled with carbon dioxide are to have thermal insulation preventing the operation of the safety valve in 24 hours after de-energizing the plant, at ambient temperature of 45°C and an initial pressure equal to the starting pressure of the refrigeration unit. The insulating materials and their liners are to be to the satisfaction of IRS, having in mind, in particular, their fire resistance and mechanical properties, as well as protection against penetration of water vapours.

5.2.5.3 Refrigerating plant

a) The vessel(s) is to be serviced by two automated completely independent refrigerating units solely intended for this purpose, each comprising a compressor and the relevant prime mover, evaporator and condenser.

b) The refrigerating plant is to comply with the relevant requirements of Pt.5, Ch.23 in so far as they are applicable. The refrigerating capacity and the automatic control of each unit are to be so as to maintain the required temperature under conditions of continuous operation during 24 hours at the sea temperature upto 32°C and ambient air temperature upto 45°C.

c) In the event of failure of either one of the refrigerating units the other is to be actuated automatically. Provision is to be made for local manual control of the refrigerating plant.

d) Each electric refrigerating unit is to be supplied from the main switchboard busbars by a separate feeder.

Cooling water supply to the refrigerating plant (where required) is to be provided from at least two circulating pumps one of which being used as a stand-by. The stand-by pump may be a pump used for other services so long as its use for cooling would not interfere with any other essential service of the ship.

Cooling water is to be taken from not less than two sea connections, preferably one port and one starboard.

5.2.5.4 Pipes and fittings

a) The pipes, valves and fittings are to be in accordance with the requirements of IRS for a design pressure not less than the design pressure of the CO_2 vessels.

b) Safety relief devices are to be provided in each section of pipe that may be isolated by block valves and in which there could be a build-up of pressure in excess of the design pressure of any of the components.

c) The piping system is to be designed in such a way that the CO_2 flows through in liquid phase upto the discharge nozzles. To this end the pressure at the nozzles are to be not less than 10 bar.

5.2.5.5 Control of smothering system operation

The machinery alarm system is to be equipped with audible and visual alarms activated when:

- the pressure in the vessel(s) reaches the low and high values according to 5.2.5.2 a)

- any one of the refrigerating units fails to operate

- the lowest permissible level of the liquid in the vessels is reached.

5.2.5.6 Release control

a) The release of CO_2 is to be initiated manually.

b) If a device is provided which automatically regulates the discharge of the rated quantity of carbon dioxide into the protected spaces it is to be also possible to regulate the discharge manually.

   If the system serves more than one space, means for control of discharge quantities of CO_2 is to be provided, e.g. automatic timer or accurate level indicators located at the control position(s).

5.2.5.7 Testing

a) The pipes, valves and fittings and assembled system are to be tested to satisfaction of the Surveyors.

b) The pipes from the vessel(s) to the release valves on the distribution manifold are to be subject to a pressure test to not less than 1.5 times the set pressure of the safety relief valves.

c) The pipes from the release valves on the distribution manifold to the nozzles are to be tested for tightness and free flow of CO_2, after assembly on board.

d) The refrigerating plant, after having been fitted on board is to be checked for its proper operation.

At the judgement of IRS, a discharge test may be required to check the fulfillment of the requirements of 5.2.5.4 c).

Section 6

Fixed Foam Fire-Extinguishing Systems

6.1 Application

This section details the specifications for fixed foam fire-extinguishing systems for the protection of machinery spaces in accordance with 4.4.1.1.2 of Chapter 3 , cargo spaces in accordance with 4.7.1.1 of Chapter 3, cargo pump-rooms in accordance with 4.9.1.2 of Chapter 3 and vehicle, special category and ro-ro spaces in accordance with 3.6.1.3 of Chapter 7. This section does not apply to cargo pump-rooms of chemical tankers carrying liquid cargoes referred to in 1.5.2 of Chapter 1, unless the Administration specifically accepts the use of these systems based on additional tests with alcohol-based fuel and alcohol resistant foam. Unless expressly provided otherwise, the requirements of this section are to apply to ships constructed on or after 1 January 2014.

6.2 Definitions

6.2.1 *Design filling rate* is at least the minimum nominal filling rate used during the approval tests.

6.2.2 *Foam is the extinguishing medium* produced when foam solution passes through a foam generator and is mixed with air.

6.2.*3 Foam solution* is a solution of foam concentrate and water.

6.2.*4 Foam concentrate* is a liquid which, when mixed with water in the appropriate concentration forms a foam solution.

6.2.5 *Foam delivery ducts* are supply ducts for introducing high-expansion foam into the protected space from foam generators located outside the protected space.

6.2.6 *Foam mixing ratio* is the percentage of foam concentrate mixed with water forming the foam solution.

6.2.*7 Foam generators* are discharge devices or assemblies through which high-expansion foam solution is aerated to form foam that is discharged into the protected space. Foam generators using inside air typically consist of a nozzle or set of nozzles and a casing. The casing is typically made of perforated steel/stainless steel plates shaped into a box that enclose the nozzle(s). Foam generators using outside air typically consist of nozzles enclosed within a casing that spray onto a screen. An electric, hydraulic or pneumatically driven fan is provided to aerate the solution.

6.2.8 *High-expansion foam fire-extinguishing systems* are fixed total flooding extinguishing systems that use either inside air or outside air for aeration of the foam solution. A high-expansion foam system consists of both the foam generators and the dedicated foam concentrate approved during the fire testing specified in 6.3.1.2

6.2.9 *Inside air foam system* is a fixed high-expansion foam fire-extinguishing system with foam generators located inside the protected space and drawing air from that space.

6.2.10 *Nominal flow rate* is the foam solution flow rate expressed in l/min

6.2.11 *Nominal application rate* is the nominal flow rate per area expressed in l/min/m^2

6.2.12 *Nominal foam expansion ratio* is the ratio of the volume of foam to the volume of foam solution from which it was made, under non-fire conditions, and at an ambient temperature of e.g. around 20ºC.

6.2.13 *Nominal foam production* is the volume of foam produced per time unit, i.e. nominal flow rate times nominal foam expansion ratio, expressed in m^3/min.

6.2.14 *Nominal filling rate* is the ratio of nominal foam production to the area, i.e. expressed in m^2/min.

6.2.15 *Nominal filling time* is the ratio of the height of the protected space to the nominal filling rate, i.e. expressed in minutes.

6.2.16 *Outside air foam system* is a fixed high-expansion foam system with foam generators installed outside the protected space that are directly supplied with fresh air.

6.3 Fixed high-expansion foam fire-extinguishing systems

6.3.1 Principal Performance

6.3.1.1 The system is to be be capable of manual release, and be designed to produce foam at the required application rate within 1 minute of release. Automatic release of the system is not permitted unless appropriate operational measures or interlocks are provided to prevent any local application systems required by 4.5.6 of chapter 3 from interfering with the effectiveness of the system.

6.3.1.2 The foam concentrates are to be approved based on the guidelines developed by IMO (MSC.1/Circ. 670). Different foam concentrate types are not to be mixed in a high-expansion foam system.

6.3.1.3 The system is to be capable of fire extinction and manufactured and tested to the satisfaction of IRS based on the guidelines developed by IMO (MSC.1/Circ.1384).

6.3.1.4 The system and its components are to be suitably designed to withstand ambient temperature changes, vibration, humidity, shock, clogging and corrosion normally encountered on ships. Piping, fittings and related components inside the protected spaces (except gaskets) are to be designed to withstand 925°C

6.3.1.5 System piping, foam concentrate storage tanks, components and pipe fittings in contact with the foam concentrate are to be compatible with the foam concentrate and be constructed of corrosion resistant materials such as stainless steel or equivalent. Other system piping and foam generators are to be full galvanized steel or equivalent. Distribution pipework has to have self-draining capability.

6.3.1.6 Means for testing the operation of the system and assuring the required pressure and flow are to be provided by pressure gauges at both inlets (water and foam concentrate supply) and at the outlet of the foam proportioner. A test valve is to be installed on the distribution piping downstream of the foam proportioner, along with orifices which reflect the calculated pressure drop of the system. All sections of piping are to be provided with connections for flushing, draining and purging with air. All nozzles are to be able to be removed for inspection in order to prove clear of debris.

6.3.1.7 Means are to be provided for the crew to safely check the quantity of foam concentrate and take periodic control samples for foam quality.

6.3.1.8 Operating instructions for the system are to be displayed at each operating position.

6.3.1.9 Spare parts are to be provided based on the manufacturer's instruction.

6.3.1.10 If an internal combustion engine is used as a prime mover for the seawater pump for the system, the fuel oil tank to the prime

mover is to contain sufficient fuel to enable the pump to run on full load for at least 3 h and sufficient reserves of fuel are to be available outside the machinery space of category A to enable the pump to be run on full load for an additional 15 h. If the fuel tank serves other internal combustion engines simultaneously, the total fuel tank capacity is to be adequate for all connected engines.

6.3.1.11 The arrangement of foam generators and piping in the protected space is not to interfere with access to the installed machinery for routine maintenance activities.

6.3.1.12 The system source of power supply, foam concentrate supply and means of controlling the system are to be readily accessible and simple to operate, and are to be arranged at positions outside the protected space not likely to be cut off by a fire in the protected space. All electrical components directly connected to the foam generators are to have at least an IP 54 rating.

6.3.1.13 The piping system is to be sized in accordance with a hydraulic calculation technique to ensure availability of flows and pressures required for correct performance of the system.

6.3.1.14 The arrangement of the protected spaces is to be such that they may be ventilated as the space is being filled with foam. Procedures are to be provided to ensure that upper level dampers, doors and other suitable openings are kept open in case of a fire. For inside air foam systems, spaces below 500 m^3 need not comply with this requirement.

6.3.1.15 Onboard procedures are to be established to require personnel re-entering the protected space after a system discharge to wear breathing apparatus to protect them from oxygen deficient air and products of combustion entrained in the foam blanket.

6.3.1.16 Installation plans and operating manuals are to be supplied to the ship and be readily available on board. A list or plan is to be displayed showing spaces covered and the location of the zone in respect of each section. Instructions for testing and maintenance are to be available on board.

6.3.1.17 All installation, operation and maintenance instructions/plans for the system are to be in the working language of the ship. If the working language of the ship is not English, French, nor Spanish, a translation into one of these languages is to be included.

6.3.1.18 The foam generator room is to be ventilated to protect against overpressure, and are to be heated to avoid the possibility of freezing.

6.3.1.19 The quantity of foam concentrate available is to be sufficient to produce a volume of foam equal to at least five times the volume of the largest protected space enclosed by steel bulkheads, at the nominal expansion ratio, or enough for 30 min of full operation for the largest protected space, whichever is greater.

6.3.1.20 Machinery spaces, cargo pump-rooms, vehicle spaces, ro-ro spaces and special category spaces are to be provided with audible and visual alarms within the protected space warning of the release of the system. The alarms are to operate for the length of time needed to evacuate the space, but in no case less than 20 s.

6.3.2 Inside air foam systems:

6.3.2.1 *Systems for the protection of machinery spaces and cargo pump rooms*

6.3.2.1.1 The system is to be supplied by both main and emergency sources of power. The emergency power supply is to be provided from outside the protected space.

6.3.2.1.2 Sufficient foam-generating capacity is to be provided to ensure the minimum design filling rate for the system is met and in addition is to be adequate to completely fill the largest protected space within 10 min.

IR 6.3.2.1.2 The term “largest protected space” applies to a machinery space of category A protected by a fixed high-expansion foam fire-extinguishing system complying with this section. Where such a machinery space includes a casing (e.g. an engine casing in a machinery space of category A containing internal combustion machinery, and/or a boiler), the volume of such casing, above the level up to which foam is to be filled to protect the highest position of the fire risk objects within the machinery space, need not be included in the volume of the protected space (Fig 6.3.2.1.2(a)). The level up to which foam is to be filled to protect the highest positioned fire risk objects within the machinery space is not to be less than:

1 m above the highest point of any such object; or

The lowest part of the casing, whichever is higher (Fig 6.3.2.1.2 (a)).

Where such a machinery space does not include a casing, the volume of the largest protected space is to be that of the space in its entirety, irrespective of the location of any fire risk object therein (Fig 6.3.2.1.2 (b)).

Fire risk objects include, but may not be limited to, those listed in 3.31 and 3.34 of chapter 1. Although not referred to in those Clauses, they may also include items having a similar fire risk such as exhaust gas boilers or oil fuel tanks

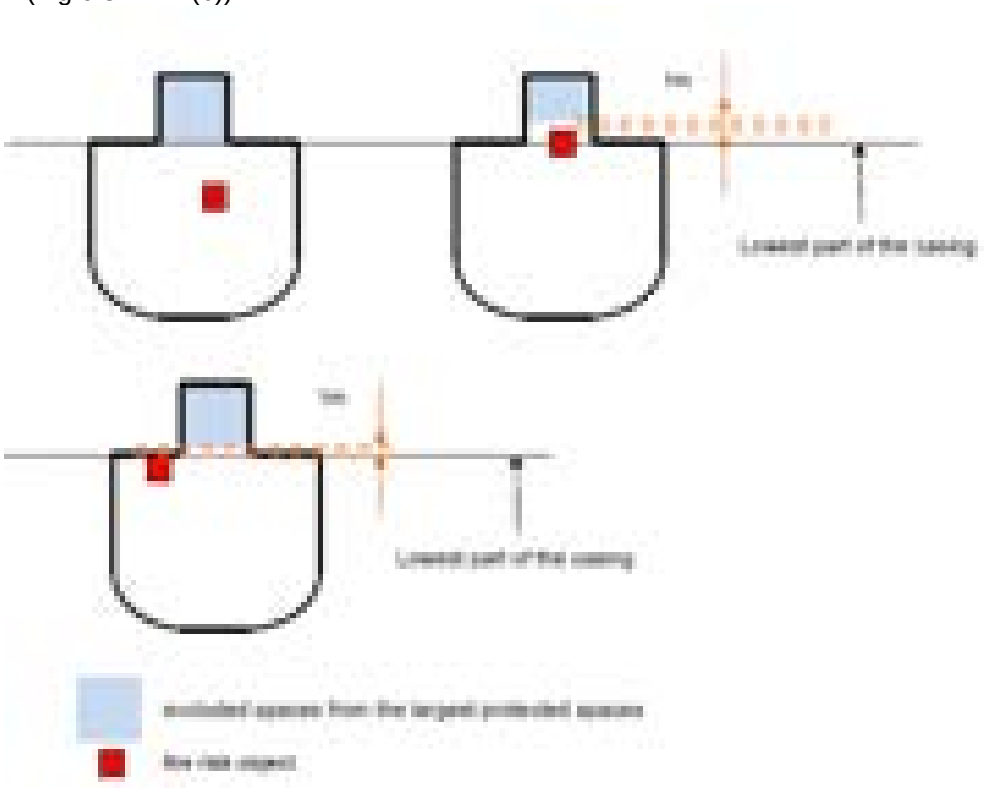

Fig 6.3.2.1.2 (a) Machinery Space including Casing

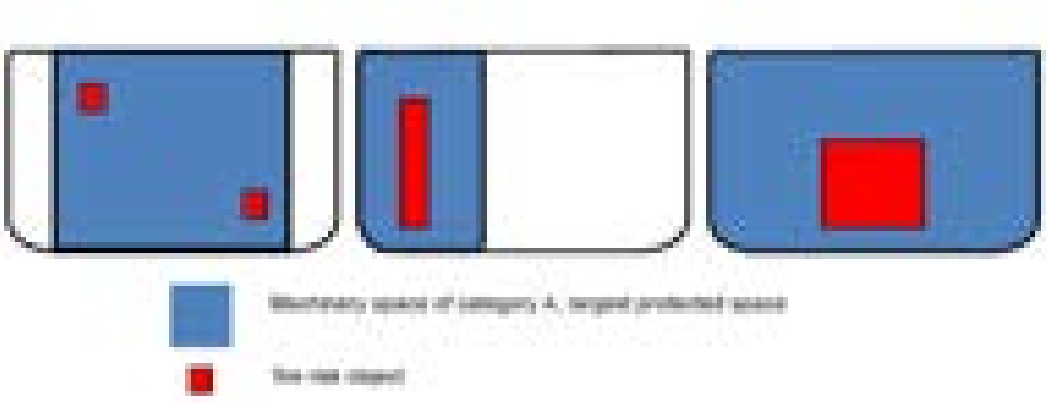

Fig 6.3.2.1.2 (b) Machinery Space not including a Casing

6.3.2.1.3 The arrangement of foam generators is in general to be designed based on the approval test results. A minimum of two generators are to be installed in every space containing combustion engines, boilers, purifiers, and similar equipment. Small workshops and similar spaces may be covered with only one foam generator.

6.3.2.1.4 Foam generators are to be uniformly distributed under the uppermost ceiling in the protected spaces including the engine casing. The number and location of foam generators are to be adequate to ensure all high risk areas are protected in all parts and at all levels of the spaces. Extra foam generators may be required in obstructed locations. The foam generators are to be arranged with at least 1 m free space in front of the foam outlets, unless tested with less clearance. The generators are to be located behind main structures, and above and away from engines and boilers in positions where damage from an explosion is unlikely.

6.3.2.2 *Systems for the protection of vehicle, ro-ro, special category and cargo spaces.*

6.3.2.2.1 The system is to be supplied by the ship's main power source. An emergency power supply is not required.

6.3.2.2.2 Sufficient foam-generating capacity is to be provided to ensure the minimum design filling rate for the system is met and in addition is to be adequate to completely fill the largest protected space within 10 min. However, for systems protecting vehicle and ro-ro spaces and special category spaces, with decks that are reasonably gas-tight and that have a deck height of 3 m or less, the filling rate are to be not less than two thirds of the design filling rate and in addition sufficient to fill the largest protected space within 10 min.

6.3.2.2.3 The system may be divided into sections, however, the capacity and design of the system is to be based on the protected space demanding the greatest volume of foam. Adjacent protected spaces need not be served simultaneously if the boundaries between the spaces are "A" class divisions.

6.3.2.2.4 The arrangement of foam generators are in general to be designed based on the approval test results. The number of generators may be different, but the minimum design filling rate determined during approval testing is to be provided by the system. A minimum of two generators are to be installed in every space. The foam generators are to be arranged to uniformly distribute foam in the protected spaces, and the layout is to take into consideration obstructions that can be expected when cargo is loaded on board. As a minimum, generators are to be located on every second deck, including movable decks. The horizontal spacing of the generators is to ensure rapid supply of foam to all parts of the protected space. This is to be established on the basis of full scale tests.

6.3.2.2.5 The foam generators are to be arranged with at least 1 m free space in front of the foam outlets, unless tested with less clearance.

6.3.3 Outside air foam systems

6.3.3.1 Systems for the protection of machinery spaces and cargo pump-rooms:

6.3.3.1.1 The system is to be supplied by both main and emergency sources of power. The emergency power supply is to be provided from outside the protected machinery space.

6.3.3.1.2 Sufficient foam-generating capacity is to be provided to ensure the minimum design filling rate for the system is met and in addition is to be adequate to completely fill the largest protected space within 10 min.

6.3.3.1.3 The arrangement of foam delivery ducts are in general to be designed based on the approval test results. The number of ducts may be different, but the minimum design filling rate determined during approval testing is to be provided by the system. A minimum of two ducts are to be installed in every space containing combustion engines, boilers, purifiers, and similar equipment. Small workshops and similar spaces may be covered with only one duct.

6.3.3.1.4 Foam delivery ducts are to be uniformly distributed under the uppermost ceiling in the protected spaces including the engine casing. The number and location of ducts are to be adequate to ensure all high risk areas are protected in all parts and at all levels of the spaces. Extra ducts may be required in obstructed locations. The ducts are to be arranged with at least 1 m free space in front of the foam delivery ducts, unless tested with less clearance. The ducts are to be located behind main structures, and above and away from engines and boilers in

positions where damage from an explosion is unlikely.

6.3.3.1.5 The arrangement of the foam delivery ducts are to be such that a fire in the protected space will not affect the foam-generating equipment. If the foam generators are located adjacent to the protected space, foam delivery ducts are to be installed to allow at least 450 mm of separation between the generators and the protected space, and the separating divisions are to be class "A-60" rated. Foam delivery ducts are to be constructed of steel having a thickness of not less than 5 mm. In addition, stainless steel dampers (single or multi-bladed) with a thickness of not less than 3 mm are to be installed at the openings in the boundary bulkheads or decks between the foam generators and the protected space. The dampers are to be automatically operated (electrically, pneumatically or hydraulically) by means of remote control of the foam generator related to them, and arranged to remain closed until the foam generators begin operating.

6.3.3.1.6The foam generators are to be located where an adequate fresh air supply can be arranged.

6.3.3.2 Systems for the protection of vehicle and ro-ro spaces and special category and cargo spaces:

6.3.3.2.1 The system is to be supplied by the ship's main power source. An emergency power supply is not required.

6.3.3.2.2 Sufficient foam-generating capacity is to be provided to ensure the minimum design filling rate for the system is met and in addition is to be adequate to completely fill the largest protected space within 10 min. However, for systems protecting vehicle and ro-ro spaces and special category spaces, with decks that are reasonably gas-tight and that have a deck height of 3 m or less, the filling rate is not to be less than two thirds of the design filling rate and in addition sufficient to fill the largest protected space within 10 min.

6.3.3.2.3 The system may be divided into sections; however, the capacity and design of the system is to be based on the protected space demanding the greatest volume of foam. Adjacent protected spaces need not be served simultaneously if the boundaries between the spaces are "A" class divisions.

6.3.3.2.4 The arrangement of foam delivery ducts are in general to be designed based on the approval test results. The number of ducts may be different, but the minimum design filling rate determined during approval testing is to be provided by the system. A minimum of two ducts are to be installed in every space. The foam generators are to be arranged to uniformly distribute foam in the protected spaces, and the layout are to take into consideration obstructions that can be expected when cargo is loaded on board. As a minimum, ducts are to be led to every second deck, including movable decks. The horizontal spacing of the ducts is to ensure rapid supply of foam to all parts of the protected space. This is to be established on the basis of full scale tests.

6.3.3.2.5 The system is to be arranged with at least 1 m free space in front of the foam outlets, unless tested with less clearance.

6.3.3.2.6 The arrangement of the foam delivery ducts are to be such that a fire in the protected space will not affect the foam-generating equipment. If the foam generators are located adjacent to the protected space, foam delivery ducts are to be installed to allow at least 450 mm of separation between the generators and the protected space, and the separating divisions are to be class "A-60" rated. Foam delivery ducts are to be constructed of steel having a thickness of not less than 5 mm. In addition, stainless steel dampers (single or multi-bladed) with a thickness of not less than 3 mm are to be installed at the openings in the boundary bulkheads or decks between the foam generators and the protected space. The dampers are to be automatically operated (electrically, pneumatically or hydraulically) by means of remote control of the foam generator related to them, and arranged to remain closed until the foam generators begin operating.

6.3.3.2.7 The foam generators are to be located where an adequate fresh air supply can be arranged.

6.3.4 Testing requirements

6.3.4.1 After installation, the pipes, valves, fittings and assembled systems are to be

tested to the satisfaction of the Administration, including functional testing of the power and control systems, water pumps, foam pumps, valves, remote and local release stations and alarms. Flow at the required pressure is to be verified for the system using orifices fitted to the test line. In addition, all distribution piping is to be flushed with freshwater and blown through with air to ensure that the piping is free of obstructions.

6.3.4.2 Functional tests of all foam proportioners or other foam mixing devices are to be carried out to confirm that the mixing ratio tolerance is within +30 to 0% of the nominal mixing ratio defined by the system approval. For foam proportioners using foam concentrates of Newtonian type with kinematic viscosity equal to or less than 100 cSt at 0ºC and density equal to or less than 1,100 kg/m^3, this test can be performed with water instead of foam concentrate. Other arrangements are to be tested with the actual foam concentrate.

6.3.5 Systems using outside air with generators installed inside the protected space:

Systems using outside air but with generators located inside the protected space and supplied by fresh air ducts may be accepted provided that these systems have been shown to have performance and reliability equivalent to systems defined in 6.3.3. For acceptance the following minimum design features will be considered:

.1 lower and upper acceptable air pressure and flow rate in supply ducts;

.2 function and reliability of damper arrangements;

.3 arrangements and distribution of air delivery ducts including foam outlets; and

.4 separation of air delivery ducts from the protected space.

6.4 Fixed low-expansion foam fire-extinguishing systems

6.4.1 Quantity and foam concentrates

6.4.1.1 The foam concentrates of low-expansion foam fire-extinguishing systems are to be approved based on the guidelines adopted by IMO. (Refer to the Guidelines for performance and testing criteria and surveys of low expansion foam concentrates for fixed fire-extinguishing systems (MSC/Circ.1312 and MSC.1/Circ.1312/Corr.1)).

6.4.1.2 The system is to be capable of discharging through fixed discharge outlets in not more than 5 min a quantity of foam sufficient to produce an effective foam blanket over the largest single area over which oil fuel is liable to spread.

6.4.2 Installation requirements

6.4.2.1 Means are to be provided for the effective distribution of the foam through a permanent system of piping and control valves or cocks to suitable discharge outlets, and for the foam to be effectively directed by fixed sprayers on other main fire hazards in the protected space. The means for effective distribution of the foam are to be proven acceptable to IRS through calculation or by testing.

6.4.2.2 The means of control of any such systems is to be readily accessible and simple to operate and are to be grouped together in as few locations as possible at positions not likely to be cut off by a fire in the protected space.

IR6.4.2.3 The distribution pipes are to be of steel and galvanized, at least, internally.

Section 7

Fixed Pressure Water-Spraying and Water-Mist Fire-Extinguishing Systems

7.1 Application

This section details the specifications for fixed pressure water-spraying and water-mist fire-extinguishing systems as required by Ch.3, Sec.4

7.2 Engineering specifications

7.2.1 Fixed pressure water-spraying fire-extinguishing systems

Fixed pressure water spraying fire extinguishing systems for machinery spaces and cargo pump rooms are to be approved by IRS based on guidelines developed by IMO (Revised Guidelines for the approval of equivalent water based fire extinguishing systems for machinery spaces and cargo pump rooms (MSC/Circ. 1165 as amended by MSC.1/Circ.1237 MSC.1/Circ.1269) and MSC.1/Circ.1386).

7.2.2 Equivalent water-mist fire-extinguishing systems

Water-mist fire-extinguishing systems for machinery spaces and cargo pump-rooms are to be approved based on the guidelines developed by IMO (Refer 7.2.1).

7.2.3 Fixed pressure water spraying fire extinguishing system for cabin balconies

Fixed pressure water spraying fire extinguishing system for cabin balconies is to be approved based on the guidelines developed by IMO (MSC.1 Circ.1268).

7.2.4 Fixed water-based fire-fighting systems for ro-ro spaces, vehicle spaces and special category spaces

Fixed water-based fire-fighting systems for ro-ro spaces, vehicle spaces and special category spaces are to be approved by IRS based on guidelines for approval of fixed water-based fire-fighting systems for ro-ro spaces and special category spaces (MSC.1/Circ.1430, Rev.3).

Section 8

Automatic Sprinkler, Fire Detection and Fire Alarm Systems

8.1 Application

This section details the specifications for automatic sprinkler, fire detection and fire alarm systems as required by Ch.3, Sec.4.

8.2 Engineering specifications

8.2.1 General

8.2.1.1 Type of sprinkler systems

The automatic sprinkler systems are to be of the wet pipe type, but small exposed sections may be of the dry pipe type where this is considered a necessary precaution, e.g. within refrigerated chambers. Control stations, where water may cause damage to essential equipment, maybe fitted with a dry pipe system as permitted by 4.6.1.1 of Chapter 3. Saunas are to be fitted with a dry pipe system, with sprinkler heads having an operating temperature up to 140°C.

8.2.1.2 Sprinkler systems equivalent to those specified in paragraphs 8.2.2 to 8.2.4

Automatic sprinkler systems equivalent to those specified in 8.2.2 to 8.2.4 are to be approved based on the requirements of the National Statutory Authority. (Refer to the Revised Guidelines for approval of sprinkler systems equivalent to that referred to in SOLAS regulation II-2/12 as adopted by IMO by resolution A.800(19)).

8.2.2 Sources of power supply

8.2.2.1 Passenger ships

There is to be not less than two sources of power supply for the sea water pump and automatic alarm and detection system. Where the sources of power for the pump are electrical, these are to be a main generator and an emergency source of power. One supply for the pump is to be taken from the main switchboard, and one from the emergency switchboard by separate feeders reserved solely for that purpose. The feeders are to be so arranged as to avoid galleys, machinery spaces and other enclosed spaces of high fire risk except in so far as it is necessary to reach the appropriate switchboards, and are to be run to an automatic changeover switch situated near the sprinkler pump. This switch is to permit the supply of power from the main switchboard so long as a supply is available therefrom, and be so designed that upon failure of that supply it will automatically change over to the supply from the emergency switchboard. The switches on the main switchboard and the emergency switchboard are to be clearly labelled and normally kept closed. No other switch is to be permitted in the feeders concerned. One of the sources of power supply for the alarm and detection system is to be an emergency source. Where one of the sources of power for the pump is an internal combustion engine it is to, in addition to complying with the provisions of 8.2.4.3, be so situated that a fire in any protected space will not affect the air supply to the machinery.

8.2.2.2 Cargo ships

There are not to be less than two sources of power supply for the sea water pump and automatic alarm and detection system. If the pump is electrically driven it is to be connected to the main source of electrical power, which is to be capable of being supplied by at least two generators. The feeders are to be so arranged as to avoid galleys, machinery spaces and other enclosed spaces of high fire risk except in so far as it is necessary to reach the appropriate switchboards. One of the sources of power supply for the alarm and detection system is to be an emergency source. Where one of the sources of power for the pump is an internal combustion engine it is in addition to complying with the provisions of 8.2.4.3, be so situated that a fire in any protected space will not affect the air supply to the machinery.

8.2.3 Component requirements

8.2.3.1 Sprinklers

8.2.3.1.1 The sprinklers are to be resistant to corrosion by marine atmosphere. In accommodation and service spaces the sprinklers are to come into operation within the temperature range from 68° to 79°C, except that in locations such as drying rooms, where high ambient temperatures might be expected, the operation temperature may be increased by not more than 30°C above the maximum deckhead temperature.

8.2.3.1.2 A quantity of spare sprinkler heads are to be provided for all types and ratings installed on the ship as follows:

Total number of heads	Required number of spares
<300	6
300 to 1000	12
>1000	24

The number of spare sprinkler heads of any type need not exceed the total number of heads installed of that type.

8.2.3.2 Pressure tanks

8.2.3.2.1 A pressure tank having a volume equal to at least twice that of the charge of water specified herein is to be provided. The tank is to contain a standing charge of fresh water, equivalent to the amount of water which would be discharged in one minute by the pump referred to in 8.2.3.3.2, and the arrangements are to provide for maintaining an air pressure in the tank such as to ensure that where the standing charge of fresh water in the tank has been used the pressure will be not less than the working pressure of the sprinkler, plus the pressure exerted by a head of water measured from the bottom of the tank to the highest sprinkler in the system. Suitable means of replenishing the air under pressure and of replenishing the fresh water charge in the tank are to be provided. A glass gauge is to be provided to indicate the correct level of the water in the tank.

8.2.3.2.2 Means are to be provided to prevent the passage of sea water into the tank.

8.2.3.3 Sprinkler pumps

8.2.3.3.1 An independent power pump is to be provided solely for the purpose of continuing automatically the discharge of water from the

sprinklers. The pump is to be brought into action automatically by the pressure drop in the system before the standing fresh water charge in the pressure tank is completely exhausted.

8.2.3.3.2 The pump and the piping system are to be capable of maintaining the necessary pressure at the level of the highest sprinkler to ensure a continuous output of water sufficient for the simultaneous coverage of a minimum area of 280 [m^2] at the application rate specified in 8.2.5.2.3. The hydraulic capability of the system is to be confirmed by the review of hydraulic calculations, followed by a test of the system, if deemed necessary by IRS.

8.2.3.3.3 The pump is to be fitted, on the delivery side, a test valve with a short open-ended discharge pipe. The effective area through the valve and pipe is to be adequate to permit the release of the required pump output while maintaining the pressure in the system specified in 8.2.3.2.1.

8.2.4 Installation requirements

8.2.4.1 General

8.2.4.1.1 Any parts of the system which may be subjected to freezing temperatures in service are to be suitably protected against freezing.

8.2.4.1.2 Special attention is to be paid to the specification of water quality provided by the system manufacturer to prevent internal corrosion of sprinklers and clogging or blockage arising from products of corrosion or scale-forming minerals.

8.2.4.2 Piping arrangements

8.2.4.2.1 Sprinklers are to be grouped into separate sections, each of which is to contain not more than 200 sprinklers. In passenger ships any section of sprinklers is not to serve more than two decks and is not to be situated in more than one main vertical zone. However, a section of sprinklers to serve more than two decks or situated in more than one main vertical zone, may be permitted, if it is shown that the protection of the ship against fire will not thereby be reduced.

8.2.4.2.2 Each section of sprinklers is to be capable of being isolated by one stop valve only. The stop valve in each section is to be readily accessible in a location outside the associated section or in cabinets within stairway enclosures. The valve’s location is to be clearly and permanently indicated. Means are to be provided to prevent the operation of the stop valves by any unauthorized person.

8.2.4.2.3 A test valve is to provided for testing the automatic alarm for each section of sprinklers by a discharge of water equivalent to the operation of one sprinkler. The test valve for each section is to be situated near the stop valve for that section.

8.2.4.2.4 The sprinkler system is to have a connection from the ship's fire main by way of a lockable screw-down non-return valve at the connection which will prevent a backflow from the sprinkler system to the fire main.

8.2.4.2.5 A gauge indicating the pressure in the system is to be provided at each section stop valve and at a central station.

8.2.4.2.6 The sea inlet to the pump wherever possible is to be in the space containing the pump and is to be so arranged that when the ship is afloat it will not be necessary to shut off the supply of sea water to the pump for any purpose other than the inspection or repair of the pump.

8.2.4.3 Location of systems

The sprinkler pump and tank are to be situated in a position reasonably remote from any machinery space of category A and are not to be situated in any space required to be protected by the sprinkler system.

8.2.5 System control requirements

8.2.5.1 Ready availability

8.2.5.1.1 Any required automatic sprinkler, fire detection and fire alarm system is to be capable of immediate operation at all times and no action by the crew is to be necessary to set it in operation.

8.2.5.1.2 The automatic sprinkler system is to be kept charged at the necessary pressure and is to have provision for a continuous supply of water as required in this chapter.

8.2.5.2 Alarm and indication

8.2.5.2.1 Each section of sprinklers is to include means for giving a visual and audible alarm signal automatically at one or more

indicating units whenever any sprinkler comes into operation. Such alarm systems are to be such as to indicate if any fault occurs in the system. Such units are to indicate in which section served by the system a fire has occurred and are to be centralised on the navigating bridge or in the continuously manned central control station and, in addition, visible and audible alarms from the unit are also to be placed in a position other than on the aforementioned spaces to ensure that the indication of fire is immediately received by the crew.

8.2.5.2.2 Switches are to be provided at one of the indicating positions referred to in 8.2.5.2.1 which will enable the alarm and the indicators for each section of sprinklers to be tested.

8.2.5.2.3 Sprinklers are to be placed in an overhead position and spaced in a suitable pattern to maintain an average application rate of not less than 5 [litres/m^2] per minute over the nominal area covered by the sprinklers. For this purpose, nominal area is to be taken as the gross horizontal projection of the area to be covered. The use of sprinklers providing other amounts of water suitably distributed, will be considered provided they are shown to be not less effective.

8.2.5.2.4 A list or plan is to be displayed at each indicating unit showing the spaces covered and the location of the zone in respect of each section. Suitable instructions for testing and maintenance are to be available.

8.2.5.3 Testing

Means are to be provided for testing the automatic operation of the pump on reduction of pressure in the system.

IR8.2.5.4 Stowage of spare sprinklers

8.2.5.4.1 Spare sprinklers are to be stowed in boxes or holders provided for that purpose, together with a tool suitable for removing and installing sprinkler heads. The boxes or holders are to be situated near the control valve for the section, and are to be clearly and permanently marked to indicate their contents.

Section 9

Fixed Fire Detection and Fire Alarm Systems

9.1 Application

9.1.1 This chapter details the specifications for fixed fire detection and fire alarm systems as required by Ch.3, Sec.1.

9.1.2 Definitions

9.1.2.1 Section is a group of fire detectors and manually operated call points as reported in the indicating unit(s).

9.1.2.2 Section identification capability means a system with the capability of identifying the section in which a detector or manually operated call point has activated.

9.1.2.3 Individually identifiable means a system with the capability to identify the exact location and type of detector or manually activated call point which has activated, and which can differentiate the signal of that device from all others.

9.2 Engineering specifications

9.2.1 General requirements

9.2.1.1 Any required fixed fire detection and fire alarm system with manually operated call points is to be capable of immediate operation at all times (this does not require a backup control panel). Notwithstanding this, particular spaces may be disconnected, for example, workshops during hot work and ro-ro spaces during on and off-loading. The means for disconnecting the detectors is to be designed to automatically restore the system to normal surveillance after a predetermined time that is appropriate for the operation requiring disconnection of the detectors. The space is to be manned or provided with a fire patrol when the required detectors are disconnected. Detectors in all other spaces are to remain operational.

9.2.1.2 The fire detection system is to be designed to:

.1 control and monitor input signals from all connected fire and smoke detectors and manual call points;

.2 provide output signals to the navigation bridge, continuously manned central control station or onboard safety centre to notify the crew of fire and fault conditions;

.3 monitor power supplies and circuits necessary for the operation of the system for loss of power and fault conditions; and

.4 the system may be arranged with output signals to other fire safety systems including:

.1 paging systems, fire alarm or public address systems;

.2 fan stops;

.3 fire doors;

.4 fire dampers;

.5 sprinkler systems;

.6 smoke extraction systems;

.7 low-location lighting systems;

.8 fixed local application fire-extinguishing systems;

.9 closed circuit television (CCTV) systems; and

.10 other fire safety systems.

IR9.2.1.2 However, for passenger ships, watertight doors complying with Reg.II-1/16 of SOLAS which also serve as fire doors are not to close automatically in case of detection of fire.

9.2.1.3 The fire detection system may be connected to a decision management system provided that:

.1 the decision management system is proven to be compatible with the fire detection system;

.2 the decision management system can be disconnected without losing any of the functions required by this section for the fire detection system; and

.3 any malfunction of the interfaced and connected equipment does not propagate to the fire detection system under any circumstance.

9.2.1.4 Detectors and manual call points are to be connected to dedicated sections of the fire detection system. Other fire safety functions, such as alarm signals from the sprinkler valves, may be permitted if in separate sections.

9.2.1.5 The system and equipment are to be suitably designed to withstand supply voltage variation and transients, ambient temperature changes, vibration, humidity, shock, impact and corrosion normally encountered in ships. All electrical and electronic equipment on the bridge or in the vicinity of the bridge are to be tested for electromagnetic compatibility, based on the IMO resolution (A.813(19)).

9.2.1.6 Fixed fire detection and fire alarm systems with individually identifiable fire detectors are to be so arranged that:

.1 means are provided to ensure that any fault (e.g. power break, short circuit, earth, etc.) occurring in the section will not prevent the continued individual identification of the remainder of the connected detectors in the section;

.2 all arrangements are made to enable the initial configuration of the system to be restored in the event of failure (e.g. electrical, electronic, informatics, etc.);

.3 the first initiated fire alarm will not prevent any other detector from initiating further fire alarms; and

.4 no section will pass through a space twice. When this is not practical (e.g. for large public spaces), the part of the section which by necessity passes through the space for a second time is to be installed at the maximum possible distance from the other parts of the section.

9.2.1.7 In passenger ships, the fixed fire detection and fire alarm system is to be capable of remotely and individually identifying each detector and manually operated call point. Fire detectors fitted in passenger ship

cabins, when activated, are also to be capable of emitting, or cause to be emitted, an audible alarm within the space where they are located. In cargo ships and on passenger ship cabin balconies the fixed fire detection and fire alarm system is to have section identification capability as a minimum.

9.2.1.8 In cargo ships and on passenger ship cabin balconies, where an individually identifiable system is fitted, notwithstanding the provisions in paragraph 9.2.1.6.1, isolator modules need not be provided at each fire detector if the system is arranged in such a way that the number and location of individually identifiable fire detectors rendered ineffective due to a fault would not be larger than an equivalent section in a section identifiable system, arranged in accordance with paragraph 9.2.4.1.

9.2.1.9 Fixed fire detection and fire alarm systems for cabin balconies are to be approved by IRS, based on the guidelines developed by the IMO (MSC.1 Circ.1242).

9.2.2 Sources of power supply

9.2.2.1 There are to be not less than two sources of power supply for the electrical equipment used in the operation of the fixed fire detection and fire alarm system, one of which is to be an emergency source. The supply is to be provided by separate feeders reserved solely for that purpose. Such feeders are to run to an automatic change over switch situated in or adjacent to the control panel for the fire detection system. The change over switch shall be arranged such that a fault will not result in the loss of both power supplies. The main/ emergency feeder is to run from the respective switchboard to the change-over switch without passing through any other distributing switchboard.

9.2.2.2 The operation of the automatic changeover switch or a failure of one of the power supplies shall not result in loss of fire detection capability. Where a momentary loss of power would cause degradation of the system, a battery of adequate capacity shall be provided to ensure continuous operation during changeover.

9.2.2.3 There is to be sufficient power to permit the continued operation of the system with all detectors activated, but not more than 100 if the total exceeds this figure.

9.2.2.4 The emergency source of power specified in 9.2.2.1 may be supplied by accumulator batteries or from emergency switchboard. The power source is to be sufficient to maintain the operation of the fire detection and fire alarm system for the periods specified in Pt. 4, Ch. 8, Sec 2.8 and at the end of that period, is to be capable of operating all connected visual and audible fire alarm signals for a period of at least 30 min.

9.2.2.5 Where the system is supplied from accumulator batteries, they shall be located in or adjacent to the control panel for the fire detection system, or in another location suitable for use in an emergency. The rating of the battery charge unit shall be sufficient to maintain the normal output power supply to the fire detection system while recharging the batteries from a fully discharged condition.

9.2.3 Component requirements

9.2.3.1 Detectors

9.2.3.1.1 Detectors are to be operated by heat, smoke or other products of combustion, flame, or any combination of these factors. Detectors operated by other factors indicative of incipient fires may be considered by IRS provided that they are no less sensitive than such detectors.

9.2.3.1.2 Smoke detectors required in all stairways, corridors and escape routes within accommodation spaces are to be certified to operate before the smoke density exceeds 12.5% obscuration per metre, but not until the smoke density exceeds 2% obscuration per metre, when tested according to standards EN 54:2001 and IEC 60092-504. Alternative testing standards may be accepted by IRS. Smoke detectors to be installed in other spaces are to operate within sensitivity limits to the satisfaction of IRS having regard to the avoidance of detector insensitivity or over-sensitivity.

9.2.3.1.3 Heat detectors are to be certified to operate before the temperature exceeds 78°C but not until the temperature exceeds 54°C, when the temperature is raised to those limits at a rate less than 1°C per minute, when tested according to standards EN 54 and IEC 60092-504. Alternative testing standards may be accepted by IRS. At higher rates of temperature rise, the heat detector is to operate within temperature limits to the satisfaction of the Surveyors having regard to

the avoidance of detector insensitivity or oversensitivity.

9.2.3.1.4 The operation temperature of heat detectors in drying rooms and similar spaces of a normal high ambient temperature may be up to 130°C, and up to 140°C in saunas.

9.2.3.1.5 Flame detectors are to be tested according to standards EN 54-10:2001 and IEC 60092-504.

9.2.3.1.6 All detectors are to be of a type such that they can be tested for correct operation and restored to normal surveillance without the renewal of any component.

9.2.3.1.7 Detectors fitted in hazardous areas are to be tested and approved for such service. Detectors required by Pt. 6, Ch. 7, Sec 3.4 and installed in spaces that comply with Pt. 6, Ch. 7, Sec 3.3.2.2 need not be suitable for hazardous areas. Detectors fitted in spaces carrying dangerous goods, required by Pt. 6, Ch. 7, Table 2.3 to comply with Pt. 6, Ch. 7, Cl. 2.3.2 are to be suitable for hazardous areas.

9.2.3.2 Control panel

The control panel for the fire detection system is to be tested according to standards EN 54-2:1997, EN 54-4:1997 and IEC 60092-504. Alternative standards may be accepted by IRS.

9.2.3.3 Cables

Cables used in the electrical circuits are to be flame retardant according to standard IEC 60332-1. On passenger ships, cables routed through other main vertical zones that they serve, and cables to control panels in an unattended fire control station are to be fire resisting according to standard IEC 60331, unless duplicated and well separated.

9.2.4 Installation requirements

9.2.4.1 Sections

9.2.4.1.1 Detectors and manually operated call points are to be grouped into sections.

9.2.4.1.2 A section of fire detectors which covers a control station, a service space or an accommodation space is not to include a machinery space of category A or a ro-ro space. A section of fire detectors which covers a ro-ro space is to not include a machinery space of category A. For fixed fire detection and fire alarm systems with remotely and individually identifiable fire detectors, a section covering fire detectors in accommodation, service spaces and control station is not to include fire detectors in machinery spaces of category A or ro-ro spaces.

9.2.4.1.3 Where the fixed fire detection and fire alarm system does not include means of remotely identifying each detector individually, no section covering more than one deck within accommodation spaces, service spaces and control stations, are normally to be provided except a section which covers an enclosed stairway. In order to avoid delay in identifying the source of fire, the number of enclosed spaces included in each section is to be limited as acceptable to IRS. If the detection system is fitted with remotely and individually identifiable fire detection, the sections may cover several decks and serve any number of enclosed spaces.

9.2.4.1.4 In passenger ships, a section of detectors and manually operated call points are not to be situated in more than one main vertical zone, except on cabin balconies.

9.2.4.2 Positioning of detectors

9.2.4.2.1 Detectors are to be located for optimum performance. Positions near beams and ventilation ducts or other positions where patterns of air flow could adversely affect performance and positions where impact or physical damage is likely is to be avoided. Detectors which are located on the overhead are to be a minimum distance of 0.5 [m] away from bulkheads, except in corridors, lockers and stairways.

9.2.4.2.2 The maximum spacing of detectors is to be in accordance with the Table 9.1.

IRS may require or permit different spacing to that specified in the above table if based upon test data which demonstrate the characteristics of the detectors. Detectors located below moveable ro-ro decks are to be in accordance with the above.

9.2.4.2.3 Detectors in stairways are to be located at least at the top level of the stair and at every second level beneath.

9.2.4.2.4 When fire detectors are installed in freezers, drying rooms, saunas, parts of

galleys used to heat food, laundries and other spaces where steam and fumes are produced, heat detectors may be used.

9.2.4.2.5 Where a fixed fire detection and fire alarm system is required by Pt. 6, Ch. 3, Sec 1.5, spaces having little or no fire risk need not be fitted with detectors. Such spaces include void spaces with no storage of combustibles, private bathrooms, public toilets, fire-extinguishing medium storage rooms, cleaning gear lockers (in which flammable liquids are not stowed), open deck spaces and enclosed promenades having little or no fire risk and that are naturally ventilated by permanent openings.

IR9.2.4.2.5 Guidance Note : The following categories of spaces having little or no fire risk generally need not be fitted with detectors:

a) For ships carrying more than 36 passengers (See Ch.3, 3.2.2.3.2):

Category (5) Open deck spaces
Category (9) Sanitary and similar spaces
Category (10) Tanks and voids having little or no fire risk.

b) For ships carrying less than 36 passengers (See Ch.3, 3.2.2.4.2):

Category (5) Service spaces (low risk)
Category (10) Open decks

c) For cargo ships except tankers, (when method IIC or IIIC is adopted) (See Ch.3, 3.2.3.3.2):

Category (5) Service spaces (low risk)
Category (10) Open decks.

Table 9.1 : Spacing of detectors

Type of detector	Max. floor area per detector	Max. distance apart between centres	Max. distance away from bulkheads
Heat	37 $[m]^2$	9 [m]	4.5 [m]
Smoke	74 $[m]^2$	11 [m]	5.5 [m]

9.2.4.3 Arrangement of cables

9.2.4.3.1 Cables which form a part of the system are to be so arranged as to avoid galleys, machinery spaces of category A, and other enclosed spaces of high fire risk except where it is necessary to provide for fire detection or fire alarms in such spaces or to connect to the appropriate power supply.

9.2.4.3.2 A section with individually identifiable capability is not to be damaged at more than one point by a fire.

9.2.5 System control requirements

9.2.5.1 Visual and audible fire signals

(Refer to the Code on alerts and Indicators as adopted by IMO by resolution A.1021(26)).

9.2.5.1.1 The activation of any detector or manually operated call point is to initiate a visual and audible fire detection alarm signal at the control panel and indicating units. If the signals have not received attention within 2 min an audible fire alarm is to be automatically sounded throughout the crew accommodation and service spaces, control stations and machinery spaces of category A. This alarm sounder system need not be an integral part of the detection system.

9.2.5.1.2 In passenger ships, the control panel is to be located in the onboard safety centre. In cargo ships, the control panel is to be located on the navigating bridge or in the control station.

9.2.5.1.3 In passenger ships, an indicating unit that is capable of individually identifying each detector that has been activated or manually operated call point that has operated is to be located on the navigation bridge. In cargo ships and on passenger cabin balconies, indicating units are to as a minimum, denote the section in which a detector or manually operated call point has operated. In ships constructed on or after 1 July 2014, with a cargo control room, an additional indicating unit is to be located in the cargo control room. In cargo ships, an indicating unit is to be located on the navigating bridge if the control panel is located in the fire control station.

IR.9.2.5.1.3 A space in which a cargo control console is installed, but does not serve as a dedicated cargo control room (e.g. ship's office, machinery control room), is to be regarded as a cargo control room in the context of 9.2.5.1.3 and therefore be provided with an additional indicating unit.

9.2.5.1.4 Clear information is to be displayed on or adjacent to each indicating unit about the spaces covered and the location of the sections.

9.2.5.1.5 Power supplies and electric circuits necessary for the operation of the system are to be monitored for loss of power or fault conditions as appropriate including:

.1 a single open or power break fault caused by a broken wire;

.2 a single ground fault caused by the contact of a wiring conductor to a metal component; and

.3 a single wire to wire fault caused by the contact of two or more wiring conductors.

Occurrence of a fault condition is to initiate a visual and audible fault signal at the control panel which is to be distinct from a fire signal.

9.2.5.1.6 Means to manually acknowledge all alarm and fault signals is to be provided at the control panel. The audible alarm sounders on the control panel and indicating units may be manually silenced. The control panel is to clearly distinguish between normal, alarm, acknowledged alarm, fault and silenced conditions.

9.2.5.1.7 The system is to be arranged to automatically reset to the normal operating condition after alarm and fault conditions are cleared.

9.2.5.1.8 When the system is required to sound a local audible alarm within the cabins where the detectors are located, a means to silence the local audible alarms from the control panel is not to be provided.

9.2.5.1.9 In general, audible alarm sound pressure levels at the sleeping positions in the cabins and 1 m from the source are to be at least 75 dB(A) and at least 10 dB(A) above ambient noise levels existing during normal equipment operation with the ship under way in moderate weather. The sound pressure level should be in the 1/3 octave band about the fundamental frequency. Audible alarm signals are not to exceed 120 dB(A).

9.2.5.2 Testing

Suitable instructions and component spares for testing and maintenance are to be provided. Detectors are to be periodically tested using equipment suitable for the types of fires to which the detector is designed to respond. On ships constructed on or after 1 July 2014, detectors installed within cold spaces such as refrigerated compartments are to be tested using procedures having due regard for such locations*. Special consideration will be given to ships with self-diagnostic systems that have in place a documented periodic cleaning procedure for detectors in areas where heads may be prone to contamination.
* Note: Refer to the recommendations of the International Electro-technical Commission, in particular publication IEC 60068-2-1 – Section one -Test Ab, *Environmental Testing – Part 2-1: Tests – Test A: Cold.*"

Section 10

Sample Extraction Smoke Detection Systems

10.1 Application

This section details the specifications for sample extraction smoke detection systems as required by Ch.3, Sec.4.

10.2 Engineering specifications

10.2.1 General requirements

10.2.1.1 Wherever in the text of following requirements the word "system" appears, it means "sample extraction smoke detection system".

10.2.1.1.1 A sample extraction smoke detection system consists of the following main components:

.1 smoke accumulators: air collection devices installed at the open ends of the sampling pipes in each cargo hold that perform the physical function of collecting air samples for transmission to the control panel through the sampling pipes and may also act as discharge nozzles for the fixed-gas fire-extinguishing system, if installed;

.2 sampling pipes: a piping network that connects the smoke accumulators to the control panel, arranged in sections to allow the location of the fire to be readily identified;

.3 three-way valves: if the system is interconnected to a fixed-gas fire-extinguishing system, three-way valves are used to normally align the sampling pipes to the control panel and if a fire is detected, the three-way valves are re-aligned to connect the sampling pipes to the fire-extinguishing system discharge manifold and isolate the control panel; and

.4 control panel: the main element of the system which provides continuous monitoring of the protected spaces for indication of smoke. It typically may include a viewing chamber or smoke sensing units. Extracted air from the protected spaces is drawn through the smoke accumulators and sampling pipes to the viewing chamber and then to the smoke sensing chamber where the air stream is monitored by electrical smoke detectors. If smoke is sensed, the repeater panel (normally on the bridge) automatically sounds an alarm (not localized). The crew can then determine at the smoke sensing unit which cargo hold is on fire and operate the pertinent three-way valve for discharge of the extinguishing agent.

Note : 'Not localized' means that the alarm is initiated at control panel as well as repeater panel(s) / indicating unit(s) as given in Cl.10.2.4.1.1.

10.2.1.2 Any required system is to be capable of continuous operation at all times except that systems operating on a sequential scanning principle may be accepted, provided that the interval between scanning the same position twice gives a maximum allowable interval determined as follows:

The interval (I) should depend on the number of scanning points (N) and the response time of the fans (T) (determined by the designer), with a 20% allowance:

$I = 1.2 \times T \times N$

However, the maximum allowable interval is not to exceed 120 s (I_{max} = 120 s).

10.2.1.3 The system is to be designed, constructed and installed so as to prevent the leakage of any toxic or flammable substance or fire-extinguishing media into any accommodation and service space, control station or machinery space.

10.2.1.4 The system and equipment are to be suitably designed to withstand supply voltage variations and transients, ambient temperature changes, vibration, humidity, shock, impact and corrosion normally encountered in ships and to avoid the possibility of ignition of flammable gas/air mixture.

10.2.1.5 The functioning of the system is to be periodically tested to the satisfaction of IRS. The system is to be of a type that can be tested for correct operation and restored to normal surveillance without the renewal of any component.

10.2.1.6 An alternative power supply for the electrical equipment used in the operation of the system is to be provided.

10.2.2 Component requirements

10.2.2.1 The sensing unit is to be certified to operate before the smoke density within the sensing chamber exceeds 6.65 per cent obscuration per metre.

10.2.2.2 Duplicate sample extraction fans are to be provided. The fans are to be of sufficient capacity to operate under normal ventilation conditions in the protected area and the connected pipe size is to be determined with consideration of fan suction capacity and piping arrangement to satisfy the conditions of clause 10.2.4.2.2. Sampling pipes are to be a minimum of 12 [mm] internal diameter. The fan suction capacity is to be adequate to ensure the response of the most remote area within the required time criteria in Cl. 10.2.4.2.2. Means to monitor airflow are to be provided in each sampling line.

10.2.2.3 The control panel is to permit observation of smoke in the individual sampling pipe.

10.2.2.4 Means are to be provided to monitor the airflow through the sampling pipes so designed as to ensure that as far as practicable equal quantities are extracted from each interconnected accumulator.

10.2.2.5 Sampling pipes are to be provided with an arrangement for periodically purging with compressed air.

10.2.2.6 The control panel for the smoke detection system is to be tested according to standards EN 54-2 (1997), EN 54-4 (1997) and IEC 60092-504 (2001). Alternative standards may be accepted by IRS.

10.2.3 Installation requirements

10.2.3.1 Smoke accumulators

10.2.3.1.1 At least one smoke accumulator is to be located in every enclosed space for which smoke detection is required. However, where a space is designed to carry oil or refrigerated cargo alternatively with cargoes for which a smoke sampling system is required, means may be provided to isolate the smoke accumulators in such compartments for the system. Such means are to be to the satisfaction of IRS.

10.2.3.1.2 Smoke accumulators are to be located overhead or as high as possible in the protected space and are to be spaced so that no part of the overhead deck area is more than 12 [m] measured horizontally from an accumulator. Where systems are used in spaces which may be mechanically ventilated, the position of the smoke accumulators is to be considered having regard to the effects of ventilation. At least one additional smoke accumulator is to be provided in the upper part of each exhaust ventilation duct. An adequate filtering system is to be fitted at the additional accumulator to avoid dust contamination.

10.2.3.1.3 Smoke accumulators are to be positioned where impact or physical damage is unlikely to occur.

10.2.3.1.4 Sampling pipe networks are to be balanced to ensure compliance with Cl. 10.2.2.4. The number of accumulators connected to each sampling pipe are to ensure compliance with Cl. 10.2.4.2.2.

10.2.3.1.5 Smoke accumulators from more than one enclosed space are not to be connected to the same sampling point.

10.2.3.1.6 In cargo holds where non-gastight “tween deck panels” (movable stowage platforms) are provided, smoke accumulators are to be located in both the upper and lower parts of the holds.

10.2.3.2 Sampling pipes

10.2.3.2.1 The sampling pipe arrangements are to be such that the location of the fire can be readily identified.

10.2.3.2.2 Sampling pipes are to be self-draining and suitably protected from impact or damage from cargo working.

10.2.4 System control requirements

10.2.4.1 Visual and audible fire signals

10.2.4.1.1 The detection of smoke or other products of combustion is to initiate a visual and audible signal at the control panel and indicating units.

10.2.4.1.2 The control panel is to be located on the navigating bridge or in the fire control station. An indicating unit is to be located on the navigation bridge if the control panel is located in the fire control station.

10.2.4.1.3 Clear information is to be displayed on or adjacent to the control panel designating the spaces covered.

10.2.4.1.4 Power supplies necessary for the operation of the system are to be monitored for loss of power. Any loss of power is to initiate a visual and audible signal at the control panel and the navigating bridge which is to be distinct from a signal indicating smoke detection.

10.2.4.1.5 Means to manually acknowledge all alarm and fault signals are to be provided at the control panel. The audible alarm sounders on the control panel and indicating units may be manually silenced. The control panel is to clearly distinguish between normal, alarm, acknowledged alarm, fault and silenced conditions.

10.2.4.1.6 The system is to be arranged to automatically reset to the normal operating condition after alarm and fault conditions are cleared.

10.2.4.2 Testing

10.2.4.2.1 Suitable instructions and component spares are to be provided for the testing and maintenance of the system.

10.2.4.2.2 After installation, the system is to be functionally tested using smoke generating machines or equivalent as a smoke source. An alarm is to be received at the control unit in not more than 180 s for vehicle decks and not more than 300 s for container and general cargo holds, after smoke is introduced at the most remote accumulator.

Section 11

Low-Location Lighting Systems

11.1 Application

This section details the specifications for low-location lighting systems as required by Ch.4, Sec.2.

11.2 Engineering specifications

11.2.1 General requirements

Any required low-location lighting systems is to be approved based on the requirements of the National Statutory Authority.

(Refer to the Guidelines for the evaluation, testing and application of low-location lighting on passenger ships as adopted by IMO resolution A.752(18)).

(Refer to the Recommendations by the International Organization for Standardization, in particular, publication ISO 15370:2001 on Low-location lighting on passenger ships).

Section 12

Fixed Emergency Fire Pumps

12.1 Application

This section details the specifications for emergency fire pumps as required by Chapter.3. This section is not applicable to passenger ships of 1,000 gross tonnage and upwards. See Ch.3, 4.2.2.3.1.1 for requirements for such ships.

12.2 Engineering specifications

12.2.1 General

12.2.1.1 The emergency fire pump is to be a fixed independently driven power-operated pump.

IR12.2.1.2 The emergency fire pump and its prime mover are to be approved. The emergency fire pump may also be used for other suitable purposes subject to approval in each case.

12.2.2 Component requirements

12.2.2.1 Emergency fire pumps

12.2.2.1.1 Capacity of the pump

.1 The capacity of the pump is not to be less than 40% of the total capacity of the fire pumps required by Ch.3, 4.2.2.4.1 and in any case not less than the following (Also see Ch.3, 4.2.2.4.1, IR .2.1):

.1	for passenger ships less than 1,000 gross tonnage and for cargo ships of 500 gross tonnage and upwards; and	32 [m^3/h]
.2	for cargo ships less than 500 gross tonnage	15 [m^3/h]

IR.2 The emergency fire pump is also to be capable of supplying two jets of water. Where a fixed water-based fire extinguishing system installed for the protection of the machinery space in accordance with Ch.3, Cl.4.4.1.1, is supplied by the emergency fire pump, the emergency fire pump capacity is

to be adequate to supply the fixed fire extinguishing system at the required pressure plus two jets of water. The capacity of the two jets is to be calculated for two biggest nozzle sizes on board from the following table (* note):

Capacity required for one jet		
Nozzle size Pressure at hydrant	16 mm	19mm
0.27 [N/mm^2]	16 [m^3/h]	23.5 [m^3/h]

*Note: When selecting the biggest nozzle size onboard, the nozzles located in the space where the main fire pumps are located can be excluded.

IR.3 On board cargo ships designed to carry five or more tiers of containers on or above the weather deck, the total capacity of the emergency fire pump need not exceed 72 [m^3/hr].

12.2.2.1.2 Pressure at hydrants

When the pump is delivering the quantity of water required by 12.2.2.1.1, the pressure at any hydrants is not to be less than the minimum pressure required by Chapter 3.

12.2.2.1.3 Suction heads

.1 The total suction head and the net positive suction head of the pump is to be determined having due regard to the requirements of Chapter 3 and this section on the pump capacity and on the hydrant pressure under all conditions of list, trim, roll and pitch likely to be encountered in service. The ballast condition of a ship on entering or leaving a dry dock need not be considered a service condition.

IR.1

IR.1.1 It is to be documented that the suction inlet is fully submerged under “all conditions of list, trim, roll and pitch likely to be encountered in service” as given below.

IR.1.1.1 Operational seagoing condition for which roll, pitch and heave is to be applied is as follows:

The lightest seagoing condition is to be considered, which is defined as the ballast condition which gives the shallowest draught at the position of the sea chest and emergency fire pump as given in the approved stability booklet (or preliminary stability calculation for new building). The following table is to be applied for the calculation of roll, pitch and heave. The heave combined pitch and heave combined roll are taken into account separately.

IR.1.1.1.1 Heave combined pitch in head sea as given in Fig.12.2.2.1.3

L_{LL} (m)	75 and below	100	125	150	175	200	225	250	300	350 and above
Φ (deg)	4.5	4	3.2	2.7	2.3	2.1	1.8	1.7	1.6	1.5
H (m)	0.73	0.8	0.87	0.93	1.03	1.07	1.11	1.19	1.25	
Note: Values at the intermediate length of ships are to be obtained by linear interpolation.										

Where:

L_{LL}: length of the ship, in meters, as defined in the International Convention on Load Lines in force, or length between perpendiculars at the ballast draught, whichever is greater

φ: pitch angle (angle is to be measured from still waterline and downwards) as defined in Fig.12.2.2.1.3

H: heave amplitude as defined in Fig.12.2.2.1.3

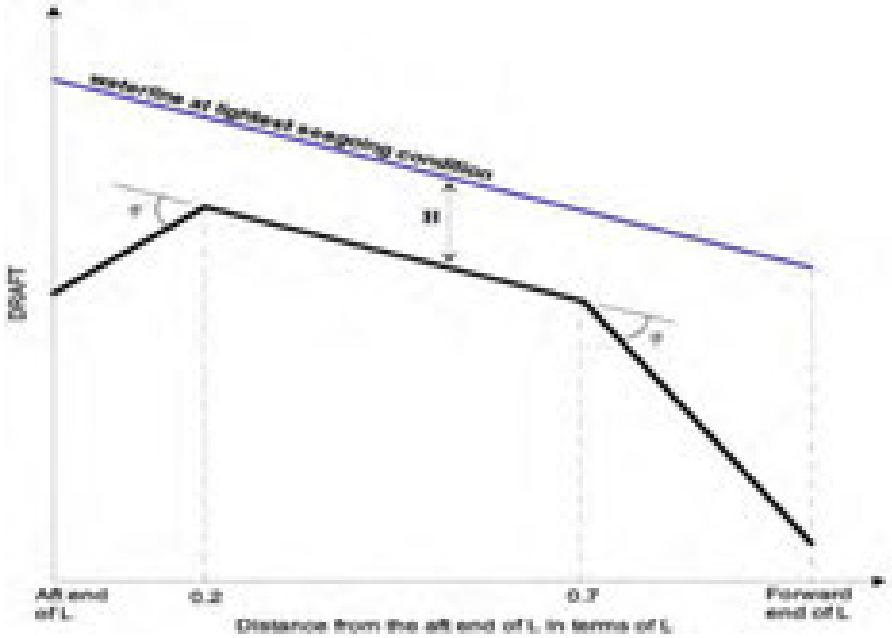

Fig.12.2.2.1.3 : Waterline for which heave combined pitch is taken into account

IR.1.1.1.2 Heave combined roll in beam sea

Heave combined roll angle (angle is to be measured from still waterline and downwards) is to be taken as:

a) ships with bilge keels: 11°; and

b) ships without bilge keels: 13°

IR.1.1.2 The emergency fire pump suction is to be submerged at the waterlines corresponding to the two following conditions:

.1 a static waterline drawn through the level of 2/3 immersion of the propeller at even keel (for pod or thruster driven ship, special consideration will be given); and

.2 the ship in the arrival ballast condition, as per the approved trim and stability booklet, without cargo and with 10% stores and fuel remaining.

For either condition, roll, pitch and heave need not be applied.

The required minimum draught at the sea chest in any condition is to be indicated in the fire fighting system / fire control plans.

IR.1.1.3 A ship operating solely in sheltered water is to be subject to compliance with the still water submergence requirements set out in IR.1.1.2.1 above.

IR.1.2 In all cases the net positive suction head (NPSH) available for the pump is to be greater than the NPSH required.

IR.1.3 Upon completion of the emergency fire pump installation, a performance test confirming the pump's capacity required as per 12.2.2.1.1, is to be carried out and, if the emergency fire pump is the main supply of water for any fixed fire- extinguishing system provided to protect the spaces where the main fire pumps are located, the pump is to have the capacity for this system. As far as practicable, the test is to be carried out at the draught corresponding to the lightest seagoing condition.

IR.2 The pump is to be designed to be of self-priming type and its suction are to be so positioned that the pump will operate efficiently at the lightest draft likely to be encountered in service (as per IR1.1.1. above) having regard to the probable deterioration of the pump and internal growth of corrosion products in suction line.

12.2.2.2 Diesel engines and fuel tank

12.2.2.2.1 Starting of diesel engine

Any diesel driven power source for the pump is to be capable of being readily started in its cold condition down to the temperature of 0°C by hand (manual) cranking. Where ready starting cannot be assured, if this is impracticable, or if lower temperature is likely to be encountered, and if the room for the diesel driven power source is not heated, electric heating of the diesel engine cooling water or lubricating oil system is to be fitted, to the satisfaction of IRS. If hand (manual) starting is impracticable, compressed air, electricity, or other sources of stored energy, including hydraulic power or starting cartridges may be used as a means of starting. These means are to be such as to enable the diesel-driven power source to be started at least six times within a period of 30 min and at least twice within the first 10 min.

12.2.2.2.2 Fuel tank capacity

.1 Any service fuel tank is to contain sufficient fuel to enable the pump to run on full load for at least six hours and sufficient reserves of fuel is to be available outside the machinery space of category A to enable the pump to be run on full load for an additional 15 h. For cargo ships of less than 5000 tons gross, the running time may be reduced to at least three hours.

IR.2 The fuel oil supplying is to be so arranged that it will not readily be affected by a fire in the compartment containing the main fire pumps and preferably located in the same compartment as where emergency fire pump is located.

Section 13

Arrangement of Means of Escape

13.1 Application

This chapter details the specifications for means of escape as required by Chapter 4.

13.2 Passenger ships

13.2.1 Width of stairways

13.2.1.1 Basic requirements for stairway width

Stairways are not to be less than 900 [mm] in clear width. The minimum clear width of stairways is to be increased by 10 mm for every one person provided for in excess of 90 persons. The total number of persons to be evacuated by such stairways is to be assumed to be two thirds of the crew and the total number of passengers in the areas served by such stairways. The width of the stairways is not be inferior to those determined by 13.2.1.2.

13.2.1.2 Calculation method of stairway width

13.2.1.2.1 Basic principles of the calculation

.1 This calculation method determines the minimum stairway width at each deck level, taking into account the consecutive stairways leading into the stairway under consideration.

.2 It is the intention that the calculation method is to consider evacuation from enclosed spaces within each main vertical zone individually and take into account all of the persons using the stairway enclosures in each zone, even if they enter that stairway from another vertical zone.

.3 For each main vertical zone the calculation is to be completed for the night time (case 1) and day time (case 2) and the largest dimension from either case used for determining the stairway width for each deck under consideration.

.4 The calculation of stairway widths are to be based upon the crew and passenger load on each deck. Occupant loads are to be rated by the designer for passenger and crew accommodation spaces, service spaces, control spaces and machinery spaces. For the purpose of the calculation the maximum capacity of a public space is to be defined by either of the following two values:

- the number of seats or similar arrangements, or

- the number obtained by assigning 2 [m^2] of gross deck surface area to each person.

13.2.1.2.2 Calculation method for minimum value

13.2.1.2.2.1 Basic formulae

In considering the design of stairway widths for each individual case which allow for the timely flow of persons evacuating to the muster stations from adjacent decks above and below, the following calculation methods are to be used (See Fig.13.1 and Fig.13.2):

when joining two decks:	$W=(N_1+N_2)$ 10 [mm];
when joining three decks:	$W=(N_1+N_2+0.5N_3)$ 10 [mm];
when joining four decks:	$W=(N_1+N_2+0.5N_3+0.25N_4)$ 10 [mm];
when joining five decks or more decks, the width of the stairways is to be determined by applying the above formula for four decks to the deck under consideration and to the consecutive deck.	

where:

W = the required tread width between handrails of the stairway.

The calculated value of W may be reduced where available landing area S is provided in stairways at the deck level defined by subtracting P from Z, such that:

$P = S \times 3.0$ persons/m^2 ; and $P_{max} = 0.25Z$

where:

Z = the total number of persons expected to be evacuated on the deck being considered;

P = the number of persons taking temporary refuge on the stairway landing, which may be subtracted from Z to a maximum value of P = 0.25Z (to be rounded down to the nearest whole number);

S = the surface area [m^2] of the landing, minus the surface area necessary for the opening of doors and minus the surface area necessary for accessing the flow on stairs (See Fig.13.1);

N = the total number of persons expected to use the stairway from each consecutive deck under consideration; N_1 is for the deck with the largest number of persons using that stairway; N_2 is taken for the deck with the next highest number of persons directly entering the stairway flow such that, when sizing the stairway width as each deck level, $N_1 > N_2 > N_3 > N_4$ (See Fig.13.2). These decks are assumed to be on or upstream (i.e. away from the embarkation deck) of the deck being considered.

Case 1: Passengers in cabins with maximum berthing capacity fully occupied; members of the crew in cabins occupied to 2/3 of maximum berthing capacity; and service spaces occupied by 1/3 of the crew.

Case 2: Passengers in public spaces occupied to 3/4 of maximum capacity; 1/3 of the crew distributed in public spaces; service spaces occupied by 1/3 of the crew; and crew accommodation occupied by 1/3 of the crew.

13.2.1.2.2.2 Distribution of persons

.1 The dimensions of the means of escape are to be calculated on the basis of the total number of persons expected to escape by the stairway and through doorways, corridors and landings (See Fig.13.3). Calculations are to be made separately for the two cases of occupancy of the spaces specified below. For each component part of the escape route, the dimension taken is not to be less than the largest dimension determined for each case.

.2 The maximum number of persons contained in a vertical zone, including persons entering stairways from another main vertical zone, is not to be assumed to be higher than the maximum number of persons authorized to be carried on board for the calculation of stairway width only.

13.2.1.3 Prohibition of decrease in width in the direction to the assembly station

(Refer to the Indication of the “assembly stations” in passenger ships (MSC/Circ.777)).

The stairway is not to decrease in width in the direction of evacuation to the assembly station, except in the case of several assembly stations in one main vertical zone the stairway width is not to decrease in the direction of the evacuation to the most distant assembly station.

13.2.2 Details of stairways

13.2.2.1 Handrails

Stairways are to be fitted with handrails on each side. The maximum clear width between handrails is to be 1,800 [mm].

All stairways sized for more than 90 persons are to be aligned fore and aft.

13.2.2.2 Alignment of stairways

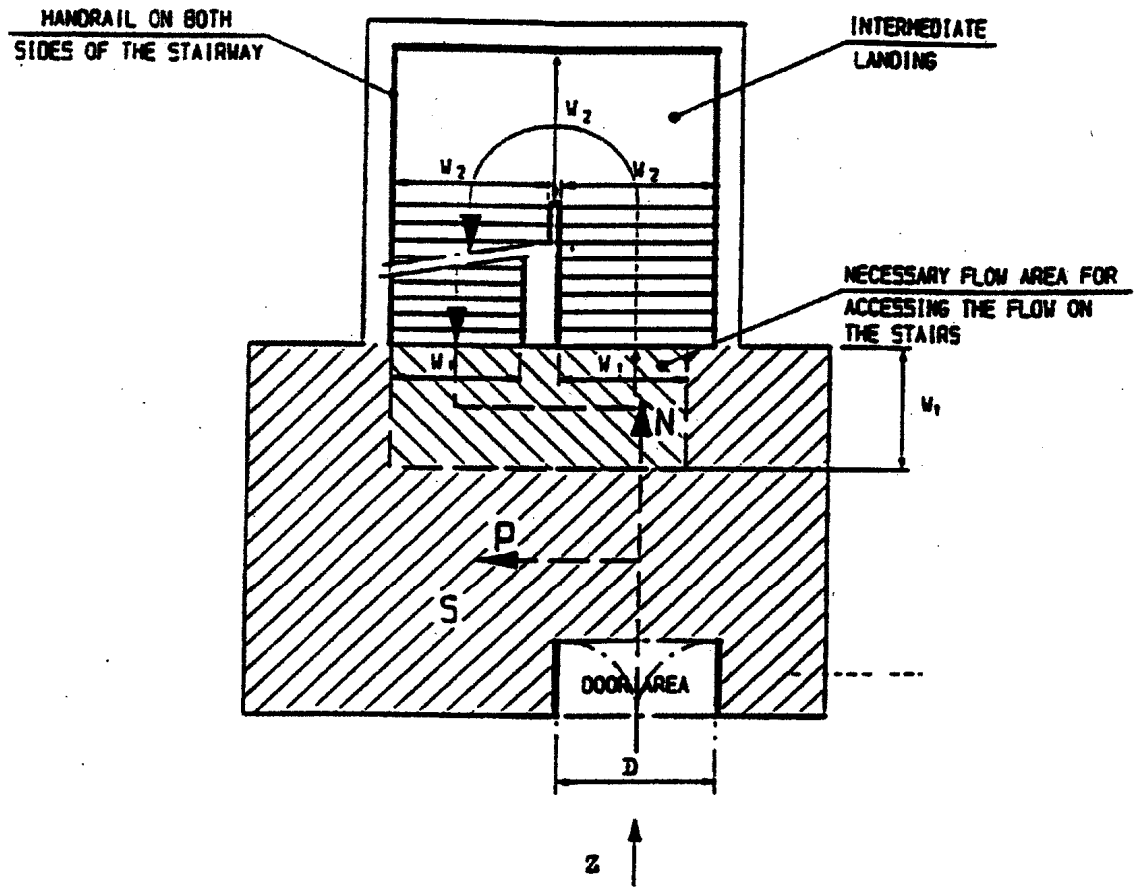

Fig.13.1 : Landing calculation for stairway width reduction

13.2.2.3 Vertical rise and inclination

Stairways are not to exceed 3.5 [m] in vertical rise without the provision of a landing and are not to have an angle of inclination greater than 45°.

13.2.2.4 Landings

With the exception of intermediate landings, landings at each deck level are not to be less than 2 [m^2] in area and is to increase by 1 [m^2] for every 10 persons provided for in excess of 20 persons but need not exceed 16 [m^2], except for those landings servicing public spaces having direct access onto the stairway enclosure. Intermediate landings are to be sized in accordance with 13.2.3.1.

13.2.3 Doorways and corridors

13.2.3.1 Doorways and corridors and intermediate landings included in means of escape are to be sized in the same manner as stairways.

13.2.3.2 The aggregate width of stairway exit doors to the assembly station are not to be less than the aggregate width of stairways serving this deck.

13.2.4 Evacuation routes to the embarkation deck

13.2.4.1 Assembly station

It is to be recognized that the evacuation routes to the embarkation deck may include an assembly station. In this case consideration is to be given to the fire-protection requirements and sizing of corridors and doors from the stairway enclosure to the assembly station and from the assembly station to the embarkation deck, noting that evacuation of persons from assembly stations to embarkation positions are to be carried out in small control groups.

13.2.4.2 Routes from the assembly station to the survival craft embarkation position

Where the passengers and crew are held at an assembly station which is not at the survival craft embarkation position, the dimension of stairway width and doors from the assembly station to this position are not to be based on the number of persons in the controlled group. The width of these stairways and doors need not exceed 1,500 mm unless larger dimensions are required for evacuation of these spaces under normal conditions.

13.2.5 Means of escape plans

13.2.5.1 Means of escape plans are to be provided indicating the following:

.1 the number of the crew and passengers in all normally occupied spaces;

.2 the number of crew and passengers expected to escape by stairway and through doorways, corridors and landings;

.3 assembly stations and survival craft embarkation positions;

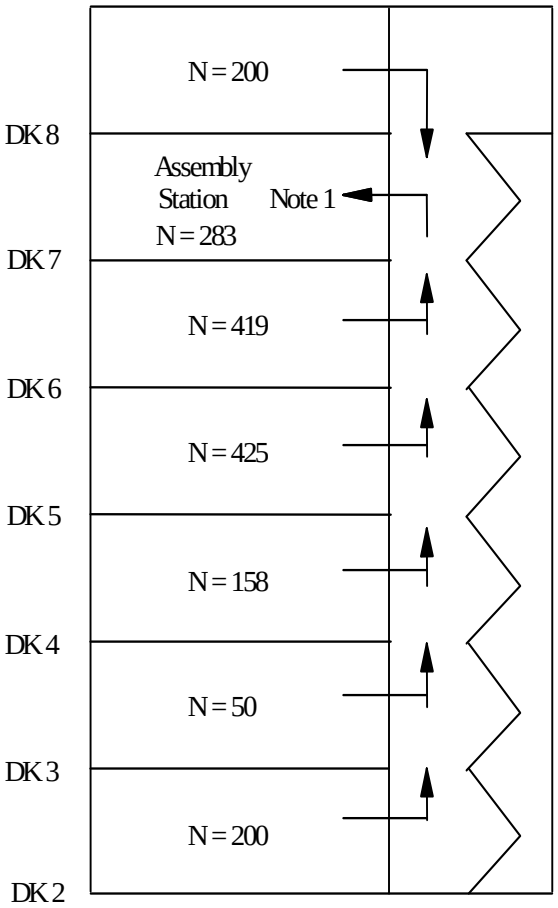
.4 primary and secondary means of escape; and

.5 width of stairways, doors, corridors and landing areas.

13.2.5.2 Means of escape plans are to be accompanied by detailed calculation for determining the width of escape stairways, doors, corridors and landing areas.

13.3 Cargo ships

Stairways and corridors used as means of escape are to be not less than 700 [mm] in clear width and is to have a handrail on one side. Stairways and corridors with a clear width of 1,800 [mm] and over is to have handrails on both sides. “Clear width” is considered the distance between the handrail and the bulkhead on the other side or between the handrails. The angle of inclination of stairways are to be, in general, 45º, but not greater than 50º, and in machinery spaces and small spaces not more than 60º. Doorways which give access to a stairway are to be of the same size as the stairway.



$N_1 = 200$
$W = 2000$

$D = 2000 + 9355 = 11,355$

$N_1 = 425, N_2 = 419, N_3 = 158, N_4 = 50$
$W = (425 + 419 + 0.50 * 158 + 0.25 * 50) * 10 = 9355$

$N_1 = 425, N_2 = 200, N_3 = 158, N_4 = 50$
$W = (425 + 200 + 0.5 * 158 + 0.25 * 50) * 10 = 7165$

$N_1 = 200, N_2 = 158, N_3 = 50$
$W = (200 + 158 + 0.5 * 50) * 10 = 3830$

$N_1 = 200, N_2 = 50$
$W = (200 + 50) * 10 = 2500$

$N_1 = 200$
$W = 200 * 10 = 2000$

Z(pers)	=	number of persons expected to evacuate through the stairway
N(pers)	=	number of persons directly entering the stairway flow from a given deck
W(mm)	=	$(N_1 + N_2 + 0.5 \times N_3 + 0.25 \times N_4) \times 10$ = calculated width of stairway
D(mm)	=	width of exit doors

$N_1 > N_2 > N_3 > N_4$ where:

N_1(pers)	=	the deck with the largest number of persons N entering directly the stairway
N_2(pers)	=	the deck with the next largest number of persons N entering directly the stairway, etc.

Note 1 : The doors to the assembly station should have aggregate width of 11,355 [mm].

Fig.13.2 : Minimum stairway width (W) calculation example

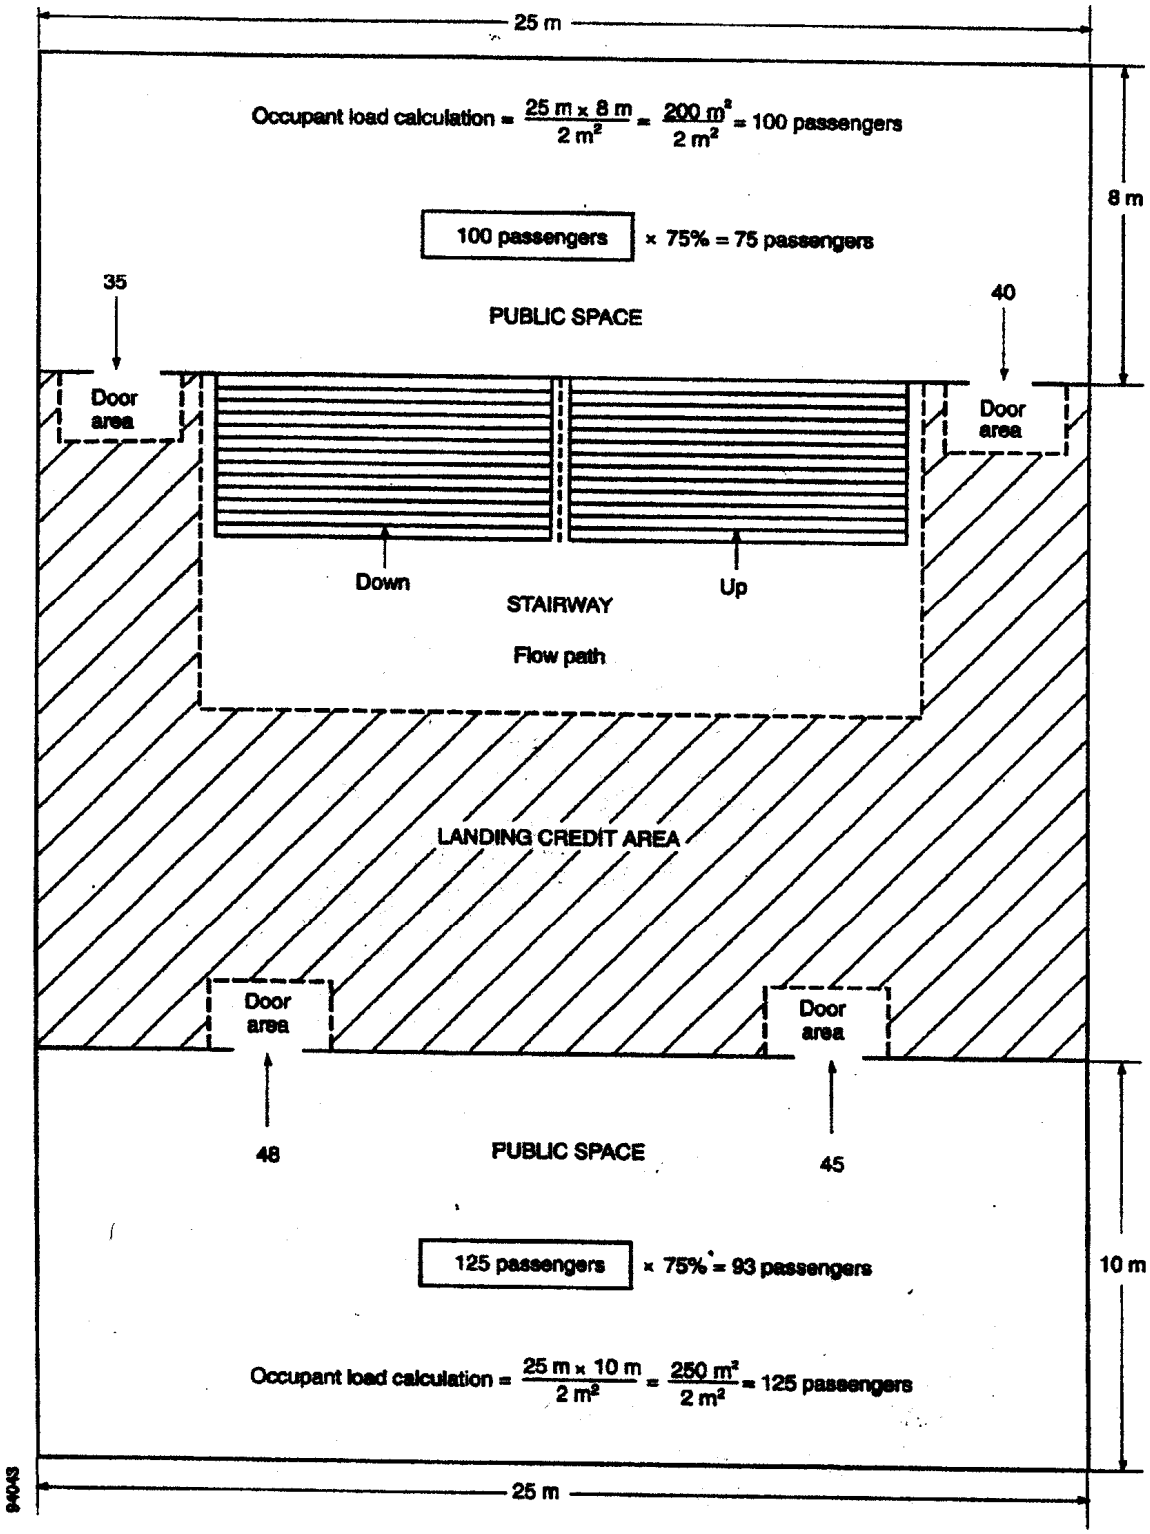


Fig.13.3 : Occupant loading calculation example

Section 14

Fixed Deck Foam Systems

14.1 Application

This section details the specifications for fixed deck foam systems which are required to be provided by Ch.3, Sec.4.

14.2 Engineering specifications

14.2.1 General

14.2.1.1 The arrangements for providing foam are to be capable of delivering foam to the entire cargo tank area as well as into any cargo tank, the deck of which has been ruptured.

14.2.1.2 The deck foam system is to be capable of simple and rapid operation.

14.2.1.3 Operation of a deck foam system at its required output is to permit the simultaneous use of the minimum required number of jets of water at the required pressure from the fire main. Where the deck foam system is supplied by a common line from the fire main, additional foam concentrate is to be provided for operation of two nozzles for the same period of time required for the foam system. The simultaneous use of the minimum required jets of water is to be possible on deck over the full length of the ship, in the accommodation, service spaces, control stations and machinery spaces.

IR14.2.1.3 A common line for fire main and deck foam line can only be considered acceptable provided it can be demonstrated that the hose nozzles can be effectively controlled by one person when supplied from the common line at a pressure needed for operation of the monitors.

The simultaneous use of the minimum required jets of water is to be possible on deck over the full length of the ship in accommodation, service spaces, control stations and machinery spaces.

14.2.2 Component requirements

14.2.2.1 Foam solution and foam concentrate

14.2.2.1.1 For tankers carrying:

.1 crude oil or petroleum products having a flashpoint not exceeding 60ºC (closed cup), as determined by an approved flashpoint apparatus, and a Reid vapour pressure which is below atmospheric pressure or other liquid products having a similar fire hazard, including cargoes in chapter 18 of the IBC Code, having a flashpoint not exceeding 60ºC (closed cup) for which a regular foam fire-fighting system is effective or

.2 petroleum products with a flashpoint exceeding 60ºC (closed cup), as determined by an approved flashpoint apparatus or

.3 IBC Code chapter 17 products with a flashpoint exceeding 60ºC (closed cup) determined by an approved flashpoint apparatus.

The rate of supply of foam solution is not to be less than the greatest of the following :

a) 0.6 [litre/minute/m^2] of cargo deck area, where the cargo deck area means the maximum breadth of the ship multiplied by the total longitudinal extent of the cargo tank spaces;

b) 6 [litres/minute/m^2] of the horizontal sectional area of the single tank having the largest such area; or

c) 3 [litres/minute/m^2] of the area protected by the largest monitor, such area being entirely forward of the monitor, but not less than 1250 litre/minute.

14.2.2.1.2 For tankers carrying chemicals in bulk listed in chapter 17 of the IBC Code having a flashpoint not exceeding 60ºC (closed cup), the rate of supply of foam solution is to be as required by the IBC Code.

14.2.2.1.3 Sufficient foam concentrate is to be supplied to ensure at least 20 min of foam generation in tankers fitted with an inert gas installation or 30 min of foam generation in tankers not fitted with an inert gas installation or not required to use an inert gas system.

14.2.2.1.4 The foam concentrate supplied on board is to be approved* by IRS for the cargoes intended to be carried. Type B foam

concentrates are to be supplied for the protection of crude oil, petroleum products and non-polar solvent cargoes. Type A foam concentrates are to be supplied for polar solvent cargoes, as listed in the table of chapter 17 of the IBC Code. Only one type of foam concentrate is to be supplied, and it is to be effective for the maximum possible number of cargoes intended to be carried. For cargoes for which foam is not effective or is incompatible, additional arrangements to the satisfaction of IRS is to be provided.

* Refer to the Guidelines for performance and testing criteria and surveys of foam concentrates for fixed fire-extinguishing systems (MSC.1/Circ.1312 and MSC.1/Circ.1312/ Corr.1).

14.2.2.1.5 Liquid cargoes with a flashpoint not exceeding 60^{o}C for which a regular foam fire-fighting system is not effective are to comply with Pt.6, Ch.1, Sec.1.5.2.1.

14.2.2.2 Monitors and foam applicators

14.2.2.2.1 Foam from the fixed foam system is to be supplied by means of monitors and foam applicators. Prototype tests of the monitors and foam applicators shall be performed to ensure the foam expansion and drainage time of the foam produced does not differ more than ± 10 per cent of that determined in paragraph 14.2.2.1.4. When medium expansion ratio foam (between 21 to 1 and 200 to 1 expansion ratio) is employed, the application rate of the foam and the capacity of a monitor installation is to be to the satisfaction of IRS. At least 50% of the foam solution supply rate required is to be delivered from each monitor. On tankers of less than 4,000 tonnes deadweight only applicators may be provided and monitors may not be required. Use of the capacity of each applicator is to be at least 25% of the foam solution required supply rate.

IR14.2.2.2.1 The requirements given in 14.2.2.2.3 and 14.2.3.3 apply to all tankers regardless of deadweight.

14.2.2.2.2 The capacity of any applicator is to be not less than 400 l/min and the applicator throw in still air conditions is to be not less than 15 [m].

14.2.3 Installation requirements

14.2.3.1 Main control station

The main control station for the system is to be suitably located outside the cargo area, adjacent to the accommodation spaces and readily accessible and operable in the event of fire in the areas protected.

14.2.3.2 Monitors

14.2.3.2.1 The number and position of monitors are to be such as to comply with 14.2.1.1.

14.2.3.2.2 The distance from the monitor to the farthest extremity of the protected area forward of that monitor is not to be more than 75per cent of the monitor throw in still air conditions.

14.2.3.2.3 A monitor and hose connection for a foam applicator are to be situated both port and starboard at the poop front or accommodation spaces facing the cargo deck. These monitors may be located in cargo area as defined in Ch.1, Sec.3 provided they are aft of cargo tanks and that they protect the areas below and aft of each other. On tankers of less than 4,000 tonnes deadweight a hose connection for a foam applicator is to be situated both port and starboard at the front of the poop or accommodation spaces facing the cargo deck.

IR14.2.3.2.3 The port and starboard monitors required by Cl. 14.2.3.2.3 may be located in the cargo area above oil bunker tanks adjacent to cargo tanks if capable of protecting the deck below and aft of each other.

14.2.3.3 Applicators

14.2.3.3.1 The number of foam applicators provided are to be not less than four. The number and disposition of foam main outlets is to be such that foam from at least two applicators can be directed on to any part of the cargo tanks deck area.

14.2.3.3.2 Applicators are to be provided to ensure flexibility of action during fire-fighting operations and to cover areas screened from the monitors.

14.2.3.4 Isolation valves

Valves are to be provided in both the foam main and fire main when this is an integral part of the deck foam system, immediately forward of every monitor position to isolate damaged sections of those mains.

Section 15

Inert Gas Systems

15.1 Application

This Section details the specifications for inert gas systems as required by Ch.2, 1.5.5.

15.2 Engineering specifications

15.2.1 Definitions

For the purposes of this Section:

15.2.1.1 *Cargo tanks* means those cargo tanks, including slop tanks, which carry cargoes, or cargo residues, having a flashpoint not exceeding 60ºC.

15.2.1.2 *Inert gas system* includes inert gas systems using flue gas, inert gas generators, and nitrogen generators and means the inert gas plant and inert gas distribution together with means for preventing backflow of cargo gases to machinery spaces, fixed and portable measuring instruments and control devices.

15.2.1.3 *Gas-safe space* is a space in which the entry of gases would produce hazards with regard to flammability or toxicity.

15.2.1.4 *Gas-free* is a condition in a tank where the content of hydrocarbon or other flammable vapour is less than 1% of the lower flammable limit (LFL), the oxygen content is at least 21%, by volume and no toxic gases are present. Refer to the *Revised recommendations for entering enclosed spaces aboard ships* (Resolution A.1050(27)).

15.2.2 Requirements for all Systems

15.2.2.1 General

15.2.2.1.1 The inert gas system referred to in Chapter 2 is to be designed, constructed and tested to the satisfaction of IRS. It is to be so designed and operated as to render and maintain the atmosphere of the cargo tanks non-flammable.

IR 15.2.2.1.1 Plans in diagrammatic form are to be submitted for appraisal and are to include the following:

- Details and arrangement of the inert gas generating plant including all control and monitoring devices;
- Arrangement of the piping system for distribution of the inert gas.

(Refer to the revised standards for the design, testing and locating of devices to prevent the passage of flame into cargo tanks in tankers (MSC/Circ.677, as amended by MSC/Circ.1009 and MSC.1/Circ. 1324) and the Revised factors to be taking into consideration when designing cargo tank venting and gas-freeing arrangements (MSC/Circ.731)).

15.2.2.1.2 The system is to be capable of:

.1 inerting empty cargo tanks and maintaining the atmosphere in any part of the tank with an oxygen content not exceeding 8% by volume and at a positive pressure in port and at sea except when it is necessary for such a tank to be gas-free;

.2 eliminating the need for air to enter a tank during normal operations except when it is necessary for such a tank to be gas-free;

.3 purging empty cargo tanks of hydrocarbon or other flammable vapours, so that subsequent gas-freeing operations will at no time create a flammable atmosphere within the tank;

.4 delivering inert gas to the cargo tanks at a rate of at least 125% of the maximum rate of discharge capacity of the ship expressed as a volume. For chemical tankers and chemical/ product tankers, IRS may accept inert gas systems having a lower delivery capacity provided that the maximum rate of discharge of cargoes from cargo tanks being protected by the system is restricted to not more than 80% of the inert gas capacity; and

.5 delivering inert gas with an oxygen content of not more than 5% by volume to the cargo tanks at any required rate of flow.

15.2.2.1.3 Materials used in inert gas systems are to be suitable for their intended purpose. In particular, those components which may be subjected to corrosive action of the gases and/ or liquids are to be either constructed of corrosion-resistant material or lined with rubber, glass fibre epoxy resin or other equivalent coating material.

15.2.2.1.4 The inert gas supply may be:

.1 treated flue gas from main or auxiliary boilers, or

.2 gas from an oil or gas-fired gas generator, or

.3 gas from nitrogen generators.

IRS may accept systems using inert gases from one or more separate gas generators or other sources or any combination thereof, provided that an equivalent level of safety is achieved. Such systems are to, as far as practicable; comply with the requirements of this Section. Systems using stored carbon dioxide are not to be used unless IRS is satisfied that the risk of ignition from generation of static electricity by the system itself is minimized.

IR 15.2.2.1.4 In all cases, automatic control capable of producing suitable inert gas under all service conditions, is to be fitted.

15.2.2.2 Safety Measures

.1 The inert gas system is to be so designed that the maximum pressure which it can exert on any cargo tank will not exceed the test pressure of any cargo tank.

.2 Automatic shutdown of the inert gas system and its components parts are to be arranged on predetermined limits being reached, taking into account the provisions of paragraphs 15.2.2.4, 15.2.3.2 and 15.2.4.2.

IR .2 The automatic shutdown of the inert gas system and its components is to involve in following:

.1 Shutdown of fans and closing of regulating valve for the following:

.1 high water level in scrubber (not applicable for N_2);

.2 low pressure/flow to scrubber (not applicable for N_2); or

.3 high-high temperature of inert gas supply

.2 closing of regulating valve in the event of:

.1 high oxygen content (in excess of 5% by volume); or

.2 failure of blowers/fans or N2 compressors

.3 activation of double-block and bleed arrangement upon:

.1 loss of inert gas supply (for ships with double block and bleed replacing water seal); or

.2 loss of power

.3 Suitable shutoff arrangements are to be provided on the discharge outlet of each generator plant.

.4 The system is to be designed to ensure that if the oxygen content exceeds 5% by volume, the inert gas shall be automatically vented to atmosphere.

.5 Arrangements are to be provided to enable the functioning of the inert gas plant to be stabilized before commencing cargo discharge. If blowers are to be used for gas-freeing, their air inlets are to be provided with blanking arrangements.

.6 Where a double block and bleed valve is installed, the system is to ensure that, upon loss of power, the block valves are automatically closed and the bleed valve is automatically open.

15.2.2.3 System Components

15.2.2.3.1 Non-Return Devices

.1 At least two non-return devices are to be fitted in order to prevent the return of vapour and liquid to the inert gas plant, or to any gas-safe spaces.

.2 The first non-return device is to be a deck seal of the wet, semi-wet, or dry type or a

double-block and bleed arrangement given in Pt.5, Ch.3, 21.1.2. Two shut-off valves in series with a venting valve in between, may be accepted by IRS provided:

.1 the operation of the valve is automatically executed. Signal(s) for opening/closing is (are) to be taken from the process directly, e.g. inert gas flow or differential pressure; and

.2 alarm for faulty operation of the valves is provided, e.g. the operation status of "blower stop" and "supply valve(s) open" is an alarm condition.

.3 The second non-return device is to be a non-return valve or equivalent capable of preventing the return of vapours and liquids and fitted between the deck water seal (or equivalent device) and the first connection from the inert gas main to a cargo tank. It is to be provided with positive means of closure. As an alternative to positive means of closure, an additional valve having such means of closure may be provided between the non-return valve and the first connection to the cargo tanks to isolate the deck water seal, or equivalent device, from the inert gas main to the cargo tanks.

.4 A water seal, if fitted, is to be capable of being supplied by two separate pumps, each of which shall be capable of maintaining an adequate supply at all times. The audible and visual alarm on the low level of water in the water seal are to operate at all times.

.5 The arrangement of the water seal, or equivalent devices, and its associated fittings is to be such that it will prevent backflow of vapours and liquids and will ensure the proper functioning of the seal under operating conditions.

.6 Provision is to be made to ensure that the water seal is protected against freezing, in such a way that the integrity of seal is not impaired by overheating.

.7 A water loop or other approved arrangement is also to be fitted to each associated water supply and drain pipe and each venting or pressure-sensing pipe leading to gas-safe spaces. Means are to be provided to prevent such loops from being emptied by vacuum.

.8 Any water seal, or equivalent device, and loop arrangements are to be capable of preventing return of vapours and liquids to an inert gas plant at a pressure equal to the test pressure of the cargo tanks.

.9 The non-return devices are to be located in the cargo area on deck.

15.2.2.3.2 Inert Gas Lines

.1 The inert gas main may be divided into two or more branches downstream of the non-return devices required by 15.2.2.3.1.

.2 The inert gas main is to be fitted with branch piping leading to the cargo tank. Branch piping for inert gas is to be fitted with either stop valves or equivalent means of control for isolating each tank. Where stop valves are fitted, they are to be provided with locking arrangements. The control system is to provide unambiguous information of the operational status of such valves to at least the control panel required in paragraph 15.2.2.4.

IR .2 Unambiguous information regarding the operational status of stop valves in branch piping leading from the inert gas main to cargo tanks means position indicators providing open/intermediate/closed status information in the control panel required in 15.2.2.4.Limits switches are to be used to positively indicate both open and closed positions. Intermediate position status is to be indicated when the valve is in neither open nor closed position.

.3 Each cargo tank not being inerted is to be capable of being separated from the inert gas main by:

.1 removing spool-pieces, valves or other pipe sections, and blanking the pipe ends; or

.2 arrangement of two spectacle flanges in series with provisions for detecting leakage into the pipe between the two spectacle flanges; or

.3 equivalent arrangements to the satisfaction of IRS, providing at least the same level of protection.

.4 Means are to be provided to protect cargo tanks against the effect of overpressure or vacuum caused by thermal variations and/ or

cargo operations when the cargo tanks are isolated from the inert gas mains.

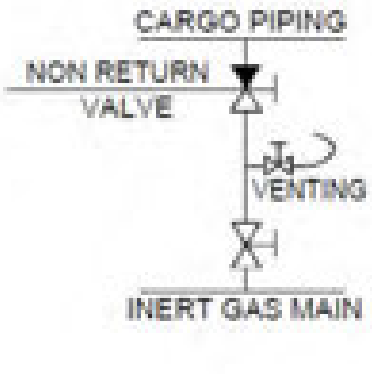
.5 Piping systems are to be so designed as to prevent the accumulation of cargo or water in the pipelines under all normal conditions.

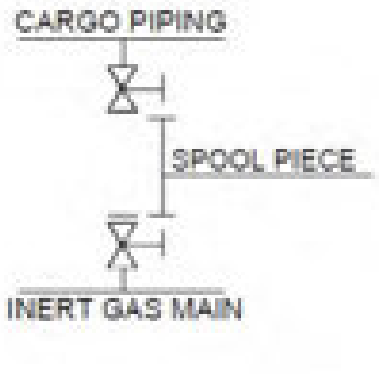
.6 Arrangements are to be provided to enable the inert gas main to be connected to an external supply of inert gas. The arrangements are to consist of a 250 [mm] nominal pipe size bolted flange, isolated from the inert gas main by a valve and located downstream of the non-return valve. The design of the flange is to conform to the appropriate class in the standards adopted for the design of other external connections in the ship's cargo piping system.

.7 If a connection is fitted between the inert gas main and the cargo piping system, arrangements are to be made to ensure an effective isolation having regard to the large pressure difference which may exist between the systems. This is to consist of two shutoff valves with an arrangement to vent the space between the valves in a safe manner or an arrangement consisting of a spool-piece with associated blanks.

.8 The valve separating the inert gas main from the cargo main and which is on the cargo main side is to be a non-return valve with a positive means of closure.

IR .8 The effective isolation required by 15.2.2.3.2.7 and 15.2.2.3.2.8 may be achieved by the two arrangements shown in the sketches below:





.9 Inert gas piping systems are not to pass through accommodation, service and control station spaces.

.10 In combination carriers, the arrangement to isolate the slop tanks containing oil or oil residues from other tanks is to consist of blank flanges which will remain in position at all times when cargoes other than oil are being carried except may be accepted by the National Statutory Authority (Refer to the revised guidelines for inert gas systems (MSC/Circ.353), as amended by MSC/Circ.387).

15.2.2.4 Indicators and Alarms (Also refer 15.2.2.2)

15.2.2.4.1 The operation status of the inert gas system is to be indicated in a control panel.

IR 15.2.2.4.1 The operational status of the inert gas system is to be based on indication that inert gas is being supplied downstream of the gas regulating valve and on the pressure or flow of the inert gas mains upstream of the non-return devices. However, the operational status of the inert gas system as required in paragraph 15.2.2.4.1 is not to be considered to require additional indicators and alarms other than those specified in paragraphs 15.2.2.4 and 15.2.3.2 or 15.2.4.2, as appropriate.

15.2.2.4.2 Instrumentation is to be fitted for continuously indicating and permanently recording, when inert gas is being supplied:

.1 the pressure of the inert gas mains downstream of the non-return devices; and

.2 the oxygen content of the inert gas.

15.2.2.4.3 The indicating and recording devices are to be placed in the cargo control room where provided. But where no cargo

control room is provided, they are to be placed in a position easily accessible to the officer in charge of cargo operations.

15.2.2.4.4 In addition, meters are to be fitted:

.1 in the navigating bridge to indicate at all times the pressure referred to in 15.2.2.4.2.1 and the pressure in the slop tanks of combination carriers, whenever those tanks are isolated from the inert gas main; and

.2 in the machinery control room or in the machinery space to indicate the oxygen content referred to in paragraph 15.2.2.4.2.2.

15.2.2.4.5 Audible and visual alarms

.1 Audible and visual alarms are to be provided, based on the system designed, to indicate:

.1 oxygen content in excess of 5% by volume;

.2 failure of the power supply to the indicating devices as referred to in paragraph 15.2.2.4.2;

.3 gas pressure less than 100 [mm] water gauge. The alarm arrangement is to be such as to ensure that the pressure in slop tanks in combination carriers can be monitored at all times;

.4 high-gas pressure; and

.5 failure of the power supply to the automatic control system

.2 The alarms required in 15.2.2.4.5.1.1, 15.2.2.4.5.1.3 and 15.2.2.4.5.1.5 are to be fitted in the machinery space and cargo control room, where provided, but in each case in such a position that they are immediately received by responsible members of the crew.

.3 An audible alarm system independent of that required in 15.2.2.4.5.1.3 or automatic shutdown of cargo pumps are to be provided to operate on predetermined limits of low pressure in the inert gas main being reached.

IR .3 The term "alarm system independent" means that a second pressure sensor, independent of the sensor serving the alarms for low pressure, high pressure and pressure indicator/recorder is to be provided. Notwithstanding the above, a common programmable logic controller (PLC) is to, however, be accepted for the alarms in the control system. The independent sensor is not required if the system is arranged for the shutdown of cargo pumps. If a system for shutdown of cargo pumps is arranged, an automatic system shutting down all cargo pumps is to be provided. The shutdown is to be alarmed at the control station. The shutdown is not to prevent the operation of ballast pumps or pumps used for bilge drainage of a cargo pump room.

.4 Two oxygen sensors are to be positioned at appropriate locations in the space or spaces containing the inert gas system. If the oxygen level falls below 19.5%, these sensors are to trigger alarms, which are to be both visible and audible inside and outside the space or spaces and are to be placed in such a position that they are immediately received by responsible members of the crew.

15.2.2.5 Instruction Manuals

.1 Detailed instruction manuals are to be provided on board, covering the operations, safety and maintenance requirements and occupational health hazards relevant to the inert gas system and its application to the cargo tank system. The manuals are to include guidance on procedures to be followed in the event of a fault or failure of the inert gas system (Refer to the revised guidelines for inert gas systems (MSC/Circ.353), as amended by MSC/Circ.387).

15.2.3 Requirements for flue gas and inert gas generators systems

In addition to the provisions in 15.2.2, for inert gas systems using flue gas or inert gas generators, the provisions of this sub-section shall apply.

15.2.3.1 System requirements

15.2.3.1.1 Inert Gas Generators

.1 Two fuel oil pumps are to be fitted to the inert gas generator. Suitable fuel in sufficient quantity is to be provided for the inert gas generators.

.2 The inert gas generators are to be located outside the cargo tank area. Spaces containing inert gas generators are to have no

direct access to accommodation service or control station spaces, but may be located in machinery spaces. If they are not located in machinery spaces, such a compartment is to be separated by a gastight steel bulkhead and/ or deck from accommodation, service and control station spaces. Adequate positive-pressure-type mechanical ventilation is to be provided for such a compartment.

15.2.3.1.2 Gas Regulating Valves

.1 A gas regulating valve is to be fitted in the inert gas main. This valve is to be automatically controlled to close, as required in 15.2.2.2.2. It is also to be capable of automatically regulating the flow of inert gas to the cargo tanks unless means are provided to automatically control the inert gas flow rate.

.2 The gas regulating valve is to be located at the forward bulkhead of the forward most gas-safe space through which the inert gas main passes.

15.2.3.1.3 Cooling and Scrubbing Arrangement

.1 Means are to be fitted which will effectively cool the volume of gas specified in 15.2.2.1.2 and remove solids and sulphur combustion products. The cooling water arrangements are to be such that an adequate supply of water will always be available without interfering with any essential services on the ship. Provision is also to be made for an alternative supply of cooling water.

.2 Filters or equivalent devices are to be fitted to minimize the amount of water carried over to the inert gas blowers.

15.2.3.1.4 Blowers

.1 At least two inert gas blowers are to be fitted and be capable of delivering to the cargo tanks at least the volume of gas required by 15.2.2.1.2. For systems fitted with inert gas generators one blower only may be accepted if that system is capable of delivering the total volume of gas required by 15.2.2.1.2 to the cargo tanks, provided that sufficient spares for the blower and its prime mover are carried on board to enable any failure of the blower and its prime mover to be rectified by the ship's crew.

.2 Where inert gas generators are served by positive displacement blowers, a pressure relief device is to be provided to prevent excess pressure being developed on the discharge side of the blower.

.3 When two blowers are provided, the total required capacity of the inert gas system is to be divided evenly between the two and in no case is one blower to have a capacity less than 1/3 of the total capacity required.

15.2.3.1.5 Inert gas isolating valves

.1 For systems using flue gas, flue gas isolating valves are to be fitted in the inert gas mains between the boiler uptakes and the flue gas scrubber. These valves are to be provided with indicators to show whether they are open or shut, and precautions are to be taken to maintain them gastight and keep the seatings clear of soot. Arrangements are to be made to ensure that boiler soot blowers cannot be operated when the corresponding flue gas valve is open.

15.2.3.1.6 Prevention of flue gas leakage

.1 Special consideration is to be given to the design and location of scrubber and blowers with relevant piping and fittings in order to prevent flue gas leakages into enclosed spaces.

.2 To permit safe maintenance, an additional water seal or other effective means of preventing flue gas leakage are to be fitted between the flue gas isolating valves and scrubber or incorporated in the gas entry to the scrubber.

15.2.3.2 Indicators and Alarms (Also refer 15.2.2.2)

.1 To permit safe maintenance, an additional water seal or other effective means of preventing flue gas leakage is to be fitted between the flue gas isolating valves and scrubber or incorporated in the gas entry to the scrubber.

.2 In addition to the requirements of 15.2.2.4.5, audible and visual alarms are to be provided to indicate:

.1 insufficient fuel oil supply to the oil-fired inert gas generator;

.2 failure of the power supply to the generator;

.3 low water pressure or low water flow rate to the cooling and scrubbing arrangement;

.4 high water level in the cooling and scrubbing arrangement;

.5 high gas temperature;

.6 failure of the inert gas blowers; and

.7 low water level in the water seal.

15.2.4 Requirements for Nitrogen Generator Systems

The provisions of this section shall apply, in addition to the provisions in 15.2.2, for inert gas systems using nitrogen generators.

15.2.4.1 System Requirements

.1 The system is to be provided with one or more compressors to generate enough positive pressure to be capable of delivering the total volume of gas required by 15.2.2.1.2.

.2 A feed air treatment system is to be fitted to remove free water, particles and traces of oil from the compressed air.

.3 The air compressor and nitrogen generator may be installed in the engine-room or in a separate compartment. A separate compartment and any installed equipment are to be treated as an "Other machinery space" with respect to fire protection. Where a separate compartment is provided for the nitrogen generator, the compartment is to be fitted with an independent mechanical extraction ventilation system providing six air changes per hour. The compartment is to have no direct access to accommodation spaces, service spaces and control stations.

Note: Supply air requirement and arrangement should take into account the need for the nitrogen generator system as well as for the compartment ventilation.

.4 Where a nitrogen receiver or a buffer tank is installed, it may be installed in a dedicated compartment, in a separate compartment containing the air compressor and the nitrogen generator, in the engine room, or in the cargo area. Where the nitrogen receiver or a buffer tank is installed in an enclosed space, the access is to be arranged only from the open deck and the access door is to open outwards. Adequate, independent mechanical ventilation, of the extraction type, is to be provided for such a compartment.

Note: Additional options for installation of the nitrogen receiver or buffer tank may be considered based on the risk and provision of adequate ventilation arrangements

15.2.4.2 Indicators and Alarms (Also refer 15.2.2.2)

.1 In addition to the requirements in 15.2.2.4.2, instrumentation is to be provided for continuously indicating the temperature and pressure of air at the suction side of the nitrogen generator.

.2 In addition to the requirements in 15.2.2.4.5, audible and visual alarms are to be provided to include:

.1 failure of the electric heater, if fitted;

.2 low feed-air pressure or flow from the compressor;

.3 high-air temperature; and

.4 high condensate level at automatic drain of water separator.

IR15.2.5 Additional Requirements for Nitrogen Generator Systems on Tankers, including Chemical Tankers, to which Ch.2, 1.5.5 applies

IR15.2.5.1 The following requirements apply where a nitrogen generator system is fitted on board as required by Part 6, Ch.2, 1.5.5.1. For the purpose, the inert gas is to be produced by separating air into its component gases by passing compressed air through a bundle of hollow fibres, semi-permeable membranes or adsorber materials.

IR15.2.5.2 In addition to the applicable requirements of 15.2.4, the nitrogen generator system is to comply with Ch.2, 1.5.2.6, 1.5.6.3 and Ch.3, 5.6.3.4.

IR15.2.5.3 A nitrogen generator is to consist of a feed air treatment system and any number of membrane or adsorber modules in parallel necessary to meet 15.2.2.1.2.4.

IR15.2.5.4 The nitrogen generator is to be capable of delivering high purity nitrogen in accordance with 15.2.2.1.2.5. In addition to

15.2.2.2.4, the system is to be fitted with automatic means to discharge "off-spec" gas to the atmosphere during start-up and abnormal operation.

IR15.2.5.5 The system is to be provided with one or more compressors to generate enough positive pressure to be capable of delivering the total volume of gas required by 15.2.2.1.2. Where two compressors are provided, the total required capacity of the system is preferably to be divided equally between the two compressors, and in no case is one compressor to have a capacity less than 1/3 of the total capacity required.

IR15.2.5.6 The feed air treatment system fitted to remove free water, particles and traces of oil from the compressed air as required by 15.2.4.1.2, is also to preserve the specification temperature.

IR15.2.5.7 The oxygen-enriched air from the nitrogen generator and the nitrogen-product enriched gas from the protective devices of the nitrogen receiver are to be discharged to a safe location(Note 1) on the open deck.

Note 1: “safe location” needs to address the two types of discharges separately:

1. oxygen-enriched air from the nitrogen generator - safe locations on the open deck are:

- outside of hazardous area;

- not within 3 [m] of areas traversed by personnel; and

- not within 6 [m] of air intakes for machinery (engines and boilers) and all ventilation inlets.

2. nitrogen-product enriched gas from the protective devices of the nitrogen receiver - safe locations on the open deck are:

- not within 3 [m] of areas traversed by personnel; and

- not within 6 [m] of air intakes for machinery (engines and boilers) and all ventilation inlets/outlets.

IR15.2.5.8 In order to permit maintenance, means of isolation are to be fitted between the generator and the receiver.

IR15.2.6 Nitrogen/ Inert Gas Systems Fitted for Purposes other than Inerting required by Ch.2, 1.5.5

IR15.2.6.1 These requirements are applicable to systems fitted on oil tankers, gas tankers or chemical carriers to which requirements of Ch. 2, 1.5.5 do not apply.

IR15.2.6.2 Paragraphs 15.2.2.2.2, 15.2.2.2.4, 15.2.2.4.2, 15.2.2.4.3, 15.2.2.4.5.1.1, 15.2.2.4.5.1.2, 15.2.2.4.5.4, 15.2.4.1.1, 15.2.4.1.2, 15.2.4.1.3, 15.2.4.1.4, 15.2.4.1.8, 15.2.4.1.10, 15.2.4.1.11, 15.2.4.1.12, 15.2.4.1.13, 15.2.4.2.1 and 15.2.4.2.2 of this Section apply to these systems, as applicable.

IR15.2.6.3 The requirements of IR15.2.5 apply except IR15.2.5.1, IR15.2.5.2, IR15.2.5.4, and IR15.2.5.5.

IR15.2.6.4 Materials used in inert gas systems are to be suitable for their intended purpose.

IR15.2.6.5 All the equipment is to be installed and tested onboard to the satisfaction of the Surveyor.

IR15.2.6.6 The two non-return devices as required by 15.2.2.3.1.1, are to be fitted in the inert gas main. The non-return devices are to comply with 15.2.2.3.1.2 and 15.2.2.3.1.3; however, where the connections to the cargo tanks, to the hold spaces or to cargo piping are not permanent, the non-return devices required by 15.2.2.3.1.1 may be substituted by two non-return valves.

Section 16

Fixed Hydrocarbon Gas Detection Systems

16.1 Application

16.1.1 This section details the specifications for fixed hydrocarbon gas detection systems required by this part of the Rules.

16.1.2 A combined gas detection system required by Ch.2, 1.5.7.3 (requirement for fixed gas detection system in double hull and bottom spaces) and 1.5.10 (condition monitoring in cargo pump rooms) may be accepted in cases where the system fully complies with the requirement of Ch.1, Sec.2.

16.2 Engineering specifications

16.2.1 General

16.2.1.1 The fixed hydrocarbon gas detection system referred to in this part of the Rules is to be designed, constructed and tested to the satisfaction of IRS based on performance standards developed by IMO*.

* Refer to the Guidelines for the design, construction and testing of fixed hydrocarbon gas detection system (MSC.1/Circ.1370).

16.2.1.2 The system is to be comprised of a central unit for gas measurement and analysis and gas sampling pipes in all ballast tanks and void spaces of double-hull and double-bottom spaces adjacent to the cargo tanks, including the forepeak tank and any other tanks and spaces under the bulkhead deck adjacent to cargo tanks.

16.2.1.3 The system may be integrated with the cargo pump-room gas detection system, provided that the spaces referred to in Cl. 16.2.1.2 are sampled at the rate required in Cl. 16.2.2.3.1. Continuous sampling from other locations may also be considered provided the sampling rate is complied with.

16.2.2 Component requirements

16.2.2.1 Gas sampling lines

16.2.2.1.1 The detection equipment is not to be fitted with common sampling lines except the lines serving each pair of sampling points as required in Cl. 16.2.2.1.3.

16.2.2.1.2 The materials of construction and the dimensions of gas sampling lines are to be such as to prevent restriction. Where non-metallic materials are used, they are to be electrically conductive. The gas sampling lines are not to be made of aluminium.

16.2.2.1.3 The configuration of gas sampling lines is to be adapted to the design and size of each space. Except as provided in Cl. 16.2.2.1.4 and 16.2.2.1.5, the sampling system is to allow for a minimum of two hydrocarbon gas sampling points, one located on the lower and one on the upper part where sampling is required. When the upper gas sampling point is required, it is not to be located lower than 1 [m] from the tank top. The position of the lower gas sampling point is to be above the height of the girder of bottom shell plating but at least 0.5 [m] from the bottom of the tank and it is to be provided with means to be closed when clogged (for maintenance). In positioning the fixed sampling points, due regard is also to be given to the density of vapours of the oil products intended to be transported and the dilution from space purging or ventilation.

16.2.2.1.4 For ships with deadweight of less than 50,000 tonnes, IRS may allow the installation of one sampling location for each tank for practical and/or operational reasons.

16.2.2.1.5 For ballast tanks in the double bottom, not intended to be partially filled and for void spaces, the upper gas sampling point is not required.

16.2.2.1.6 Means are to be provided to prevent gas sampling lines from clogging when tanks are ballasted by using compressed air flushing to clean the line after switching from ballast to cargo loaded mode. The system is to have an alarm to indicate if the gas sampling lines are clogged.

16.2.2.2 Gas analysis unit

16.2.2.2.1 The gas analysis unit is to be located in a safe space and is to be located in areas outside the ship’s cargo area; for example, in the cargo control room and/or navigation bridge or in the hydraulic room

when mounted on the forward bulkhead of the cargo area provided the following requirements are observed:

.1 sampling lines are not to run through gas safe spaces, except where permitted under .5 below;

.2 the hydrocarbon gas sampling pipes are to be equipped with flame arresters. Sample hydrocarbon gas is to be led to the atmosphere with outlets arranged in a safe location, not close to a source of ignitions and not close to the accommodation area air intakes;

.3 a manual isolating valve, which is easily accessible for operation and maintenance is to be fitted in each of the sampling lines at the bulkhead on the gas safety side;

.4 the hydrocarbon gas detection equipment including sample piping, sample pumps, solenoids, analyzing units etc. is to be located in a reasonably gas-tight cabinet (e.g. fully enclosed steel cabinet with a door with gaskets) which is to be monitored by its own sampling point. At a gas concentration above 30% of the lower flammable limit inside the steel enclosure the entire gas analysing unit is to be automatically shut down; and

.5 where the enclosure cannot be arranged directly on the bulkhead, sample pipes from the boundary bulkhead of cargo area are to be of steel or other equivalent material and without detachable connections, except for the connection points for isolating valves at the bulkhead and analyzing unit and are to be as short as possible.

16.2.2.3 Gas detection equipment

16.2.2.3.1 The gas detection equipment is to be designed to sample and analyse from each sampling line of each protected space, sequentially at intervals not exceeding 30 min.

16.2.2.3.2 Means are to be provided to enable measurements with portable instruments, in case the fixed system is out of order or for system calibration. In case the system is out of order, procedures are to be in place to continue to monitor the atmosphere with portable instruments and to record the measurement results.

16.2.2.3.3 Audible and visual alarms are to be initiated in the cargo control room, navigation bridge and at the analyzing unit when the vapour concentration in a given space reaches a pre-set value, which is not be higher than the equivalent of 30% of the lower flammable limit.

16.2.2.3.4 The gas detection equipment is to be so designed that it may readily be tested and calibrated.

Section 17

Helicopter Facility Foam Firefighting Appliances

17.1 Application

17.1.1 This section details the specifications for foam firefighting appliances for the protection of helidecks and helicopter landing areas as required by previous chapters..

17.2 Definitions

17.2.1 D-value means the largest dimension of the helicopter used for assessment of the helideck when its rotors are turning. It establishes the required area of foam application.

17.2.2 Deck integrated foam nozzles are foam nozzles recessed into or edge mounted on the helideck.

17.2.3 Foam-making branch pipes are air-aspirating nozzles in tube shape for producing and discharging foam, usually in straight stream only.

17.2.4 Helicopter landing area is as defined in Chapter 1, 3.57.

17.2.5 Helideck is as defined in Chapter 1, 3.26.

17.2.6 Hose reel foam station is a hose reel fitted with a foam-making branch pipe and non-collapsible hose, together with fixed foam proportioner and fixed foam concentrate tank, mounted on a common frame.

17.2.7 Monitor foam station is a foam monitor, either self-inducing or together with separate fixed foam proportioner, and fixed foam concentrate tank, mounted on a common frame.

17.2.8 Obstacle free sector is the take-off and approach sector which totally encompasses the safe landing area and extends over a sector of at least 210º, within which only specified obstacles are permitted.

17.2.9 Limited obstacle sector is a 150º sector outside the take-off and approach sector that extends outward from a helideck where objects of limited height are permitted.

17.3 Engineering specifications for helidecks and helicopter landing areas

17.3.1 The system is to be capable of manual release, and may be arranged for automatic release.

17.3.2 For helidecks the foam system is to contain at least two fixed foam monitors or deck integrated foam nozzles. In addition, at least two hose reels fitted with a foam-making branch pipe and non-collapsible hose sufficient to reach any part of the helideck are to be provided. The minimum foam system discharge rate is to be determined by multiplying the D-value area by 6 [l/min/m^2]. The minimum foam system discharge rate for deck integrated foam nozzle systems is to be determined by multiplying the overall helideck area by 6 [l/min/m^2]. Each monitor is to be capable of supplying at least 50% of the minimum foam system discharge rate, but not less than 500 [l/min]. The minimum discharge rate of each hose reel is to be at least 400 [l/min]. The quantity of foam concentrate is to be adequate to allow operation of all connected discharge devices for at least 5 [min].

17.3.3 Where foam monitors are installed, the distance from the monitor to the farthest extremity of the protected area is to be not more than 75% of the monitor throw in still air conditions.

17.3.4 For helicopter landing areas, at least two portable foam applicators or two hose reel foam stations are to be provided, each capable of discharging a minimum foam solution discharge rate, in accordance with the following table.

Category	**Helicopter overall length (D-Value)**	**Minimum foam solution discharge rate (l/min)**
H1	Up to but not including 15 [m]	250
H2	From 15 [m] up to but not including 24 [m]	500
H3	From 24 [m] up to but not including 35 [m]	800

The quantity of foam concentrate is to be adequate to allow operation of all connected discharge devices for at least 10 [min]. For tankers fitted with a deck foam system, IRS may consider an alternative arrangement, taking into account the type of foam concentrate to be used.

17.3.5 Manual release stations capable of starting necessary pumps and opening required valves, including the fire main system, if used for water supply, are to be located at each monitor and hose reel. In addition, a central manual release station is to be provided at a protected location. The foam system is to be designed to discharge foam with nominal flow and at design pressure from any connected discharge devices within 30 [sec] of activation.

17.3.6 Activation of any manual release station is to initiate the flow of foam solution to all connected hose reels, monitors, and deck integrated foam nozzles.

17.3.7 The system and its components are to be designed to withstand ambient temperature changes, vibration, humidity, shock impact and corrosion normally encountered on the open deck, and are to be manufactured and tested to the satisfaction of IRS.

17.3.8 A minimum nozzle throw of at least 15 [m] is to be provided with all hose reels and monitors discharging foam simultaneously. The discharge pressure, flow rate and discharge pattern of deck integrated foam nozzles are to be to the satisfaction of IRS, based on tests that demonstrate the nozzle's capability to extinguish fires involving the largest size helicopter for which the helideck is designed.

17.3.9 Monitors, foam-making branch pipes, deck integrated foam nozzles and couplings are to be constructed of brass, bronze or stainless steel. Piping, fittings and related components, except gaskets, are to be designed to withstand exposure to temperatures up to 925 [ºC].

17.3.10 The foam concentrate is to be demonstrated effective for extinguishing aviation fuel spill fires and is to conform to performance standards not inferior to the following:

a) International Civil Aviation Organization Airport Services Manual, part 1, Rescue and Fire Fighting, chapter 8, Extinguishing Agent Characteristics, paragraph 8.1.5, Foam specifications table 8-1, Performance Level B, or

b) Revised Guidelines for the performance and testing criteria, and surveys of foam concentrates for fixed fire-extinguishing systems (MSC.1/Circ.1312).

Where the foam storage tank is on the exposed deck, freeze protected foam concentrates are to be used, if appropriate, for the area of operation.

17.3.11 Any foam system equipment installed within the take-off and approach obstacle-free sector is not to exceed a height of 0.25 [m]. Any foam system equipment installed in the limited obstacle sector is not to exceed the height permitted for objects in this area.

17.3.12 All manual release stations, monitor foam stations, hose reel foam stations, hose reels and monitors are to be provided with a means of access that does not require travel across the helideck or helicopter landing area.

17.3.13 Oscillating monitors, if used, are to be pre-set to discharge foam in a spray pattern and have a means of disengaging the oscillating mechanism to allow rapid conversion to manual operation.

17.3.14 If a foam monitor with flow rate up to 1000 [l/min] is installed, it is to be equipped with an air-aspirating nozzle. If a deck

integrated nozzle system is installed, then the additionally installed hose reel is to be equipped with an air-aspirating handline nozzle (foam branch pipes). Use of non-air-aspirating foam nozzles (on both monitors and the additional hose reel) is permitted only where foam monitors with a flow rate above 1000 [l/min] are installed. If only portable foam applicators or hose reel stations are provided, these are to be equipped with an air-aspirating handline nozzle (foam branch pipes).

End of Chapter
